For improved diagnostic support, install the Windows Support Tools that ship with Windows Server 2003 SP1. The SP1 version of Windows Support Tools includes enhanced versions of the Dcdiag.exe tool. The Dcdiag.exe command-line tool now provides new reporting on the overall health of replication with respect to Active Directory security as well as new DNS diagnostic tests.

Make sure that the SP1 version of Windows Support Tools is installed on all DNS servers running Windows Server 2003 with SP1.

**Options for Running SP1 Windows Support Tools**
You can run Windows Support Tools that ship with Windows Server 2003 SP1 on computers running the following operating systems:

- Windows Server 2003 with SP1
- Windows Server 2003 without SP1

You can also run Dcdiag.exe on computers running Windows XP Professional, Windows XP Professional with SP1, or Windows XP Professional with Service Pack 2 (SP2). Options for other tools vary by tool.

**Options for Installing SP1 Windows Support Tools**
The SP1 version of Windows Support Tools can be installed as an .msi package only on computers running Windows Server 2003 with SP1. To run Dcdiag from computers running Windows Server 2003 without SP1 or from computers running Windows XP Professional, you must copy the respective executable files to those computers.

### Requirements

- Administrative credentials: To complete this procedure, you must be a member of the Builtin Administrators group.
- Operating system: Windows Server 2003 with SP1. You cannot use Suptools.msi to install the SP1 version of Windows Support Tools on a computer that is not running Windows Server 2003 with SP1.

### To install Windows Support Tools

1. Insert the Windows CD into your CD-ROM drive.

2. If you are prompted to reinstall Windows, click **No**.
3. When the **Welcome** screen appears, click **Perform additional tasks**, and then click **Browse this CD**.
4. Go to the \Support\Tools folder. For complete setup information, see the Readme.htm file in this folder.
5. Double-click **suptools.msi**.
6. Follow the instructions that appear on your screen.

**Install Network Monitor**
You can use Network Monitor to troubleshoot connectivity issues by tracing network traffic between computers. For information about installing and using Network Monitor, see Network Monitor on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42987).

**Enable DNS Debug Logging**
DNS debug logging creates a Dns.log file that contains debug logging activity. By default, this file is located in the C:\Windows\System32\DNS folder. Using debug logging options slows DNS server performance; therefore, all debug logging options are disabled by default. You can use the following procedure to enable DNS debug logging.

### Administrative credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using the **Run as** command to perform this procedure.

### To enable DNS debug logging

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **DNS**.
2. In the console tree, right-click the applicable DNS server, then click **Properties**.
3. Click the **Debug Logging** tab.
4. Select **Log packets for debugging**, and then select the events that you want the DNS server to record for debug logging

### Notes

- To set the debug logging options, you must first select **Log packets for debugging**.
- To obtain useful debug logging output, select an option under **Packet direction**, an option under **Transport protocol**, and at least one more option.
- In addition to selecting events for the DNS debug log file, you can specify the file name, location, and maximum file size for the file. In most cases, the default selections are adequate. You may want to limit the traffic that the logging captures. If you want to limit the logging traffic to traffic between your server and a specific DNS server, select the **Filter packets by IP address** check box, and then click **Filter** to add the appropriate IP addresses.

# Troubleshooting Domain Name System Problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Domain Name System (DNS) problems can prevent users from accessing the Internet or other computers on your intranet. This section addresses some of the most common DNS-related problems that you might experience.

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Secure dynamic updates fail
- DNS server resolves some Internet names incorrectly
- DNS client fails to resolve name
- Zone transfers from a secondary DNS server fail
- Dynamic updates for host records fail

If you suspect that domain controllers are having difficulty resolving DNS names, see Perform DNS Health Check (http://go.microsoft.com/fwlink/?LinkId=111844).

# Secure dynamic updates fail

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem occurs when attempts by hosts fail to update a Domain Name System (DNS) zone that is configured for secure dynamic updates.

**Cause**
The host might not be configured properly to allow secure dynamic DNS updates. It might be configured to use an external DNS server, or it might be experiencing other DNS configuration problems.

**Solution**
First, try to solve this problem by using the troubleshooting information in Dynamic updates for host records fail.

Hosts that perform secure dynamic updates should be members of a Windows 2000 Server or Windows Server 2003 domain, and they should be in a domain that is in the same forest as the DNS server.

Verify that there is no problem with the machine account of the host that is attempting the update. Determine whether other hosts successfully perform secure dynamic updates. If the problem is occurring on only one host, try removing the host from the domain and then rejoining it to the domain.

Verify that a record does not already exist with the same name. By default, records that are created by one host cannot be modified or removed by a different host. If there is an existing record with the same name, delete the existing record and have the host attempt to register again.

**To initiate a dynamic update for host and PTR records**

- At a command prompt, type the following command, and then press ENTER:

  **ipconfig /registerdns**

# DNS server resolves some Internet names incorrectly

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The symptom for this problem is that the Domain Name System (DNS) server stops resolving some Internet names correctly. It might give inaccurate responses or fail to resolve Internet names completely, while other Internet names resolve accurately. This problem may get worse over time. Clearing the DNS server cache, restarting the DNS service, or restarting the DNS server resolves the problem temporarily, but the problem may continue to occur.

**Cause**

The DNS server might be experiencing cache pollution. This is caused by the DNS server receiving and caching an inaccurate start of authority (SOA) record for a portion of the Internet namespace. For example:

1. A DNS server queries a specific name server to resolve host.contoso.com.

2. The DNS server that is being queried gives a response. Along with the response — in the authority section — it gives an incorrect record for the .com namespace.

3. This record is cached and all new queries that contain the top-level domain name of com will not resolve, or they resolve to an incorrect Internet Protocol (IP) address.

**Solution**

Configure the DNS server for protection against cache pollution by completing the following procedure.

**To configure the DNS server for protection against cache pollution**

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **DNS**.

2. In the console tree, right-click the DNS server that you want to protect against cache pollution, click **Properties**, and then click the **Advanced** tab.

3. Select the **Secure cache against pollution** check box, and then click **OK**.

# DNS client fails to resolve name

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem may occur when a user is trying to access another computer on the intranet or the Internet. A user typically receives a Domain Name System (DNS) error from the operating system or the browser.

**Cause**

Several problems can cause DNS name resolution to fail. If you have reviewed the topics for other problems in Troubleshooting Domain Name System Problems and they do not seem to be the cause of the problem, DNS settings might be configured incorrectly on the DNS client.

**Solution**

Verify that the client does not have an external DNS server, such as a DNS server from an Internet service provider (ISP), in its TCP/IP configuration. In most cases, the client should not use a DNS server from an ISP as either the preferred or alternate DNS server, because the DNS server at the ISP is unable to resolve internal names. Using a DNS server from an ISP in a client's TCP/IP configuration can also cause problems with conflicting internal and external namespaces.

**To verify DNS configuration in TCP/IP settings**

1. Log on to the DNS client computer with the Administrator account.
2. Click **Start**, click **Control Panel**, and then double-click **Network Connections**.
3. In **Network and Dial-up Connections**, right-click the local area connection that you want, and then click **Properties**.
4. In **Local Area Network Connection Properties**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
5. Ensure that the appropriate DNS server IP addresses are configured in **Preferred DNS server** and **Alternate DNS server**. If **Obtain an IP address automatically** is selected, click the **Alternate Configuration** tab, and then review all the IP settings that are configured there.
6. Type the following at a command prompt, and then press ENTER:

   **ipconfig /all**
7. Review the DNS server settings, and verify that they are correct.
   a. If the DNS server settings are not correct, ensure the appropriate settings are configured on the Dynamic Host Configuration Protocol (DHCP) server.
   b. If your computer has an IP address that begins with 169.254, it is not obtaining an IP address from a DHCP server and likely does not have **Alternate Configuration** enabled. In this case, diagnose the issue with the DHCP server or set an appropriate static IP address either directly or as an alternate configuration.

Next, use the following procedure to verify that the name can be resolved by the DNS server.

**To verify name resolution**

- At a command prompt, type the following command, and then press ENTER:

  **nslookup** *host_name server_IP_address*

Substitute the actual host name that you are trying to resolve for *host_name* and the IP address of the DNS server for *server_IP_address*. For example, if the host name that you are trying to resolve has a fully qualified domain name (FQDN) of server5.contoso.com and the DNS server's IP address is 192.168.0.200, type the following command, and then press ENTER:

**nslookup server5 192.168.0.200**

You can also try using the FQDN:

**nslookup server5.contoso.com 192.168.0.200**

If the host name alone does not resolve, but the FQDN does resolve, confirm that the primary or connection-specific DNS suffix

is configured correctly. You can use the following procedure to add a DNS suffix search list.

**To add a DNS suffix search list**

1. Click **Start**, right-click **My Network Places**, and then click **Properties**.
2. Right-click **Local Area Connection**, and then click **Properties**.
3. Double-click **Internet Protocol (TCP/IP)**, and then click **Advanced**.
4. Click the **DNS** tab, and then click **Append these DNS suffixes (in order)**.
5. Click **Add**, type the domain suffix of the desired domain, and then click **Add**.

If both Nslookup commands fail to resolve the name, the problem is likely with the DNS server records or configuration, or it may be the result of a connectivity issue between the DNS client and DNS server, such as a firewall blocking DNS queries (which are typically offered on TCP port 53). You can use the Portqry tool to test network connectivity between two computers. For more information about downloading and using Portqry, see article 832919 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=111855).

If the connection is not successful, look for a firewall on the DNS client, DNS server, or somewhere between the two that could cause the connection failure. If you are diagnosing a connection failure between two computers, you can try using the Portqry tool to test it. For more information about downloading and using Portqry, see article 832919 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=111855).

If Portqry fails, there may be a connectivity issue between the computers. You can try using the Tracert or Pathping tools to find out where the failure exists. However, these tools are not always reliable because many hosts and servers disable the Internet Control Message Protocol (ICMP) echo functionality on which these tools depend. However, using one of these tools may help locate the source of a problem. For more information about using Tracert, see article 314868 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=111861). For information about using Pathping, see Pathping (http://go.microsoft.com/fwlink/?LinkId=111864)

| **Note** |
| --- |
| If you locate and correct any issues on the DNS server, it is probable that your client computer cached the incorrect information, and your name resolution queries may still fail. To resolve this issue, clear the DNS client resolve cache on the client computer. To clear the cache, type the following command at a command prompt, and then press ENTER:<br><br>**Ipconfig /flushdns** |

For additional information about troubleshooting the DNS client configuration, see Validate DNS Client Settings (http://go.microsoft.com/fwlink/?LinkId=111865).

# Zone transfers from a secondary DNS server fail

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In the DNS management console, the secondary zone has a red X in the right pane, along with an error message that reads as follows:

```
The DNS server encountered a problem while attempting to load the zone. The transfer of
zone data from the master server failed.
Correct the problem then either press F5, or on the Action menu, click Refresh.
For more information about troubleshooting DNS zone problems, see Help.
```

**Cause**

The primary DNS server might not be configured properly to allow zone transfers from the secondary DNS server.

**Solution**

Use the following procedure to verify that the primary DNS server is configured to allow zone transfers from the secondary DNS server.

**To verify that the primary DNS server is configured to allow zone transfers from the secondary DNS server**

1. On the primary DNS server, click **Start**, point to **All Programs**, click **Administrative Tools**, and then click **DNS**.
2. In the console tree, double-click the DNS server.
3. In the console tree, double-click **Forward Lookup Zones** or **Reverse Lookup Zones**, as applicable.
4. Right-click the zone, click **Properties**, and then click the **Zone Transfers** tab.
5. Ensure that the **Allow zone transfers** check box is selected.

If zone transfer fails with Event ID 6525 “Zone transfer for secondary zone <zone_name> refused by master server” and the master server allows dynamic updates for the zone, these failures are due to the zone transfer throttling mechanism, and they are expected. This mechanism limits the number of zone transfers to allow regular dynamic updates to take place.

# Dynamic updates for host records fail

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Computers can fail to register the following host records:

- Address (A) records, for a forward lookup zone
- Pointer (PTR) records, for a reverse lookup zone

There might not be any error messages associated with these events. The only symptom of the problem might be the fact that the host's records do not show up in the Domain Name System (DNS) zone.

**Cause**

The host might not be configured properly to allow dynamic DNS updates. It might be configured to use an external DNS server, or it might be experiencing other DNS configuration problems.

**Solution**

You can use the following procedure to verify that the host is configured for dynamic DNS updates.

**To verify that the host is configured for dynamic DNS updates**

1. Log on to the computer with the Administrator account.
2. Click **Start**, click **Control Panel**, and then double-click **Network Connections**.
3. In **Network Connections**, right-click **Local Area Connection**, and then click **Properties**.
4. In **Local Area Network Connection Properties**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
5. In **Internet Protocol (TCP/IP) Properties**, click **Advanced**, and then click the **DNS** tab.
6. Ensure that both of the following check boxes are selected:
   - **Register this connection's addresses in DNS**
   - **Use this connection's DNS suffix in DNS registration**
7. Click **OK**.

You can use the following procedure to verify that the client does not have an external DNS server, such as a DNS server from an Internet service provider (ISP), in its TCP/IP configuration. In most cases, the client should not use a DNS server from an ISP as either the preferred or alternate DNS server, because the DNS server at the ISP is unable to resolve internal names. Using a DNS server from an ISP in a client's TCP/IP configuration can also cause problems with conflicting internal and external namespaces.

**To verify DNS configuration in TCP/IP settings**

1. Log on to the computer with the Administrator account.
2. Click **Start**, click **Control Panel**, and then double-click **Network Connections**.
3. In **Network Connections**, right-click **Local Area Connection**, and then click **Properties**.
4. In **Local Area Network Connection Properties**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
5. If **Obtain an IP address automatically** is selected, type the following at a command prompt:

   **ipconfig /all**
6. Review the DNS server settings and verify that they are correct.

You can use the following procedure to verify that the start-of-authority (SOA) resource record can be resolved by the DNS servers. In this procedure, you use the Nslookup.exe tool to test name resolution for the SOA record for the domain that the

client is attempting to register in. Test this name resolution from each one of the DNS servers that the client is configured to use.

**To verify that the SOA record can be resolved by the DNS servers**

1. At a command prompt, type the following command, and then press ENTER:

   **nslookup**

2. At the **nslookup:** prompt, type the following command, and then press ENTER:

   **set querytype=SOA**

3. At the **nslookup:** prompt, type the full name of the DNS zone that the client should be registering in — and include a terminating dot at the end of the domain name — and then press ENTER.

4. To test another DNS server, at the **nslookup:** prompt, type the following command, and then press ENTER:

   **server** *IP_address*

   Then, type the domain name to be tested, and then press ENTER.

If this query attempt fails from any of your DNS servers, you might need to remove that DNS server from the client's TCP/IP settings.

You can use the following procedure to verify that the DNS zone is enabled for dynamic updates. Open the DNS management console to verify that the zone that the clients need to register in is configured to accept dynamic updates.

**To verify that the DNS zone is enabled for dynamic updates**

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **DNS**.

2. In the console tree, double-click the appropriate DNS server name, and then double-click **Forward Lookup Zones**.

3. Right-click the zone, and then click **Properties**.

4. On the **General** tab, view the **Dynamic updates** setting and make sure that it is set to **Nonsecure and secure** or **Secure only**.

5. If the setting is already set to **Secure only** and updates are still failing, try setting the zone to **Nonsecure and secure** for testing. If failures are seen only for **Secure only**, see Secure dynamic updates fail.

You can use the following procedure to verify that the Dynamic Host Configuration Protocol (DHCP) Client service is started. The DHCP Client service is used to perform dynamic updates, and it must be running.

**To verify the status of DHCP or to start DHCP**

1. Click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Services**.

2. In the details pane, double-click **DHCP Client** and verify that the status of that service is **Started**. If the status is not **Started**, click **Start** to start the service.

You can use the following procedure to verify whether a single-label DNS domain name is being used.

**To verify whether a single-label DNS domain name is being used**

1. At a command prompt, type the following, and then press ENTER:

   **ipconfig /all**

2. View the Primary DNS Suffix and the **Connection-specific DNS Suffix** to make sure that the specified domain name has at least two parts, separated by a dot, for example, fabrikam.com. An example of a single-label domain is fabrikam.

3. If the host is using a single-label domain name, and this is correct for the environment, you have to use the registry setting of **UpdateTopLevelDomainZones**. For more information about this registry setting, see article 300684, "Information about configuring Windows for domains with single-label DNS names," in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=37924).

# Additional Resources for Domain Name System

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For information about how Domain Name System (DNS) works, see the following resources:

- DNS Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=48145)
- DNS Support for Active Directory Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=48147)

For information about troubleshooting DNS problems, see Troubleshooting Domain Name System.

# Group Policy Operations Guide

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Group Policy Operations Guide provides troubleshooting information for Group Policy in Microsoft Windows Server 2003 with Service Pack 1 (SP1). This guide also covers troubleshooting issues for earlier operating systems including Windows 2000 and Windows XP. It assumes that you are using the Group Policy Management Console (GPMC).

**In this guide**

- Group Policy Troubleshooting

# Group Policy Troubleshooting

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides a framework for troubleshooting Group Policy in an Active Directory environment. It includes checklists for quick fixes, a summary of troubleshooting tools, flowcharts for root cause analysis, recommendations for solving specific Group Policy problems, and guidance for interpreting log files.

**In this guide**

- Introduction to Group Policy Troubleshooting
- Verifying Administrative Workstation Settings for Troubleshooting Group Policy
- Group Policy Quick Fixes
- Configuring Administrative Workstation Settings for Group Policy Troubleshooting
- Troubleshooting Group Policy Problems
- Additional Resources for Group Policy

# Introduction to Group Policy Troubleshooting

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to troubleshoot Group Policy. If you are using this guide for the first time, review the following sections of this introduction.

**When to Use this Guide**
This troubleshooting guide is designed to help you identify and resolve problems related to Group Policy. You should use this guide when:

- You have configured a policy setting but it is not applying as expected.
- You have specified the scope of Group Policy through filtering but it is not applying as expected.
- You are having problems using a specific Group Policy extension, such as Security Settings or Folder Redirection.

**Who Should Use this Guide**
This guide is written for IT professionals in small, medium, and large organizations. It assumes a basic understanding of what Group Policy is, how it works, and why your organization uses it. You should also have a thorough understanding of how Group Policy is deployed and managed in your organization. This includes understanding how Group Policy is configured throughout your organization and the mechanism that your organization uses to configure Group Policy settings.

**How to Use this Guide**
This guide is divided into four sections. Each section addresses a type of problem, ranging from less complex to more complex.

Verifying Administrative Workstation Settings for Troubleshooting Group Policy

This section provides a list of prerequisites and settings that must be verified before you troubleshoot. Read this section first.

Group Policy Quick Fixes

This section provides quick solutions to the most common Group Policy problems. Read this section if you have verified your computers settings, but your problem persists.

Configuring Administrative Workstation Settings for Group Policy Troubleshooting

This section describes how to configure your computer for advanced troubleshooting. Read this section if you cannot find a solution in the Group Policy Quick Fixes section.

Troubleshooting Group Policy Problems

This section provides information and diagnostic procedures that help you identify and fix Group Policy problems.

Additional Resources for Group Policy

This section provides links to additional information that you can use to identify and fix Group Policy problems.

# Verifying Administrative Workstation Settings for Troubleshooting Group Policy

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic provides information about ensuring you have the appropriate permissions to administer and troubleshoot Group Policy and provides other tips for setting up your administrative workstation. Before you begin troubleshooting, verify that your computer is configured properly and that Group Policy is set up and running properly.

**Settings to Verify Before You Troubleshoot**
Verify all of the following items:

Security permissions are configured for administering Group Policy

The correct domain controller is selected in the Group Policy Object Editor and GPMC

**Security permissions are configured for administering Group Policy**
In order to administer Group Policy, you must have the necessary privileges to use GPMC and the Group Policy Object Editor. You also need privileges to create GPOs or to manage links from a specific site, domain, or OU to GPOs. Control of existing GPOs can be delegated to specific users or groups, so it is possible for an administrator to be able to use GPMC to view GPOs, but not be able to modify, delete, or link them. Use the following guidelines to help ensure that permissions are configured appropriately:

- Use Active Directory Users and Computers to verify that the account you are using is a member of a group that has these privileges. (Check the group memberships for the user account, and also verify that the privileges for the group have not been changed.)

- Avoid adding the privileges to an individual user account. If necessary, create a new group with a name that clearly indicates its purpose.

- Changes to security groups' memberships or privileges, or to the permissions on Group Policy objects or actions, need to be replicated to domain controllers throughout the system. Until this replication is completed the changes might be applied unevenly. In rare cases you might want to force replication.

To see or change the access control lists that affect management of a GPO, open the GPO in GPMC and look at the **Delegation** tab. The GPO can only be applied by members of groups that have Read permissions. To change the security filters, click **Advanced**.

**The correct domain controller is selected in the Group Policy Object Editor and GPMC**
Each domain controller has a copy of every GPO in the domain. The default and best practice is to edit GPOs on the primary domain controller (the PDC Emulator), and allow the changes to replicate to other domain controllers.

If that is not practical due to bandwidth or other issues, administrators can change the domain controller focus for the instances of GPMC that they are using.

If administrators in your organization edit GPOs on different domain controllers, set up processes to avoid this sort of conflict. For example, you might delegate editing permissions on individual GPOs to specific users, or to a group that focuses on the same domain controller.

# Group Policy Quick Fixes

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic provides tips for quickly addressing common Group Policy problems. Problems with the application of Group Policy often involve the technologies on which Group Policy depends, or implementation errors.

This section provides a summary of the most common Group Policy problems and the solutions to those problems. You can use the information in this section to resolve problems in the same way you would use a FAQ to find answers to common questions. Read this section before you begin any advanced troubleshooting.

**Common Group Policy Problems**
Listed below are common Group Policy problems and quick fixes:

I want Group Policy changes to be applied immediately.

Some policy areas are missing when I open up the Group Policy Object Editor.

Some settings are missing in the Group Policy Object Editor.

Some policies are not applied over dial-up connections.

Security Options are not applied.

Account Policies are not applied for domain users.

**I want Group Policy changes to be applied immediately.**
Sometimes you may want to see the effect of a Group Policy change without having to wait for the default refresh intervals (90 minutes for domain members and 5 minutes for domain controllers). To see the effect of Group Policy immediately, open a command prompt and run GPUPdate. To force GPOs to reapply even if they have not changed, at a command prompt type **gpupdate /force**. To see other parameters, type **gpupdate /?**.

To run **gpupdate /force** automatically, click the Fix this problem link. Then, click Run in the File Download dialog box.

Fix this problem

| Note |
| --- |
| This wizard may be in English only; however, the automatic fix also works for other language versions of Windows. |

| Note |
| --- |
| If you are not on the computer that has the problem, save the automatic fix to a flash drive or to a CD so that you can run it on the computer that has the problem. If you do not want to use the automatic fix, you can do it yourself by performing the steps in the procedure above. |

**Some policy areas are missing when I open up the Group Policy Object Editor.**
Each area of Group Policy functionality is implemented by a Microsoft Management Console snap-in DLL that is registered by default. For example, Administrative Templates and Scripts use gptext.dll, folder redirection uses fde.dll, and Security Settings uses wsecedit.dll. If these DLLs are un-registered or removed, the underlying Group Policy editing functionality that they implement will not appear in the Group Policy Object Editor.

To resolve this issue, you need to re-register the appropriate MMC snap-in DLL that implements the missing functionality.

**To reregister MMC snap-in DLLs**

1. Open a command prompt.
2. Type the following command: **regsvr32** *snap-inDLLname*

By default, you can find all of the MMC snap-in DLLs related to Group Policy in %systemroot%\system32.

**Some settings are missing in the Group Policy Object Editor.**
Administrative Templates can contain both true policies and preferences, but by default the Group Policy Object Editor exposes only true policies. To show all possible settings, you need to expose preferences in the Group Policy Object Editor.

### To expose preferences in the Group Policy Object Editor

1. Highlight the Administrative Templates node for which you want to see preferences.
2. On the **View** menu, click **Filtering**, and then clear the **Only show policy settings that can be fully managed** check box.

**Some policies are not applied over dial-up connections.**
By default, certain Group Policies are not applied to users who connect to your network over dial-up connections. If you want to make sure that users receive all Group Policies regardless of the speed of their connection, you can change the definition of what counts as a slow link. The default setting for this is 500 Kbps or less, which means that anybody who accesses your network with a connection that is 500 Kbps or slower might not receive all GPOs intended for them. To change the Group Policy settings that define a slow link, modify the following settings:

- **For users:** Click **User Configuration**, click **Administrative Templates**, click **System**, click **Group Policy**, and then click **Group Policy Slow Link Detection**.
- **For computers:** Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Group Policy**, and then click **Group Policy Slow Link Detection**.

| **Note** |
| --- |
| If a user connects to the network with cached credentials, Group Policy is not processed. To ensure that Group Policy is applied over a slow link, the user must select the **Logon using dialup connection** check box in the Windows Logon dialog box. |

**Security Options are not applied.**
The following Security options are only processed if they are applied at the domain level:

- Network Security: Force logoff when logon hours expire
- Accounts: Administrator account status
- Accounts: Guest account status
- Accounts: Rename administrator account
- Accounts: Rename guest account

If these Security Options are configured at the site or OU level they are ignored. You need to configure these Security Options at the domain level.

**Account Policies are not applied for domain users.**
Account Policies are only processed for domain user accounts if they are applied at the Domain level. Account Policies configured elsewhere, such as at the Site or OU level, are ignored. All settings found under Account Policies under Security Settings in Group Policy should only be configured at the domain level. If you are having trouble applying a Security Setting that is found under Account Policies, ensure that you have configured the setting only at the domain level.

# Configuring Administrative Workstation Settings for Group Policy Troubleshooting

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic provides information about the tools you use to troubleshoot Group Policy.

**Configuration Tasks for Troubleshooting**
To configure your administrative workstation for troubleshooting, you will need to perform one or more of the following tasks:

Install tools

Learn about built-in troubleshooting tools

Install tools for troubleshooting external issues

Enable auditing

Enable logging

**Install tools**
If you are administering or troubleshooting Group Policy, you should be using the Group Policy Management Console (GPMC) and other tools as necessary.

**Group Policy Management Console**
Group Policy Management Console is the preferred tool for administering Group Policy and it is an excellent tool for troubleshooting Group Policy. GPMC provides the following reporting functionality:

- Group Policy Modeling reports are used to predict the policies that will be applied at a specific client. A Windows Server 2003 domain controller is required to generate Group Policy Modeling reports.

- Group Policy Results reports gather information directly from the client to show the policies in effect, and include key policy events that have been logged at that client.

Both of these reports include valuable troubleshooting information. For example, you can see a list of the GPOs applied, and also the denied GPOs with the reason for denial. You can see which settings are or would be applied, and the winning GPO that supplied the value for the setting.

**Sample scripts**
GPMC also includes sample scripts that you can use to quickly perform a number of different troubleshooting tasks. If you cannot find a sample script that fits your needs, you can easily modify a sample script, or create your own script. The following sample scripts will help you troubleshoot various issues:

- List All GPOs in a Domain: ListAllGPOs.wsf

- List Disabled GPOs: FindDisabledGPOs.wsf

- List GPO Information: DumpGPOInfo.wsf

- List GPOs at a Backup Location: QueryBackupLocation.wsf

- List GPOs by Policy Extension: FindGPOsByPolicyExtension.wsf

- List GPOs by Security Group: FindGPOsBySecurityGroup.wsf

- List GPOs Orphaned in SYSVOL: FindOrphanGPOsInSYSVOL.wsf

- List GPOs With Duplicate Names: FindDuplicateNamedGPOs.wsf

- List GPOs Without Security Filtering: FindGPOsWithNoSecurityFiltering.wsf
- List SOM Information: DumpSOMInfo.wsf
- List SOMs With Links to GPOs in External Domains: FindSOMsWithExternalGPOLinks.wsf
- List Unlinked GPOs in a Domain: FindUnlinkedGPOs.wsf
- Print the SOM Policy Tree: ListSOMPolicyTree.wsf

For a complete list of available sample scripts, script documentation, and a list of scripting interfaces exposed by GPMC, please see the Group Policy Management Console SDK located at %programfiles%\gpmc\scripts\gpmc.chm on any computer where GPMC has been installed. (The Group Policy Management Console SDK is available in English only.)

For information about downloading and installing GPMC, see Group Policy Management Console with Service Pack 1 on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=21813).

**GPResult.exe**
There are two versions of GPresult.exe.

- The Windows Server 2003 version is included with Windows Server 2003 operating systems. GPresult.exe gathers and reports the RSoP data available from computers running Windows XP or Windows Server 2003. The report is similar to what you would get by generating a Group Policy Results report in GPMC. For more information, see Command-Line Reference for Windows Server 2003 on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=20331).
- The Windows 2000 version is included with the Microsoft Windows® 2000 Server Resource Kit Tools. To download the Windows 2000 version for free, see Windows 2000 Tools and Utilities at the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=12920). GPresult.exe estimates the Group Policy settings that would be applied at a specific computer. This version provides information that is not available in the Windows Server 2003 version: It shows the registry value name set by each policy setting and lets you associate the GPO GUID that appears in Sysvol with the friendly name that was given to the policy setting (for example, Remove Run Command). For this reason, you might want to have both versions of Gpresult available. For more information, see the readme file included with the download.

**GPOTool.exe**
GPOTool.exe is a command-line tool to be used in replicated domains—domains that contain more than one domain controller. It traverses all of your domain controllers and checks each for consistency between the Group Policy container (that is, information contained in the directory service) and the Group Policy template (that is, information contained in the SYSVOL share on the domain controller). The tool also determines whether the policies are valid and consistent between all of your domain controllers and displays detailed information about the GPOs that have been replicated between your domain controllers.

- If you suspect that you are having problems with replication of Group Policy information, this tool helps you diagnose and isolate where Group Policy is not being replicated properly.
- The latest version of GPOTool is included in Windows Server 2003 Resource Kit Tools. For more information, see Windows Server 2003 Resource Kit Tools on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=27766). GPOTool.exe originally shipped with the Microsoft Windows 2000 Server Resource Kit. To download GPOTool.exe for free, see Gpotool.exe: Group Policy Verification Tool on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=17911).

**Software Installation Diagnostics Tool (Addiag.exe)**
Windows Server 2003 includes an advanced troubleshooting tool, Software Installation Diagnostics (Addiag.exe) that you can use to gather additional diagnostic information when troubleshooting Software Installation policy issues.

The binary executable for this tool is Addiag.exe. Running **addiag.exe /?** from a command prompt provides the usage syntax.

This tool displays detailed information about the applications visible in Active Directory and installed for the current user, as well as general diagnostic information and related Event Log entries.

Addiag.exe is included in the Windows Server 2003 Support Tools. Support tools not installed with the Windows operating system; you must install them separately from the \Support\Tools folder of the Windows operating system CD.

For more information, see Addiag.exe: Application Deployment Diagnosis on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43037).

**Learn about built-in troubleshooting tools**

This section provides information about using Group Policy Modeling and Group Policy Results in GPMC to generate reports.

**Group Policy Results**

GPMC leverages the Resultant Set of Policy (RsoP) functionality in Windows Server 2003 and Windows XP to provide reports on the way Group Policy is applied at individual clients. Because these reports rely on functionality that is new with Windows XP and Windows Server 2003, the clients for which you generate the reports must be running one of these operating systems.

| **Note** |
| --- |
| Group Policy Results depends on Windows Management Instrumentation (WMI). If WMI is not working, you will not be able to use RSoP or Group Policy Results. In this case, viewing the userenv log file in verbose mode provides you with information you will need to troubleshoot, for example, by showing you which GPOs did not apply. For more information about userenv, see Fixing Group Policy problems by using log files. |

**To generate a Group Policy Results report**

1. In the **Group Policy Management** console, right-click **Group Policy Results**, and then at the bottom of the navigation pane click **Group Policy Results Wizard**.
2. In the wizard, specify the computer or computer/user combination you want to investigate. The report that appears in the details pane provides information about Group Policy application on the client.

**Group Policy Modeling**

Before you implement a GPO, use Group Policy Modeling to validate the effect it will have. The Group Policy Modeling report has the information about the Summary and Settings tabs similar to what you would see for a Group Policy Results report. Group Policy Modeling reports do not collect policy events from the client. Instead of the **Policy Events** tab, a list of the conditions that were applied when creating the model appears on the **Query** tab.

**To generate a Group Policy Modeling report**

1. In the **Group Policy Management** console, right-click **Group Policy Modeling**, near the bottom of the navigation pane, and select **Group Policy Modeling Wizard**.
2. In the **Group Policy Modeling Wizard**, specify the computer or computer/user combination you want to investigate. The report that appears in the details pane provides information about the anticipated Group Policy application on that client.

**Summary Tab**

On the **Summary** tab, the sections that appear under both Computer Configuration and User Configuration headings are listed and described in the following table.

**Table 1 Summary Tab of Group Policy Results Reports**

| Section | Information |
| --- | --- |
| General | Computer name<br><br>The domain and site of which the computer is a member<br><br>The last time Group Policy from the computer's Active Directory hierarchy was applied<br><br>User name (if any)<br><br>The domain and site of which the user is a member<br><br>The last time Group Policy from the user's Active Directory hierarchy was applied |

| | |
|---|---|
| Group Policy Objects Applied | List of GPOs that were applied |
| Group Policy Objects Denied | List of GPOs that were denied, with the reason for the failure. |
| Security Group Membership when Group Policy was applied | Security group memberships in effect when group policies were evaluated |
| WMI Filters | WMI filters that were applied, whether they evaluated as True or False, and what GPO called them |
| Component Status | Success or failure, including errors, of core client Group Policy functionality and client side extensions (CSEs) |

**Settings Tab**

The **Settings** tab lists the actual settings applied. These are sorted by the source of the setting (for example Computer Configuration/Windows Settings or User Configuration/Administrative Templates). The report includes the winning GPO for each setting.

With this information, you can locate the GPO in the navigation pane. The information that is exposed when you click the GPO depends on the privileges granted to your user account. If you have sufficient privileges, you can review or edit the settings and also get a list of the sites, domains, and OUs that link to that GPO.

**Policy Events Tab**

When you use GPMC to generate a report of the resulting set of policy on a client, events that were logged at that client and pertain to Group Policy are listed on the **Policy Events** tab. Sources for these events include the core Group Policy engine on the client (the Userenv process) and the CSEs for Group Policy.

The display on the **Policy Events** tab is similar to the Event Viewer display. This is an especially useful troubleshooting feature of GPMC because it filters only the Group Policy events from the Event Viewer. Table 2 lists and defines the sources.

**Note**

To view the Group Policy events on computers running Windows XP SP1 or Windows Server 2003 you must be a local administrator on that computer. If you have the necessary privileges to generate a Group Policy Results report but you do not have the privileges to view Group Policy events on the client, the Policy tab displays the message "Unable to open event log: Access is Denied" instead of the list of events.

**Table 2 Policy Events Tab of Group Policy Results Reports**

| Source name in Policy Events log | Full name of source | Functionality |
|---|---|---|
| UserEnv | User Environment (Group Policy core engine) | Locates and applies GPOs at start up, log on, or the configured Policy Refresh Interval |
| SceCli | Security CSE | Reads all GPOs that reach the client and determines which policy settings are applied |
| Application Management | Software Installation CSE | Processes Software Installation settings, including installation, upgrades, and removal |
| Folder Redirection | Folder Redirection CSE | Processes Folder Redirection |
| UserInit | Scripts CSE | Implements logon, logoff, startup, and shutdown scripts |

To avoid flooding the client log file, some logging is blocked in certain situations. For example, if a computer is not connected to the network and a user logs on with cached credentials, the Component Status entries on the **Summary** tab of the Group Policy Results report show the failure to access and apply Group Policies. However, the list of associated failure events do not appear in the Application event log on the client or on the **Policy Events** tab.

**Note**

By default, UserEnv logging is not verbose — only errors and warnings are reported, and appear on the **Policy Events** tab. For more information, see Fixing Group Policy problems by using log files.

**Install tools for troubleshooting external issues**
Group Policy has dependencies on several operating system technologies such as Active Directory, Domain Name System (DNS), and File Replication Service (FRS). The following tools can help you troubleshoot problems related to these dependent technologies.

**Sonar.exe**
Sonar is a command-line tool that allows administrators to monitor key statistics and status about members of a file replication service (FRS) replica set. Use Sonar to watch key statistics on a replica set in order to monitor traffic levels, backlogs, and free space. To download Sonar for free, see Sonar.exe: FRS Status Viewer on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=16719).

**Active Directory Support Tools**
Help and Support Center in Windows Server 2003 provides a list of Active Directory support tools in the topic "Active Directory support tools." Use these tools to troubleshoot Active Directory issues.

**Other Windows Server 2003 Command-Line Tools**
Windows Server 2003 includes a number of command line tools including ping.exe, netdiag.exe, and dcdiag.exe. For a complete reference of the tools included with Windows Server 2003, see Windows Server 2003 Technical Reference: Tools and Settings Collection on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=4972).

**Enable auditing**
Administrators can use Group Policy to enable auditing of Windows registry keys, or they can use a Security Template to Audit Registry Keys, or they can use Registry Editor for this purpose. Administrators must also configure SACLs on the registry keys that are being audited.

To enable auditing for the Windows registry, you can use the **Audit object access** policy setting in **Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policies**.

The **Audit object access** policy setting determines whether to audit the event of a user accessing an object (for example, a file, folder, registry key, printer, and so on) that has its own system access control list (SACL) specified. Default: No auditing.

To configure permissions for auditing the registry keys, in **Group Policy Object Editor** console, in **Computer Configuration\Windows Settings\Security Settings**, right-click **Registry**, click **Add Key**, select the registry key for which you want to allow auditing, and then click **Advanced**. In the **Database Security** dialog box, click the **Auditing** tab, and then specify the users or groups that you want to give permissions to and set the permissions you want to use.

For more information about enabling auditing of registry keys, see article ID 324739 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=35275).

**Enable logging**
To troubleshoot problems with Group Policy administration or application, you can enable logging based on the functionality you are investigating.

For more information about enabling logging for client-side extensions and server-side logging, see the subsections or Fixing Group Policy problems by using log files.

# Enable Logging for Group Policy Management Console

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To troubleshoot problems with administering Group Policies using the Group Policy Management Console, you can enable GPMC logging. This logging covers all Group Policy administration tasks, except editing Group Policy objects.

**When To Enable GPMC Logging**

GPMC logging, by default, is set to only log errors. To avoid using unnecessary disk space, you should leave GPMC logging at the default setting. You can enable GPMC logging to gather verbose troubleshooting information when an administrative task causes errors.

**Enabling Verbose GPMC Logging**

| ⚠Caution |
| --- |
| This section contains information about modifying the registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, see Description of the Microsoft Windows Registry on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35500). |

**To enable GPMC logging on the administrative computer**

1. Log on to the administration computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or, , if the value already exists, modify it):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics**
3. Enter the following:

   **Value: gpmgmttracelevel**

   **Value Type: REG_DWORD**

   **Value Data: 2 (Hexadecimal)**

**Gpmgmttracelevel** can have the following values:

- **NORMAL 0x00000001**
- **VERBOSE 0x00000002**

The default value is **NORMAL (0x00000001)**.

**To restrict GPMC logging to file output**

1. Log on to the administration computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or, if the value already exists, modify it):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics**
3. Enter the following:

   **Value: gpmgmtlogfileonly**

   **Value Type: REG_DWORD**

   **Value Data: 1 (Hexadecimal)**

**Gpmgmtlogfileonly** can have the following values:

- **LOGTOFILEONLY 0x00000001**

- **LOGTOFILEANDDEBUGGER 0x00000002**

The default value is **LOGTOFILEONLY (0x00010001)**.

GPMC writes to the following log files in the **%Temp** folder:

- GPmgmt.log: contains all other GPMC logging information.

- GPmgmtManaged.log: Contains logging information for the reporting functionality.

**See Also**

Fixing Group Policy problems by using log files

# Enabling Logging for Group Policy Editor

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can enable logging of events generated by the Group Policy Object Editor for its core operations on the administrative computer.

**When To Enable Group Policy Object Editor Logging**
Group Policy Object Editor logging, by default, is set to only log errors. To avoid using unnecessary disk space, you should leave Group Policy Object Editor logging at the default setting. You can enable Group Policy Object Editor logging to gather verbose troubleshooting information when a Group Policy Object editing task causes errors.

**Enabling Group Policy Object Editor Logging**

| ⚠**Caution** |
| --- |
| This section contains information about modifying the registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, see Description of the Microsoft Windows Registry on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35500). |

**To enable GPedit logging on the administrative computer**

1. Log on to the client computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or, if the value already exists, modify it):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon**
3. Enter the following:

   **Value: GPEditDebugLevel**

   **Value Type: REG_DWORD**

   **Value Data: 10002 (Hexadecimal)**

**GPEditDebugLevel** can have the following values:

- **NONE 0x00000000**
- **NORMAL 0x00000001**
- **VERBOSE 0x00000002**
- **LOGFILE 0x00010000**
- **DEBUGGER 0x00020000**

The default value is **NORMAL|LOGFILE (0x00010001)**.

To disable logging, select **NONE (0X00000000)**.

You can also combine the **GPEditDebugLevel** values. For example, you can combine **VERBOSE 0x00000002** and **LOGFILE 0x00010000** to get 0x00010002. If you set **DGPEditDebugLevel** to 0x00010002, you turn on both **LOGFILE** and **VERBOSE**. By combining these values, you achieve the same effect as using an **OR** statement as follows:

0x00010000 OR 0x00000002 = 0x00010002

The log file is written to the **GPEdit.log** file in the **%Systemroot%\Debug\UserMode** folder.

**Concepts**
Enable Logging for Group Policy Object Editor Client Side Extensions

# Enable Logging for Group Policy Object Editor Client Side Extensions

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can enable logging of events generated by the Group Policy Object Editor for its Client Side Extensions on the administrative computer.

**When To Enable Group Policy Object Editor Client Side Extensions Logging**
Group Policy Object Editor CSE logging, by default, is set to only log errors. To avoid using unnecessary disk space, you should leave CSE logging at the default setting. You can enable CSE logging to gather verbose troubleshooting information when a Group Policy Object CSE editing task causes errors.

**Enabling Group Policy Object Editor Client Side Extensions Logging**

| ⚠Caution |
| --- |
| This section contains information about modifying the registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, see Description of the Microsoft Windows Registry on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35500). |

**To enable CSE Extensions logging on the client**

1. Log on to the client computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or modify it, if the value already exists):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon**
3. Enter the following:

   **Value: GPTextDebugLevel**

   **Value Type: REG_DWORD**

   **Value Data: 10002 (Hexadecimal)**

**GPTextDebugLevel** can have the following values:

- **NONE 0x00000000**
- **NORMAL 0x00000001**
- **VERBOSE 0x00000002**
- **LOGFILE 0x00010000**
- **DEBUGGER 0x00020000**

The default value is **NORMAL|LOGFILE (0x00010001)**.

To disable logging, select **NONE (0X00000000)**.

You can also combine the **GPTextDebugLevel** values. For example, you can combine **VERBOSE 0x00000002** and **LOGFILE 0x00010000** to get 0x00010002. If you set **GPTextDebugLevel** to 0x00010002, you turn on both **LOGFILE** and **VERBOSE**. By combining these values, you achieve the same effect as using an **OR** statement as follows:

0x00010000 OR 0x00000002 = 0x00010002

The log file is written to the **GPText.log** file in the **%Systemroot%\Debug\UserMode** folder.

**Concepts**

Fixing Group Policy problems by using log files

# Enable Logging for Core Group Policy

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To troubleshoot problems with user profiles and Group Policy processing, you can enable userenv logging.

| ⚠Caution |
| --- |
| This section contains information about modifying the registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, see Description of the Microsoft Windows Registry on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35500). |

**To enable userenv logging on the client**

1. Log on to the client computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or, if the value already exists, modify it):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon**
3. Enter the following:

   **Value: UserEnvDebugLevel**

   **Value Type: REG_DWORD**

   **Value Data: 10002 (Hexadecimal)**

**UserEnvDebugLevel** can have the following values:

- **NONE 0x00000000**
- **NORMAL 0x00000001**
- **VERBOSE 0x00000002**
- **LOGFILE 0x00010000**
- **DEBUGGER 0x00020000**

The default value is **NORMAL|LOGFILE (0x00010001)**.

To disable logging, select **NONE (0X00000000)**.

You can also combine the **UserEnvDebugLevel** values. For example, you can combine **VERBOSE 0x00000002** and **LOGFILE 0x00010000** to get 0x00010002. If you set **UserEnvDebugLevel** to 0x00010002, you turn on both **LOGFILE** and **VERBOSE**. By combining these values, you achieve the same effect as using an **OR** statement as follows:

0x00010000 OR 0x00000002 = 0x00010002

The log file is written to the **Userenv.log** file in the **%Systemroot%\Debug\UserMode** folder. If the **Userenv.log** file exists and is greater than 300 KB, the existing file is renamed to **Userenv.bak**, and a new log file created.

**Concepts**
Fixing Group Policy problems by using log files

# Enable Logging for Security Settings

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The security settings configuration and analysis tools include scecli.dll, which implements the client-side extension for Group Policy. Scecli.dll provides client-side interfaces to the security configuration engine and does Resultant Set of Policies (RSoP) logging during policy propagation.

Administrators can enable logging for scecli.dll. The log is written to the Winlogon.log file, which is created in the %SYSTEMROOT%\Security\Logs folder.

**To configure logging output for Security Configuration Client**

1. Start Registry Editor (Regedt32.exe).
2. Locate and click the following key in the registry:

   **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\GPExtensions\{827D319E-6EAC-11D2-A4EA-00C04F79F83A}**

   | **Note** |
   | --- |
   | The registry key is one path; it has been wrapped for readability. |

3. On the **Edit** menu, click **Add Value**, and then add the following registry value:

   **Value name: ExtensionDebugLevel**

   **Data type: DWORD**

   **Value data: 2**

To reproduce the failure, refresh the policy settings by typing the following at the command prompt: **gpupdate /force**.

For more information, see the Tools and Setting Collection in the Windows Server 2003 Technical Reference.

# Enable Logging for Folder Redirection Client Side Extension

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Folder Redirection can provide a detailed log that you can use to troubleshoot Group Policy issues.

**When To Enable Folder Redirection Logging**
Folder redirection CSE logging, by default, is set to only log errors. To avoid using unnecessary disk space, you should leave folder redirection logging at the default setting. You can enable folder redirection logging to gather verbose troubleshooting information when investigating folder redirection errors on a client computer.

**Enabling Verbose Folder Redirection Logging**

| ⚠**Caution** |
| --- |
| This section contains information about modifying the registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, see Description of the Microsoft Windows Registry on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35500). |

### To enable Folder Redirection logging on the client computer

1. Log on to the administration computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or modify it, if the value already exists):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics**
3. Enter the following:

   **Value: FdeployDebugLevel**

   **Value Type: REG_DWORD**

   **Value Data: 0F (Hexadecimal)**

**FdeployDebugLevel** can have the following values:

- **NORMAL 0x00000000**
- **VERBOSE 0x0000000F**

The default value is **NORMAL (0x00000000)**.

The log file can be found at: %Systemroot%\debug\usermode\fdeploy.log.

**See Also**
**Concepts**
Fixing Group Policy problems by using log files

# Enable Logging for Software Installation Client Side Extension

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Software installation can provide a detailed log that you can use to troubleshoot Group Policy issues.

**When To Enable Software Installation Logging**
Software Installation CSE logging, by default, is set to only log errors. To avoid using unnecessary disk space, you should leave software installation logging at the default setting. You can enable software installation logging to gather verbose troubleshooting information when investigating software installation errors on a client computer.

**Enabling Verbose Folder Redirection Logging**

| ⚠**Caution** |
| --- |
| This section contains information about modifying the registry. Before you modify the registry, make sure to back it up and make sure that you understand how to restore the registry if a problem occurs. For information about how to back up, restore, and edit the registry, see Description of the Microsoft Windows Registry on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35500). |

**To enable software installation logging on the client computer**

1. Log on to the administration computer as the administrator.
2. Click **Start**, **Run**, and then run Regedit to add the following registry value (or modify it, if the value already exists):

   **Key: HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics**

3. Enter the following:

   **Value: AppmgmtDebugLevel**

   **Value Type: REG_DWORD**

   **Value Data: 9B (Hexadecimal)**

**FdeployDebugLevel** can have the following values:

- **NORMAL 0x00000000**
- **VERBOSE 0x0000009B**

The default value is **NORMAL (0x00000000)**.

The log file can be found at: %Systemroot%\debug\usermode\appmgmt.log.

Fixing Group Policy problems by using log files

# Enable Logging for Internet Explorer Client Side Extension

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Internet Explorer logs Internet Explorer Maintenance CSE Group Policy processing by default.

Internet Explorer logs Internet Explorer Maintenance CSE Group Policy processing events in the Brndlog.txt file. The Brndlog.txt file can be found in one of the following two locations depending on the version of Internet Explorer:

- %USERPROFILE%\Application Data\Microsoft\Internet Explorer
- %USERPROFILE%\Local Settings\Application Data\Microsoft\Internet Explorer

# Troubleshooting Group Policy Problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic introduces the recommended framework for troubleshooting Group Policy.

**Understanding Group Policy Processing**
Before discussing Group Policy troubleshooting, you need to develop a general understanding of how Group Policy is processed at the client. Group Policy processing has two distinct phases:

- Core Group Policy processing. When a client begins to process Group Policy, it must determine whether it can reach a domain controller, whether any GPOs have changed, and what policy settings (based on client side extension) must be processed. The core Group Policy engine performs the processing of this in the initial phase.

- Client side extension (CSE) processing. Policy settings are grouped into different categories, such as Administrative Templates, Security Settings, Folder Redirection, Disk Quota, and Software Installation. The settings in each category require a specific CSE to process them, and each CSE has its own rules for processing settings. The core Group Policy engine calls the CSEs that are required to process the settings that apply to the client.

**Recommended Process for Troubleshooting**
**High level steps to troubleshoot Group Policy**

1. Check the required infrastructure. Make sure required services and components are running and configured as expected.

2. Check the core configuration. Verify that the computer is connected to the network, joined to the domain, and has the correct system time.

3. Check Group Policy exceptions. Verify that exceptions (scope of management) such as security filtering, WMI filters, block inheritance, enforcement , loopback processing and slow link settings are not affecting normal GPO processing.

4. Use tools like GPResult.exe, GPOTool.exe and the GPMC to ensure that Group Policy settings that are expected to be delivered are actually delivered and that Group Policy objects on domain controllers are consistent and available.

5. Use event logs, userenv logs, and CSE logs to analyze the problem and find a solution.

After checking network connectivity, it's recommended to first verify whether a problem can be traced to core Group Policy. Because CSEs cannot begin to work until core Group Policy processing is completed, the issues described in the topics in Fixing Core Group Policy problems apply regardless of which CSE processes the setting. Therefore, you should make sure that your problem is not a core Group Policy problem before you begin to troubleshoot the other areas listed above.

To help determine what kind of Group Policy problems you have, do the following:

1. Generate a Group Policy Results report using GPMC.

2. Examine the results of the report to find the answers to three questions that are used in navigating the flowchart:

    - Does Group Policy Results list the GPO as applied?

    - Is the setting listed in Group Policy Results Report?

    - Is the GPO listed in the Denied List?

3. Compare the results of the report to the flowchart in Figure 1.

4. Most of the results in the report map to core Group Policy problems in the flowchart. Investigate the core Group Policy problems first, even if the results of your report point to a specific CSE.

5. If the problem persists, assess whether a CSE is involved.

6. If you still haven't located the problem, you might need to look at log files to determine the cause.

7. If you experience a component failure, check the userenv log and see if the Local Security Authority has logged any events.

For more information about running the Group Policy Results Report and interpreting the flowchart, see Fixing Core Group Policy problems.

To troubleshoot Group Policy, you need to address one or more of the following areas:

- Fixing Core Group Policy problems

  This section begins with a flowchart for troubleshooting Group Policy core functionality. It's designed to help you pinpoint likely causes of the problem and quickly eliminate other possible causes. For more information about specific problems, see the following:

  - Fixing Group Policy networking issues
  - Fixing Group Policy processing issues
  - Fixing Group Policy scoping issues
  - Fixing Group Policy structural issues

- Fixing issues relating to a specific CSE or type of policy setting. This section includes ways of troubleshooting that are unique to a specific type of policy. For information about specific problems, see the following:

  - Fixing Administrative Template policy setting problems
  - Fixing Security Settings Problems
  - Fixing Scripts policy settings problems
  - Fixing Software Installation policy setting problems

- Fixing Folder Redirection policy settings problems
- Fixing Disk Quota extension problems

- Fixing Group Policy problems by using log files

  This section helps you interpret many of the errors found in logs such as userenv.log and winlogon.log. Sometimes, you need to enable verbose logging on log files and analyze the results.

**Asynchronous Processing and Logon Optimization in Windows XP**

Group Policy can be applied during startup and logon (synchronous processing) or as a background task after startup or logon has completed (asynchronous processing). Changes received during periodic Group Policy refresh or in response to the gpupdate command are processed asynchronously. On computers running Windows XP, group policies received during logon are also processed asynchronously by default, so that the logon is completed more quickly.

Software Installation and scripts processing must be applied during startup or logon. Folder Redirection assigned to the user must be applied during logon. By default, Windows XP logs a user on in asynchronous mode. Group Policy is then applied in the background after the user is logged on. This results in faster logons. However, when a new GPO setting for Software Installation, Scripts, or Folder Redirection arrives at a computer running Windows XP, the user has already logged on by the time Group Policy has been evaluated. It is too late to apply the Software Installation setting. In this case a flag is set so that the next time computer is rebooted or the user logs on Group Policy will be evaluated and applied before the startup or logon is completed.

In situations where you need for users to receive software, implement folder redirection, or run new scripts in a single logon, apply a GPO with the setting **Always wait for the network at computer startup and logon to the computer**. This setting is located under **Computer Configuration\Administrative Templates\System\Logon** in the Group Policy Object Editor. For this setting to take effect, Group Policy must be refreshed or the computer restarted.

**Table 1 Timing of Synchronous and Asynchronous Processing**

| By default, how is policy processed on the client? | At Startup | At Logon | At Policy Refresh |
|---|---|---|---|
| Windows 2000 | Synchronously | Synchronously | Asynchronously |
| Windows XP Pro | Asynchronously | Asynchronously | Asynchronously |
| Windows Server 2003 | Synchronously | Synchronously | Asynchronously |

| Note |
|---|
| Servers do not perform asynchronous processing. |

For more information about different types of client side extension problems, see the following:

- Fixing Administrative Template policy setting problems
- Fixing Security Settings Problems
- Fixing Scripts policy settings problems
- Fixing Software Installation policy setting problems
- Fixing Folder Redirection policy settings problems
- Fixing Disk Quota extension problems

# Fixing Core Group Policy problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic uses a structured approach and flowcharts to troubleshoot Group Policy core functionality. In Windows XP and Windows Server 2003, you can use Resultant Set of Policy (RSoP) to track the final set of processed policy settings. GPMC provides an easy view into the RSoP data through its Group Policy Results tool. This topic is based on the use of Group Policy Results reports to view and analyze RSoP data. It is recommended that you read through this topic before moving to one of the subsections listed below.

**In this section**

- Fixing Group Policy networking issues
- Fixing Group Policy processing issues
- Fixing Group Policy scoping issues
- Fixing Group Policy structural issues

**Flowchart for Troubleshooting Group Policy Core Functionality**

Use the flowcharts in this topic to quickly identify the likely root causes for unexpected Group Policy behavior, based on three questions that are easily answered from the Group Policy Results report.

**Navigating the Troubleshooting Flowchart**

The troubleshooting flowcharts in this topic focus on core Group Policy processing. Their primary purpose is to help you validate that the underlying infrastructure is in place to support delivery of GPOs to the client, that the user and computer are appropriately targeted to receive the intended GPOs, and that Group Policy processing puts the correct GPOs into effect.

A Group Policy Results report is the primary resource for troubleshooting Group Policy using this flowchart. Specifically, when investigating a problem, the administrator — where possible — should generate a Group Policy Results report for the user and computer combination encountering the problem. The sections of the report contain the information you use to navigate through the flowchart.

**To generate a Group Policy Results report**

1. Open the Group Policy Management Console.

2. In the console tree, double-click the forest in which you want to create a Group Policy Results query, right-click **Group Policy Results**, and then click **Group Policy Results Wizard**.
3. In the **Group Policy Results Wizard**, click **Next** and enter the appropriate information.
4. After completing the wizard, click **Finish**.
5. If you want to print or save the report, right-click the settings report in the results pane, and then do one of the following:
    - Select **Print** to print the report.
    - Select **Save Report** to save the report.

An example of a Group Policy Results report is shown in Figure 2.

This example shows the **Summary** tab of the report with the Group Policy Objects sections under Computer Configuration Summary and User Configuration Summary expanded.

By examining the GPMC Results report, you can find answers to the following questions that are associated with the flowchart:

- Was the GPO applied to the client? The **Summary** tab shows this information.
- Is the policy setting listed in GPMC Results? The **Settings** tab shows this information in a way that reflects the user interface of the Group Policy Object Editor.
- Is the GPO listed as Denied in GPO Results? The **Summary** tab shows this information.

In this scenario the client has successfully received the GPO and the specific policy setting is in effect at the client. This means that the only problem is that the actual value of the policy setting is incorrect. For information about the individual settings that have been applied, see the **Settings** tab of the Group Policy Results report.

**GPO Applied, Policy Setting Listed in Group Policy Results Report**
The scenario used for "Navigating the Troubleshooting Flowchart" applies to this section.

**GPO Inheritance (Setting Listed)**
Although GPOs have been applied and the correct policy setting is listed, Group Policy inheritance might result in an unexpected GPO "winning" and providing a different value from the one expected. The settings are nested by source and type. To expose the settings, click **Show** on the nested rows, and then look at the **Winning GPO** column to discover which GPO defines the value for the policy setting. For more information, see GPO provides unexpected value.

**Replication (Setting Listed)**
After a change is made to either the GPO or the user or computer, that change must be replicated throughout the network. If you expected the winning GPO to supply a value for the setting other than the value that was actually applied, it might be that the GPO was changed recently and the change has not yet been replicated to the domain controller that supplied the GPO to the client. For more information, see Group Policy does not replicate.

**Group Policy Refresh (Setting Listed)**
If Group Policy Refresh has not occurred since the winning GPO was modified and replicated, the old value for the setting is applied. After the changes to a GPO have been replicated to the client's domain controller, they need to be transmitted to the client. This occurs when the client refreshes Group Policy. Until this has occurred the change will not be reflected at the client. You can either wait for a background refresh or force the refresh. For more information, see Group Policy does not refresh.

**Asynchronous Application of Group Policy (Setting Listed)**
Group Policy can be applied after the computer has started and the user has logged on. This is called asynchronous application of Group Policy, in contrast to synchronous processing that occurs as part of startup or logon.

If the problem is with a setting that can only be applied during startup or logon, it might have been detected during asynchronous Group Policy processing (for example, as part of a Group Policy refresh or during the asynchronous processing used for logon optimization in Windows XP).

**Client-Side Extension Issue (Setting Listed)**
After the core Group Policy engine has completed initial processing of the GPOs, it passes specific settings to CSEs to process. If the setting is listed but the value is wrong or the behavior on the client does not reflect the setting value, the failure might have occurred after this setting was passed to a CSE to process. For example, even if a Folder Redirection setting has been successfully passed to the Folder Redirection CSE, the CSE might not be able to complete processing for the setting. For more information, see the appropriate topic for the CSE. For example, for more information about Administrative Templates, see Fixing Administrative Template policy setting problems).

**Loopback Processing (Setting Listed)**
Loopback processing is a way to enforce a set of user settings at a computer regardless of who logs on at that computer. Typically, user settings are applied based on the site and OU membership of the user. If loopback processing is set for a computer, the user settings for anyone logged on to that computer are dependent (partially or fully) on the site and OU membership of the computer. The behavior depends on the mode of loopback processing. In Replace mode, only the user

settings defined in GPOs applied to the computer are used. In Merge mode, user settings from GPOs that would normally apply to the user are used provided they do not conflict with user settings in GPOs that apply to the computer.

Loopback processing only works if the computer and user are both in Windows 2000 or Windows Server 2003 domains. They can be in different domains, and one can be in a Windows 2000 domain while the other is in a Windows Server 2003 domain. You cannot deploy Group Policy to users in a Windows NT 4.0 domain by applying loopback to a computer in a Windows 2000 or Windows Server 2003 domain.

Security filters can affect the way loopback processing is applied. Even when the GPOs associated with the computer are used to define user settings, the user's credentials — not the computer's credentials — are validated against the GPO's security filter. Therefore the user's credentials determine whether the GPO should be applied.

For example, you could create a GPO with a security filter that restricts the GPO to system administrators, and then associate that GPO with a computer that is configured for loopback processing. The settings in that GPO would only be applied when a system administrator is logged on.

To determine whether loopback processing is in effect, look for the User Group Policy loopback processing mode setting on the **Settings** tab of the report, which appears under Computer Configuration\Administrative Templates\System\Group Policy. For more information, see Loopback processing does not work.

**GPO Applied, Policy Setting Not Listed in Group Policy Results Report**

In the Group Policy Results report, the structure of the **Settings** tab is similar to the structure used in the Group Policy Object Editor. Expand the sections on the **Settings** tab by clicking **Show**. If the expected policy setting does not appear at all, either no updated GPO containing the expected setting reached the client, or the setting might not be processed at the client.

**Replication (Setting Not Listed)**

After a setting is added to a GPO, that change must be replicated throughout the network. If the setting is specified in the GPO but is not listed in the Group Policy Results report on the client, it might be that the setting was recently added to the GPO, but the change has not yet been replicated to the domain controller that supplied the GPO to the client. For more information, see Group Policy does not replicate.

**Group Policy Refresh (Setting Not Listed)**

If Group Policy Refresh has not occurred since the winning GPO was modified and replicated, a newly added setting will not be applied. After the changes to the GPO have been replicated to the client's domain controller, they need to be transmitted to the client. This occurs during Group Policy refresh. You can either wait for a background refresh or force the refresh by running gpupdate, by logging off and logging on again (that is, for user configuration), or by restarting the computer (that is, for computer configuration). For more information, see Group Policy does not refresh.

**Lack of Operating System Support (Setting Not Listed)**

Some policy settings are supported on certain operating systems only or they require a minimum service pack to be applied. When a GPO delivers a policy setting to a client computer that does not support that setting, the operating system ignores the setting. For more information, see Policy setting is not supported.

**Slow Link (Setting Not Listed)**
Some policy settings do not apply over a slow link, which is defined by default as 500 kilobits-per-second. These settings include:

- Software Installation
- Scripts
- Folder Redirection settings

For more information, see Group Policy does not apply when connecting remotely over a slow link.

**GPO Not Applied, Listed in Denied List in Group Policy Results Report**
If the GPO successfully reaches the client, it appears either in the list of **Denied GPOs** or in the list of **Applied GPOs**. A GPO can be explicitly denied for any number of reasons. To determine whether a GPO is denied, look on the **Summary** tab or the Group Policy Results report. Under Computer Configuration Summary and again under User Configuration Summary, click **Show** to expand Group Policy Objects, and then show **Denied GPOs**. The reason for the denial is provided for each denied GPO.

**Security Filtering (GPO Denied)**
The user or computer does not have the user rights assigned for the GPO. The required privileges are Read and Apply Group Policy. Alternatively, a GPO might be associated with a Deny ACE, which overrides any other privileges granted to the user or computer. For more information, see Policy settings incorrectly applied or denied due to security filtering.

**Disabled Link (GPO Denied)**
There is a link to the GPO from a site, domain, or OU in the hierarchy of the user or computer, but that link has been explicitly disabled. You can quickly scan the navigation pane of GPMC for disabled links.

**Inaccessible GPO (GPO Denied)**
There is a link to the GPO, but the GPO cannot be accessed. There are several possible reasons for this:

- The permissions on the GPO or on folders in the path to the Group Policy template are insufficient for it to be accessed and read. If this situation occurs the Component Status section of the Group Policy Results report will indicate Failure for the component Group Policy Infrastructure.
- The GPO might have been deleted, but the link to it remains for some reason (such as replication lag).
- Network connectivity problems might prevent access to the GPO.
- The client is unable to contact any domain controller.

**Empty GPO (GPO Denied)**
A GPO will be denied if it has no settings. This occurs when an administrator has configured a GPO and linked to it, but has not set any policy settings within the GPO. Either remove the link to the GPO or add policy settings to the GPO. If there are no remaining links to the GPO, you should consider deleting it.

**WMI Filter (GPO Denied)**
A WMI filter applied to a GPO is essentially a Boolean (true/false) decision as to whether the entire GPO should be applied to the client computer. The filter is evaluated at the client when GPO is applied. Based on the embedded WQL query, the GPO will either be enabled or disabled. For more information, see Policy settings incorrectly applied or denied due to WMI filtering.

**GPO Not Applied, Not Listed in Denied List in Group Policy Results Report**
All the GPOs that reach the client appear on the **Summary** tab in either the **Group Policy Objects Applied** section or the **Group Policy Objects Denied** section. There are four lists altogether: two lists (that is, Applied GPOs and Denied GPOs) under **Computer Configuration Summary** for settings that are delivered from the computer's Active Directory hierarchy, and another two under **User Configuration Summary** for settings that are delivered from the user's Active Directory hierarchy. If the GPO is not listed as either **Applied** or **Denied** under either **Configuration Summary**, it did not reach the client.

Also note whether the GPO is listed in the expected **Configuration Summary** (Computers or Users) because this can affect which settings are actually applied, particularly if loopback processing is in effect.

**Scope of Management (GPO Not at Client)**
One of the most common causes of a GPO not being applied to a user or computer is that the GPO is not linked to a site, domain, or OU of which the computer or user is a member. GPOs are delivered to clients based on the site and OU memberships of the computer and the logged-on user. Group memberships are only used to further restrict application of the GPO. For more information, see GPO provides unexpected value.

**Replication (GPO Not at Client)**
After an administrator has linked a GPO to a site, domain, or OU in the hierarchy of the user or computer, the change must be replicated to the domain controller from which the client retrieved its GPOs. Also, if the user or computer has recently been added to an OU, the GPOs that apply to that OU might not be applied to the client until the change in OU membership has been replicated to the domain controller from which the client retrieves GPOs. For more information, see Group Policy does not replicate.

**Group Policy Refresh (GPO Not at Client)**
After an administrator has linked a GPO to a site, domain, or OU in the hierarchy of the user or computer, and the change has been replicated to the client's domain controller, the GPO still needs to reach the client. This occurs during Group Policy refresh. You can either wait for a background refresh or force the refresh.

**Network Connectivity (GPO Not at Client)**
Group Policy requires a reliable networking infrastructure to ensure appropriate communication between the client computer and a domain controller. This includes TCP/IP, DNS, and other dependent technologies. For more information, see Group Policy

does not refresh.

# Fixing Group Policy networking issues

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic includes a procedure you can use to verify your network configuration and addresses other network connectivity issues.

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Group Policy does not apply when connecting remotely over a slow link
- Unable to access domain controller
- Group Policy does not replicate

**Network Connectivity and Configuration**

For Group Policy to be received at the client, there must be network connectivity between the client and the domain controller. This section includes information about troubleshooting network connectivity.

To test for network connectivity problems, check system event logs on the client computer (that is, look for failed access attempts). You can also use the **ping** or **netdiag** commands to test network connectivity.

**To verify a properly configured connection:**

1. Type the following command at the command prompt:

   **netsh interface ip show config**

2. If you get an error, open **Network Connections**, and then resolve the problem by enabling or repairing the connection.
   - To enable the connection, right-click the connection and select **Enable**.
   - To repair the connection, right-click the connection and select **Repair**.
3. If the network connection is enabled, you should see a list showing values for IP address, subnet mask, default gateway, and so on.
4. If necessary, check each network setting to verify that it is configured properly.

# Group Policy does not apply when connecting remotely over a slow link

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Certain policy settings do not apply over a slow link. In addition, Internet Control Message Protocol (ICMP) must be working in order for slow link detection to function. This topic describes how to adjust the default values for slow links and includes registry keys for manually creating registry settings to disable slow links.

**Cause**

By default, Group Policy defines a slow link as 500 kilobits per second or less. The following types of policy settings are always applied over a slow link:

- Security Settings
- Administrative Template settings

The following types of policy settings are not applied over a slow link:

- Software Installation
- Scripts
- Folder Redirection settings

| **Note** |
| --- |
| If a user connects to the network over a slow link with cached credentials, Group Policy will not be processed. |

**Solution**

You can change this setting in the computer configuration, the user configuration, or both. See the policy setting **Group Policy slow link detection**, located in **Computer Configuration\Administrative Templates\System\Group Policy processing**. For example, if you have a 300 kilobit per second network connection, you could specify 150 kilobits per second. This would mean that if bandwidth on the remote connection is less than what would be tested as a 150 kilobit-per-second connection at the time a user logs on, the link will be flagged as a slow link.

To ensure that Group Policy is applied remotely, select the **Logon using dialup connection** check box while using the **Logon** dialog box.

Even if Group Policy settings are configured to run scripts over slow links, the scripts might run so slowly that they exceed the configured time-out period. In this case the script will fail to complete and a UserInit event will be posted. In addition, Gpresult will tell you if a slow link was detected.

**To configure slow link detection**

1. Open the policy setting Group Policy slow link detection, located in **Computer Configuration\Administrative Templates\System\Group Policy processing**
2. In **Connection speed**, type a decimal number between **0** and **4,294,967,200** (0xFFFFFFA0) to indicate a transfer rate in kilobits per second. Any connection slower than this rate is considered to be slow. To disable slow link detection, enter **0** (all connections will be considered to be fast).

If you are trying to disable slow link detection when Group Policy is not applying (and therefore, you cannot configure the policy setting), you can manually create the registry value **"GroupPolicyMinTransferRate" (DWORD)** under the following keys and set each of them to 0.

- **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon**

- **HKEY_CURRENT_USER\Software\Microsoft\Windows NT\CurrentVersion\Winlogon**

**Troubleshooting ICMP**
You can verify that ICMP is not working by looking at the Userenv log, which will indicate that ping computer fails.

Fixing Group Policy problems by using log files

# Unable to access domain controller

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic provides guidance for troubleshooting connectivity issues that can be traced to Domain Name System (DNS) configuration.

**Cause**

Group Policy application requires clients to access specified servers, including domain controllers and other servers such as share points and install points. Group Policy management also requires access to domain controllers. DNS is used to locate and identify these servers. In Windows Server 2003, Active Directory requires DNS support.

If the network is functioning, but clients or GPMC consoles are unable to locate the servers, there might be a problem with your network's DNS system.

**Solution**

To determine whether there is a problem in DNS, use the Ping tool against the computer using the NetBIOS name, and then use the Ping tool using the fully qualified domain name of the target computer. If the first Ping works but the second does not, this indicates that there probably is a DNS problem. Use Netdiag.exe to research the problem further.

Use Dcdiag.exe to troubleshoot domain controllers and use Netdiag.exe to troubleshoot client computers. These tools can help determine both server and client DNS misconfigurations. To run Dcdiag.exe, type **dcdiag /v** at a command prompt on a domain controller. To run Netdiag.exe, type **netdiag /v** at a command prompt on a workstation or member server.

To download these tools and obtain more information, see DCDiag and NetDiag in Windows 2000 Facilitate Domain Join and DC Creation on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43036).

Fixing Group Policy problems by using log files

# Group Policy does not replicate

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains how to troubleshoot replication issues for Group Policy.

**Causes**

There can be a lag time after a change has been made on one domain controller before the change is replicated to all other domain controllers. The propagation and resolution of these changes throughout the network is an ongoing process called replication convergence.

Until changes to a GPO have been replicated to the domain controller that a client is accessing, that client will receive the earlier version of the GPO during Group Policy refresh. If you suspect both replication and Group Policy refresh issues, address the replication issue first. Then refresh Group Policy at the client.

Changes to the OU memberships of computers and users also need to be replicated before they can be reflected in Group Policy application at the client. For more information see GPO does not apply to a specific user or computer.

In general, it is best to use the same domain controller for all GPO editing or to agree a process — such as delegated administration of GPOs — to minimize the likelihood of the same GPO being edited on a different domain controller. If changes are made to the same GPO at two different domain controllers, the last change wins. In addition, if you delegate control of a specific GPO to a user group, members of that group might be unable to perform the delegated tasks until the permissions have been replicated to their domain controller.

Although Remote Procedure Call (RPC) is not required for general application of policy settings, FRS does require RPC to be working on the domain controller. In addition, anything that calls the Local Security Authority (LSA) requires RPC.

**Solutions**

There are several options for troubleshooting replication issues:

- The Group Policy container and Group Policy template are each assigned version numbers, which are incremented when the GPO is modified. Use GPOTool to verify that the versions are synchronized.
- Use Event Viewer to examine the directory service for event log on the domain controller. Active Directory replication errors appear with source=KCC.
- Use Event Viewer to examine the File Replication service event log on the domain controller. FRS errors appear with source=NTFRS.
- Verify that the SYSVOL share exists on the domain controller. You should be able to find *domain_controller_name*\SYSVOL, where *domain_controller_name* is the fully qualified domain name (not the NetBIOS name) of the domain controller.
- Use Gpotool.exe to determine if there is an inconsistency between Active Directory and SYSVOL versions of the same GPO across peer domain controllers. This information can help you determine if replication latency is causing the Windows client to not receive the correct policy. If you think this is the case, use Replmon.exe and Repadmin.exe (included with Windows 2000 Support Tools) to determine the replication partners for the domain controller that the client used as a source for the Group Policy and determine if replication is succeeding.
- To troubleshoot file replication issues, check the status of the Directory File Service links and targets. Group Policy requires Directory File Service. For more information, see "To check status of a DFS root, DFS link, or target" in Help and Support Center for Windows Server 2003.
- You can use the Sonar.exe tool to check the health of the SYSVOL share.

Group Policy does not refresh

# Fixing Group Policy processing issues

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section explains Group Policy processing rules and points to troubleshooting tips. Group Policy objects (GPOs) are applied according to a set of standard processing rules, as explained below. You can apply exceptions to these rules and sometimes these exceptions — if not applied carefully — can lead to unexpected behavior.

- Standard processing rules
- Exceptions to processing rules
- Fixes for specific processing issues

**Standard processing rules**

This section provides details about the order in which Group Policy settings for users and computers are processed.

Group Policy settings are processed in the following order:

1. **Local Group Policy object—**Each computer has exactly one Group Policy object that is stored locally. The Local GPO processes for both computer and user Group Policy processing.

2. **Site—**Any GPOs that have been linked to the site that the computer belongs to are processed next. Processing is in the order that is specified by the administrator, on the **Linked Group Policy Objects** tab for the site in Group Policy Management Console (GPMC). The GPO with the lowest **link order** is processed last, and therefore has the highest precedence.

3. **Domain—**Processing of multiple domain-linked GPOs is in the order specified by the administrator, on the **Linked Group Policy Objects** tab for the domain in GPMC. The GPO with the lowest **link order** is processed last, and therefore has the highest precedence.

4. **Organizational units—**GPOs that are linked to the organizational unit that is highest in the Active Directory hierarchy are processed first, then GPOs that are linked to its child organizational unit, and so on. Finally, the GPOs that are linked to the organizational unit that contains the user or computer are processed.

   At the level of each organizational unit in the Active Directory hierarchy, one, many, or no GPOs can be linked. If several GPOs are linked to an organizational unit, their processing is in the order that is specified by the administrator, on the **Linked Group Policy Objects** tab for the organizational unit in GPMC. The GPO with the lowest **link order** is processed last, and therefore has the highest precedence.

This order means that the local GPO is processed first, and GPOs that are linked to the organizational unit of which the computer or user is a direct member are processed last, which overwrites settings in the earlier GPOs if there are conflicts. (If there are no conflicts, the earlier and later settings are merely aggregated.)

**Exceptions to processing rules**

The default order for processing settings is subject to the following exceptions:

- A GPO link may be enforced, or disabled, or both. By default, a GPO link is neither enforced nor disabled. For troubleshooting information, see GPO provides unexpected value.

- A GPO may have its user settings disabled, its computer settings disabled, or all settings disabled. By default, neither user settings nor computer settings are disabled on a GPO.

- An organizational unit or a domain may have **Block Inheritance** set. By default, **Block Inheritance** is not set. For troubleshooting information, see GPO provides unexpected value.

- A computer that is a member of a workgroup processes only the local Group Policy object.
- Loopback may be enabled. For troubleshooting information, see Loopback processing does not work.
- GPOs can be subject to security filtering or WMI filtering to limit the scope of application. For troubleshooting information, see Fixing Group Policy scoping issues.

**Fixes for specific processing issues**

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Policy setting is not supported
- GPO provides unexpected value
- Group Policy does not refresh
- Policy settings do not apply for software installation, scripts, or folder redirection
- Group Policy is not applied due to cached credentials
- Machine required resources are not available
- Loopback processing does not work

# Policy setting is not supported

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are trying to apply a policy setting to a computer running an earlier operating system or service pack, the policy setting may not apply.

**Cause**

Many Group Policy settings were introduced for Windows XP, Windows XP with Service Pack 2 (SP2) and Windows Server 2003 that are not supported by earlier operating systems. If a setting is not supported, Group Policy will set the registry key to the specified value, but it is effectively ignored because no application or component will read that registry key. Computers running Windows operating systems that are earlier than Windows 2000 do not support Group Policy.

**Solution**

Verify that the setting is supported by the client's operating system. The Group Policy Object Editor displays the operating systems where each policy setting is supported. For more information about policy settings, see the Group Policy Settings Reference for .adm files and Security Settings included with Windows XP Professional Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=15165).

# GPO provides unexpected value

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains common causes for unexpected GPO values due to GPO precedence, inheritance, and related scope of management issues.

**Causes**

- Conflict resolution applies to individual settings, not to entire GPOs. It could easily happen that one setting in a GPO encounters a conflict but all other settings in that GPO are applied.
- The GPO with the lowest link number prevails over other GPOs that the same site, domain or OU is linked to. You can use GPMC to change the order of links for a specific site, domain, or OU. (The links are a property of the site, domain, or OU; they are not a property of the GPO.)
- If a Group Policy link is disabled the GPO will not apply to users or computers within the container to which that GPO is linked.
- The **Enforce** setting is a property of the link between an Active Directory container and a GPO. It is used to force that GPO to all Active Directory objects within a container, no matter how deeply they are nested. The settings within a GPO that is enforced override other settings that would prevail because they are applied later. If there are conflicting settings in GPOs that are enforced at two levels of the hierarchy, the setting enforced furthest from the client prevails. This is a reversal of the usual rule, in which the setting from the nearest-linked GPO would prevail.

The actual effect of **Enforce** is to change the order of processing. The settings in an Enforced GPO are processed after all other GPOs settings are processed.

- The **Block Inheritance** setting applies to an entire Active Directory container. It blocks the inheritance of all GPOs except for those for which the link from the parent Active Directory object to the GPO has the **Enforce** setting enabled.
- Administrators who have set **Block Inheritance** on their domain or OU can still make explicit links to GPOs elsewhere in the domain, including GPOs that might otherwise be inherited. (Domains do not inherit GPOs from parent domains.) When **Block Inheritance** is applied at a domain level, it blocks GPOs that are linked to sites.

**Solutions**

Perform the following procedures to resolve this issue.

**To view or change precedence order of GPOs**

1. Open GPMC and click any site, domain, or organizational unit node.
2. Click the **Group Policy Inheritance** tab and examine the precedence order of the GPOs. Within each domain, site, and organizational unit, the link order controls when links are applied.
3. To change the precedence of a link, you can change the link order, moving each link up or down in the list to the appropriate location. The link with the higher order (with 1 being the highest order) has the higher precedence for a given site, domain, or organizational unit. For example, if you add six GPO links and later decide that you want the last one that you added to have highest precedence, you can move the GPO link to the top of the list.

**To check GPO links**

1. In GPMC, select the GPO you are troubleshooting, and then click the **Scope** tab. You will see the containers that are linked to the GPO and the status of those links.
2. To change the status of a link, click the **Details** tab, and then in **GPO Status**, choose an option. You can enable all settings, disable only computer settings, or disable only user settings.

# Group Policy does not refresh

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic describes how Group Policy refresh rules affect processing and explains how to collect refresh information using the Group Policy Management Console.

**Cause**

Group Policy refresh refers to the retrieval of GPOs by a client. During Group Policy refresh, the client contacts an available domain controller. If any GPOs have changed, the domain controller provides a list of all the appropriate GPOs, regardless of whether their version numbers have actually changed.

Replication and Group Policy refresh are both instances of lag-time issues: the system is working properly, but changes have not yet appeared at the client.

By default, GPOs are processed by client side extensions (CSEs) at the computer only if the version number of at least one GPO has changed on the domain controller that the computer is accessing. You can use policy settings to change this behavior.

Some CSEs process unchanged GPOs if the user's group membership has changed. At startup, Group Policy is refreshed, and computer settings are applied. Group Policy is refreshed and computer and user settings are applied in the following instances:

- When a user logs on
- When **gpupdate** is run at the client computer
- At the refresh interval, if one is configured at that computer (by default, domain controllers are refreshed every five minutes, and all other computers are refreshed every 90 minutes, with a random factor of up plus or minus 30 minutes)

**Solution**

To see the last time the GPOs from the computer's OU were processed, on the Group Policy Results report, under **Computer Configuration Summary**, and then under **General**, click the **Summary** tab.

To see the last time the GPOs from the user's OU were processed, on the Group Policy Results report, under **User Configuration Summary**, and then under **General**, click the **Summary** tab.

To collect Group Policy refresh information from clients and store them at a central location, use GPMonitor.exe. For more information and to download GPMonitor.exe, see Windows Server 2003 Resource Kit Tools on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=27766).

| **Note** |
| --- |
| Some types of settings can only be applied when a user logs on. These include Folder Redirection, Roaming Profiles, and Software Installation settings. If these settings are received when Group Policy is refreshed, the settings are evaluated, but they are not applied until the next time the user logs on.<br><br>If the computer is running Windows XP and these settings first reach the computer during logon, they might not be applied until the next time the user logs on. For some extensions, it might take two or three logons for the settings to be applied. |

A simple way to troubleshoot a suspected Group Policy refresh issue is to force the refresh by running **gpupdate** and either restarting the computer, or by logging off and logging on again. If Folder Redirection, roaming profiles, or Software Installation is involved and the computer is running Windows XP, run **gpupdate**, and then log off and log back on. You might need to log off and log back on more than once.

# Policy settings do not apply for software installation, scripts, or folder redirection

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Group Policy can be applied during startup and logon (synchronous processing) or as a background task after startup or logon has completed (asynchronous processing). Changes received during periodic Group Policy refresh or in response to the **gpupdate** command are processed asynchronously. On computers running Windows XP, Group Policy settings received during logon are also processed asynchronously by default, so that the logon is completed more quickly. This is also known as "fast boot" logging.

**Cause**

Software Installation and scripts processing must be applied during startup or logon. Folder Redirection assigned to the user must be applied during logon. By default, Windows XP logs a user on in asynchronous mode (that is, fast boot). Group Policy is then applied in the background after the user is logged on. However, when a new GPO setting for Software Installation, Scripts, or Folder Redirection arrives at a computer running Windows XP, the user has already logged on by the time Group Policy has been evaluated. It is too late to apply the Software Installation setting. In this case a flag is set so that the next time computer is rebooted or the user logs on Group Policy will be evaluated and applied before the startup or logon is completed.

**Solution**

In situations where you need for users to receive software, implement folder redirection, or run new scripts in a single logon, apply a GPO with the setting **Always wait for the network at computer startup and logon to the computer**. This setting is located under **Computer Configuration\Administrative Templates\System\Logon** in the Group Policy Object Editor. For this setting to take effect, Group Policy must be refreshed or the computer restarted. To ensure a consistent experience in a mixed desktop environment, consider enabling this setting for all your Windows XP computers.

**Table 1 Timing of Synchronous and Asynchronous Processing**

| By default, how is policy processed on the client? | At Startup | At Logon | At Policy Refresh |
|---|---|---|---|
| Windows 2000 | Synchronously | Synchronously | Asynchronously |
| Windows XP Professional | Asynchronously | Asynchronously | Asynchronously |
| Windows Server 2003 | Synchronously | Synchronously | Asynchronously |

| Note |
|---|
| Servers do not perform asynchronous processing. |

# Group Policy is not applied due to cached credentials

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains how cached credentials can prevent Group Policy from applying correctly.

**Cause**

When a user successfully logs on to the network, the credentials for that user can be cached on the local computer. If network connectivity problems prevent the user from being authenticated the next time the user logs on to the same computer, these cached credentials can be used to give the user access to resources on that computer. If the computer successfully connects to the network later, the cached credentials can be used to provide access to network resources, including GPOs that are received at the next Group Policy refresh.

If a domain controller is not available when the user logs on Group Policy cannot be refreshed at logon. In this case, new Group Policy settings will not be applied until a Group Policy refresh occurs while a domain controller is available.

When the logon is done with cached credentials and then a remote access connection is established, Group Policy is not applied during logon. For example, if users connecting through a VPN connection are logging on using cached credentials, folder redirection settings will not be processed because folder redirection policy can only be processed at user logon, not in the background refresh.

| **Note** |
| --- |
| Some user settings can only be applied during logon. These include roaming user profile path, Folder Redirection path, and Software Installation settings. If the user is already logged on when these settings are detected, they will not be applied until the next time the user is logged on. |

**Solution**

To avoid using cached credentials in a remote access connection, users should select the **Logon using dial-up connection** check box on the Windows Logon dialog box. When this occurs, both User and Computer Group Policy is applied, provided the computer is a member of the domain that the remote access server belongs to or trusts. However, computer-based software installation settings are not processed because, typically, computer policy would have been processed before the logon screen, but since no network connection is available until logon, the application of computer policy is done as background refresh at the time of logon.

# Machine required resources are not available

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This error indicates that memory allocation failed, or that some other necessary machine resource could not be obtained. Group Policy processing for the computer or user has failed and will continue to fail until this error is resolved.

**Cause**

This error is usually caused by low memory or low disk space on the machine at the time that Group Policy was processing.

The following Event Numbers trigger this error:

- 1002
- 1035
- 1063
- 1075
- 1078
- 1081
- 1082
- 1094
- 1107

**Solution**

To troubleshoot this problem, try one or all of the following:

- Review the event description to obtain additional details.
- Ensure that an adequate amount of memory is available on the machine. If the machine is very low on memory, take steps to free up the necessary resources.
- Ensure that adequate disk space is available on the machine. If the machine is very low on disk space, take steps to free up the necessary resources.

# Loopback processing does not work

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains how loopback processing alters the way GPOs are normally applied and provides tips for troubleshooting.

**Loopback Processing**

Loopback is an advanced Group Policy setting that is useful in scenarios where you are managing computers in closely managed environments, such as servers, kiosks, laboratories, classrooms, and reception areas. Loopback only works when both the user account and the computer account are in a Windows 2000 or later domain. Loopback does not work for computers joined to a workgroup. Setting loopback causes the User Configuration settings in GPOs that apply to the computer to be applied to every user logging on to that computer, instead of (in replace mode) or in addition to (in merge mode) the User Configuration settings of the user. This allows you to ensure that a consistent set of policies is applied to any user logging on to a particular computer, regardless of their location in Active Directory. Loopback is controlled by the **User Group Policy loopback processing mode** setting, which is located under **Computer Configuration\Administrative Templates\System\Group Policy** in Group Policy Object Editor (GPMC).

By default, a user's policy settings come from the set of GPOs that are applied to the user object in Active Directory. During Group Policy processing on the client, the Group Policy engine assembles an ordered list of GPOs from the site, domain, and all organizational units for that user object.

Loopback can be set to Not Configured, Enabled, or Disabled. In the Enabled state, loopback can be set to Merge or Replace. In either case the user only receives user-related policy settings.

- **Loopback with Replace**—In the case of Loopback with Replace, the GPO list for the user is replaced in its entirety by the GPO list that is already obtained for the computer at computer startup. The User Configuration settings from this list are applied to the user.

- **Loopback with Merge**—In the case of Loopback with Merge, the Group Policy object list is a concatenation. The default list of GPOs for the user object is obtained, as normal, but then the list of GPOs for the computer (obtained during computer startup) is appended to this list. Because the computer's GPOs are processed after the user's GPOs, they have precedence if any of the settings conflict.

To find out whether loopback processing was applied when Group Policy was evaluated on the client, look in the Group Policy Results report under **Computer Configuration\Administrative templates\System\Group Policy** on the **Settings** tab.

**Troubleshooting Loopback Processing**

- If the loopback processing is appropriate for this client you might need to educate the users so they know what to expect.

- If loopback is desired and it appears that it is not being applied, first verify the loopback policy setting (which is a computer configuration policy) has been applied to the computer through an appropriate GPO.

- For specific information about troubleshooting loopback replace in a cross-forest environment, see Loopback Replace does not work in cross forest environment.

# Loopback Replace does not work in cross forest environment

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Group Policy Loopback-Replace mode allows you to force a user to use a particular set of user GPOs instead of the ones that the user account is normally tied to. This is helpful in terminal server environments because it guarantees the integrity of your terminal servers. It is also useful in a public computer environment, such as a kiosk or library, where many different people log on to computers.

Cross-forest trust was introduced in Windows Server 2003. With a cross-forest trust you can connect two root domains, which gives both domains access to each other's domain. In addition, any new domains that are created under either root domain is automatically given the same access as the parent root domain. This enables different forests to communicate with each other, and it also enables users to log on to computers in either forests with ease.

Problems with Loopback-Replace in a cross-forest environment can be difficult to troubleshoot, due to the number of factors that can effect it. Even if your Group Policy is set up correctly, you can still have problems getting Loopback-Replace to work in a cross-forest environment.

**Event IDs**

The following event IDs are relevant to this section:

| Source | Event ID | Event Text |
|---|---|---|
| Userenv | 1529 | Loopback Group Policy processing will be applied, using the Group Policy objects scoped to the machine. |
| Userenv | 1109 | A User from a different forest logged onto this machine. Cross Forest Group Policy processing is disabled and loopback processing has been enforced in this forest for this user account. |

**Cause**

To understand how Loopback-Replace works, you need to understand the processing order of GPOs. When a computer is turned on, the computer applies the machine GPOs from the site, domain, and each nested OU that applies to it. When the user logs on to the computer, it processes the user GPOs in the same order. With Loopback-Replace you are changing how the computer processes the GPOs. Instead of the user's GPOs processing the normal way, they get the GPOs that you specify instead; regardless of which domain they are coming from or what GPOs are applied to them normally.

A number of things can cause Loopback-Replace to fail, and due to the complexity of cross-forest environments, the number of potential problems increases when the two technologies are used together. Potential causes of a Loopback-Replace failure could be that loopback was set up inappropriately, Organizational Units do not have the necessary user Group Policy for the Loopback to reference, or RPC is not running on the machine's domain controller.

If you have Loopback-Replace running in a cross-forest environment, you can have some additional problems. The main ones are tied to network health and connectivity. It is important to make sure that the domains are able to communicate with each other and still have full two-way trust. Firewalls between the two domains can also cause problems by blocking access from the machine that the user is attempting to log on to and the domain controller that user belongs to.

**Solution**

Verify that you have setup Loopback-Replace Mode correctly in Group Policy. To turn on Loopback-Replace Mode, create a GPO linked to the server OU you just created. Under **User Configuration**, click **Administrative Templates**, click **System**, click **Group Policy**, and then double-click the **User Group Policy Loopback Processing Mode** policy setting. Activate the policy by clicking **Enabled**. After you have enabled the setting, click **Mode**, click **Replace**, and then click **OK**.

If this does not fix the problem, try troubleshooting network connectivity between the target computer and the domain controller in the user's originating forest. In order for the computer to be able to contact the domain controller of the computer and for the user, RPC must be running. Run the rpings.exe and the rpingc.exe commands to determine the health of RPC on your network. You can also try running a network trace from the target machine to the user's domain controller. If possible, it would also be helpful to run a network trace at the same time from the domain controller to the target machine, which should help you determine the location of any network problems. A network trace will also help you determine if a firewall is causing this issue.

**Supported Operating Systems**

Cross-forest trust and Loopback-Replace are not available on all current Microsoft operating systems. Use the following table to determine whether your network is capable of running this setup.

| **Operating System** | **Supported** |
|---|---|
| Windows Server 2003 | Yes |
| Windows XP Service Pack 2 (SP2) | Yes |
| Windows XP Service Pack 1 (SP1) or earlier | No |
| Windows 2000 Service Pack 4 (SP4) | Yes |
| Windows 2000 Service Pack 3 (SP3) or earlier | No |

# Fixing Group Policy scoping issues

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section explains scoping rules and points to troubleshooting tips.

**Scoping the GPO**
Determining which users and computers will receive the settings in a GPO is referred to as "scoping the GPO." Scoping a GPO is based on three factors:

- The site, domain, or organization unit where the GPO is linked
- The security filtering on the GPO
- The WMI filter on the GPO

You can use the site, domain, and OU links from a GPO as the primary targeting principle for defining which computers and users should receive a GPO. You can then use security filtering and WMI filtering to further reduce the set of computers and users to which the GPO will apply.

If incorrectly configured, security filtering or WMI filtering can lead to unexpected results. This section provides ways to troubleshoot these areas.

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Policy settings incorrectly applied or denied due to WMI filtering
- Policy settings incorrectly applied or denied due to security filtering

# Policy settings incorrectly applied or denied due to security filtering

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are using security filtering, you may need to check permissions on the GPO if you are encountering unexpected behavior.

**Cause**

You can use Group Policy to provide or deny access to programs and data in your network, and to enforce policies regarding computer configuration based on assigned privileges and security group memberships. You accomplish this by using the access control functionality built in to Windows 2000 Server and Windows Server 2003 domains and is known as security filtering.

You can restrict application of all the settings in a GPO on the basis of security group memberships by setting a security filter on that GPO. If the computer account or user account does not meet the security filtering criteria, the entire GPO will be denied at that client. For example, you can assign special settings to all the administrators in a portion of the hierarchy by setting the security filter to apply the GPO to all administrators, and then linking the GPO to the highest node in the portion of the hierarchy where you want the settings to apply. All users in that portion of the hierarchy will receive the GPO, but only members of the administrators group will be affected by it.

A security group, user or computer must have both Read and Apply Group Policy permissions for a policy to be applied. By default, all users and computers have these permissions for all new Group Policy Objects. These permissions are inherited from their membership in the implicit group Authenticated Users. An authenticated user is any user (or computer) that has logged on to the domain and been authenticated.

**Solution**

To see the security groups that were in effect when Group Policy was applied to a specific computer, look in the Group Policy Results report for that computer. Under both Computer Configuration Summary and User Configuration Summary, expand Security Group Membership when Group Policy was applied.

**To check security filtering on a GPO**

1. In GPMC, open **Group Policy Objects** node, select the GPO you are troubleshooting, and then in the right pane select the **Scope** tab. The **Security Filtering** and **WMI Filtering** panels show the current filtering configuration.
2. To see the exact set of permissions for users, groups and computers, select the **Delegation** tab and then click **Advanced**. Select the security group, user or computer you want to review. Keep the following in mind:
   - If the policy object should be applied to the security group, user or computer, the minimum permissions should be set to allow **Read** and **Apply Group Policy**.
   - If the policy object should not be applied to the security group, user or computer, the minimum permissions should be set to allow **Read** and deny **Apply Group Policy**.

If a GPO is incorrectly denied or applied due to security filtering because the user or computer had different security group memberships than expected, use Active Directory Users and Computers to check and, if necessary change, the security group memberships.

When restricting the application of a GPO, be sure to remove **Authenticated Users**. Otherwise all users will always be affected by the GPO.

Computers are members of the Authenticated Users group. If you remove **Authenticated Users** from the list on the **Scope** tab and you want the GPO to apply to a computer, you must specifically ensure that the computer belongs to a group that is included in the **Security Filtering** section on the **Scope** tab.

# Policy settings incorrectly applied or denied due to WMI filtering

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

WMI filters can affect whether or not a particular GPO is being processed. If a WMI returns a false value, the GPO that it is linked to will not be processed.

**Cause**
If the GPO is linked to a WMI filter, the queries in the WMI filter are evaluated against the data provided by WMI on the client. Such data can include hardware and software inventory, settings, and configuration information.

- If all of the criteria are true, the GPO is applied.
- If any of the criteria is false, the GPO is denied.

If a WMI filter is deleted, the links to the WMI filter are not automatically deleted. If there is a link to a non-existent WMI filter, the GPO with that link will not be processed until the link is removed or the filter is restored.

**Note** Only Windows XP and Windows Server 2003 support WMI filtering. If the computer is running an earlier operating system (such as Windows 2000), the WMI filter is ignored and the GPO is applied.

**Solution**
GPMC shows any WMI filters linked to GPOs that are processed by the computer and the result of the filter as it was evaluated for that computer (or user).

**To check WMI filters using GPMC**

1. Open GPMC, click the GPO that you want to troubleshoot, and then click the **Scope** tab. The **WMI Filtering** section shows whether a WMI filter is linked to the GPO.
2. If you need to edit the filter, click **Open**, and then click **Edit**.

# Fixing Group Policy structural issues

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This page explains linking rules and points to troubleshooting tips.

**Active Directory and Group Policy**
Active Directory organizes objects by sites, domains, and OUs. Domains and OUs are organized hierarchically, making the containers and the objects within them easy to manage. The settings defined in a GPO can only be applied when the GPO is linked to one or more of these containers.

By linking GPOs to sites, domains, and OUs, you can implement Group Policy settings for as broad or as narrow a portion of the organization as you want. GPO links affect users and computers in the following ways:

- A GPO linked to a site applies to all users and computers in the site.
- A GPO linked to a domain applies directly to all users and computers in the domain and by inheritance to all users and computers in child OUs. Policy is not inherited across domains.
- A GPO linked to an OU applies directly to all users and computers in the OU and by inheritance to all users and computers in child OUs.
- When a GPO is created, it is stored in the domain. When the GPO is linked to an Active Directory container, such as an OU, the link is a component of that container, not a component of the GPO.

**Fixes for specific structural issues**
From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- GPO does not apply to a specific user or computer
- Critical files on domain controllers or client computers are missing or corrupted
- Trust relationships are not working
- Group Policy does not apply after migration

# GPO does not apply to a specific user or computer

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains the importance of correct Organizational Unit memberships and GPO linking and shows how to check these issues using GPMC and other tools.

**Cause**
GPOs are applied to a client only if they are linked to a site, domain, or OU to which the computer or the user at that computer belongs.

For troubleshooting purposes, you need a solid understanding of your organization's Active Directory structure and the Group Policy inheritance and filtering rules. With this information and the Resultant Set of Policy (RSoP) functionality in Windows Server 2003 and Windows XP, you can manipulate your Active Directory structure and your Group Policy links and filters to deliver targeted settings to the users and computers in your organization. The same information is needed to troubleshoot situations where these manipulations produce an unexpected result.

**Solution**
Check Active Directory Users and Computers to see what site, domain, and OU the user and the computer are in.

In GPMC, expand the Active Directory containers that contain the affected client. In the navigation pane, scan the list of GPOs for each container for disabled links.

GPOs are filtered according to the Active Directory groups that the users and computers belong to. The Active Directory objects in which you place your Active Directory groups and the ways you group users or computers affect how GPOs can be distributed and applied.

Active Directory and FRS replication lag can affect either part of the GPO.

If you have an OU that contains other OUs and you remove Read permissions to the parent OU, then no policy will be processed by computers or users in that OU hierarchy.

If there are conflicting settings in the GPOs that apply to the client, they are resolved according to the Group Policy inheritance rules.

**Adding a User or Computer to an OU**
When a user or computer is added to an OU, two things need to happen before the GPOs that the new OU links to are applied to the client:

- The new OU assignment must be replicated to the client's domain controller.
- After the replication is complete, you must either log off and log back on again if the user account moved to the new OU, or restart the computer if the computer moved to the new OU.

# Critical files on domain controllers or client computers are missing or corrupted

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Group Policy might not apply due to missing or corrupted files.

**Cause**
Group Policy information is contained in files on both the domain controllers and the clients. If any of these files are missing or corrupted, only some or none of the policies can be applied.

**Solution**
Examine files on the domain controller and the client.

**Domain controller**
Use GPOtool.exe to check for the presence and integrity of the following files in the SYSVOL share and its subfolders on the domain controller.

- Files in the Group Policy template.
- Registry.pol (Search %windir%\debug\usermode\UserEnv.log for references to this file). This file is used for processing administrative templates through the registry CSE.

Check the Policy Events tab in the Group Policy Results report for events that point to problems accessing files. When a process is unable to access a file, it generates an event. Whether this event is recorded depends on the event severity and whether verbose logging is enabled for that process.

You can also use Event Viewer on the client to view the Application logs, and you can enable and view verbose logging for UserEnv and for specific CSEs to Group Policy. For more information, see Fixing Group Policy problems by using log files.

**Client**
On the client, check for the presence and integrity of the following files in the %windir%\system32 folder. Replace suspect or files missing from the CD for the client's operating system. The System File Checker (Sfc.exe) can be used to scan all protected files to verify their versions.

- UserEnv.dll. Used for core Group Policy processing including registry CSE and profiles.
- Dskquota.dll. Used for Disk Quota CSE processing.
- Fdeploy.dll. Used for Folder Redirection CSE processing.
- Gptext.dll. Used for Scripts, IP Security, QoS Packet Scheduler, and Wireless settings processing.
- Appmgmts.dll. Used for Software Installation CSE processing.
- Scecli.dll. Used for Security Settings CSE processing.

# Trust relationships are not working

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains how to check if GPOs are not applying because trust relationships are not working.

**Cause**
You can link GPOs across domains, provided there is a trust relationship between the domains. If the trust relationship is broken, clients will be unable to access the GPO and related files. You might also encounter performance issues with links across domains.

You cannot link a GPO in one forest to a site, domain, or OU in a different forest.

**Solution**
If the GPO cannot be applied due to lack of trust, it will appear in the list of Denied GPOs and the reason given will be Inaccessible.

Use Active Directory Domains and Trusts or nltest.exe to verify the trust relationship, and to if repair it if necessary.

If you are not concerned about the identical GPO being applied in both domains, copy the GPO to the domain with the Active Directory containers you want to link to it.

# Group Policy does not apply after migration

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A Group Policy object often does not apply as expected after it has been migrated from another domain or forest — from a test environment to a production environment, for example.

**Cause**
Simply backing up and importing the GPO often does not produce the results you want because GPOs include domain-specific information such as security principals and UNC paths.

**Solution**
GPMC includes migration support, including a migration table editor, to address these issues. If a GPO that worked in one forest is not working as expected in the new forest, you might need a migration table. You also might need to back up and import the GPO instead of copying it.

- Check for a trust relationship between the source domain and the target domain. It there is trust, copy the GPO; if not, import it.

- If the GPO has references to security principles or UNC paths, use a migration table. The migration table editor that is included with GPMC provides error checking. However there is still a possibility of mistyped UNC paths.

For more information see the white paper, Migrating GPOs Across Domains with GPMC on the Microsoft Web site at (http://go.microsoft.com/fwlink/?LinkId=14321).

# Fixing Administrative Template policy setting problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic highlights issues related to processing of the Administrative Templates extension, also known as the registry extension.

**Administrative Templates**
Administrative Template settings take the form of **true policies** or **preferences**. Preferences can be deployed using Group Policy, but they cannot be enforced to the same degree as true policies. For this reason they are hidden by default in the Group Policy Object Editor.

Users can change preferences, but they cannot change true policies.

True policies are more secure because they are stored in secured registry hives.

Changes to true policies override but do not overwrite user preferences. If the policy is later removed, the user setting will again prevail.

If the GPO ceases to apply to the user or computer, policies no longer apply but preferences remain. This occurs if the user or computer moves out of the site, domain, or OU that the GPO is linked to, or if the GPO is deleted.

If the setting you are using is a preference rather than a true policy be aware that because preferences can be overwritten but are not removed, the end user might see their behavior as unpredictable. As a result, there might be perceived problems even when preferences are behaving as intended. Troubleshooting preferences requires knowledge about changes to both the GPO and the preferences set by the user.

The registry CSE writes the value for the setting to the registry. Some settings take effect as soon as they are written to the registry, but others take effect only at startup or logon. If you are not seeing the expected results and the Group Policy Results report shows that the policy has been applied, restart the computer or log off and log back on.

# Administrative Templates CSE is processed with errors

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

One or more registry-based policy settings are not applied to the computer or user. As a result some components and applications that are managed through registry-based Group Policy will not function according to administrator defined policies.

**Cause**
This error indicates that there is a missing file in a Group Policy object (GPO). GPOs reside on the domain controller's SYSVOL share, and a local GPO also resides on the local computer's system drive.

The event indicates that it was trying to access a file named "registry.pol" The file registry.pol might be corrupt and the event log describes the location of the corrupted file.

This error can also occur in the event of an improper registry configuration. Group Policy stores registry-based policy settings in the registry. If these registry keys have Access Control Lists (ACLs) that prevent the system from writing to this values, this failure can occur.

The following Userenv event numbers trigger this alert:

- 1019
- 1020 : Windows cannot create registry key <registry key>. (The parameter is incorrect. ).
- 1022
- 1043 : Windows cannot access the registry information at C:\WINDOWS\System32\GroupPolicy\Machine\registry.pol. (Access is denied).
- 1096 : Windows cannot access the registry policy file, <path to .pol file>. (<error description>).

**Solution**
If a problem with the registry.pol is indicated, verify that the file is present at the indicated path on all domain controllers. The Windows Server 2003 Group Policy Infrastructure whitepaper describes the layout of Group Policy information about domain controllers. Domain replication problems are indicated if replicas of the file are missing or if the files cannot be accessed by the targets of the GPO. Troubleshooting the File Replication service (FRS) and the Distributed File System (DFS) of the domain controller's SYSVOL share can diagnose the cause of the replication errors. Replication is not an issue if the file is part of the local GPO.

If the file is present, it might be corrupt. To determine this, use the Group Policy Object Editor snap-in to edit the GPO in which the file resides. If the Administrative Templates node under either User Configuration or Computer Configuration displays an error, you can safely assume that this file is corrupted.

To recover a corrupt or missing registry.pol file, use the Group Policy Management Console (GPMC) to restore the GPO from a backup.

If the file is missing due to replication errors, the replication issue with FRS or DFS must be addressed. After you resolve the replication problems, the error condition will also be resolved. The SONAR tool can be used to diagnose FRS problems.

If an improper registry configuration caused the error, examine the policy registry keys of the trees HKEY_LOCAL_MACHINE (and HKEY_CURRENT_USER if the problem occurred with a specific user logged in). Deleting these subtrees can fix the problem, but be aware that any edits to the registry can cause unexpected problems and must never take place without backup precautions.

# Group Policy Object Editor loads with "[strings] section is too long and has been truncated" message

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Some of the new Administrative templates that are included with the SP2 updated for Windows XP will not fully load on earlier versions of gpedit. If you attempt to load one of the SP2 Administrative templates from an older version of gpedit, you will get multiple error messages about "The following entry in the [strings] section is too long and has been truncated".

**Cause**

This is caused by the earlier versions of gpedit incorrectly handling the `"#if ver >=5"` construct in the new Administrative templates. Once opened through gpedit, you get several error messages. If you click OK on all of the error messages, the Administrative template will load correctly. However, any policy settings that reference the new LISTBOX syntax will not be displayed. To fix this, update the version of gpedit that is installed on the computer. You can also update your computer's operating system to Windows XP SP2.

**Solution**

To fix this problem, update your software to Windows XP SP2 or Windows Server 2003 SP1. To download hot fixes for all operating systems, see "The following entry in the [strings] section is too long and has been truncated" error message when you try to modify or to view GPOs in Windows Server 2003, Windows XP Professional, or Windows 2000 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43056).

# Some policy settings do not show in GPMC reports

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The behavior of the LISTBOX ADDITIVE keyword was modified for the administrative template files in Windows XP with Service Pack 2 (SP2).

There is a problem with this new functionality that occurs when you attempt to run GPMC Reporting for Policy Settings. GPMC Reports does not properly format the information that it receives for policy settings that use the LISTBOX ADDITIVE functionality.

**Cause**

This problem is caused by how GPMC handles the new Administrative templates that were added in Windows XP SP2. It does not recognize entries in the Administrative templates that are enclosed by the `"#if version >= 5" / "#endif"` statement. Because it is unable to recognize those entries, when you run a Reporting for Policy Settings modeling report, GPMC displays all of the data from those entries at the bottom of the document under Extra Registry Settings instead of User Configuration or Computer Configuration. Also, it does not show the display names for these settings, although it does provide information about the name of the registry key and the state of the setting.

**Solution**

This problem affects administrative reports only. It does not effect the functionality of the LISTBOX ADDITIVE keyword. Currently, there is no fix for this problem in GPMC.

# Custom ADM settings do not display in the Group Policy Editor

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Certain settings defined in a custom Administrative Template (ADM) file are not displayed in the Group Policy Object Editor by default.

**Cause**

ADM files define registry settings (also referred to as individual policy settings) that are displayed in the Group Policy Object Editor under the Administrative Templates node for both Computer and User Configuration. Two different types of settings can be defined.

In Windows 2000 and later, all policy settings set registry keys and values in one of the following locations:

- HKLM\Software\Policies (preferred location)
- HKLM\Software\Microsoft\Windows\CurrentVersion\Policies
- HKCU\Software\Policies (preferred location)
- HKCU\Software\Microsoft\Windows\CurrentVersion\Policies

Policy settings that are stored in these specific locations of the registry are known as true policies. This type of setting is displayed in the Group Policy Object Editor with a blue icon.

Preferences are settings that are stored outside these specific locations of the registry. If a preference is not reversed before the Group Policy object is disabled, the setting on the client computer remains, a process referred to as "tattooing." These settings are identifiable in the Group Policy Object Editor with a red icon.

The Group Policy Object Editor identifies policy settings that are preferences and does not display them by default. The default policy templates (Conf.adm and System.adm) loaded into the Group Policy Object Editor by default do not contain any preferences, and therefore none are displayed.

**Solution**

**To view preference settings for all ADM files in the Group Policy Object Editor**

1. Right-click any administrative template node and then click **View**.
2. Click **Filtering** and in the filtering dialog box, clear the check box for **Only show policy settings that can be fully managed**.
3. Click **OK**.

For more information, see article ID 228723 in the Microsoft Knowledge Base (http://go.microsoft.com/fwlink/?LinkId=48209).

# Fixing Security Settings Problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section discusses how to troubleshoot problems related to Security Settings policy.

**Security Settings CSE Background**
The Security Settings CSE provides client side interfaces to the security configuration engine and performs Resultant Set of Policies (RsoP) logging during policy propagation.

The binary file that contains the Security CSE is Scecli.dll. This name will usually appear in Events, error messages, and log entries generated and logged during processing of Security GPOs. Scecli manages application of the Security policy settings that appear under the Security Settings node in the Group Policy Object Editor. Scecli is responsible for the following areas:

- Account Policies
- Local Policies
- Event Log
- Restricted Groups
- System Services
- Registry
- File System

When the Security CSE is notified by the Group Policy engine, it is provided a list of GPOs to apply. The Security CSE then copies the gpttmpl.inf file from the folder structure of each policy in the Sysvol. It copies that file locally to the hidden folder %SYSTEMROOT%\Security\Templates\Policies. The settings are read from the gpttmpl.inf in the Sysvol and written to an intermediary file named tmpgptfl.inf. Once the copy has completed successfully the file is copied off and is named incrementally starting from gpt00000.inf. If the GPO is linked to the domain then the cached template will be named with the .dom extension, otherwise it will be named with the .inf extension.

This is done because some settings are only applied if they are linked to the domain. For more information, see Group Policy Application Rules for Domain Controllers on the Microsoft Web site at (http://go.microsoft.com/fwlink/?LinkId=39978). The templates are then applied from the cached location in order from least to greatest. This means that the gpt00000.inf will be applied before gpt00001.inf and that gpt00001.inf will have a higher precedence in the case of a conflict.

**Fixes for specific Security Settings issues**
From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Replication of Group Policy settings between domain controllers fails
- Password Policy settings changes do not take effect
- Account Policy templates are applied incorrectly
- Security Settings policies are propagated with warnings
- Scecli.dll errors occur when opening Account Policies or Local Policies
- Default Group Policy objects become corrupted: disaster recovery
- Windows Security Settings remain in effect after removal

# Replication of Group Policy settings between domain controllers fails

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Replication of Group Policy settings between domain controllers fails.

**Cause**
A replication problem may occur if you assign incorrect permissions to the %SystemRoot%\Winnt\Sysvol folder or when you assign improper groups to the **Bypass Traverse Checking** User Rights Assignment. The replication issue also occurs if the sysvol share permissions are too restrictive.

**Solution**
To troubleshoot this issue:

- Ensure that the permissions for the %SystemRoot%\Winnt\Sysvol folder and sub-folders are set as described in Event ID 1000, 1001 Is Logged Every Five Minutes in the Application Event Log on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35272).

- In Group Policy Management Console, right-click the **Default Domain Controllers Policy** GPO (in the Domain Controllers OU), click **Edit**, and verify that the **Bypass traverse checking** security setting (in Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment) contains the following default groups:

    - Authenticated Users

    - Everyone

    - Administrators

- Refresh security policy by running **gpupdate /force**.

**See Also**

Event ID 1000, 1001 Is Logged Every Five Minutes in the Application Event Log

# Password Policy settings changes do not take effect

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Password Policy settings do not take effect.

**Cause**

If you have made changes to password policy settings and they do not get applied, this may mean that the policy settings have not been updated.

**Solution**

### To trigger a policy refresh

- Click **Start**, click **Run**, type **gpupdate**, and then click **OK**. This refreshes policy settings, and it updates the changes to password policy on the computer.

**Gpupdate** refreshes local Group Policy settings and Group Policy settings that are stored in Active Directory, including security settings. This command supersedes the now obsolete **/refreshpolicy** option for the **secedit** command.

# Account Policy templates are applied incorrectly

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An administrator applies a security template that sets the account policies to something the administrator does not want to use, such as settings that cause users to change their password when the administrators do not want them to. Setting the Account Policies to Not Defined does not resolve the problem.

**Cause**

Incorrectly applied Account Policy settings. In this case, the administrator applied a security template that had unintended effects.

**Solution**

To resolve misapplied templates issues, do the following:

1. Re-apply the default settings for Account Policies. The default settings in the **Default Domain Policy GPO** for a clean installation of Windows Server 2003 are located in %windir%\inf\dcfirst.inf. The **Dcfirst.inf** security template is the template that is used to populate the security settings in the **Default Domain Policy GPO** when the first domain controller is installed in the domain. Importing this template into the **Default Domain Policy** (and checking the **Clear this database before importing** option) restores the security settings back to a clean install state.

   The same information applies to the **Defdcgpo.inf** security template which contains the default security settings in the **Default Domain Controller Policy GPO** (for a clean installation of Windows Server 2003). **Defdcgpo.inf** is located in **%windir%\inf**.

   | **Note** |
   | --- |
   | For domain accounts, the account policy must be defined in the Default Domain Policy or in a new policy that is linked to the root of the domain and given precedence over the Default Domain Policy, which is enforced by the domain controllers that make up the domain. If more than one GPO containing account policy settings is linked at the domain level, the domain's account policy consists of the cumulative policy settings from all the domain-linked GPOs. A domain controller always obtains the account policy from a GPO linked to the domain, which by default is the **Default Domain Policy GPO**. This behavior occurs even if there is a different account policy applied to the OU that contains the domain controller. By default, workstations and servers joined to a domain (such as member computers) also receive the same account policy for their local accounts. However, local account policies for member computers can be differentiated from the domain account policy by defining an account policy for the OU that contains the member computers. Modifying the Default Domain Policy is not recommended. If you need to set some account policy that differs from that in the **Default Domain Policy GPO**, you can create a new GPO and link to the root of domain, set the policy you want to use, and assign it higher precedence than **Default Domain Policy GPO**. |

2. Wait for replication changes to propagate to the domain controller.

3. Verify that the policy applied to the clients.

**To reapply default security settings using the Windows interface**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. Do one of the following:
   - To create a new console, on the **File** menu, click **New**.
   - To open an existing console, on the **File** menu, click **Open**, click the console that you want to open, and then click **Open**.
3. On the **File** menu, click **Add/Remove Snap-in**, and then, in **Add/Remove Snap-in**, click **Add**.
4. Click **Security Configuration and Analysis**, click **Add**, click **Close**, and then click **OK**.

5. In the console tree, right-click **Security Configuration and Analysis**, and then click **Open Database**.
6. In **File name**, type the file name, and then click **Open**.
7. Do one of the following:
   - For a domain controller, in the console tree, right-click **Security Configuration and Analysis**, click **Import Template**, click **Look in** in the **Import Template** dialog box, and then select **dcfirst.inf** in the **%windir%\inf** folder.
   - For other computers, in the console tree, right-click **Security Configuration and Analysis**, click **Import Template**, and then click **Setup security**.
8. Select the **Clear this database before importing** check box, and then click **Open**.
9. In the console tree, right-click **Security Configuration and Analysis**, and then click **Configure Computer Now**.
10. Do one of the following:
    - To use the default log specified in **Error log file path**, click **OK**.
    - To specify a different log, in **Error log file path**, type a valid path and file name, and then click **OK**.
11. When the configuration is done, right-click **Security Configuration and Analysis**, and then click **View Log File**.

**Important**

Applying the entire setup security template is a drastic measure that should be avoided; it is best to limit the settings being reset to the smallest possible number. Instead, use the **secedit** command-line tool with the **/areas** switch to apply default settings for specific areas.

**Note**

Different permissions are required to perform this procedure, depending on the environment in which you reapply default security settings.

If you reapply default security settings to your local computer: To perform this procedure, you must be an Administrator or a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using **Run as** to perform this procedure.

If you reapply default security settings to a computer that is joined to a domain: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have a local Administrator account or an account in the local Administrators group.

**To open Security Configuration and Analysis**

1. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. Do one of the following:
   - To create a new console, on the **File** menu, click **New**.
   - To open an existing console, on the **File** menu, click **Open**, click the console that you want to open, and then click **Open**.
3. On the **File** menu, click **Add/Remove Snap-in**, and then, in **Add/Remove Snap-in**, click **Add**.
4. Click **Security Configuration and Analysis**, click **Add**, click **Close**, and then click **OK**.

The default path for the log file is: **systemroot\Documents and Settings\UserAccount\My Documents\Security\Logs**.

When you reapply default security settings, all settings that are defined in **Setup security.inf** are set as the template specifies, but other settings that are not defined in the template may persist.

**To reapply default security settings using a command line**

1. Click **Start**, point to **All Programs**, point to **Accessories**, and then click **Command Prompt**.
2. For a server or workstation, type:

   **secedit /configure /DB FileName /CFG "%windir%\Security\Templates\Setup security.inf" [/overwrite][/areas** *Area1 Area2* **...] [/log** *LogPath* **] [/quiet]**

3. For a domain controller, type:

   **secedit /configure /DB** *FileName***/CFG "%windir%\inf\dcfirst.inf" [/overwrite][/areas** *Area1Area2***...] [/log** *LogPath***] [/quiet]**

The following table describes the **Secedit** arguments used in the procedure.

| Argument | Description |
|---|---|
| **/DB** *FileName* | Required. Provides the path to a database that contains the security template that should be applied. To create a new database, type the database file name and path. |
| **/CFG "%windir%\Security\Templates\Setup security.inf"** | Specifies the Setup Security.inf template that contains the default security settings. |
| **/overwrite** | Specifies that the database should be emptied prior to importing the security template. If this parameter is not specified, the settings in the security template are accumulated into the database. If this parameter is not specified and there are conflicting settings in the database and the template being imported, the template settings win. |
| **/areas** *Area1 Area2* **...** | Specifies the security areas to be applied to the system. If this parameter is not specified, all security settings defined in the database are applied to the system. To configure multiple areas, separate each area by a space. The following security areas are supported:<br>• **SECURITYPOLICY** Includes account policies, audit policies, event log settings, and security options.<br>• **GROUP_MGMT** Includes Restricted Group settings.<br>• **USER_RIGHTS** Includes user rights assignment.<br>• **REGKEYS** Includes registry permissions.<br>• **FILESTORE** Includes file system permissions.<br>• **SERVICES** Includes System Service settings. |
| **/log** *LogPath* | Specifies a file in which to log the status of the configuration process. If not specified, configuration data is logged in the Scesrv.log file, which is located in the %windir%\Security\Logs folder. |
| **/quiet** | Specifies that the configuration process should take place without prompting the user. |

**To view the complete syntax for the secedit command**

- At a command prompt, type: **secedit /?**

# Security Settings policies are propagated with warnings

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In Windows 2000, Scecli.dll events 1202 and 1000 may occur every 5 minutes on domain controllers and every 90 minutes on clients in some situations. As a result, security settings propagate with warnings and the Security Settings Group Policy client side extension may fail.

**Cause**

These Scecli.dll events might occur in cases such as the following:

- An administrator has installed a program which creates user accounts and assigns rights to those user accounts. Later, the administrator removes the program, which deletes the user accounts, but does not remove the rights from Group Policy before the accounts are deleted.

- An administrator adds a user account and assigns rights to the account. Later, the administrator deletes the account, but does not remove the account from the user rights policy.

These events can indicate a failure to resolve a security account to a security identifier (SID) or a broken trust relationship.

**Solution**

There are several different issues that make up the Scecli.dll event ID 1202 category of warnings; these are collectively referred to as "1202 events." The error code in the event log warning specifies the type of problem that was encountered.

To see diagnostic and troubleshooting information about the 1202 events:

- Determine the error code from the event log notification (for example 0x4b8).

- Find the error code section in Troubleshooting SCECLI 1202 Events on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39979), and then follow the troubleshooting steps in that section.

- For information about security policies propagating with warning 0x534, see Error Message: Security Policies Are Propagated with Warning. 0x534 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39980).

# Scecli.dll errors occur when opening Account Policies or Local Policies

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Scecli.dll errors may occur when you open Account Policies or Local Policies in Local Computer Policy.

**Cause**

When you attempt to open Account Policies or Local Policies in Local Computer Policy, you may receive the following error messages:

- "Windows cannot open the local policy database. An unknown error occurred when attempting to open the database."
- SceCli Event ID 1202: "Security policies are propagated with warning 0x4b8: An extended error has occurred."

This error message can occur if the Local Group Policy log files are corrupted. This usually indicates that the secedit.sdb file is corrupted.

**Solution**

**To verify and restore secedit.sdb**

1. Determine if secedit.sdb is corrupt by running **esentutl /g** %windir%\security\database\secedit.sdb.
2. Try to restore secedit.sdb from a backup before the problem started.
3. If secedit.sdb is corrupt, attempt a soft recovery first by running **esentutl /r edb** in the %windir%\security directory.
4. If soft recovery fails, attempt a repair with **esentutl /p** %windir%\security\Database\secedit.sdb. Then delete the log files %windir%\security*edb* and %windir%\security*log.
5. Rebuild secedit.sdb. Delete the following files: %windir%\security*edb*, %windir%\security*log, and %windir%\security\database\secedit.sdb.
6. Restart the computer.

| **Note** |
| --- |
| If you perform a repair with **esentutl /p** on a computer running Windows 2000, the local security policy settings are lost and you must recreate them.<br><br>If you perform a repair with **esentutl /p** on a computer running Windows Server 2003, persistent security settings (also referred to as tattoo table) are lost so when Group Policy settings are undefined, the server's settings do not revert to their original values. |

For more information, see the following articles which describe other known issues that can cause the 0x4b8 error, see the following:

- Event ID 1000 and 1202 After Configuring Policies on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39982).
- ESENT Event IDs 1000, 1202, 412, and 454 Are Logged Repeatedly in the Application Event Log on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39984).

# Default Group Policy objects become corrupted: disaster recovery

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The default domain GPOs become corrupted and there are no GPO backups for the Default Domain Policy GPO and Default Domain Controller Policy GPO.

**Cause**

The default domain GPOs are corrupted (for example, because of misconfiguration) and you do not have backed up versions of the Default Domain Policy GPO or the Default Domain Controller Policy GPO.

**Solution**

If you are in a disaster recovery scenario, you may consider using the Dcgpofix tool. If you use the Dcgpofix tool, it is strongly recommended that as soon as you run it, you review the security settings in these GPOs and manually adjust the security settings to suit your requirements.

Dcgpofix restores the default Group Policy objects to their original default state after initial installation of a domain controller. The Dcgpofix tool recreates the two default Group Policy objects and creates the settings based on the operations that are performed only during Dcpromo. It is important to understand that Dcgpofix does not restore the security settings to the state they were in before you run Dcpromo.

**Important**

The Dcgpofix tool is intended for use only as a last-resort disaster-recovery tool.

To create regular backups of the default domain and all other GPOs, you must use Group Policy Management Console (GPMC).

It is also recommended that you backup the Sysvol directory with a regularly scheduled backup procedure.

**To run Dcgpofix**

- Type the following at the command prompt: **dcgpofix [/ignoreschema][/target: {domain | dc | both}]**

Where:

**/ignoreschema** is an optional parameter. If you set this parameter, the Active Directory schema version number is ignored.

**/target: {domain | dc | both}** is an optional parameter that specifies the target domain, domain controller, or both. If you do not specify **/target**, dcgpofix uses both by default.

**Note**

Dcgpofix.exe is located in the C:\Windows\Repair folder.

You must be a domain or enterprise Administrator to use this tool.

Dcgpofix.exe checks the Active Directory schema version number to ensure compatibility between the version of Dcgpofix you are using and the Active Directory schema configuration. If the versions are not compatible, Dcgpofix.exe does not run.

The following extension settings are maintained in a default Group Policy object: Remote Installation Services (RIS), security settings, and Encrypting File System (EFS). The following extension settings are not maintained or restored in a default Group Policy object: Software Installation, Internet Explorer maintenance, scripts, folder redirection, and administrative templates.

The following changes are not maintained or restored in a default Group Policy object: Security settings made by Exchange 2000 Setup, security settings migrated to default Group Policy during an upgrade from Windows NT to Windows 2000, and policy object changes made through Systems Management Server (SMS).

You can run this tool only on servers running the Windows Server 2003 family.

For more information about using GPMC to back up and restore GPOs, see the Administering Group Policy with the GPMC

white paper on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=17528).

For more information about restoring system state data by using the Backup utility in Windows Server 2003, see Backing Up and Recovering Data on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=22347).

For more information about managing the Sysvol directory, see Best Practices for Sysvol Maintenance on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=39986).

For more information about use of Dcgpofix, see The Dcgpofix tool does not restore security settings in the Default Domain Controller Policy to their original state on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35269).

# Windows Security Settings remain in effect after removal

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

This problem typically occurs when a security setting is defined through Group Policy and later set to "undefined."

**Solution**

Under some circumstances Windows Security Settings remain in effect after being set to undefined. The flow chart below will help you determine if your security setting is remaining in effect because of this behavior.

**Account Policy, User Rights Assignment and Audit Policy**

If the security setting that is in effect is under Account Policy, Local Policy\User Rights Assignment or Local Policy\Audit Policy use the flow chart below to determine how this particular setting will behave when removed through Group Policy:

**Security Options**

If the security setting that is in effect is under Security Options use the flow chart below to determine how this particular setting will behave when removed through Group Policy:

**Event Log and System Services**

If the security setting that is in effect is under Event Log or System Services use the flow chart below to determine how this particular setting will behave when removed through Group Policy:

**Restricted Groups**

If the security setting that is in effect is under Event Log or System Services use the flow chart below to determine how this particular setting will behave when removed through Group Policy:

**All Other Windows Security Settings**

For Windows 2003 and Windows XP security settings not addressed in the sections above revert to their previous value when removed through Group Policy. For Windows 2000 security settings not addressed in the sections above will revert to their previous value unless the setting is defined in local policy in which case it will reflect the local policy setting.

# Fixing Scripts policy settings problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section discusses troubleshooting issues related to Scripts policy settings.

**Scripts Processing Background**
Startup, logon, logoff, and shutdown scripts can be applied using Group Policy settings. The Scripts CSE processes these script settings. The Scripts CSE updates the registry with the location of one or more script files so that the UserInit process can find those values in the course of its normal processing. When a CSE reports success, it might only mean that the value has been placed in the registry. Even though the setting is in the registry, there could be problems preventing the setting from being applied to the client. For example, if a script specified in a Script setting has an error that prevents it from completing, that Script CSE does not detect error.

Scripts processing contains two steps--Group Policy processes a GPO and stores the script information in the registry:

- HKEY_CURRENT_USER\Software\Policies\Microsoft\Windows\System\Scripts (User Scripts)
- HKEY_LOCAL_MACHINE\Software\Policies\Microsoft\Windows\System\Scripts (Machine Scripts)

| **Note** |
| --- |
| Script is run by means of a UserInit process. (By default, scripts that cannot be completed time out after 10 minutes.) |

Only Windows XP, Windows Server 2003, and later operating systems support WMI filtering. If the computer is running an earlier operating system, the WMI filter is ignored and the GPO is applied.

| **Note** |
| --- |
| The time-out is the time allotment for all scripts to run. This can be modified using the Computer policy setting **Maximum wait time for Group Policy Scripts**. |

Common script errors include:

- Incorrect script path.
- Script time-out.
- Access to script is restricted by means of ACLs (typically for startup/shutdown scripts that run as computer, not user).

If a logon script fails, it typically does not affect the other scripts. However, startup scripts are often run synchronously, and a failure of one of these scripts can affect scripts intended to run later.

To investigate, check the Application Event Log for entries with UserInit as the source.

**Fixes for specific Scripts policy settings issues**
From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Startup scripts do not run as expected on a computer running Windows XP SP1 or Windows XP SP2
- Scripts deployed to computer do not run (Userinit events 1000 and 1001)

# Startup scripts do not run as expected on a computer running Windows XP SP1 or Windows XP SP2

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You start a computer running Windows XP Service Pack 1 (SP1) or Windows XP Service Pack 2 (SP2) on a wired network or on a wireless network that has IEEE 802.11 authentication, and Group Policy startup scripts and logon scripts do not run as expected, or the computer does not join the Active Directory directory service.

**Cause**

The following entries may appear in the log files in Event Viewer:

**Event ID: 1054**

**Source: NT AUTHORITY/SYSTEM**

**Type: Error**

**Description: Windows cannot obtain the domain controller name for your computer network. (The specified domain either does not exist or exist or could not be contacted). Group Policy processing aborted. Data: (unavailable)**

**Event ID: 1000**

**Source: UserInit**

**Type: Error**

**Description: Could not execute the following script AdminPassword.bat. The system cannot find the file specified. Data: (unavailable)**

This problem may occur if the Group Policy engine or Active Directory time out while waiting for the network to start. A race condition may occur between the TCP/IP protocol and the network adaptor driver when they try to register with the Microsoft Network Driver Interface Specification (NDIS). If the TCP/IP protocol registers with NDIS before the network adaptor driver, for a short time it prompts higher user mode networking components that network connectivity is not available. As a result, during this short time, the Group Policy startup script cannot be downloaded.

This problem is more likely to occur on fast networks that use 1 gigahertz (GHz) network adaptors or in teaming environments where the network takes several additional cycles to negotiate link speed.

**Solution**

For computers running Windows XP SP1, you can obtain a supported hotfix from Microsoft to correct this problem. For detailed instructions, see Group Policy startup scripts do not run as expected on a computer that is running Windows XP Service Pack 1 (SP1) or Service Pack 2 (SP2) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43049).

For computers running Windows XP Service Pack 2, you must add the **GpNetworkStartTimeoutPolicyValue** registry entry. This entry defines the number of seconds to wait before trying to run the Group Policy startup script again. For more information, see Group Policy startup scripts do not run as expected on a computer that is running Windows XP Service Pack 1 (SP1) or Service Pack 2 (SP2) on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43049).

# Scripts deployed to computer do not run (Userinit events 1000 and 1001)

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A logon, logoff, machine startup, or machine shutdown script deployed to the computer through Group Policy does not run.

**Cause**
The event logs may show one of the following Userinit events:

**Event ID 1000**

**Message: Could not execute the following script %1. %2.**

**Event ID 1001**

**Message: Could not locate the script command lines in the Group Policy object**.

These Userinit events may be caused by one of the following issues:

- Network problems that prevent the computer from accessing the domain controller or the network location of the script executable files
- Invalid script command lines
- Replication problems on the domain controller

**Solution**
**Network Errors**
Network errors that occur during script execution can cause these errors. In this case, troubleshooting and resolving the network problems will resolve this error. For information about troubleshooting network issues, see Fixing Group Policy networking issues.

A script may also be inaccessible because of file sharing violations. In this case, the administrator of the network share on which the script resides must determine which users or computers are locking the file and close their connection to the file. To perform this diagnosis, you can use file system tools (such as net.exe).

For information about file sharing violations and replication issues, see FRS Encounters "ERROR_SHARING_VIOLATION" Errors When It Tries to Replicate Data That Is Still in Use on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43053).

**Script command lines errors**
**To troubleshoot command line errors**

- Run the command line listed in the event log, using the directory from which the script originates as your default directory. The script directory is either the user\scripts or the machine\scripts directory, depending on whether the script is a logon/logoff script or a machine startup/shutdown script. You can use the Group Policy Management Console (GPMC) to find the GPO containing this path. If the policy is a computer policy, use an account that has access to the network location listed in the script.
- If the command line execution fails, investigate this as you would investigate any error related to running a command. For example, look for typographical mistakes in the path or the specification of a relative path that is not present on the local computer.
- To change an incorrect path, use GPMC to edit the GPO for which you want to modify the path, and type the correct path. To fix this problem, you must be a network administrator with rights to the GPO.

**Domain Controller replication issues**
When scripts are stored on the domain's sysvol share, replication problems can cause the script to not be present or to have incorrect access permissions. For information about troubleshooting replication issues, see Group Policy does not replicate.

# Fixing Software Installation policy setting problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains issues related to deploying software using Group Policy software installation.

**Software Installation CSE Background**
A number of special issues affect Group Policy software installation. For example, network connectivity issues can disrupt access to the software installation packages. Software installation processing is never performed while the user is logged on because doing so could disrupt work and result in data loss. This has implications when Group Policy is configured to run asynchronously.

Software Installation is managed by the Software Installation CSE, which appears as the source Application Manager on the Policy Events tab in Group Policy Results reports. If you need additional logging information, enable verbose logging for the Software Installation CSE and Microsoft® Windows® Installer, as described under Troubleshooting Group Policy Using Log Files.

The Software Installation Diagnostics tool (addiag.exe) provides detailed information about the applications visible in Active Directory and installed for the current user, as well as general diagnostic information and related Event Log entries. It is available in the Windows 2000 Server Resource Kit.

**Fixes for specific Software Installation policy setting issues**
From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Software Installation changes do not apply after logon
- Failure to access software share points
- User uninstalls a deployed application on a computer and application is unavailable to the user on every computer
- Software is not listed in Add or Remove Programs
- Install on demand fails
- Software Installation operation fails

# Software Installation changes do not apply after logon

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When the Fast Logon Optimization feature is set on computers running Windows XP Professional (default), Group Policy software installation changes do not take effect after the user logs on.

**Cause**

In Windows XP Professional, the Fast Logon Optimization feature is set by default for both domain and workgroup members. As a result, Windows XP does not wait for the network to be fully initialized at startup and logon. Existing users are logged on using cached credentials. This results in shorter logon times. Group Policy is applied in the background after the network becomes available. Note that because this is a background refresh, extensions such as Software Installation and Folder Redirection take two logons to apply changes.

Software Installation processing occurs only during computer startup or when the user logs on. This is because processing periodically could cause undesirable results. For example, if an application is no longer assigned, it is removed. If a user were using the application while Group Policy tries to uninstall it or if an assigned application upgrade takes place while someone is using the application, errors would occur.

If the software installation settings are applied through computer configuration, they are applied at startup. If software installation settings are applied through user configuration, they are applied at logon.

**Solution**

If the computer is running Windows XP with logon optimization enabled, the user will need to log on after Group Policy refresh. This can entail logging on two or three times.

Administrators can turn off Fast Logon Optimization, by using the **Always wait for the network at computer startup and logon** policy setting in the **Computer Configuration\Administrative Templates\System\Logon** node of Group Policy Object Editor.

For more information, see Description of the Windows XP Professional Fast Logon Optimization Feature on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43045).

# Failure to access software share points

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An administrator has deployed a software package, but software installation fails. Event logs indicate the package can not be accessed.

**Cause**

One of the reasons that software installation may fail is if the installation source for the software is not available. This may be due to an incorrect path statement for the package or inadequate permissions.

**Solution**

Test for mistyped elements in the path specification by manually following the path. If the path is incorrect, provide the correct path to the share that contains the source package you are deploying. To do this, edit the GPO that you used to deploy the software, and correct the path.

**To correct the default path for packages**

1. In Group Policy Management console, right-click the GPO that contains the software installation policy settings for the package you are deploying, and click **Edit**.
2. Expand either **User Configuration** or **Computer Configuration** (depends on where you configured the software installation policy), click **Software Settings**, right-click **Software installation**, and then click **Properties**.
3. In **Software installation Properties**, on the **General** tab, type the path in the **Default package location** text box.

Verify that the user account or system account has the necessary privileges to traverse the path and access those resources. The account whose OU supplied the GPO is the one that needs to traverse the path.

# User uninstalls a deployed application on a computer and application is unavailable to the user on every computer

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A user with a roaming user profile uninstalls a deployed application on his or her computer, and the user can no longer access that application when the user roams to another computer.

**Cause**

If the user has a roaming user profile and the user uninstalled the application on another computer using **Add or Remove Programs**, the application will be unavailable to that user on every computer (with the possible exception of computers where loopback processing rules apply). For more information about roaming user profiles, see “Using roaming user profiles” in Help and Support Center for Windows Server 2003.

**Solution**

If the application was deployed with the **Uninstall this application when it falls out of the scope of management** option, verify that the computer and user are still in the necessary security groups and that the GPO is still linked to a site, domain, or OU that the user or computer is in.

# Software is not listed in Add or Remove Programs

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An administrator deploys a software package and the software does not appear in users' computers in Add or Remove Programs in Control Panel.

**Cause**
For the software to appear in the Add New Programs section of Add or Remove Programs, it must be Published (not Assigned) in Group Policy.

Other possible causes for this issue include:

- Group Policy did not apply
- The network can not be reached (can not query the domain controller for the user or computer)

**Solution**
Choose the **Published** software deployment method when you deploy the package.

The Windows Installer package must be written such that the software can appear in **Add or Remove Programs**.

To troubleshoot Group Policy application failure, see Fixing Core Group Policy problems.

To troubleshoot network connection issues, see Fixing Group Policy networking issues.

# Install on demand fails

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When users try to install an advertised application by opening a document that is associated with the application, the installation fails. Document activation of a published application does not trigger an application installation.

**Cause**
This issue might occur if the administrator did not set autoinstall options for the software being deployed, or the file name extension for the application was not set correctly.

**Solution**
To troubleshoot this issue:

- Ensure that the autoinstall option is set for the application being deployed.

| **Note** |
| --- |
| To complete these procedures, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group. |

**To set the autoinstall option for an application**

1. In Group Policy Management console, right-click the GPO that contains the software installation settings for the application you are deploying, and click **Edit**.
2. In Group Policy Object Editor console, expand **Computer Configuration** or **User Configuration** (depends on where you configured the software installation policy), click **Software Settings**, and click **Software installation**.
3. In the details pane, right-click the application that you want to be installed automatically when the user tries to open a file with the associated extension.
4. Click **Properties**, and then click the **Deployment** tab.
5. Under **Deployment options**, select the **Auto-install this application by file extension activation** check box, and then click **OK**. This option is recommended, and it is selected by default.

- Check the order of file name extensions specified for the GPO and ensure that the file name extension is associated with the application.

**To specify automatic installation options based on file name extension**

1. In Group Policy Management console, right-click the GPO that contains the software installation settings for the application you are deploying, and click **Edit**.
2. In Group Policy Object Editor console, expand **Computer Configuration** or **User Configuration** (depends on where you configured the software installation policy), click **Software Settings**, right-click **Software installation**, and click **Properties**.
3. In the **Software installation Properties** dialog box, click the **File Extensions** tab.
4. On the **File Extensions** tab, specify the following option:
    - **Select file extension**. Displays a list of all available file name extensions for the managed software. When an extension is selected, all applications in Active Directory that are associated with the selected file name extension are displayed in the **Application precedence** list box. For example, for an .htm extension, many applications can be associated, such as Microsoft Word, Microsoft Internet Explorer, Netscape Communicator, and so on.

- Check the client computer for applications that have been installed locally. If there is a conflict, the locally installed

application is used instead of the deployed application.

# Software Installation operation fails

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

An application could not be installed or uninstalled. One or more of these software installation operations fails: installing, uninstalling, upgrading, and reinstalling software.

**Cause**

The cause of the failure depends on the type of operation that failed: an uninstall, install, reinstall, or the domain controller query to determine administrative policy. The event logs indicate that software was assigned in addition to being installed. Assignment is simply the first phase of an installation. For troubleshooting purposes, treat assignment failures in the same manner as installation failures.

Possible causes include:

**Uninstall failure:**

- The Group Policy Software Installation extension might need to uninstall software.
- The system is using a file that needs to be accessible when the application is uninstalled.
- The Windows Installer package that was used to deploy the application was authored incorrectly.

**Install or reinstall failure:**

- The installation source for the software is not available.
- The application is already installed on the computer but has a different set of transforms from the application deployed through Group Policy.
- An existing application on the computer conflicts with the application and is preventing it from being installed.
- The Windows Installer package of the deployed application is incorrectly authored.

**Upgrade failure:**

- The Group Policy Software Installation extension attempted to upgrade an application, but was unable to do so due to an installation or uninstallation error; the event logs provide additional information.

**Domain Controller query failed:**

- The Group Policy Software Installation extension could not access the network, and was not able to query a domain controller for the user or computer.

**Solution**

To troubleshoot software installation issues, try one or more of the following:

- Determine whether any other related events are logged in Event Viewer. Windows Installer usually logs a related event that provides details about why the operation could not be completed.
- Check for errors in any application deployed to the computer and look for Windows Installer events.
- Enable logging for Application Management and Windows Installer.
- Log on to another computer as an administrator, verify that the application can be manually installed and uninstalled on that computer. If this verification fails, the problem is probably a software issue. Contact the software support provider.

- In the case of an install or uninstall failure, manually uninstall the software.

- If the event indicated that the transforms of the deployed application are different from the transforms of an instance of the same application already installed on the computer, deploy a new version of the application that has the same set of transforms as the existing installation, and then remove the deployment that has the conflict.

  Deployment changes can be made by a network administrator with the right to manage Group Policy objects (GPOs) in the Windows domain of the user or computer.

- If the problem is the Group Policy Software Installation extension failing to access network information related to software installation policy, run the **Ping**, **DCdiag.exe**, and the **Nslookup** tools on the computer that is having the problem. This helps determine where on the network the problem is occurring.

- You can use Group Policy to enable logging for Windows Installer by using the **Logging** policy setting in the **Computer Configuration\Administrative Templates\Windows Components\Windows Installer** node of Group Policy Object Editor.

- You can use the **Software Installation Diagnostics** tool (**addiag.exe**) to gather additional diagnostic information. You can run **addiag.exe /?** from a command prompt for information about the syntax.

To learn more about the tools that you can use to force an application uninstall, see the Windows Installer documentation. For more information about Windows Installer, see the MSDN article Roadmap to Windows Installer Documentation on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=21878).

For information about Windows Installer event entries, see the MSDN article Event Logging on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=21877).

For more information about enabling Windows Installer Logging for Windows XP clients, see How to Enable Windows Installer Logging in Windows XP on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35731).

For more information about enabling Windows Installer Logging for Windows 2000 computers, see How to Enable Windows Installer Logging on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=35593).

For more information about using **DCDiag**, see DCDiag and NetDiag in Windows 2000 Facilitate Domain Join and DC Creation on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=20908).

# Fixing Folder Redirection policy settings problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic discusses troubleshooting for Folder Redirection issues.

**Folder Redirection CSE Background**
The Folder Redirection client side extension, fdeploy.dll, processes Group Policy settings for Folder Redirection. Folder Redirection also includes the following components:

- {25537BA6-77A8-11D2-9B6C-0000F8080861}.ini: A locally cached redirection information file specific to each user profile.
- {1C08E84D-F112-4252-978B-EC82A225CC20}.ini: A file indicating the status of the previous locations used for redirected folders. This file is used to detect server location changes and user name changes.

Folder Redirection is used to maintain user data in a centralized location. This permits regular backups of the information, and also provides the user with access to the data from any computer in the network.

The following folders can be redirected:

- My Documents
- Application Data
- Desktop
- Start Menu

The Folder Redirection CSE manages folder Redirection. When events from this CSE are listed on the Policy Events tab in Group Policy Results reports, the source is listed as Folder Redirection.

Fdeploy.dll is loaded during the logon process by the Group Policy engine. The Folder Redirection policies are passed to fdeploy.dll, which then examines the policy settings and redirects user folders based on those settings.

The first step in Folder Redirection is to get a list of all Folder Redirection policies and evaluate them. The policies are handed down to the fdeploy.dll by the Group Policy engine through an API call into fdeploy.dll. The policies come in the form of two linked lists. The first list is a list of added policies. This refers to a list of Folder Redirection policies that are still applicable to the user. The second list is a list of deleted policies that refers to policies that used to be applicable to the user but are no longer applicable. The changes that result from Folder Redirection are then updated with the shell. The client-side cache, also referred to as offline files, is also updated to reflect the files moved by Folder Redirection.

**Fixes for specific Folder Redirection policy setting issues**
This section provides information for troubleshooting the following Folder Redirection problem:

- Folder Redirection encounters errors and redirection fails
- Folder Redirection CSE processing is delayed

# Folder Redirection encounters errors and redirection fails

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Folder redirection encounters errors when redirecting the user's folders on the client. As a result, the user's folders are not redirected successfully.

**Cause**

Several conditions must be met in order for users' folders to be redirected successfully. If these conditions are not met, the following Folder Redirection errors may occur:

- Folder redirection initialization fails.
- The Folder redirection path specified by the administrator is invalid, too long, inaccessible, or offline.
- You do not have adequate privileges to create or access the redirected folders on the server, or there is not enough free disk space on the server.
- Folder redirection is unable to set the shell folder registry keys to redirect the folders to the required destination.
- Configuration errors occur in the event that a parent folder was redirected to a subfolder.
- Folder redirection is unable to acquire the fdeploy.ini config file from the GPO.
- Some files to be moved as part of redirection are locked on the client.

**Solution**

To troubleshoot Folder Redirection problems, try one or all of the following:

- Look at the Event Viewer logs for Folder Redirection events. Based on the event, one or a combination of the following steps may be required to resolve the issue.
- If Folder redirection initialization fails, ensure that there are no memory or security issues on the client and that there are no issues with the GPO (this applies only if there was an error extracting the fdeploy.ini file). Ensure that the correct Fdeploy.ini file is available on the domain controller that the client is accessing.
- Verify that the folder redirection path specified by the administrator is valid and accessible. If the target paths are longer than the set limit, you need to make them shorter (look at the event log to see if the path length exceeds permitted number of characters). If the path to the folder does not exist (for example if the path specification is mistyped in the policy setting, if folders in the path have been renamed or removed, or if the server is unavailable), Folder Redirection will fail.
- Ensure that the folder redirection configuration is correct and that you are not redirecting parent folders to subfolders.
- Ensure that no files to be moved are locked by an application or service.
- Ensure that the user has the required ACLS on all the folders and shell folder registry keys.
- Verify that the user has appropriate permissions to create folders at the redirected location and that there is adequate free disk space to create the redirected folders. If disk quotas are applied, adjust the quotas to ensure the user has the required disk space required.

**Note**

In order to use the folder, the file system and share permissions must be set such that the user can navigate the path to the folder, and if the folder exists the user must have ownership privileges on it. (The user is given ownership of the folder by default if you allow the folder to be created automatically.) This is a common cause of confusion with Folder Redirection. When using Folder Redirection Policies, it is best to allow the system to create and set permissions on the folder. This reduces the likelihood of errors due to incorrect security settings. For more information about Folder Redirection permissions, see the "User Data and Settings Management for Windows Server 2003" white paper on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=26719.

If you need to set permissions manually, you must ensure that the user has the appropriate minimum file system and share permissions. For more information about the required permissions, search for "Folder Redirection" in Windows Server 2003 Help and Support.

For more information about disk quotas, search for "Manage Disk Quotas" in Windows Server 2003 Help and Support.

- Folder Redirection, like Software Installation settings, can only be applied during computer startup or user logon. On computers running Windows XP with logon optimization enabled, this can mean that the user needs to log on more than once before the setting takes effect.

# Folder Redirection CSE processing is delayed

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Application of the user's folder redirection policy is delayed until the next logon, because Group Policy logon optimization is in effect. As a result, the user's folders are not redirected during the current logon.

**Cause**

Folder Redirection cannot redirect the user's folders because the Group Policy asynchronous foreground processing setting is turned ON. Folder Redirection requires that the redirection policy be applied synchronously, so that the folders are redirected as part of the login and prior to user access.

The **Always wait for the network at computer startup and logon** policy setting determines whether Windows XP waits for the network during computer startup and user logon. By default, Windows XP does not wait for the network to be fully initialized at startup and logon. Existing users are logged on using cached credentials, which results in shorter logon times. Group Policy is applied in the background once the network becomes available.

If the **Always wait for the network at computer startup and logon** policy is set to **Not configured** or **Disabled**, Windows XP does not wait for the network to be fully initialized at startup and logon. Group Policy is applied asynchronously in the background.

In order for Folder Redirection settings to apply with the first logon, Windows must wait for the network to be fully initialized at startup and logon before applying policy. This means policy must apply synchronously in the foreground. The same applies to Software Installation and roaming user profiles.

**Solution**

To guarantee the application of Folder Redirection in just one logon, enable the **Always wait for the network at computer startup and logon** policy setting to ensure that Windows waits for the network to be available before applying policy. When this setting is enabled, logons are performed in the same way as for Windows 2000 clients, in that Windows XP waits for the network to be fully initialized before users are logged on. Group Policy is applied in the foreground, synchronously.

For more information about this policy, see the **Explain** tab in the **Always wait for the network at computer startup and logon** policy setting.

# Fixing Disk Quota extension problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic discusses troubleshooting for Disk Quota issues.

**Disk Quota CSE Background**
Disk quotas allow administrators to control the usage of hard drive space by their users. The policy is applied on a per user/per drive letter basis. This allows an administrator to keep a user from filling up a hard drive that multiple people share.

If the Disk Quota CSE is unable to read the registry on the target computer, or is unable to access a list of the available hard drives on the target computer, the Disk Quota will not be applied. This could be potentially lead to a user unwittingly filling up all the hard drive space on a server or other unwanted situations.

**Fixes for specific Disk Quota extension issues**
From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- Disk Quota CSE processed with errors

# Disk Quota CSE processed with errors

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This error indicates that the Disk Quota Group Policy client-side extension (CSE) has failed to apply Group Policy settings to one or more volumes on the target computer.

**Cause**

This could be caused by one of the following issues:

- Unable to open a registry key containing the Group Policy information.
- Unable to create the class factory object for ProgID "Microsoft.DiskQuota.1".
- Unable to instantiate the "quota control" object; ProgID "Microsoft.DiskQuota.1".
- Unable to obtain the list of disk drives on the target computer.
- Unable to apply quota settings to a volume on the target computer.
- Insufficient memory to perform an operation.

The following event numbers with a source of DiskQuota can trigger this alert:

- 1
- 2
- 3
- 4
- 5
- 6
- 7
- 8

**Solution**

To troubleshoot this problem, try one or all of the following:

- Review the Event Viewer for events logged by the Disk Quota client-side extension and use the information in the event description to troubleshoot the problem.
- If the event description indicates that a class factory or quota object could not be created, perform the following tasks:
    - Check for the existence of the file "%SystemRoot%\system32\dskquota.dll"
    - Re-register dskquota.dll using regsvr32.exe
- An event description that indicates that a list of disk drives on the target computer could not be obtained is created when no logical drive(s) are present on the target computer.

- In cases other than these, Disk Quota failure is usually caused by low memory conditions on the target computer.

# Fixing Group Policy problems by using log files

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic provides information related to troubleshooting Group Policy problems by using log files.

**Troubleshooting Group Policy by Using Log Files**
If other tools do not provide the information you need to identify the problems affecting Group Policy application, you can enable verbose logging and examine the resulting log files. Verbose logging can reduce performance and consume significant disk space, so as a best practice enable verbose logging only when necessary.

For example, enabling Userenv.dll logging allows administrators to view information about what occurs in the background when a user logs on to the computer. Userenv.dll is part of the code of the Group Policy engine and is always called whenever policy settings are processed.

**Client Log Files**
Log files can be generated by the core client engine (Userenv) and by every CSE except the Scripts CSE. Scripts processing is logged in the Application log on the client with source=UserInit. Use Event Viewer to view the Application log on the client, or look for these entries on the **Policy Events** tab of the Group Policy Results report.

The **Policy Events** tab in Group Policy Results reports generated in GPMC displays the Group Policy–related events that you would see if you used Event Viewer to view these events in the Application log on the client for which you generated the report.

The following table lists several log files you can generate at the client that relate to Group Policy troubleshooting.

**Client Log Files for Troubleshooting Group Policy**

| Output from: | Is located in this file: | Enable verbose logging by adding this key or value... | ...to this registry key |
|---|---|---|---|
| Group Policy core (UserEnv) and registry CSE | %windir%\debug\usermode\UserEnv.log | UserEnvDebugLevel = REG_DWORD 30002 | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon |
| Security CSE | %windir%\security\logs\winlogon.log | ExtensionDebugLevel = REG_DWORD 0x2 | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\GpExtensions\{827d319e-6eac-11d2-a4ea-00c04f79f83a}\ |
| Folder Redirection CSE | windir%\debug\usermode\fdeploy.log | FdeployDebugLevel = Reg_DWORD 0x0f | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics |
| Software Installation CSE | %windir%\debug\usermode\appmgmt.log | Appmgmtdebuglevel=dword:0000009b | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics |

| | | | |
|---|---|---|---|
| Windows Installer (deployment-related actions) | %windir%\temp \MSI*.log | Logging = voicewarmup<br><br>Debug = DWORD: 00000003 | HKEY_LOCAL_MACHINE \Software \Policies \Microsoft \Windows \Installer |
| Windows Installer (user-initiated actions) | %temp% \MSI*.log | Logging = voicewarmup<br><br>Debug = DWORD: 00000003 | HKEY_LOCAL_MACHINE \Software \Policies \Microsoft \Windows \Installer |

**Note**

The UserEnv logs entries pertaining to profiles as well as Group Policy core processing and registry (.adm) processing on the client. The entries pertaining to profiles are intermingled with the Group Policy entries and not easily distinguished from them. Use Wilogutl.exe to analyze the Windows Installer log files. For more information, see Wilogutl.exe on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=16156).

**Server Log Files**

You can enable logging of events generated by the Group Policy Object Editor on the Server. There are two different log files, one for events relating to core Group Policy processing and the registry CSE, and another for events relating to all other CSEs.

The following table lists several log files you can generate at the server that relate to Group Policy troubleshooting.

**Server Log Files for Troubleshooting Group Policy**

| **Output from:** | **Is located in this file:** | **Enable verbose logging by adding this keyword...** | **...to this registry key** |
|---|---|---|---|
| GPMC: error logging only | %temp%\gpmgmt.log | gpmgmttracelevel=1 | HKEY_LOCAL_MACHINE \Software \Microsoft \Windows NT \CurrentVersion \Diagnostics |
| GPMC: error and verbose logging | %temp%\gpmgmt.log | gpmgmttracelevel=2 | HKEY_LOCAL_MACHINE \Software \Microsoft \Windows NT \CurrentVersion \Diagnostics |
| GPMC: Output only to log file (not to debugger) | %temp%\gpmgmt.log | gpmgmtlogfileonly=1 | HKEY_LOCAL_MACHINE \Software \Microsoft \Windows NT \CurrentVersion \Diagnostics |
| Group Policy Object Editor: Core-specific entries | %windir%\debug\usermode \gpedit.log | GPEditDebugLevel = REG_DWORD 0x10002 | HKEY_LOCAL_MACHINE \Software \Microsoft \Windows NT \CurrentVersion \Winlogon |

| | | | |
|---|---|---|---|
| Group Policy Object Editor: CSE-specific entries | %windir%\debug\usermode<br><br>\gptext.log | GPTextDebugLevel = REG_DWORD 0x10002 | HKEY_LOCAL_MACHINE<br>\Software<br>\Microsoft<br>\Windows NT<br>\CurrentVersion<br>\Winlogon |

**Userenv Logging**

Because Userenv tracks the Group Policy engine and registry-based Group Policy, it is the most frequently used log file for Group Policy troubleshooting. Userenv is especially useful in a Windows 2000 environment because you don't have the benefit of using Resultant Set of Policy (RSoP). Most of the questions that RSoP answers, are in the userenv log.

To use userenv.log you need to first enable verbose logging.

**To enable verbose logging**

1. Log onto the client computer as the administrator and run Regedit.
2. Locate the following key: **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon**.
3. Right click **Winlogon**, select **New**, and then click **DWORD Value**.
4. Enter the following name for the **DWORD Value**: **UserEnvDebugLevel**.
5. Enter 30002 as the hexadecimal value. This writes the userenv into userenv.log, located in the \%windir%\debug directory.
6. Run "**gpupdate /force**" to ensure a full listing of total Group Policy processing.

# Interpreting Userenv log files

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains how to interpret userenv log files.

**Userenv Logging**

When you enable userenv logging, you can perform debug logging of the user profile and the system policy processes. Userenv log files also contain information about the status of each Group Policy extension, such as Application Deployment, Security, and Folder Redirection. Userenv log files reveal what is occurring in the background as a user logs on. Userenv log files are especially useful because they be can be used to troubleshoot Windows 2000 operating systems, in which you cannot use Resultant Set of Policy (RSoP). In addition, if Active Directory replication is not working, RSoP will not work, leaving userenv log files as the only troubleshooting option. RSoP also depends on Windows Management Instrumentation (WMI), which might also fail and leave you with no option but to analyze the userenv log files. With verbose logging, information is logged every second; if something fails you can review the userenv logs and pinpoint the likely source of failure.

Userenv log files contains information about the following:

- Group Policy settings that are not processed or not applied as expected
- Folder redirection that does not occur
- Profile or registry hive load, unload, or deletion failures
- Logon script, or script not applied as expected
- Default behaviors occurring because a slow link was detected
- Roaming profile issues
- Slow logon issues
- Whether a given GPO is accessible, and if not, why access was denied.
- The name of the domain controller that is accessing SYSVOL.

**What is in the Userenv log?**

The example of the Userenv log in this section shows the type of details of errors in core Group Policy processing that the Userenv log provides. Reading from left to right, this log shows a process code (for example, cc.500), the time it was processed (note the date is not displayed), the process name, and a short statement of the error. The Userenv log displays Group Policy process failures and warnings.

**Sample Userenv log**

```
USERENV(178.17c) 13:48:51:089 MyRegUnLoadKey:  Failed to unmount hive 00000005
USERENV(178.17c) 13:48:51:089 DumpOpenRegistryHandle: 3 user registry Handles leaked
from \Registry\User\S-1-5-21-2127521184-1604012920-1887927527-2193396
USERENV(178.17c) 13:48:51:089 UnloadUserProfileP: Didn't unload user profile <err = 5>
USERENV(178.2e8) 13:52:00:708 GetGPOInfo:  Local GPO's gpt.ini is not accessible,
assuming default state.
USERENV(178.600) 13:52:09:452 GetGPOInfo:  Local GPO's gpt.ini is not accessible,
assuming default state.
USERENV(178.4d4) 13:52:15:020 PolicyChangedThread: UpdateUser failed with 6.
```

| **Note** |
| --- |
| The Userenv log has a maximum size of 1 megabyte (MB). At system startup, if the log file exceeds 1 MB, the contents is copied into a Userenv.bak file and a new Userenv log is created. If the system remains running and is not restarted, the log file exceeds 1 MB. |

**General Userenv.log Messages**
The following messages have the same meaning no matter where they appear in the log:

- Failed to Allocate...
- Failed to Create...
- Failed to Set...
- Failed to Get...
- These errors normally indicate a problem with system resources at the time when they were called. If you receive multiple errors at the same time, your computer could be having integrity problems. To avoid these problems, try to ensure that the computer is as close to a base install of Windows as possible by removing all third party software programs. If this option is not possible for you, install a new version of Windows and all available service packs on a test machine. If the error is no longer appearing in the log file, slowly install third party software, one program at a time. Monitor the Userenv log after each program is installed to determine which program is causing the error.

The following messages also have the same meaning no matter where they appear in the log:

- Calling function <function failed>
- Calling function <function returned>
- These entries indicate that an underlying function was called and that there was an error in the transaction. Determine which function the entry is causing the error by viewing the error text, and then locate the function that failed in the log. After you have identified the failed function entry in the log, get the return code and start troubleshooting the failed function from there.

**ApplyGroupPolicy Messages**
**ApplyGroupPolicy: Entering. Flags = %x**
You use flags to determine what processing Group Policies need to do and what some of the Client Side Extensions (CSEs) are doing. Flags are hexadecimal bits that might need to be converted if the number is above nine.

| Hexadecimal | Description |
|---|---|
| 0x00000001 | Machine Policy (The absence of a 1 = User Policy) |
| 0x00000002 | Background Refresh |
| 0x00000004 | Apply Directory Services Policy |
| 0x00000008 | Do not Wait on Network Services |

The values listed in the following table are added to the flags after processing.

| Hexadecimal | Description |
|---|---|
| 0x00010000 | Background Thread Processing |
| 0x00020000 | Change in Control Panel Settings |
| 0x00040000 | Slow Network Connection |
| 0x00080000 | Verbose output to the event Log |
| 0x00100000 | Forced Refresh |

| | |
|---|---|
| 0x00800000 | Planning Mode |

**CheckGPOs Messages**
Most of the log messages from this function are self-explanatory. The following is the most common error that users ask about in relation to CheckGPOs log messages.

**CheckGPOs: No GPO changes but couldn't read extension %s's status or policy time.**
Group Policy stores the status and the time of each extension as needed for the machine and every user that logs onto the machine. They are stored in the following registry locations:

MACHINE

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Group Policy\State\Machine\Extension-List

USER

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Group Policy\State\<SID>\Extension-List

If you receive this error, check your registry permissions for any explicit denials on the registry settings. Also, check for any third-party software that might manipulate this key. Some third parties change the Group Policy cache in both the file system and registry to have their product mimic Group Policy.

**EnterCriticalPolicySection Messages**
This is a potentially serious log message. It could indicate that certain portions of the operating system have become corrupt due to improper shut-down or system crashes. It could also indicate a system resource problem, similar to the "Failed to..." errors mentioned earlier in this section. To troubleshoot this issue, remove all third-party software to determine if a non-Microsoft program is causing this error. If that does not fix the problem, start with a clean installation of Windows, install all necessary service packs, and then introduce the clean computer into your environment. Monitor the Userenv log while installing any additional programs to determine what could be causing this error.

**GPOThread**
**GPOThread: Next refresh will happen in %d minutes**
This is an informational message. It is the only place within the operating system that indicates when the next time Group Policy will refresh.

**LeaveCriticalPolicySection**
See the "EnterCriticalPolicySection" section earlier in this document.

**LibMain**
**LibMain: Process Name: %s"**
This is an informational message. This message appears in the userenv.log when an application loads Userenv.dll within its space. Userenv has many exported functions that deal with loading and unloading the user's profile. Therefore, many application need to go through Userenv to get the profile of the currently logged on user for application specific settings. This message indicates which application is loading an instance of Userenv.dll.

**ProcessGPO**
**ProcessGPO: Found flags of: %d"**
This is an informational message. To determine what the flag in the message means, see the following list:

- 0 = Both user and Computer Configuration are Enabled
- 1 = User Configuration is Disabled
- 2 = Computer Configuration is Disabled

**ProcessGPO: Found machine version of: GPC is %d, GPT is %d"**
**ProcessGPO: Found user version of: GPC is %d, GPT is %d"**
These two messages are misrepresented in the Userenv log. It states GPC and GPT but it does not actually read from the GPT. It reads both settings from the GroupPolicyContainer Object (GPC) and not SYSVOL. The Attribute it reads is the Version number, which is stored as an integer value. If you believe you have a SYSVOL problem, run GPOTOOL to determine where errors might exist.

**ProcessGPORegistryPolicy**
**ProcessGPORegistryPolicy: Failed to create archive file with %d"**

The archive file in question is named ntuser.pol and is located in the user's profile. If you receive this error in the Userenv log, determine whether you are having problems with profile loading or unloading. Also, make sure that the user has write permissions to the profile folder because ntuser.pol is created in the root of the user profile.

**ProcessGPOs: Machine role is %d."**
This entry includes a decimal number at the end (%d). To determine what processing is going on within Userenv, see the following list:

- 0 = Standalone machine that is not a member of a Directory Services Domain
- 1 = The machine is a member of a NT4 domain
- 2 = The machine is a member of a domain which supports Directory Services.
- 3 = The machine is a domain controller

This information helps you determine what kind of machine you are troubleshooting, which could indicate why a policy is or is not applying.

**ProcessGPOs: The DC for domain %s is not available. aborting"**
**ProcessGPOs: The DC for domain %s is not available."**
These messages can be caused by network problems or the Windows XP Fast-User logon Optimization option. Try turning off the Fast-User Optimization option. If that does not cause the errors to stop, you might have a network problem. Troubleshoot this as you would any network problem.

**ProcessGPOs: DSGetDCName failed with %d."**
DsGetDCName is a public API that performs Domain Controller discovery. Troubleshooting this most of the time will involve name resolution. You can simulate this call by using the utility nltest.exe. Use the command **ipconfig /flushdns** before using nltest when you are taking a network monitor trace. Windows has a client-side cache, and you want to capture the DNS data in the trace. The syntax for **nltest** is:

**nltest /DSGETDC:** *DomainName*

**ProcessGPOs: GetNetworkName failed with %d."**
This function writes the FQDN of the domain into the Group Policy Cache. Many of the CSEs and Components that are policy implemented look for this name in the cache. This return code should be used wit the net command to determine the error message. Some of the lower-level functions in this name are Winsock library calls. If this is appearing and you are seeing some policies fail, make sure the machine is free from any viruses, worms, or other forms of malicious software.

**ProcessGPOs: Calling GetGPOInfo for normal policy mode"**
This is an informational message. This lets you know that you are processing policy in normal mode.

**ProcessGPOs: Calling GetGPOInfo for replacement user policy mode"**
This is an informational message. This message appears if the computer is in Group Policy loopback mode. Group Policy uses the user policy settings from the location of the computer object, and Group Policy does not honor any of the user policy settings based on the user’s object in Active Directory.

**ProcessGPOs: Calling GetGPOInfo for merging user policy mode"**
This is an informational message. This message appears when the computer is in Group Policy loopback mode. Group Policy merges the user specific policy settings based on where the user’s object is located in Active Directory along with the location of the computer object settings in Active Directory.

**ProcessGPOs: Extension %s skipped with flags 0x%x."**
This message indicates that a client-side extension was skipped. Use the flag values to determine why the extension was skipped. Typically, it is background processing, but make sure it was not caused by an error.

**ProcessGPOs: Extension %s ProcessGroupPolicy failed, status 0x%x."**
This message appears if the extension has actually failed. Use the **net** command with the return status to determine what the possible causes are. Enable additional logging for the extension specified to determine a more accurate error. Remember the status returned to ProcessGPOs is mapped to a more standard Windows Error. More specific errors might be revealed in the extension's debug log.

**ProcessGPOs: Couldn't read status data for %s. Error %d. ignoring..**
This is an informational message. This message appears to be an error, however the Group Policy engine automatically processes the extension because it cannot read the status data, hence the "ignoring" notation at the end of the message.

**ProcessGPOs: Computer Group Policy has been applied.**
**ProcessGPOs: User Group Policy has been applied.**
These are informational messages. These messages indicate that the Group policy has applied policy to the best of its ability. It does not mean that there were not any errors.

**ProcessGPOs: Leaving with %d."**
This is an informational message. If this value is not 0, the policy encountered a problem when it was applied. The fact that it appears in the log as well as the two messages above means the Group Policy was able to handle the error gracefully and move on.

**SearchDSObject**
**SearchDSObject: Searching <%s>"**
This function is used to determine which policy objects are within scope for the logging on user or computer. It should have a Distinguished Name (DN) of the object in Active Directory. The DN should either be a Site object, Domain object, or an Organizational Unit object. This is the location in Active Directory in which the Group Policy engine is searching for linked policy objects.

**SearchDSObject: Too many linked GPOs in search.**
This error message is not actually a Group Policy error but rather an LDAP Error, LDAP_SIZELIMIT_EXCEEDED. The value is determined by the Search Request.

**SearchDSObject: Found GPO(s): <%s>**
Here is an example from a Userenv.log file.

```
SearchDSObject:  Found GPO(s):  <[LDAP://CN={31B2F340-016D-11D2-945F-
00C04FB984F9},CN=Policies,CN=System,DC=corp,DC=mstep,DC=com;0]>
```

Notice there is a `;0]` at the end of the message. This value has meaning and it will appear on every policy that is linked. To determine the value, see the following table :

- 0 = This is the default setting. The policy is enabled
- 1 = This policy is disabled
- 2 = This policy will be forced or cannot be overridden and will win all ties against block policy inheritance
- 3 = Settings 1 and 2 are both enabled hence the policy will be disabled.

**SearchDSObject: <%s> has the Block From Above attribute set"**
The Block From Above attribute prevents a linked policy from being inherited by a Site, Domain, or OU beneath it. Generally, this is only set at an OU level, however the option is available anywhere a policy can be linked. This setting is stored on the actual container object, just as the policies that are linked to the container. This specific value can be found in on the attribute Gpoption. This attribute is an integer value and only has two settings: zero (0) (default) indicates normal propagation of the policy to the container, and one (1) turns on Block Policy Inheritance, which prevents polices higher in the tree from applying to the container or objects in the container. A policy that has No Override or Force, ignores the Block Policy Inheritance flag and still applies.

**RETURN CODES**
This section contains the return codes listed throughout a Userenv.log. You can use this section to determine what the codes mean and how to apply them to the specific function that is returning them.

**General Rules**
Most functions return true, false, or a status code. For this documentation true or successful is represented by a 0. False or unsuccessful is represented by a 1. Status codes have different meanings. This section documents most of the well known status messages.

Most return codes, after they are converted from hexadecimal to decimal, can be described by using the **net** command. The command-line syntax is:

**NET HELPMSG** *Number*

Messages that begin with 0xC or anything similar will probably not work with the **net** command and are listed in the "Return Codes that cannot be converted with the net command " table later in this document.

**Return Codes**

| Return Code | Description |
|---|---|
| 1332 | None Mapped. This usually means you have a SID designated in either Group Policy or Security Policy that is no longer valid on the domain. Typically, this happens when a user or group is created in the domain, assigned to a specific setting, and then later is deleted from the domain without updating the policy to remove the user. This is typically associated with a user or group instead of a computer account. Usually you can look through the event logs and find an event that has a return ID of 1332. This message is also represented as 0x534. To solve the problem, find the entry that has the user or group name or a SID that does not resolve to a user name and remove it. |
| 1355 | No such Domain. Typically, this is a name resolution problem, and most of the time it will be with DNS. There are some functions that return as 1355. If you are using a legacy operating system such as Windows NT, these messages are not as serious as if you are using Windows 2000, Windows XP, or Windows Server 2003. Another possible cause is NetBois. Some environments have DNS lookups look to a WINS server for name resolution. If you are certain you have ruled out Name resolution then start with a network trace to determine where the computer is trying to contact and troubleshoot from there. This error is also seen as 0x54b |
| 1722 | RPC Server is unavailable. This error can mean several different things. Check for name resolution problems first. This is a common cause of this error. The next thing is to use a utility, like Port Query or RPC Ping, to make sure that client and the target server are communicating. Due to Windows dependency on RPC, any failures in RPC can have a repercussions. Make sure the critical services like the RPC Endpoint Mapper and RPCSS are turned on. Also make sure port 135 is not blocked so clients can bind and connect to the endpoint mapper. Finally, you can take a network trace to make sure RPC connectively is valid. Because RPC traffic is usually encrypted, you need someone that knows how to look for RPC in a network trace. |
| 14 | Not enough storage is available to complete this operation. This is usually a resource problem, specifically memory allocation. Verify that the computer has enough resources to complete its tasks. If a process started exceeding its virtual memory limit, you can get this message. Restarting usually clears the problem, however this might be temporary and the problem might continue to occur. Start monitoring the computer's performance after the restart to see if you can determine what is causing the heavy resource usage. Use Performance Monitor to base line and spot memory usage trends. |
| 1908 | Domain Controller could not be found for this domain. Use the same troubleshooting as you would for a 1355 error message |
| 5 | Access Denied. There is a security descriptor that is preventing the current credentials from accessing the resource. This could also be a privilege access that is being denied. For example, the SeNetworkLogonRight allows security principals to connect to the machine and access resources. If a user was not given this privilege they would get the Access Denied error. Check the Permission on the resource. If the function is accessing the registry, find out which key it is attempting to use. If it is attempting to access a file, check the permissions on the file. After you have exhausted the possibility of checking permissions, check the security policy for the proper privileges. |
| 1115 | Shutdown in Progress. The system is shutting down. This event overrides most events that occur in the operating system. If the shutdown is unexpected, check the event logs to determine why the system shut down. |
| 1326 | Unknown user name or bad password. Check the user name and password you are logged on with. If you had a password change log off and log on again with the new password and see if that resolves the problem. |
| 1753 | There are no more endpoints available from the endpoint mapper. Start off by stopping third-party services because this error usually occurs when a RPC application consumes all of the available endpoints or the server is very busy. Follow up with troubleshooting steps provided by the 1722 error. |
| 1317 | The specified user does not exist. This is usually the case where you have a SID that no longer resolves to a user name, either because it has been deleted or because it is a SID from a trusted domain where the trust is not working. It could also be that you have a user name that cannot be converted to a SID. You can use either the name2sid.exe or lua.exe utility to see if the name is valid in the current domain as well as trusted domains. |
| 1398 | There is a time or date difference between the client and server. Verify that your client, server and the KDC are within five minutes of each other. Make sure time zones and date are correct as well. Check the event log to see if you are having any W32time errors. Kerberos defaults to five minutes of allowable time skew. Any time past five minutes causes errors. |

| | |
|---|---|
| 2 | The system cannot find the file specified. This message is very similar to the error 3 message and you troubleshoot them the same way. This message indicates that the computer cannot locate either the file or the path that you have told it to look for. This occurs if you try to connect to a UNC path that is not valid (for example, reading policy from SYSVOL). Find the path or file in question and attempt to navigate to that path under the proper credentials. If you want to navigate to the path under the computer context. use **/interactive** at a command line. If you perform a network trace during the event, you can get some good information about the problem. |
| 3 | The system cannot find the path specified. For more information, see Error 2. |
| 53 | The network path was not found. This usually is the sign of a name resolution problem and most of the time it is referencing a NetBIOS name resolution problem. Verify that the NetBIOS cache using the tool nbtstat is not causing this error. Also, make sure there is not a LMHOSTS file on the computer, and, if there is, make sure it is correct. Finally, verify that WINS is configured correctly. When you have exhausted NetBIOS resolution do not forget to look at DNS resolution because DNS can effect lookup names in WINS and vice versa. You can also identify the path and attempt to connect to it via IP address. Also, IPSec can generate this error message too. When a computer has IPSec turned off and it is attempting to communicate with a machine that has IPSec turned on, this error can occur. |
| 32 | The process cannot access the file because it is being used by another process. Another process has a lock on the file and is preventing access to the file. Restarting usually fixes this issue. If you discover that you need to restart often, you need to identify the process that is not releasing the file. You can use a tool like OH.exe to locate the offending process. After you identify the process, you will need assistance from the vendor to determine why the process is not releasing the file. Verify that you do not have any user mode applications that are holding the process open. To fix this problem, try stopping services, such as Realtime virus scanners, Open File Agents. |

**Return Codes that cannot be converted with the net command**

| Return Code | Description |
|---|---|
| 0xc000015b | Requested Logon type was not granted. Windows provides for multiple Logon types. Interactive Logon is logging on at the console of the machine. Network Logon is connecting to a resource on a remote machine. The function has requested to log on with certain credentials that do not permit the requested log on type. |
| 0xc000023c | The network is unreachable. There is an underlying networking problem. Start by troubleshooting basic connectivity. When using TCP/IP, check to make sure that the address, subnet mask and gateway are correct. To determine the location of the problem, use the ping utility to ping the loop back adapter first, then the IP address of the current machine that is having a problem, then the default gateway and then an address that is past the gateway. |
| 0xc000026d | DFS is unavailable. Troubleshoot basic connective to DFS shares. If possible, use a network sniffer, such as Network Monitor, to assess whether the problem is on the server or the client. |
| 0xc00000be | Bad Network Path. The path that was used to connect to another machine was invalid or there could be name resolution issues. Verify the path does not have invalid characters. Look for additional errors in the log that could support a name resolution problem. These errors can include 53 and 1355. Trying doing a directory of the path from a command prompt using the fully qualified name, the NetBIOS name and lastly the IP address itself. Also rule out the possibility of IPSec. |
| 0xc0000064 | No such user. A request specified a user account that is not on the system the function targeted. Verify that the user does exist. If the user requested resides in Active Directory make sure Active Directory replication is working, and that the user is present on the authenticating domain controller. |
| 0xc000006a | Wrong Password. The function attempted to use an invalid password for the credentials it was impersonating or in the context of. Check and make sure Active Directory replication is working. A large number of these events could be a service account that has had a password change but the entry in the machine has not been updated with the new password. Additionally, multiple versions of these events can trigger account lockouts. |

| | |
|---|---|
| 0x80090303 | Target Unknown. Typically, this error occurs when a security function fails. Start your troubleshooting by looking at the calling function to try to determine what Group Policy was attempting to do when it called the security related function. Look at the event logs to see if the computer is having other security related problems such as policy not applying, logon problems, or prompting for credentials when the credentials are good. Another area where you can see this is with Kerberos when the Service Principal Name that is being requested is not listed in the database. Use a network trace to determine if this is the cause. Also, turn on Kerberos logging at the targeted computer. |
| 0x8009030c | Logon Denied. Group Policy impersonates both the computer and the user when it determines the scope of policy, meaning it acts on behalf the user. This could be a machine account needing its password reset or a user account that has some problem. Check Active Directory to make sure the user account is set up correctly. Use a utility, like netdom or nltest, to test the computer account's password. |
| 0x80090324 | Time Skew. The majority of the time this is a Kerberos issue. Make sure your client, server and the KDC are within five minutes of each other. Verify that time zones and date are correct too. Check the event log to see if you are having any W32time errors. Kerberos defaults to five minutes of allowable time skew. Any time past that causes errors. |
| 0x80090311 | No authenticating authority. Normally, this implies that the machine cannot contact a Domain Controller or from a Kerberos perspective (that is, a KDC). Troubleshoot this by turning on Kerberos Logging and getting a network monitor trace to determine where the computer is trying to contact for authentication. If you are traversing a trust then Netlogon log on Domain Controllers in both domains and if possible run a simultaneous trace to help pinpoint the failure. |

**LDAP ERROR CODES**

Some of the messages return LDAP Error codes. You can recognize these error codes because the function usually starts with **ldap_**.

| Error Code | Description |
|---|---|
| 85 | Timeout. Verify network connectivity. Ping the target computer and check the response time. Verify that the targeted server is responding on port 389 and port 3268 if it is a Global Catalog server. |
| 82 | Local Error. Check the Directory Services event log and make sure Active Directory is healthy on this machine. Check for memory consumption as well as CPU time for LSASS. If these checks do not turn up any other errors, turn on Directory Services logging. |
| 53 | Unwilling to Perform. The specific command was refused by the LDAP Server. The most direct way to find the problem is to turn on Directory Service Logging on the targeted server that returned the error message. By getting a network monitor trace while this happening, you can identify the request that the client is sending to the server. The additional logging helps you determine why the server is returning the message. This is not always an error message. It is uncommon, but occasionally Group Policy requests that the computer do something that it cannot, which causes this error. |
| 7 | Authentication Method not supported. Look at the type of Authentication you are using to connect to the targeted LDAP server. In most cases, you should begin Kerberos Troubleshooting. Turn on Kerberos Logging on the client and the KDC. Also, a network trace might help you locate the problem. |
| 81 | Server Down. The targeted LDAP Server is not responding. Check the network, the proper LDAP ports for the given server, and any router connections. Start investigating the health of the targeted server. |

# Interpreting Security Settings log files

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This topic explains how to get started in interpreting Security Settings log files.

**Using Winlogon.log**
When you enable logging for the Security Settings client-side extension, a file named Winlogon.log is created in the %SYSTEMROOT%\Security\Logs folder. Winlogon.log provides debug logging information for security events and errors (Scecli.dll).

You can use Winlogon.log to look for security configuration-related errors such as the following:

- Mapping problems between account names and security IDs.
- Incorrect permissions for performing tasks (Access denied errors).
- Problems with trust relationship between the primary domain and trusted domains.
- Extended errors. These refer to generic errors that may be caused by a number of different problems.

For information about enabling Scecli logging, see the "Enabling Logging for Security Settings" section in Configuring Administrative Workstation Settings for Group Policy Troubleshooting.

To reproduce the policy failure, refresh the policy settings by typing the following at the command prompt: **gpupdate /force**.

**Example**
After you enable logging for Scecli, you can examine the Winlogon.log file to look for errors such as an account causing a Scecli failure or the wrong policy applying to a computer. For example, you can determine if an account was removed from policy or deleted, the account name contains typographical errors, or an account name cannot be resolved in Restricted Groups policy and as a result the security policy settings do not apply.

To identify the problem account, problem setting, and the problem GPO, perform the following tasks:

1. To find the problem account, type the following at the command prompt, and then press ENTER:

   **find /I "cannot find" %SYSTEMROOT%\security\logs\winlogon.log**

   The **Find** output identifies the problem account names, for example, "Cannot find MichaelAlexander." In this example, the user account MichaelAlexander does not exist in the domain, or it has a different spelling, for example, MichelleAlexander.

   Determine why this account cannot be resolved. Look for issues such as typographical errors, a deleted account, the wrong policy applied to this computer, or a trust problem. You may decide that the account has to be removed from the policy.

2. After you find the account problem, you can find the affected policy setting and GPO. To do this, type the following at the command prompt on the computer that is producing the Scecli error:

   "**c:\>find /i ?<account name>? %SYSTEMROOT%\security\templates\policies\gpt*.***" (without the quotation marks)

   The following example shows the **Find** command syntax and the results:

   **c:\>find /i "MichaelAlexander" %SYSTEMROOT%\security\templates\policies\gpt*.***

   ```
   D:\WINNT\SECURITY\TEMPLATES\POLICIES\GPT00000.DOM

   D:\WINNT\SECURITY\TEMPLATES\POLICIES\GPT00001.INF
   ```

```
D:\WINNT\SECURITY\TEMPLATES\POLICIES\GPT00002.INF SeInteractiveLogonRight = TsInternetUser,*S-1-5-32-549,*S-1-5-32-550,MichaelAlexander,*S-1-5-32-551,*S-1-5-32-544,*S-1-5-32-548

D:\WINNT\SECURITY\TEMPLATES\POLICIES\GPT00003.DOM
```

In this case, GPT00002.INF is the cached security template from the problem GPO that contains the problem security setting. It also identifies the problem setting as **SeInteractiveLogonRight**. The display name for **SeInteractiveLogonRight** is **Logon locally**.

For more information about the security settings constants (for example, SeInteractiveLogonRight) and their associated display names (for example, Logon locally), see the Microsoft Windows 2000 Server Resource Kit, "Distributed Systems Guide." The map of security settings constants is in the "User Rights" section of the Appendix.

3. After you identify the cached security template, you can determine which GPO contains the problem setting by searching the cached security template for the text "GPOPath=".

   In this example, you would see the following: **GPOPath={6AC1786C-016F-11D2-945F-00C04FB984F9}\MACHINE**. The GPO's GUID is {6AC1786C-016F-11D2-945F-00C04FB984F9}.

4. You can use the Resource Kit utility **Gpotool.exe** to find the friendly name for the GPO GUID. Type the following at the command prompt, and then press ENTER: **gpotool /verbose**.

   Search the output for the GUID that you identified in step 3. The four lines that follow the GUID contain the friendly name of the policy. For example:

```
Policy {6AC1786C-016F-11D2-945F-00C04FB984F9}

Policy OK

Details:

----------------------------------------------------------

DC: domcntlr1.wingtiptoys.com

Friendly name: Default Domain Controllers Policy
```

**GPOTool.exe** ships with the Microsoft Windows® 2000 Server Resource Kit and is also available as a free download from Gpotool.exe: Group Policy Verification Tool on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=17911). For more information see the Windows 2000 Server Resource Kit.

# Additional Resources for Group Policy

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For information about identifying and fixing Group Policy problems, see the following resources:

- Managing Windows XP Service Pack 2 Features Using Group Policy on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=29269)
    - This white paper explains how to deploy Group Policy settings that are delivered with Microsoft Windows XP Service Pack 2 (SP2) as well as how to assess and use new policy settings.
- Group Policy Collection on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=35202)
    - This page introduces Group Policy management concepts and architecture, summarizes the areas included in the Group Policy collection, and describes Group Policy scenarios.
- Tools and Settings Collection on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=4972)
    - These resources provide technical information about tools and settings related to Microsoft Windows Server 2003.
- Group Policy Deployment Kit: Designing a Managed Environment on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=15311)
    - This book provides the foundation you need to understand and deploy Group Policy within Windows Server 2003. It will help you to manage a diverse set of organizational and computing needs and to centrally manage domain-wide and forest-wide security, servers, computers, and users.
- Group Policy Infrastructure White Paper (Windows Server 2003) on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=60547)
    - This white paper explains Group Policy infrastructure and shows how Group Policy Management Console fits into this infrastructure. The white paper also includes detailed information about Group Policy processing as well as many best practices useful to Group Policy administrators.
- Administering Group Policy with GPMC on the Microsoft Web site (http://go.microsoft.com/fwlink/?linkid=14320)
    - This white paper provides an overview of Group Policy Management Console (GPMC) and outlines functionality necessary to administer Group Policy with the GPMC. Highlights of the white paper include new functionality such as backup, restore, import, copy, and reporting of Group Policy objects (GPOs).

# Security Technologies Operations Guide

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This Operations Guide provides troubleshooting information for security technologies in Microsoft® Windows Server™ 2003 and Windows® 2000 operating systems.

**In this guide**

- Troubleshooting Kerberos
- Troubleshooting Access Control

# Troubleshooting Kerberos

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides troubleshooting information for Kerberos authentication in Windows 2000 and Windows Server 2003 domains. It is designed to help you identify and resolve problems that are related to the Kerberos version 5 authentication protocol.

**In this guide**

- Introduction to Troubleshooting Kerberos
- Verifying Computer Settings for Troubleshooting Kerberos
- Configuring a Computer for Troubleshooting Kerberos
- Troubleshooting Kerberos Problems
- Additional Resources for Troubleshooting Kerberos

# Introduction to Troubleshooting Kerberos

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are using this guide for the first time, review the following sections of this introduction.

**When to Use This Guide**
You should use this guide when:

- You have an issue related to authentication such as console logon, network logon, access to network resources, or remote access and Kerberos is the default authentication protocol.
- The System event log shows errors from any services that provide authentication, such as Kerberos Key Distribution Center (kdc), Local Security Authority Server (LsaSrv), or Net Logon (Netlogon).
- Failure audits in the Security event log show that the Kerberos protocol was being used when a logon failure occurred.

Do not use this guide to find out how to perform a task, such as enabling the Kerberos protocol or adding a program or port to the Kerberos exceptions list.

This guide assumes a basic understanding of Windows authentication using the Kerberos protocol, how it works, and why your organization uses it to authenticate users and services. You should also have a thorough understanding of how Kerberos authentication is deployed and managed in your organization. This includes an understanding of the mechanism your organization uses to configure and manage authentication settings generally and Kerberos settings specifically.

**How to Use This Guide**
This guide is divided into three sections. Each section addresses a type of problem, ranging from less complex to more complex.

Verifying Computer Settings for Troubleshooting Kerberos

This section provides a list of prerequisites and settings that must be verified before you troubleshoot. Read this section first.

Configuring a Computer for Troubleshooting Kerberos

This section describes how to configure your computer for troubleshooting. Read this section if you cannot find a solution in the Quick Fixes section.

Troubleshooting Kerberos Problems

This section provides step-by-step diagnostic procedures and possible solutions that help you identify and fix Kerberos-related problems.

# Verifying Computer Settings for Troubleshooting Kerberos

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you begin troubleshooting, verify that your computer is configured properly and that the Kerberos authentication infrastructure is set up and running properly.

**Settings to Verify Before You Troubleshoot**
Verify all of the following items:

Make sure you have administrative rights on the computer you are troubleshooting.

Install all critical updates and security updates for Windows Server 2003.

Update all of your software, including non-Microsoft software.

Restart the computer if you are running a server operating system.

Make sure that required services and server are available.

Make sure that the clocks are synchronized across the domain.

**Make sure you have administrative rights on the computer you are troubleshooting.**
You cannot modify Kerberos-related settings unless you are a member of the Administrators group on the computer that you are administering.

### To verify that you are a member of the Administrators group

1. Open the Computer Management snap-in.
2. In the console tree, double-click **Local Users and Groups**, and then click **Groups**.
3. In the details pane, double-click **Administrators** and verify that your account name or a group to which your account is a member appears in the **Members** list.

**Install all critical updates and security updates for Windows Server 2003.**
Some updates might be required for the Kerberos protocol to function properly.

### To verify that you have all critical updates and security patches

- Click **Start**, click **Windows Update**, and then follow the instructions that appear on your screen.

**Update all of your software, including non-Microsoft software.**
The Kerberos protocol might not function properly with some programs unless you update the programs with the most recent service pack or software update.

**Restart the computer if you are running a server operating system.**
If you are running any Windows Server 2003 operating system, and you have made configuration changes that affect Kerberos authentication, you need to restart your computer.

**Make sure that required services and servers are available.**
The Kerberos authentication protocol requires a functioning domain controller, Domain Name System (DNS) infrastructure, and network in order to work properly. Verify that you can access these resources before you begin troubleshooting the Kerberos protocol.

**Make sure that the clocks are synchronized across the domain.**
Many network services, including Kerberos authentication are dependant on time synchronization throughout the domain. You can manually synchronize a computer with the time on the domain.

### To synchronize the computer's time with the current time on the domain

1. Click **Start**, and then click **Run**.
2. Type **net time /domain /set**, and then click **OK**.

# Configuring a Computer for Troubleshooting Kerberos

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and resolve Kerberos related problems, you need to configure your computer for troubleshooting. In addition, you need a basic understanding of troubleshooting concepts, procedures, and tools.

**Configuration Tasks for Troubleshooting**
To configure your computer for troubleshooting, perform the following tasks:

Install the Windows Support Tools

Configure Tools for Troubleshooting

Enable Account Logon Failure Auditing

**Install the Windows Support Tools**
The Windows Support Tools assist support personnel and network administrators in managing their networks and troubleshooting problems. They are not installed with the Windows operating system; you must install them separately from the \Support\Tools folder of the Windows operating system CD.

**Configure Tools for Troubleshooting**
Configure the following tools as needed:

- Ldifde

  Ldifde.exe is present on domain controllers but can be copied and used on client computers running Windows XP and Windows Server 2003. Ldifde provides a method to quickly extract and display certain Service Principal Names (SPNs) in a forest or domain.

- LDP

  LDP.exe is included with the Windows Support Tools.

- Setspn

  Setspn.exe is included with the Windows Support Tools.

- Tokensz

  For information about downloading Tokensz, see Tokensz.exe on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42933).

**Enable Account Logon Failure Auditing**
You can configure the Windows Server 2003 audit log so that it records information about failed logon attempts. To record this information in the audit log, you must enable the **Audit account logon events** policy.

**To enable Account Logon Failure auditing**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage the Audit Policy settings in your organization.
2. In the console tree, open **Computer Configuration**, open **Windows Settings**, open **Security Settings**, open **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click **Audit account logon events**.
4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

5. To audit unsuccessful attempts, select the **Failure** check box.

# Troubleshooting Kerberos Problems

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Any authentication problem with console logon, network logon, access to network resources, or remote access might indicate some sort of Kerberos error because the Kerberos protocol is the default authentication protocol.

To determine whether a problem is occurring with Kerberos authentication, check the System event log for errors from any services such as Kerberos, kdc, LsaSrv, or Netlogon that provide authentication. If any such errors exist, there might be errors associated with the Kerberos protocol as well. In addition, failure audits in the Security event log might show that the Kerberos protocol was being used when a logon failure occurred.

**Where to start**

In most cases, a Kerberos-related error is a symptom of another service failing. The Kerberos protocol relies on many services that must be available and functioning properly in order for any authentication to take place. The following is a list of the services or conditions that you will want to make sure are functioning properly before you scrutinize the Kerberos protocol.

- Make sure that the network infrastructure is functioning properly and that all computers and services can communicate.
- Make sure that a domain controller is accessible.
- Make sure that DNS is configured properly and resolving host names and services appropriately.
- Make sure that the clocks are synchronized across the domain.

**To synchronize the computer's time with the current time on the domain**

1. Click **Start**, and then click **Run**.
2. Type **net time /domain /set**, and then click **OK**.

| ⚠Caution |
| --- |
| You should not use the Net time command to configure or set time when the Windows Time service is running. Also, running the command **Net time /querysntp** will display the name of an NTP server with which a computer is configured to synchronize, but that NTP server is used only when the computer's time client is configured as NTP or AllSync. Most domain member computers have a time client type of NT5DS, which means they synchronize time from the domain hierarchy. The only typical exception to this is the domain controller that functions as the primary domain controller (PDC) emulator operations master of the forest root domain, which is typically configured to synchronize time with an external time source. To view the time client configuration of a computer, run the **W32tm /query /configuration** command (from an elevated Command Prompt in Windows Vista and Windows Server 2008) and read the Type line in the command output. For more information, see How Windows Time Service Works (http://go.microsoft.com/fwlink/?LinkId=117753) and Windows Time Service Tools and Settings (http://go.microsoft.com/fwlink/?LinkID=42984). |

If you have examined all these conditions and are still having authentication problems or Kerberos errors, you need to look further for the solution to your problems. Problems can be caused by the way the Kerberos protocol is configured or they can be caused by the way other technologies that work with the Kerberos protocol are configured.

**In this section**

Service Logons Fail Due to Incorrectly Set SPNs

Authentication Uses NTLM instead of Kerberos

Authentication Fails in a Mixed Windows and UNIX Environment

Authentication Fails Due to User PAC

Authentication Using UDP Causes Errors

Authentication Errors are Caused by Unsynchronized Clocks

# Service Logons Fail Due to Incorrectly Set SPNs

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Kerberos authentication is not possible for services without properly set Service Principal Names (SPNs). SPNs are unique identifiers for services running on servers. Each service that uses Kerberos authentication needs to have an SPN set for it so that clients can identify the service on the network. It is registered in Active Directory under a user account as an attribute called **Service-Principal-Name**. The SPN is assigned to the account under which the service the SPN identifies is running. Any service can look up the SPN for another service. When a service wants to authenticate to another service, it uses that service's SPN to differentiate it from other services running on that computer.

In general, only one SPN should be set for each service. Multiple SPNs can cause clients to connect to the wrong system or the ticket may be encrypted with the wrong key.

**Cause**

No SPN has been set for a specific service or it has been set incorrectly. If an SPN is not set for a service, then clients have no way to locate that service. Thus, common results of not setting an SPN are the following errors:

- "0x6 - KDC_ERR_C_PRINCIPAL_UNKNOWN: Client not found in Kerberos database"
- "0x7 - KDC_ERR_S_PRINCIPAL_UNKNOWN: Server not found in Kerberos database"

These two errors usually indicate that an SPN has not been set correctly. There are many other errors for which the cause might be a missing or incorrectly set SPN including:

- "0x29 - KRB_AP_ERR_MODIFIED: Message stream modified"
- "0x1B - KDC_ERR_MUST_USE_USER2USER: Server principal valid for user2user only"
- "0x8 - KDC_ERR_PRINCIPAL_NOT_UNIQUE: Multiple principal entries in database"
- "0x1F - KRB_AP_ERR_BAD_INTEGRITY: Integrity check on decrypted field failed"

**Solution**

To enable a service to authenticate properly, you need to set an SPN for that service.

Because multiple services can run simultaneously under the same account, setting an SPN requires four pieces of information that will make the SPN unique. These four pieces of information uniquely identify any service running on a network and can be used to mutually authenticate to any service.

An SPN itself consists of *ServiceClass***/***Host***:***Port*, where *ServiceClass* is the service class of the SPN.

You can use the following procedures to configure an SPN.

**To add an SPN**

- Type the following at a command prompt:

  **setspn -A** *ServiceClass* **/** *Host* **:** *Port AccountName*

**To delete an SPN**

- Type the following at a command prompt:

  **setspn -D** *ServiceClass* **/** *Host* **:** *Port AccountName*

**To view the SPNs that are registered for an account**

- Type the following at a command prompt:

  **setspn -L** *AccountName*

**To reset the default SPN registrations for the host names for an account**

- Type the following at a command prompt:

  **setspn -R** *AccountName*

**Setspn Parameters**
The following section describes the parameters for the Setspn.exe tool:

**-A**
Adds the specified SPN for the computer.

**-D**
Deletes the specified SPN for the computer.

**-L**
Lists the currently registered SPN for the computer. This parameter is the default: setspn run without this parameter also lists the registered SPNs.

**-R**
Resets the default SPN registrations for the host names for Computer.

***ServiceClass***
SPN service class assigned to the service.

***Host***
The computer to which the SPN belongs is all the names by which a computer on which the service is running can be referenced. This usually includes a NetBIOS name, a fully qualified domain name (FQDN), and any aliases that might have been assigned to this computer. A separate SPN will need to be set for each name by which the computer can be referenced, with the Host parameter changing respectively.

***Port***
The port that the service is running on. It is recommended to include the port even if it is a default port for the service.

***AccountName***
The name of the domain account under which the service runs. If the service runs as Local System or the network service, you usually do not need to set an SPN explicitly for the service because most common SPN service classes will automatically be mapped to the HOST/ SPN which is in turn automatically generated for each computer account.

For more information about using Setspn.exe to manipulate service principal names for accounts, see Setspn.exe: Manipulate Service Principal Names for Accounts on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43030).

**Cause**
Duplicate SPNs are set for the service, and the Kerberos Distribution Center (KDC) does not know which one is correct. Thus, common results of duplicate SPNs are the following errors:

- 0x8 - KDC_ERR_PRINCIPAL_NOT_UNIQUE: Multiple principal entries in database

- 0x29 - KRB_AP_ERR_MODIFIED: Message stream modified errors

These two errors usually indicate that there are duplicate SPNs. Furthermore, there are many other errors for which the cause might be duplicate SPNs. Kerberos authentication is not possible without properly set SPNs.

**Solution**
To enable a service to authenticate properly, you need to make sure that the service has only one SPN. First, find the duplicate SPNs and then delete one of them.

**To find the duplicate SPNs by using the LDP tool**

1. Click **Start**, then click **Run**, type **LDP**, and then click **OK**.

2. On the **Connection** menu, click **Connect**.

3. If you are on the domain controller, leave the default settings, and then click **OK**. If you are not on the domain controller, type the domain controller name in the Server text box, and then click **OK**.

4. On the **Connection** menu, click **Bind**.
5. Type **User**, **Password**, and **Domain** in the corresponding text boxes, and then click **OK**.
6. On the **View** menu, click **Tree**.
7. In the **Tree View** dialog box, type the base distinguished name in the **BaseDN** text box or select it from the pull-down menu.
8. On the **Browse** menu, click **Search**.
9. In the **Search** dialog box, type the base distinguished name in the **BaseDN** box or select from the pull-down menu.
10. In the **Search** dialog box, type the following in the **Filter** box:

    serviceprincipalname=*SPN/FQDN*

    For SPN, type the Service Principal Name that the error refers to - for example, HOST for computer accounts, HTTP for Web services.
11. Under **Scope**, click the **Subtree** option.
12. Click **Run**.

For more information about using Ldp.exe to search Active Directory, see Using Ldp.exe to Find Data in the Active Directory on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=23064).

If there are duplicate SPNs listed, delete the appropriate SPN by using the following command:

**To delete an SPN**

- Type the following at a command prompt:

  **setspn -D** *ServiceClass* **/** *Host* **:** *Port AccountName*

For information about the parameters for setspn.exe, see Setspn parameters.

For more information about how to use the Windows Support Tools, see Introduction to Support Tools on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkID=38906).

# Authentication Uses NTLM instead of Kerberos

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You might find that the Security log recorded an event in which logon occurred by using NTLM when it should have occurred by using Kerberos authentication.

**Cause**
The system attempts authentication by using the Kerberos protocol but it fails. As a result, the system attempts to authenticate by using NTLM. Windows Server 2003, Windows XP, and Windows 2000 use an algorithm called Negotiate (SPNEGO) to negotiate which authentication protocol is used. Although the Kerberos protocol is the default, if the default fails, Negotiate will try NTLM.

**Solution**
Investigate by examining errors or warnings in the event logs.

**Cause**
A call to Negotiate returns NTLM as the only protocol available. This situation is much more difficult to diagnose. There are two common causes of this situation — when Internet Explorer is being used and the Kerberos protocol is not being attempted:

- **Enable Integrated Windows Authentication (requires restart)** setting is not selected in Internet Explorer 6.0.
- Internet Explorer is accessing a site in the Internet zone instead of the intranet zone.

**Solution**
Internet Explorer 6.0 will, by default, not attempt to use the Kerberos protocol to authenticate to any site.

**To enable Internet Explorer 6.0 to respond to a negotiate challenge and perform Kerberos authentication:**

1. In Internet Explorer, on the **Tools** menu click **Internet Options**.
2. Click the **Advanced** tab, in the **Security** group select the **Enable Integrated Windows Authentication (requires restart)** check box, and then click **OK**.
3. Restart Internet Explorer.

For more information, see Unable to Negotiate Kerberos Authentication After Upgrading to Internet Explorer 6 in the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=23045).

The second common cause is that Internet Explorer 6.0 is attempting to access a site located in the Internet zone. Internet zone sites are prevented from using Integrated Windows authentication because these protocols do not typically work through Web proxies, among other reasons. If a site is located in the Internet zone, Internet Explorer 6.0 does not attempt to use Kerberos authentication, and automatically tries NTLM. In all versions of Internet Explorer, when accessing a Web site to which you want to use Kerberos authentication, you must verify that the Web site appears as being in the local intranet zone. An icon in the lower right corner of the Internet Explorer window indicates what zone a Web site is in. It displays “Internet” for the Internet zone and “Local Intranet” for the intranet zone. If the Web site appears as being in the Internet zone, you must manually add the site to the local intranet sites list.

**To add an Internet site to the local intranet sites list**

1. On the **Tools** menu, click **Internet Options**.
2. Click the **Security** tab, then click **Local Intranet**, then click **Sites**, and then click **Advanced**.
3. In the box under **Add this Web site to the zone**, type the name of the Web site that you want to authenticate with Kerberos authentication, and then click **Add**.
4. Click **Close**, and then click **OK**.

After you perform this procedure, if you find that NTLM authentication is still being used, or that Kerberos is not even being attempted in a situation where Kerberos authentication should be used, contact Product Support Services for help in diagnosing the problem.

# Authentication Fails in a Mixed Windows and UNIX Environment

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The logon from a computer running Windows NT 4.0 in a mixed Windows and UNIX environment fails and the Active Directory domain controller returns an Access denied error.

In an environment where a trust exists between a Kerberos realm and an Active Directory domain, authentication data can come from one of two sources, either a UNIX Key Distribution Center (KDC) or the Active Directory domain controller.

If the authentication data is coming from a UNIX KDC, Windows users have account mappings set up for them to map their UNIX user account to a Windows user account. Normally, the password on the Windows account does not matter, because all authentications are done by the UNIX KDC.

**Cause**
The size of a ticket is too large to be transmitted reliably by means of the User Datagram Protocol (UDP). In a Windows environment, this message is purely informational. A computer running a Windows operating system will automatically try TCP if UDP fails.

In a mixed UNIX and Windows authentication environment, many errors can be attributed to the UNIX KDC not running the latest MIT distribution of the Kerberos protocol. One of the errors that can result is "0x34 - KRB_ERR_RESPONSE_TOO_BIG: Response too big for UDP, retry with TCP."

**Solution**
If this error occurs in a mixed operating system environment, consult the Vendor specific documentation to upgrade the UNIX KDCs to the latest MIT distribution of the Kerberos protocol, which supports TCP connections if UDP fails.

**Cause**
The "0x19 - KDC_ERR_PREAUTH_REQUIRED: Additional pre-authentication required" error often occurs in UNIX interoperability scenarios. MIT Kerberos clients do not request pre-authentication when they send a KRB_AS_REQ message. If pre-authentication is required (the default), Windows operating systems send this error. Most MIT-Kerberos clients respond to this error by giving the pre-authentication, in which case the error can be ignored, but some clients might not respond in this way.

**Solution**
Set the **Do not require Kerberos pre-authentication** flag on the user's account. Alternatively, consider upgrading to the most recent MIT reference distribution of Kerberos authentication.

**To set the Do not require Kerberos pre-authentication flag on the user's account using Active Directory Users and Computers:**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**. (Or, click the folder that contains the user account.)
3. Right-click the user account, and then click **Properties**.
4. On the **Account** tab, scroll through the **Account options** and select the **Do not require Kerberos pre-authentication** checkbox, and then click **OK**.

| **Note** |
| --- |
| To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated an assignment of administrative responsibility to a user, computer, group, or organization. |

**Cause**
When the KDC, server, or client receives a packet for which it does not it have a key of the appropriate encryption type, this can cause the "0xF - KDC_ERR_SUMTYPE_NOSUPP: KDC has no support for checksum type" error. The result is that the computer is unable to decrypt the ticket. This error is common in UNIX interoperability scenarios when a new account is created. The new

account might have an incompatible key associated with it.

**Solution**
Change the password on the account to re-create the key, which should eliminate the error.

**Cause**
The UNIX KDC attempts to use 3DES to encrypt its tickets which can cause the "0xE - KDC_ERR_ETYPE_NOTSUPP: KDC has no support for encryption type" error.

**Solution**
Consult the vendor-specific documentation to configure the UNIX KDC to use another encryption type, such as DES or RC4. Windows operating systems do not support 3DES.

**Cause**
The target server does not support the encryption type used by the KDC in some UNIX and Windows interoperability scenarios.

**Solution**
Consult the vendor-specific documentation to configure the target server to support the RFC standard encryption type RC4 or contact the vendor for assistance.

**Cause**
The Windows NT 4.0 operating system does not support Kerberos authentication. Therefore, if there are Windows NT–based computers on the network running services, any authentications involving these computers occur by using NTLM and these authentications are conducted by the domain controller. In this scenario, the password on the domain controller must match the password stored on the UNIX KDC. The passwords must match because the fallback to NTLM occurs transparently. If the passwords do not match, the domain controller returns an Access denied error because the user has provided a password that does not match the one stored on the user's Active Directory account.

**Solution**
Consult the vendor-specific documentation to reset the password on the account that the user’s UNIX principal is mapped to in order to match the password stored on the UNIX KDC.

# Authentication Fails Due to User PAC

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In certain scenarios when a user is a member of more than 70 groups, Kerberos authentication might fail. In order to provide the proper authorization information to a user after the user logs on with Kerberos authentication, the KDC will transmit Privilege Attribute Certificate (PAC) data in the ticket-granting ticket (TGT). The PAC contains various types of authorization data including groups that the user is a member of, rights the user has, and what policies apply to the user. When the client receives a ticket, the information contained in the PAC is used to generate the user's access token.

**Cause**

In order to optimize performance, the buffer size for the PAC is pre-allocated. The pre-allocated buffer size is usually adequate to hold all the required authorization data. However, if a user has a very high group membership — from over 70 to over 120, depending on what groups — the size of the PAC might exceed the pre-allocated buffer size. In such a case, the system generates a memory allocation error, PAC creation fails, and the Kerberos ticket-granting service either fails to generate a valid ticket or generates a ticket with an empty PAC. This sort of error usually manifests itself in the form of a memory allocation error, which gets reported as "0x3C - KRB_ERR_GENERIC: Generic error." This also can result in the failure of clients to apply Group Policy settings.

**Solution**

You can use the following procedure on a Windows Server 2003-based computer to calculate the number of groups that a user is a member of by using the Kerberos Token Size (Tokensz.exe) tool.

**To calculate the groups that a user belongs to by using the Tokensz.exe tool**

- Type the following at a command prompt:

  **tokensz /calc_groups** *ClientName* **/user:** *UserName* **/domain:** *UserDomain* **/password:** *ClientPassword* **/system**

The following describes the parameters used with this command:

**/calc_groups**
This option is only available if you are using Windows Server 2003 KDCs and running the tool on a computer running Windows Server 2003. The parameter passed to this option is a user and (optionally) a domain that this user is a member of. Tokensz will list all the groups that this user is a member of.

***ClientName***
The user that you are listing the groups for

**/user: *UserName***
The user name of an account with permission to query the group membership of the user.

**/domain: *UserDomain***
The domain that the above account exists in.

**/password: *ClientPassword***
The password that corresponds to the user account specified in the **/user** parameter.

**/system**
You must have administrator rights to use this switch, which runs the test under the Local System context of the computer that the test is being run on. In these cases, you must use the [**/user:***UserName*] [**/domain:***UserDomain*] [**/password:***ClientPassword*] switches, because the tool will be running under the Local System context. This switch is useful to see what groups are present in the Local System logon context.

| **Note** |
| --- |
| This command is available only if you are using Windows Server 2003 KDCs and running the tool on a computer running Windows Server 2003. The parameter passed to this option is a user and (optionally) a domain that this user is a member of. Tokensz.exe lists all the groups that this user is a member of. |

You can solve this problem in two ways:

- Reduce the number of groups that the user is a member of. Because nested groups are expanded out within the PAC, the actual number of groups that the user is a member of might be greater than you suspect.

- Alternatively, install a hotfix that will enable you to set the maximum size of a Kerberos token by using the registry. For information about installing this hotfix, see New Resolution for Problems That Occur When Users Belong to Many Groups on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=23044).

# Authentication Using UDP Causes Errors

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Packets sent along the network by using the User Datagram Protocol (UDP) sometimes get lost or fragmented on the way to their destination.

**Cause**
The UDP protocol can also sometimes cause the "KRB_ERR_RESPONSE_TOO_BIG: Response too big for UDP, retry with TCP" error.

The size of a ticket is too large to be transmitted reliably by means of UDP. In a Windows environment, this message is purely informational. A computer running a Windows operating system will automatically try TCP if UDP fails.

**Solution**
If this error occurs in a mixed operating systems environment, consult your vendor-specific documentation to upgrade the UNIX KDCs to the latest MIT distribution of the Kerberos protocol, which supports TCP connections if UDP fails.

For information about forcing Kerberos to use TCP, see How to Force Kerberos to Use TCP Instead of UDP on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=23043).

**Cause**
By default, Kerberos authentication uses UDP to transmit its data. UDP provides no guarantee that a packet sent along the network will reach its destination intact. Thus, in environments with a high amount of network congestion it is common for packets to get lost or fragmented on the way to their destination.

If you have discovered the "0x7 - KDC_ERR_S_PRINCIPAL_UNKNOWN: Server not found in Kerberos database" error message and the Service Principal Name (SPN) is set, or if the request failed for an initial TGT (requesting a TGT does not require any SPNs to be set manually), UDP fragmentation might be causing the failure.

If you have discovered the "0x28 - KRB_AP_ERR_MSG_TYPE: Invalid msg type" error message, then UDP is being attempted with User-to-User protocol. User-to-User is an extension of Kerberos authentication that enables secure servers to be run on personal computers.

**Solution**
Because the only way to decrease the likelihood of UDP fragmentation occurring is to reduce network traffic — a usually impractical solution — it is almost always better to configure the Kerberos authentication service to use TCP instead of UDP. TCP provides a guarantee that a packet that is sent will reach its destination intact and can therefore be used in any network environment.

In order to support the User-to-user extension to the Kerberos protocol you must force Kerberos authentication to use TCP.

For information about forcing Kerberos to use TCP, see How to Force Kerberos to Use TCP Instead of UDP on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=23043).

# Authentication Errors are Caused by Unsynchronized Clocks

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Clients can be prevented from authenticating by the mechanisms that Kerberos authentication uses to prevent "replay" attacks. In a replay attack, a malicious user captures the network traffic and replays it to trick the authenticating server into accepting the attacker as a legitimate user who is providing credentials.

Kerberos authentication prevents a replay attack by using two mechanisms:

- The Kerberos client on the local computer encrypts a timestamp inside the authenticator and then sends it to the Key Distribution Center (KDC). If the KDC verifies that the time it decrypts from the authenticator is within a specified amount of the local time on the KDC (the default is five minutes), the system can assume that the credentials presented are genuine.

- All tickets issued by the KDC have an expiration time. Thus, if a ticket is compromised, it cannot be used outside of a specified time range — usually short enough to make the risk of a replay attack minimal.

Because of these mechanisms, Kerberos authentication relies on the date and time that are set on the KDC and the client. If there is too great a time difference between the KDC and a client requesting tickets, the KDC cannot determine whether the request is legitimate or a replay. Therefore, it is vital that the time on all of the computers on a network be synchronized in order for Kerberos authentication to function properly.

Clock skew can be easily diagnosed by reviewing the information in the System log.

**Causes**
If the ticket presented to the server is not yet valid (in relationship to the server time), the "0x21 - KRB_AP_ERR_TKT_NYV: Ticket not yet valid" error will be recorded. The most probable cause is that the clocks on the KDC and the client are not synchronized.

In addition, the errors "0xB - KDC_ERR_NEVER_VALID: Requested start time is later than end time," "KDC_ERR_PREAUTH_FAILED: Pre-authentication information was invalid," and "KDC_ERR_NEVER_VALID: Requested start time is later than end time" are caused because the times on the KDC and the client do not match.

**Solution**
In this case no action is needed. In a Windows environment, the domain controller will supply the correct time on the domain controller to the Kerberos client. The Kerberos client then uses the correct domain controller time to attempt the authentication request a second time. Presuming that the user's credentials are valid, the user will be authenticated on the second try.

**Cause**
Typically, when the value for the **Maximum lifetime for user ticket Kerberos policy** setting is set too low, the "KRB_AP_ERR_TKT_EXPIRED: Ticket expired" error occurs.

**Solution**
Because ticket renewal is automatic, you should not have to do anything if you get this message.

**Cause**
If Kerberos authentication fails when it is being attempted between realms, the clocks in the KDC in the target realm and the KDC in the client realm might not be synchronized.

**Solution**
For non-Windows Kerberos realms, consult the operating system documentation to synchronize clocks on the KDCs in the two realms.

**Cause**
If a client requests the postdating of a Kerberos ticket, the "0xA - KDC_ERR_CANNOT_POSTDATE: Ticket not eligible for postdating" error can occur. Postdating is the act of requesting that a ticket's start time be set into the future. Postdating is not allowed therefore the client will not be authenticated.

**Solution**
No action is necessary. This behavior is by design.

**Cause**

Typically, when the difference between client timestamp in the authenticator or KRB_AS_REQ and the server is greater than **the Maximum tolerance for computer clock synchronization** setting in the domain policy, the "0x25 - KRB_AP_ERR_SKEW: Clock skew too great" error occurs. This error is logged if a client computer sends a timestamp whose value differs from that of the server's timestamp by more than the number of minutes found in the **Maximum tolerance for computer clock synchronization** setting in Kerberos policy.

**Solution**

Although the "0x25 - KRB_AP_ERR_SKEW: Clock skew too great" error might show up in the logs, it will not prevent a user from being authenticated. When this error is returned, the domain controller also supplies the correct time on the domain controller. The Kerberos client uses the correct domain controller time to attempt the authentication request a second time. Presuming that the user's credentials are valid, the user will be authenticated on the second try.

This error can more commonly occur as the number of portable, or frequently disconnected, computers in your network increases.

To avoid getting this error, you can change the value of the **Maximum tolerance for computer clock synchronization** setting to a higher value.

| ⚠**Caution** |
| --- |
| Beware that the higher you set this value, the more susceptible the network becomes to replay attacks. |

**To set Maximum tolerance for computer clock synchronization Kerberos policy by using Active Directory Users and Computers**

1. Click **Start**, click **All Programs**, click **Administrative Tools**, and then click **Active Directory Users and Computers**.
2. Right-click the domain whose policy you wish to change, and then click **Properties**.
3. Click the **Group Policy** tab, select the **Default Domain Policy**, and then click the **Edit** button to launch the Group Policy Object Editor.
4. Open **Computer Configuration**, open **Windows Settings**, and then open **Security Settings**.
5. Click **Account Policies**, double-click **Kerberos Policy**, and then double-click **Maximum tolerance for computer clock synchronization**.
6. Increase the value in the **Maximum tolerance** box, and then click **OK**.
7. You can wait for the policy change to propagate or you can run **gpupdate /force** on the client computers to force propagation immediately.

# Additional Resources for Troubleshooting Kerberos

Updated: March 2, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For additional information about troubleshooting Kerberos problems, see the following resources:

- DCOM Client May Put Memory on the Wire in Microsoft Knowledge Base article 300367 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;300367)

- SMS administrator issues after you modify the Kerberos MaxTokenSize registry value in Microsoft Knowledge Base article 297869 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;297869)

- Kerberos authentication may not work if user is a member of many groups in Microsoft Knowledge Base article 280830 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;280830)

- Internet Explorer logon fails due to an insufficient buffer for Kerberos in Microsoft Knowledge Base article 277741 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;277741)

- Internet Explorer Kerberos authentication does not work because of an insufficient buffer connecting to IIS in Microsoft Knowledge Base article 269643 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;269643)

- Group Policy may not be applied to users belonging to many groups in Microsoft Knowledge Base article 263693 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;263693)

- How to use SPNs when you configure Web applications that are hosted on IIS 6.0 in Microsoft Knowledge Base article 929650 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;929650)

- FIX: Error Message: "Timeout expired" Occurs When You Connect to SQL Server Over TCP/IP and the Kerberos MaxTokenSize is Greater Than 0xFFFF in Microsoft Knowledge Base article 313661 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;313661)

- FIX: You receive an "Error 413" error message when you try to log on to Site Builder by clicking to select the "Login as <CurrentUser>" check box in Content Management Server 2001 in Microsoft Knowledge Base article 867431 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;867431)

- INF: List of Bugs Fixed by SQL Server 7.0 Service Packs in Microsoft Knowledge Base article 313980 (http://support.microsoft.com/default.aspx?scid=kb;EN-US;313980)

Web applications and services, such as Internet Explorer, Internet Information Server, and Outlook Web Access may require additional Kerberos maximum settings adjusted, which are discussed in the following articles:

- MaxBufferedSendBytes – Used to resolve slow performance when Internet Server Application Programming Interface (ISAPI) applications or Common Gateway Interface (CGI) applications are hosted on Microsoft Internet Information Services (IIS) 6.0, as described in Microsoft Knowledge Base article 906977 (http://support.microsoft.com/kb/906977/)

- MaxClientRequestBuffer, MaxFieldLength, and MaxRequestBytes – Used to resolve HTTP 400 Bad Request (Request Header Too Long) errors, as described in Microsoft Knowledge Base article 920862 (http://support.microsoft.com/kb/920862).

- MaxPacketSize – Used to resolve Kerberos failures that results in "There are currently no logon servers available to service the logon request" error messages, as described in Microsoft Knowledge Base article (http://support.microsoft.com/kb/244474).

# Troubleshooting Access Control

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**In this guide**

- Introduction to Troubleshooting Access Control
- Verifying Computer Settings for Troubleshooting Access Control
- Access Control Quick Fixes
- Configuring a Computer for Access Control Troubleshooting
- Troubleshooting Access Control Problems
- Additional Resources for Troubleshooting Access Control

This guide provides troubleshooting information for access control in Microsoft® Windows® XP and Microsoft® Windows Server™ 2003. It is designed to help you identify and resolve problems that are related to access control.

# Introduction to Troubleshooting Access Control

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to troubleshoot access control. If you are using this guide for the first time, review the following sections of this introduction:

When to Use this Guide

How to Use this Guide

**When to Use This Guide**
You should use this guide when:

- You believe that a user is accessing a resource he or she should not have access to.
- A user has been changing discretionary access control lists (DACLs) or system access control lists (SACLs) and you need to discover who is performing the changes.
- A user who should have permission cannot access a resource.

Do not use this guide to find out how to perform a task, such as designing an access control strategy. Most access control problems arise due to the way the access control strategy was designed. While this guide can give you some guidance about how to best assign permissions and perform auditing, you should review the design documents listed in Additional Resources for Troubleshooting Access Control for more definitive advice.

This guide assumes that you have a basic understanding of access control, how it works, and why your organization uses it to control access to resources. You should also have a thorough understanding of how access control is deployed and managed in your organization. This includes an understanding of the mechanism your organization uses to configure and manage access control settings.

**How to Use This Guide**
This guide is divided into four sections. Each section addresses a type of problem, ranging from less complex to more complex.

Verifying Computer Settings for Troubleshooting Access Control

This section provides a list of prerequisites and settings that must be verified before you troubleshoot. Read this section first.

Access Control Quick Fixes

This section provides quick solutions to the most common access control problems. Read this section if you have verified your computer settings, but your problem persists.

Configuring a Computer for Access Control Troubleshooting

This section describes how to configure your computer for troubleshooting. Read this section if you cannot find a solution in the Quick Fixes section.

Troubleshooting Access Control Problems

This section provides step-by-step diagnostic procedures and possible solutions that help you identify and fix access control problems.

Additional Resources for Troubleshooting Access Control

# Verifying Computer Settings for Troubleshooting Access Control

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you begin troubleshooting, verify that your computer is configured properly and that access control is set up properly.

**Settings to Verify Before You Troubleshoot**
Verify all of the following items:

Determine what type of file system you are using

Make sure you have administrative rights on the computer you are troubleshooting

Install all critical updates and security updates for your system (Windows Server 2003 or Windows 2000 Server)

Update all of your software, including non-Microsoft software

**Determine what type of file system you are using.**
Windows Server 2003 and Windows 2000 Server support the FAT16, FAT32, and NTFS file systems. Because NTFS is required for many advanced, specific security options, it is strongly recommended that you use NTFS. Perform the following procedure to determine what file system is present on your computer.

### To determine your computer's file system

1. Open the Computer Management snap-in. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
2. In the console tree, expand **Storage**, and then click **Disk Management**.
3. In the details pane, note the file system listed under the **File System** column.

**Make sure you have administrative rights on the computer you are troubleshooting.**
You cannot modify access control settings unless you are a member of the Administrators group on the computer that you are administering.

### To verify that you are a member of the Administrators group

1. Open the Computer Management snap-in. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
2. In the console tree, double-click **Local Users and Groups**, and then click **Groups**.
3. In the details pane, double-click **Administrators** and verify that your account name or a group to which your account is a member appears in the **Members** list.

You can also tell if you have the appropriate administrative rights to configure access control by opening **Local Security Policy** in Control Panel under Administrative Tools. If you do not have administrative rights, all of the controls in the **Local Security Policy** user interface (UI) will appear dimmed and a warning will appear telling you that you need to be a computer administrator to change any settings.

**Install all critical updates and security updates for your system (Windows Server 2003 or Windows 2000 Server).**
Some updates might be required for the Windows access control system to function properly.

### To verify that you have all critical updates and security patches

- Click **Start**, click **Help and Support**, click **Windows Update**, and then follow the instructions that appear on your screen.

If you are using Windows Update Services, check that all updates have been approved and applied to your computer.

**Update all of your software, including non-Microsoft software.**
The Windows access control system might not function properly with some programs unless you update the programs with the most recent service pack or software update. Newer versions of many applications, such as antivirus programs, will

automatically configure access control and might resolve any problems you have.

You should also work with any vendors to ensure that all custom applications are up to date.

# Access Control Quick Fixes

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides the most common access control problems and their solutions. You can use the information in this section to resolve problems in the same way you would use a FAQ to find answers to common questions. Read this section before you begin any advanced troubleshooting.

**Common Access Control Problems**
Listed below are common access control problems and quick fixes:

You are unable to access a file or folder as a result of a Deny ACE applied to Everyone

Security policy is not being enforced

**You are unable to access a file or folder as a result of a Deny ACE applied to Everyone**
If a Deny access control entry (ACE) is applied to the Everyone security group, no one will be able to access the resource and only the owner will be able to change the permissions. Anyone, including the owner, who attempts to access the file or folder will receive an "Access is denied" error.

Perform the following procedure to determine whether a Deny ACE is applied to a user or group. You must be an administrator or the owner of the file or folder to perform this task.

**To determine whether a Deny ACE is applied to a user or group**

1. Right-click the file or folder that the user or group is unable to access and then click **Properties**.
2. Click the **Security** tab, and in **Group or user names**, click the user or group you want to examine ACEs for.
3. In **Permission for <user or group>**, examine the permissions and determine whether a Deny ACE is applied to a user or group.

You can recover access to the file or folder, though, by modifying the resource's permissions. Before you can modify the permissions, you must be the owner of the file or folder. Perform the following procedure if you are not the resource's owner. You must be an administrator or have been granted the **Take ownership of files or other objects** user right.

**To take ownership of a file or folder**

1. Open **Windows Explorer**, and then locate the file or folder you want to take ownership of.
2. Right-click the file or folder, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Owner** tab.
4. In the **Change owner to** box, do one of the following:
   - To change the owner to a user or group that is not listed, double-click **Other users and groups**. In the **Enter the object name to select (examples)** box, type the name of the user or group, and then click **OK**.
   - To change the owner to a user or group that is listed, click the new owner.
5. (Optional) To change the owner of all subcontainers and objects within the tree, select the **Replace owner on subcontainers and objects** check box.

| **Note** |
| --- |
| You can transfer ownership in two ways: 1) the current owner can grant the **Take ownership** permission to others, allowing those users to take ownership at any time. A user granted the **Take ownership** permission can take ownership of the object or assign ownership to any group that the user is a member of. 2) A user who has the **Restore files and directories** privilege can double-click **Other users and groups** and choose any user or group to assign ownership to. |

| **Note** |
| --- |

| |
|---|
| An administrator can take ownership of any file on the computer. |

Once you have taken ownership of the file or folder, perform the following procedure to remove the Deny ACE from the Everyone group's ACL.

**To remove the Deny ACE applied to the Everyone group**

1. Open **Windows Explorer**, and then locate the file or folder you want to modify permissions for.
2. Right-click the file or folder, click **Properties**, and then click the **Security** tab.
3. In the **Group or user names** box, select **Everyone**.
4. In the **Permissions for Everyone** box, select **Full Control**.

**Security policy is not being enforced**

After the local security policy or a policy administered through Group Policy has been modified, you might need to refresh the policy on a local computer if it is not enforcing the policy.

Perform the following procedure to refresh the security policy on a Windows 2000 Server–based computer.

**To force a Windows 2000 Server–based computer to refresh its security policy settings and Group Policy settings**

1. Open a command prompt.
2. Type **secedit /refreshpolicy**.

The **/refresh** option ignores all processing optimizations and reapplies all settings.

The Gpupdate command-line tool refreshes local Group Policy settings and Group Policy settings that are stored in Active Directory, including security settings. This command supersedes the now obsolete **/refreshpolicy** option for the **secedit** command for Windows Server 2003.

Perform the following procedure to refresh the security policy on a Windows Server 2003–based computer.

**To force a Windows Server 2003–based computer to refresh its security settings and Group Policy settings**

1. Open a command prompt.
2. Type **gpupdate /force**.

The **/force** option ignores all processing optimizations and reapplies all settings.

# Configuring a Computer for Access Control Troubleshooting

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and fix access control problems, you need to configure your computer for troubleshooting. In addition, you need a basic understanding of troubleshooting concepts, procedures, and tools.

To configure your computer for troubleshooting access control, you can install Xcacls.exe.

**Install Xcacls.exe**

The Xcacls command-line tool sets all file-system security options that are accessible in Windows Explorer. Xcacls does this by displaying and modifying the access control lists (ACLs) of files.

The tool is part of the Windows 2000 Resource Kit Tools. To download the Xcacls tool, see Free Tool Downloads on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=18748).

# Troubleshooting Access Control Problems

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The problems that typically occur with the Windows access control system are problems with user access to files and folders.

Share permissions are set on folders only and apply to folders that have been shared on a file server or computer. NTFS permissions apply to discs that are formatted with the NTFS file system. NTFS permissions can be applied on local files and folders and shared folders.

**In this section**

- Anonymous user cannot access a shared folder
- Unknown user is attempting to access a file or folder he or she should not have access to
- Unknown user is changing ACLs on files or folders
- User cannot access a file or folder but should have permission
- Users cannot write to a shared folder after migration to Windows Server 2003

# Anonymous user cannot access a shared folder

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem typically occurs when someone logging on with a Guest account attempts to access a shared folder. Users or services that attempt to access an object anonymously are not granted access if the access control list (ACL) on the object includes the Everyone group.

**Cause**

While Windows NT 4.0 and Windows 2000 allowed anonymous access to the server, the inclusion of the Everyone security group in the anonymous user access token is disabled by default in Windows Server 2003 and Windows XP. In Windows XP and in Windows Server 2003, the Everyone group does not contain the security identifier (SID) "Anonymous." Anonymous access is only granted for objects whose ACL explicitly contains the anonymous SID.

**Solution**

Add the Anonymous SID to the Everyone access token.

| ⚠Caution |
| --- |
| For security reasons, it is strongly recommended that you do not allow anonymous access to your server. |

However, if anonymous access is needed, perform one of the following procedures.

Enable anonymous access on a local computer

Enable anonymous access on a domain controller

**Enable anonymous access on a local workstation or server computer**

Perform the following procedure to enable anonymous access on a local workstation or server computer.

**To enable anonymous access on a local workstation or server computer**

1. Open Local Security Settings. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
2. In the console tree, double-click **Local Policies**, and then click **Security Options**.
3. In the details pane, right-click **Network access: Let Everyone permissions apply to anonymous users**, and then click Properties.
4. On the **Local Security Settings** tab, click **Enabled**, and then click **OK**.

**Enable anonymous access on a domain controller**

Perform the following procedure to enable anonymous access on a domain controller.

**To enable anonymous access on a domain controller**

1. Open Local Security Settings. Click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Domain Security Policy**.
2. In the console tree, double-click **Security Settings**, double-click **Local Policies**, and then click **Security Options**.
3. In the details pane, right-click **Network access: Let Everyone permissions apply to anonymous users**, and then click **Properties**.
4. Select the **Define this policy setting** check box, click **Enabled**, and then click **OK**.

For more information, see Article 278259, Everyone Group Does Not Include Anonymous Security Identifier, on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47167).

# Unknown user is attempting to access a file or folder he or she should not have access to

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem typically occurs when someone is attempting to access a file or folder he or she either has not been given permission to access or has been explicitly denied access. This problem can be caused unintentionally by a user mistakenly attempting to access a resource or it can be caused intentionally by a user trying to circumvent the access control policy on the file or folder.

**Cause**
When an audit policy is not in place, it is difficult to determine exactly who is attempting to access unauthorized resources.

**Solutions**
Because a Windows-based computer can be managed with Group Policy or be a standalone computer, there are two different solutions for this problem. Choose one of the following options and follow the corresponding procedures.

- Computer is managed with Group Policy
- Computer is not managed with Group Policy

Please check with your system administrator to determine whether the computer is managed with Group Policy.

**Computer is managed with Group Policy**
If the computer you would like to audit events for is managed by Group Policy, perform the following procedures to discover which user is attempting to access the file or folder.

1. Enable auditing of the object access event category
2. Apply auditing policy settings for an object using Group Policy
3. Analyze the Security events in Event Viewer
4. Adjust permissions or enforce a new security policy

| Note |
| --- |
| You can set up file and folder auditing only on NTFS drives. |

| Note |
| --- |
| To perform this set of procedures, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been granted the Manage auditing and security log right in Group Policy. As a security best practice, consider using Run as to perform this procedure. |

**Step One: Enable auditing of the object access event category**
Choose among the following object access auditing configuration options, depending on your environment:

- For your local computer
- For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed
- For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed

- For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

**For your local computer**
Perform the following procedure:

**For your local computer**

1. Open **Local Security Policy**. Click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
2. In the console tree, expand **Security Settings**, expand **Local Policies**, and click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. Select the **Failure** check box.

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**
Perform the following procedure:

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**

1. Open **Domain Controller Security Policy**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.
2. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
5. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**
Perform the following procedure:

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**

1. Open **Active Directory Users and Computers**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.
5. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
6. In the details pane, double-click **Audit object access**.
7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
8. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**
Perform the following procedure:

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a**

**domain**

1. Open Microsoft Management Console (MMC). Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the **Group Policy Wizard**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit—or create a new one—click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, and then click **Audit Policy**.
8. In the details pane, double-click **Audit object access**.
9. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
10. Select the **Failure** check box.

**Step Two: Apply auditing policy settings for an object by using Group Policy**

| **Important** |
| --- |
| Before setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files will be audited. |

| **Note** |
| --- |
| To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been granted the **Manage auditing and security log** right in Group Policy. As a security best practice, consider using Run as to perform this procedure. |

**Apply auditing policy settings for an object by using Group Policy**

1. Open Microsoft Management Console (MMC). Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the **Group Policy Wizard**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit—or create a new one, click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, and then click **File System**.
8. If you want to add a file or folder to this GPO to audit, right-click **File System**, and then click **Add File**. Browse to the file that you want, or make a new folder, and then click **OK**.
9. If you want to apply or modify auditing settings on a file or folder that has already been added to this GPO, in the details pane, right-click the file or folder, click **Properties**, and then click **Edit Security**.
10. Click **Advanced**, and then click the **Auditing** tab.
11. Do one of the following:

- To set up auditing for a new user or group, click **Add**. In **Name**, type the name of the user or group that you want, and then click **OK**.
- To view or change auditing for an existing group or user, click the name that you want, and then click **Edit**.
- To remove auditing for an existing group or user, click the name that you want, click **Remove**, click **OK**, and then skip the rest of this procedure.

12. Select the appropriate entry in the **Apply onto** list.
13. In the **Access** box, select the **Failed** check box.

    If you want to prevent files and subfolders in the tree from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.
14. Click **OK**.

For best system performance, minimize the number of entries in the SACL for an object. One entry in a SACL that contains 1000 users does not degrade system performance as much as 1000 separate entries.

Because the Security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the Security log. The maximum size for the Security log is defined in **Event Viewer**.

If you are unsure about what user might be attempting to access the restricted file or folder, audit object access for groups. Make sure to change the location to the local computer if you want to include a local group, such as Users.

**Step Three: Analyze the Security events in Event Viewer**

After applying the audit policy to the desired file or folder, view the Security log in Event Viewer to determine what user has been attempting to access the restricted file or folder.

Perform the following procedure to view the Security log.

**To view the Security log**

1. Open **Event Viewer**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. If you want to see more details about a specific event, in the details pane, double-click the event.

Once you have accessed Event Viewer, you should take advantage of the filter to eliminate irrelevant data in the Security log. Perform the following procedure to filter for Success and Failure events for the object access event category.

**To filter the Security log view**

1. Open **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. In the **File** menu, click **View**, and then click **Filter**.
4. In **Event types**, clear the **Information**, **Warning**, and **Error** check boxes and ensure that the **Success** and **Failure** check boxes are selected.
5. In the **Event Source** list, select **Security**.
6. In the **Category** list, select **Object Access**.
7. Click **OK**.

| **Note** |
| --- |
| You can use the other fields in the Filter page to further filter the Security events by event ID, user, and computer. You can also filter events by using a time-period range. Filtering by a range of time can be useful if you believe that someone tried to access a restricted file or folder during a specific time on a particular day. |

Once you have filtered the events, examine the Success and Failure audits to see if they apply to restricted files or folders that someone attempted to access. The user name of the person attempting to access the restricted file or folder will be listed within the security event, along with the action that the user was attempting to perform or successfully performed.

| **Important** |
| --- |
| The view filter that you set will remain on the event log unless you manually change the filter. Filtering the view of the event log can help you narrow the scope of the events presented and make it much easier to find potential security problems. |

**Step Four: Adjust permissions or enforce a new security policy**
After you have discovered which user is attempting to access a file or folder, you must then decide on a course of action to complete the solution. There are two possible solutions, depending upon the original intent of the person who attempted to access a file or folder.

If the user is trusted and attempted to access the file or folder believing that he or she was performing an action that complies with your security policy, you should either further refine your security policy or educate the user about the proper way to follow the policy.

If the user is not trusted and attempted to change the file or folder to intentionally contradict the established security policy, then you should lock down the user's permissions. Make sure to reevaluate your security policy and adhere to best practices. For guidance about applying permissions, see Users cannot write to a shared folder after migration to Windows Server 2003.

**Computer is not managed with Group Policy**
If the computer you would like to audit events for is not managed by Group Policy, perform the following procedures to discover which user is attempting to access the file or folder.

1. Enable auditing of the object access event category
2. Apply auditing policy to a specified object
3. Analyze the Security events in Event Viewer
4. Adjust permissions or enforce a new security policy

You must first decide what objects you would like to audit and whether you want to audit a specific computer or use Group Policy to manage auditing within an organization unit (OU) or domain.

| **Note** |
| --- |
| You can set up file and folder auditing only on NTFS drives. |

**Step One: Enable auditing of the object access event category**
Choose between the following object access auditing configuration options, depending on your environment:

- For your local computer
- For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed
- For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed
- For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

**For your local computer**
Perform the following procedure:

**For your local computer**

1. Open **Local Security Policy**. Click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**,

and then double-click **Local Security Policy**.

2. In the console tree, expand **Security Settings**, expand **Local Policies**, and click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. Select the **Failure** check box.

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**
Perform the following procedure:

### For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

1. Open **Domain Controller Security Policy**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.
2. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
5. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**
Perform the following procedure:

### For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed

1. Open **Active Directory Users and Computers**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.
5. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
6. In the details pane, double-click **Audit object access**.
7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
8. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**
Perform the following procedure:

### For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

1. Open **Microsoft Management Console (MMC)**. Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. In the File menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the **Group Policy Wizard**, click **Browse**.

5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit—or create a new one—click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, and then click **Audit Policy**.
8. In the details pane, double-click **Audit object access**.
9. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
10. Select the **Failure** check box.

**Step Two: Apply auditing policy to a specified object**

To perform the following procedure, you must be logged on as a member of the Administrators group or you must have been granted the **Manage auditing and security log** right in Group Policy.

| **Important** |
| --- |
| In addition to setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files or folders will be audited. |

**To apply or modify auditing policy settings for a local file or folder**

1. Open **Windows Explorer**. To open **Windows Explorer**, right click **Start** and click **Explore**.
2. Right-click the file or folder that you want to audit, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Auditing** tab.
4. Do one of the following:
   - To set up auditing for a new user or group, click **Add**. In **Enter the object name to select**, type the name of the user or group that you want, and then click **OK**.
   - To view or change auditing for an existing group or user, click its name, and then click **Edit**.
5. In the **Apply onto** box, click the location(s) where you want auditing to take place. This is only applicable for a folder.
6. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes, and then click **OK**:
   - To audit successful events, select the **Successful** check box.
   - To stop auditing successful events, clear the **Successful** check box.
   - To audit unsuccessful events, select the **Failed** check box.
   - To stop auditing unsuccessful events, clear the **Failed** check box.
   - To stop auditing all events, click **Clear All**. This option removes the auditing entry.
7. If you want to prevent subsequent files and subfolders of the original object from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

If you see the one of the following, auditing has been inherited from the parent folder:

- In the **Auditing Entry for File or Folder** dialog box, in the **Access** box, the check boxes are unavailable.
- In the **Advanced Security Settings for File or Folder** dialog box, the **Remove** button is unavailable.

For best system performance, minimize the number of entries in the SACL for an object. One entry in a SACL that contains 1000 users does not degrade system performance as much as 1000 separate entries.

Because the Security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the Security log. The maximum size for the Security log is defined in **Event Viewer**.

If you are unsure about what user might be attempting to access the restricted file or folder, audit object access for groups. Make sure to change the location to the local computer if you want to include a local group, such as Users.

**Step Three: Analyze the Security events in Event Viewer**
After applying the audit policy to the desired file or folder, view the Security log in Event Viewer to determine what user has been attempting to access the restricted file or folder.

Perform the following procedure to view the Security log.

**To view the Security log**

1. Open **Event Viewer**. To open **Event Viewer**, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. If you want to see more details about a specific event, in the details pane, double-click the event.

Once you have accessed Event Viewer, you should take advantage of the filter to eliminate irrelevant data in the Security log. Perform the following procedure to filter for Success and Failure events for the object access event category.

**To filter the Security log view**

1. Open **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. In the **File** menu, click **View**, and then click **Filter**.
4. In **Event types**, clear the **Information**, **Warning**, and **Error** check boxes and ensure that the **Success** and **Failure** check boxes are selected.
5. In the **Event Source** list, select **Security**.
6. In the **Category** list, select **Object Access**.
7. Click **OK**.

| **Note** |
| --- |
| You can use the other fields in the Filter page to further filter the Security events by Event ID, user, and computer. You can also filter events by using a time-period range. Filtering by a range of time can be useful if you believe that someone tried to access a restricted file or folder during a specific time on a particular day. |

Once you have filtered the events, examine the Success and Failure audits to see if they apply to restricted files or folders that someone attempted to access. The user name of the person attempting to access the restricted file or folder will be listed within the security event, along with the action that the user was attempting to perform or successfully performed.

| **Important** |
| --- |
| The view filter that you set will remain on the event log unless you manually change the filter. Filtering the view of the event log can help you narrow the scope of the events presented and make it much easier to find potential security problems. |

**Step Four: Adjust permissions or enforce a new security policy**
After you have discovered which user is attempting to access a file or folder, you must then decide on a course of action to complete the solution. There are two possible solutions, depending upon the original intent of the person who attempted to access a file or folder.

If the user is trusted and attempted to access the file or folder believing that he or she was performing an action that complies

with your security policy, you should either further refine your security policy or educate the user about the proper way to follow the policy.

If the user is not trusted and attempted to change the file or folder to intentionally contradict the established security policy, you should lock down the user's permissions. Make sure to reevaluate your security policy and adhere to best practices. For guidance about applying permissions, see Users cannot write to a shared folder after migration to Windows Server 2003.

# Unknown user is changing ACLs on files or folders

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem typically occurs in any of the following circumstances:

- A user has excessive permissions.
- A user has the appropriate level of permissions and is unsure of how the Windows access control system works and mistakenly changes ACLs.
- A user has the appropriate level of permissions and intentionally changes ACLs to circumvent or alter an existing access control policy.

**Cause**
A user has been granted the NTFS Full Control permission on a file or folder or is an administrator.

**Solutions**
Because a Windows-based computer can be managed with Group Policy or be a standalone computer, there are two different solutions for this problem. Choose one of the following options and follow the corresponding procedures.

- Computer is managed with Group Policy
- Computer is not managed with Group Policy

Please check with your system administrator to determine whether the computer is managed with Group Policy.

**Computer is managed with Group Policy**
If the computer you would like to audit events for is managed by Group Policy, perform the following procedures to discover which user is attempting to access the file or folder.

1. Enable auditing of the object access event category
2. Apply auditing policy settings for an object by using Group Policy
3. Analyze the Security events in Event Viewer
4. Adjust permissions or enforce a new security policy

| **Note** |
| --- |
| You can set up file and folder auditing only on NTFS drives. |

| **Note** |
| --- |
| To perform this set of procedures, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been granted the Manage auditing and security log right in Group Policy. As a security best practice, consider using Run as to perform this procedure. |

**Step One: Enable auditing of the object access event category**
Choose among the following object access auditing configuration options, depending on your environment:

- For your local computer
- For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

- For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed
- For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

**For your local computer**
Perform the following procedure:

**For your local computer**

1. Open **Local Security Policy**. Click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
2. In the console tree, expand **Security Settings**, expand **Local Policies**, and click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. Select the **Failure** check box.

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**
Perform the following procedure:

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**

1. Open **Domain Controller Security Policy**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.
2. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
5. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**
Perform the following procedure:

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**

1. Open **Active Directory Users and Computers**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.
5. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
6. In the details pane, double-click **Audit object access**.
7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
8. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**
Perform the following procedure:

### For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

1. Open Microsoft Management Console (MMC). Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. In the File menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the **Group Policy Wizard**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit—or create a new one—click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, and then click **Audit Policy**.
8. In the details pane, double-click **Audit object access**.
9. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
10. Select the **Failure** check box.

**Step Two: Apply auditing policy settings for an object by using Group Policy**

| **Important** |
| --- |
| Before setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files will be audited. |

| **Note** |
| --- |
| To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been granted the **Manage auditing and security log** right in Group Policy. As a security best practice, consider using Run as to perform this procedure. |

### Apply auditing policy settings for an object by using Group Policy

1. Open Microsoft Management Console (MMC). Click **Start**, click **Run**, type **mmc**, and then click **OK**.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the **Group Policy Wizard**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit—or create a new one, click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, and then click **File System**.
8. If you want to add a file or folder to this GPO to audit, right-click **File System**, and then click **Add File**. Browse to the file that you want, or make a new folder, and then click **OK**.
9. If you want to apply or modify auditing settings on a file or folder that has already been added to this GPO, in the details pane, right-click the file or folder, click **Properties**, and then click **Edit Security**.

10. Click **Advanced**, and then click the **Auditing** tab.
11. Do one of the following:
    - To set up auditing for a new user or group, click **Add**. In **Name**, type the name of the user or group that you want, and then click **OK**.
    - To view or change auditing for an existing group or user, click the name that you want, and then click **Edit**.
    - To remove auditing for an existing group or user, click the name that you want, click **Remove**, click **OK**, and then skip the rest of this procedure.
12. Select the appropriate entry in the **Apply onto** list.
13. In the **Access** box, select the **Failed** check box.

    If you want to prevent files and subfolders in the tree from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.
14. Click **OK**.

For best system performance, minimize the number of entries in the SACL for an object. One entry in a SACL that contains 1000 users does not degrade system performance as much as 1000 separate entries.

Because the Security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the Security log. The maximum size for the Security log is defined in **Event Viewer**.

If you are unsure about what user might be attempting to access the restricted file or folder, audit object access for groups. Make sure to change the location to the local computer if you want to include a local group, such as Users.

**Step Three: Analyze the Security events in Event Viewer**

After applying the audit policy to the desired file or folder, view the Security log in Event Viewer to determine what user has been attempting to access the restricted file or folder.

Perform the following procedure to view the Security log.

**To view the Security log**

1. Open **Event Viewer**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. If you want to see more details about a specific event, in the details pane, double-click the event.

Once you have accessed Event Viewer, you should take advantage of the filter to eliminate irrelevant data in the Security log. Perform the following procedure to filter for Success and Failure events for the object access event category.

**To filter the Security log view**

1. Open **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. In the **File** menu, click **View**, and then click **Filter**.
4. In **Event types**, clear the **Information**, **Warning**, and **Error** check boxes and ensure that the **Success** and **Failure** check boxes are selected.
5. In the **Event Source** list, select **Security**.
6. In the **Category** list, select **Object Access**.
7. Click **OK**.

**Note**

You can use the other fields in the Filter page to further filter the Security events by event ID, user, and computer. You can also filter events by using a time-period range. Filtering by a range of time can be useful if you believe that someone tried to access a restricted file or folder during a specific time on a particular day.

Once you have filtered the events, examine the Success and Failure audits to see if they apply to restricted files or folders that someone attempted to access. The user name of the person attempting to access the restricted file or folder will be listed within the security event, along with the action that the user was attempting to perform or successfully performed.

**Important**

The view filter that you set will remain on the event log unless you manually change the filter. Filtering the view of the event log can help you narrow the scope of the events presented and make it much easier to find potential security problems.

**Step Four: Adjust permissions or enforce a new security policy**

After you have discovered which user is attempting to access a file or folder, you must then decide on a course of action to complete the solution. There are two possible solutions, depending upon the original intent of the person who attempted to access a file or folder.

If the user is trusted and attempted to access the file or folder believing that he or she was performing an action that complies with your security policy, you should either further refine your security policy or educate the user about the proper way to follow the policy.

If the user is not trusted and attempted to change the file or folder to intentionally contradict the established security policy, then you should lock down the user's permissions. Make sure to reevaluate your security policy and adhere to best practices. For guidance about applying permissions, see Users cannot write to a shared folder after migration to Windows Server 2003.

**Computer is not managed with Group Policy**

If the computer you would like to audit events for is not managed by Group Policy, perform the following procedures to discover which user is attempting to access the file or folder.

1. Enable auditing of the object access event category
2. Apply auditing policy to a specified object
3. Analyze the Security events in Event Viewer
4. Adjust permissions of enforce a new security policy

You must first decide what objects you would like to audit and whether you want to audit a specific computer or use Group Policy to manage auditing within an organization unit (OU) or domain.

**Note**

You can set up file and folder auditing only on NTFS drives.

**Step One: Enable auditing of the object access event category**

Choose between the following object access auditing configuration options, depending on your environment:

- For your local computer
- For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed
- For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed
- For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

**For your local computer**
Perform the following procedure:

**For your local computer**

1. Open **Local Security Policy**. Click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
2. In the console tree, expand **Security Settings**, expand **Local Policies**, and click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. Select the **Failure** check box.

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**
Perform the following procedure:

**For domain controllers only, when you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed**

1. Open **Domain Controller Security Policy**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.
2. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click **Audit object access**.
4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
5. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**
Perform the following procedure:

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**

1. Open **Active Directory Users and Computers**. Click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.
5. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, expand **Local Policies**, and then click **Audit Policy**.
6. In the details pane, double-click **Audit object access**.
7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
8. Select the **Failure** check box.

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**
Perform the following procedure:

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**

1. Open Microsoft Management Console (MMC). Click **Start**, click **Run**, type **mmc**, and then click **OK**.

2. In the File menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the **Group Policy Wizard**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit—or create a new one—click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, expand **Computer Configuration**, expand **Windows Settings**, expand **Security Settings**, and then click **Audit Policy**.
8. In the details pane, double-click **Audit object access**.
9. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.
10. Select the **Failure** check box.

**Step Two: Apply auditing policy to a specified object**

To perform the following procedure, you must be logged on as a member of the Administrators group or you must have been granted the **Manage auditing and security log** right in Group Policy.

| **Important** |
| --- |
| In addition to setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files or folders will be audited. |

**To apply or modify auditing policy settings for a local file or folder**

1. Open **Windows Explorer**. To open **Windows Explorer**, right-click **Start** and click **Explore**.
2. Right-click the file or folder that you want to audit, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Auditing** tab.
4. Do one of the following:
   - To set up auditing for a new user or group, click **Add**. In **Enter the object name to select**, type the name of the user or group that you want, and then click **OK**.
   - To view or change auditing for an existing group or user, click its name, and then click **Edit**.
5. In the **Apply onto** box, click the location(s) where you want auditing to take place. This is only applicable for a folder.
6. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes, and then click **OK**:
   - To audit successful events, select the **Successful** check box.
   - To stop auditing successful events, clear the **Successful** check box.
   - To audit unsuccessful events, select the **Failed** check box.
   - To stop auditing unsuccessful events, clear the **Failed** check box.
   - To stop auditing all events, click **Clear All**. This option removes the auditing entry.
7. If you want to prevent subsequent files and subfolders of the original object from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

If you see the one of the following, auditing has been inherited from the parent folder:

- In the **Auditing Entry for File or Folder** dialog box, in the **Access** box, the check boxes are unavailable.
- In the **Advanced Security Settings for File or Folder** dialog box, the **Remove** button is unavailable.

For best system performance, minimize the number of entries in the SACL for an object. One entry in a SACL that contains 1000 users does not degrade system performance as much as 1000 separate entries.

Because the Security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the Security log. The maximum size for the Security log is defined in **Event Viewer**.

If you are unsure about what user might be attempting to access the restricted file or folder, audit object access for groups. Make sure to change the location to the local computer if you want to include a local group, such as Users.

**Step Three: Analyze the Security events in Event Viewer**
After applying the audit policy to the desired file or folder, view the Security log in Event Viewer to determine what user has been attempting to access the restricted file or folder.

Perform the following procedure to view the Security log.

**To view the Security log**

1. Open **Event Viewer**. To open **Event Viewer**, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. If you want to see more details about a specific event, in the details pane, double-click the event.

Once you have accessed Event Viewer, you should take advantage of the filter to eliminate irrelevant data in the Security log. Perform the following procedure to filter for Success and Failure events for the object access event category.

**To filter the Security log view**

1. Open **Event Viewer**.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. In the **File** menu, click **View**, and then click **Filter**.
4. In **Event types**, clear the **Information**, **Warning**, and **Error** check boxes and ensure that the **Success** and **Failure** check boxes are selected.
5. In the **Event Source** list, select **Security**.
6. In the **Category** list, select **Object Access**.
7. Click **OK**.

| **Note** |
| --- |
| You can use the other fields in the Filter page to further filter the Security events by Event ID, user, and computer. You can also filter events by using a time-period range. Filtering by a range of time can be useful if you believe that someone tried to access a restricted file or folder during a specific time on a particular day. |

Once you have filtered the events, examine the Success and Failure audits to see if they apply to restricted files or folders that someone attempted to access. The user name of the person attempting to access the restricted file or folder will be listed within the security event, along with the action that the user was attempting to perform or successfully performed.

| **Important** |
| --- |
| The view filter that you set will remain on the event log unless you manually change the filter. Filtering the view of the event log can help you narrow the scope of the events presented and make it much easier to find potential security problems. |

**Step Four: Adjust permissions or enforce a new security policy**

After you have discovered which user is attempting to access a file or folder, you must then decide on a course of action to complete the solution. There are two possible solutions, depending upon the original intent of the person who attempted to access a file or folder.

If the user is trusted and attempted to access the file or folder believing that he or she was performing an action that complies with your security policy, you should either further refine your security policy or educate the user about the proper way to follow the policy.

If the user is not trusted and attempted to change the file or folder to intentionally contradict the established security policy, you should lock down the user's permissions. Make sure to reevaluate your security policy and adhere to best practices. For guidance about applying permissions, see Users cannot write to a shared folder after migration to Windows Server 2003.

# User cannot access a file or folder but should have permission

Updated: May 8, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem occurs when a user attempts to access a file or folder and receives an "Access Denied" error.

**Cause**
This problem results when an administrator, the owner of the file or folder, or a user with the Change Permissions permission for a file or Full Control permission for a folder, changes the access control list (ACL) on the file or folder. Some of the changes that could deny a user access to a file or folder they should be able to access include:

- The user or group was unintentionally removed from **Group or User names** on the file's or folder's **Security** tab.
- An explicit **Deny** has mistakenly been applied to the user or group.
- A conflict between share permissions and NTFS permissions was created when someone changes permissions without examining both types of permissions.

**Solutions**
There are two separate scenarios where a user may be denied access to a file or folder:

- A user is denied access to a local file or folder
- A user is denied access to a shared folder

**A user is denied access to a local file or folder**
There are three possible solutions for this problem:

Examine a user's permissions on a file or folder using Xcacls

Examine a user's or group's permissions on a file or folder

View a user's or group's effective permissions on files and folders

**Solution One: Examine a user's permissions on a file or folder using Xcacls**
The Xcacls command-line tool sets all file system security options that are accessible in Windows Explorer. Xcacls does this by displaying and modifying the ACLs of files. Perform the following procedure to investigate ACLs by using the Xcacls tool.

| **Important** |
| --- |
| Xcacls does not ship with Windows Server 2003. For information about how to install the Xcacls tool, see Configuring a Computer for Access Control Troubleshooting. |

### To examine a user's permissions on a file or folder using Xcacls

1. Open a command prompt. Click **Start**, click **Run**, and type **cmd**.
2. Type:

   **Xcacls** *FileOrFolderPath*

3. Examine the user's permissions and compare with the desired permissions.

The following is an example of the preceding Xcacls command:

**Xcacls C:\Tools**

**Solution Two: Examine a user's or group's permissions on a file or folder**

| **Note** |
| --- |

The use of access control lists (ACLs) to control users' or groups' permissions on a file or folder is supported on computers that use the NTFS file system but not on computers that use the FAT file system or that use Windows XP Simple File Sharing. If ACLs are not supported, the file or folder properties do not have Security properties available. Windows XP Home Edition is an example of an operating system that does not support ACLs.

**To examine a user's or group's permissions on a file or folder**

1. Right-click the file or folder you wish to administer permissions for, click **Properties**, and then click the **Security** tab.

   **Note**

   If you are logged in with an account that has not been granted rights to administer permissions on the file or folder, the **Security** tab is not available.

2. In **Group or User names**, select the user or group whose permissions you want to view.
3. In **Permissions for <group name or user name>**, examine the user's permissions and compare with the desired permissions.

**Solution Three: View a user's or group's effective permissions on files and folders**

You can also use the Effective Permissions tool to view effective permissions of a user or group. The Effective Permissions tool does not display share permissions; it displays only cumulative NTFS permissions for a particular user or group.

**To view effective permissions on files and folders**

1. Open **Windows Explorer**, and then locate the file or folder for which you would like to view effective permissions.
2. Right-click the file or folder, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, click the **Effective Permissions** tab, and then click **Select**.
4. In **Enter the object name to select (examples)**, enter the name of a user or group, and then click **OK**. The selected check boxes indicate the effective permissions of the user or group for that file or folder.

**A user is denied access to a shared folder**

Both share and NTFS permissions can be applied to a folder that is shared. However, share permissions and NTFS permissions behave differently. As a result, there are different processes for investigating permissions problems if share only or if a mixture of share and NTFS permissions have been applied. First you should determine what share permissions have been applied. Then determine which, if any, NTFS permissions have been applied.

**Important**

When share and NTFS permissions conflict, the most restrictive setting takes precedence.

Perform the following procedure to examine share permissions on a specific folder.

**To examine user and group share permissions on a shared folder**

1. Right-click the shared folder you want to examine, and then click **Properties**.
2. Click the **Sharing** tab, and then click **Permissions**.
3. Examine the permissions and change any settings that contradict the desired permissions.

After you examine the share permissions, use the Xcacls tool to determine what NTFS permissions apply to a specific user or group. Perform the following procedure to investigate ACLs by using the Xcacls tool.

**Important**

Xcacls does not ship with Windows Server 2003. For information about how to install the Xcacls tool, see Configuring a Computer for Access Control Troubleshooting.

**To examine user and group NTFS permissions on a shared folder**

1. Open a command prompt.
2. Type the following command:

   **Xcacls** *FileorFolderPath*

3. Examine the permissions and note any settings that contradict the desired permissions.
4. Open Windows Explorer, right-click the shared folder, and then click **Properties**.
5. Based on the outcome of the Xcacls data, adjust either the share permissions on the **Sharing** tab or the NTFS permissions on the **Security** tab. You can also use the Xcacls tool to adjust NTFS permissions using the command line.

Use the following guidelines when examining and adjusting share and NTFS permissions on a shared folder:

- Inherited Deny permissions do not prevent access to an object if the object has an explicit Allow permission entry.
- Explicit permissions take precedence over inherited permissions, even inherited Deny permissions.

NTFS permissions affect access to files and folders both locally and remotely and apply regardless of protocol. Share permissions, by contrast, apply only to shared folders (on a network). Share permissions do not restrict access to any local user, or to any terminal server user, on the computer on which you have set share permissions. Thus, share permissions do not provide privacy between users on a computer used by several users, nor on a terminal server accessed by several users.

If you want to manage folder access by using NTFS permissions exclusively, set share permissions to Full Control for Everyone. This frees you from having to think about share permissions, but because NTFS permissions are more complex than share permissions, using NTFS permissions correctly requires deeper understanding on your part. For more information about NTFS permissions, search for the term "NTFS permissions" on TechNet on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=38772).

| **Caution** |
| --- |
| Granting a user Full Control NTFS permission on a folder enables that user to take ownership of the folder unless the user is restricted in some other way. Be cautious in granting Full Control. |

# Users cannot write to a shared folder after migration to Windows Server 2003

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem typically occurs after a migration of computers from Windows NT 4.0 or Windows 2000 to Windows Server 2003. Certain default settings have changed in Windows Server 2003, and these changes might affect the expected behavior of your server.

**Cause**
The Everyone group has the Full Control share permission by default in Windows NT and Windows 2000. However, the Everyone group has the Read share permission by default in Windows Server 2003 and Windows XP. If the default permissions are applied to a Windows NT–based or Windows 2000–based computer before migration to Windows Server 2003, user accounts may no longer be able to write to the shared folders.

**Solutions**
To solve this problem, consider either creating new groups with the required permissions or adding the Full Control share permission for the Everyone group.

**Solution One: Create new groups and assign share permissions**
Create the groups that you need and assign the appropriate permissions on shared folders to these groups. As a best practice, assign permissions to groups rather than to users. Because it is inefficient to maintain user accounts directly, assigning permissions on a user basis should be the exception. The Everyone group is automatically assigned the Read permission, which is the most restrictive, to assist you in the administration of resources.

The following are also best practices for managing permissions and user rights:

- Assign permissions to an object as high on the tree as possible and then apply inheritance to propagate the security settings throughout the tree.

  You can quickly and effectively apply access control settings to all children or a subtree of a parent object. By doing this, you gain the greatest breadth of effect with the least effort. The permission settings you establish should be adequate for the majority of users, groups, and computers.

- Deny permissions should be used for certain special cases

  - Use Deny permissions to exclude a subset of a group which has Allowed permissions.

  - Use Deny to exclude one special permission when you have already granted Full Control to a user or group.

- If possible, avoid changing the default permission entries on file system objects, particularly on system folders and root folders. Changing default permissions can cause unexpected access problems or reduce security.

**Solution Two: Change share permissions for the Everyone group**
You can assign the following types of access permissions to shared folders or drives:

**Read**
Read is the default permission that is assigned to the Everyone group. Read allows:

- Viewing file names and subfolder names

- Viewing data in files

- Running program files

**Change**
Change is not a default permission for any group. The Change permission allows all Read permissions, plus:

- Adding files and subfolders
- Changing data in files
- Deleting subfolders and files

**Full Control**
Full Control is the default permission that is assigned to the Administrators group on the local computer. Full Control allows all Read and Change permissions, plus:

- Changing permissions (NTFS files and folders only).

Perform the following procedure to assign the Full Control share permission to the Everyone group.

**To assign the Full Control share permission to the Everyone group**

1. Open **Windows Explorer**.
2. Right-click the folder for which you want to administer share permissions, click **Properties**, and then click the **Sharing** tab.
3. Click **Permissions**.
4. Click **Everyone**, and then click **Full Control**.

# Additional Resources for Troubleshooting Access Control

Updated: June 8, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For specific information about troubleshooting access control problems, see the following resources:

- TechNet Newsgroup: Windows Server Security on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47169).
- Technet Newsgroup: Windows File System on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47172).
- TechNet Newsgroup: Windows NT File System on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47168).
- Article 834859, "The specified domain either does not exist or could not be contacted" error message in Windows Server 2003 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47170).

For general information about how access control works and how to manage and configure access control, see the following resource:

- Security Descriptors and Access Control Lists Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47171).

# Server Cluster Operations Guide

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Server Cluster Operations Guide provides troubleshooting information for the quorum resource in a server cluster running Microsoft® Windows Server™ 2003 or Windows Server 2003 with Service Pack 1 (SP1) operating systems.

**In this guide**

- Troubleshooting the Quorum Resource in a Server Cluster

# Troubleshooting the Quorum Resource in a Server Cluster

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to troubleshoot the quorum resource in a server cluster running Microsoft Windows Server 2003, Enterprise Edition, or Microsoft Windows Server 2003, Datacenter Edition, operating systems. The guide includes information for these operating systems as originally released and for these operating systems with Service Pack 1 (SP1). Some of the information will also apply to server clusters running the Windows 2000 Advanced Server or Windows 2000 Datacenter Server operating systems.

This guide covers only clusters using the single quorum device model, not the majority node set model.

To get started with this guide, review the following sections of this introduction.

When to Use This Guide

How This Guide Is Organized

Terminology Used in This Guide

**When to Use This Guide**

You should use this guide when, on a server cluster that uses a single quorum device (storage that is attached to all nodes of the cluster), the Cluster service will not start normally on any node, and the problem seems as if it might be related to the quorum resource. In some cases, you can use this guide when you can start the Cluster service, but messages in the event log or cluster log indicate that you have a problem with the quorum resource.

For information about distinguishing quorum problems from other problems that interfere with starting the Cluster service, see Troubleshooting Quorum Resource Problems.

Do not use this guide to find out how to perform a task, such as configuring the quorum resource for a new server cluster. You can find information about how to perform tasks and configure settings on the following pages on the Microsoft Web site:

- Designing and Deploying Server Clusters
- Checklists: Creating Server Clusters
- Server Cluster How To...

This guide assumes that you have a basic understanding of the quorum resource in a single quorum device server cluster, how the quorum works, and how the quorum helps ensure that all nodes in the cluster have the same view of the cluster membership and cluster configuration. You should also have a thorough understanding of how the quorum resource is configured in your organization.

**How This Guide Is Organized**

This guide is divided into several sections:

- Verifying Permissions, Hardware, and Software Before Troubleshooting the Quorum Resource

  This section provides a list of prerequisites to verify before you troubleshoot the quorum resource. Read this section first.

- Configuring a Computer for Troubleshooting the Quorum Resource in a Server Cluster

  This section describes how to configure your computer for troubleshooting the quorum resource. Read this section to prepare for troubleshooting.

- Troubleshooting Quorum Resource Problems

  This section provides step-by-step diagnostic procedures and possible solutions that help you identify and fix quorum resource problems in a single quorum device cluster.

- Additional Resources for Troubleshooting the Quorum Resource in a Server Cluster

This section provides additional resources that are related to server clusters and the quorum in a server cluster.

#### Terminology Used in This Guide

To use this guide, you should be familiar with basic terminology for a server cluster, particularly the following terms:

**single quorum device server cluster**

A cluster configuration that has two or more nodes and is configured so that every node is attached to one or more cluster storage devices. The cluster configuration data is stored on a single cluster storage device, called the quorum resource.

There are two other possible cluster configurations: a single node server cluster and a majority node set server cluster.

**cluster configuration database**

A database containing configuration data for all cluster objects. Copies of the cluster configuration database are located on the quorum resource and on each cluster node. Under normal conditions, the copies are synchronized and contain the same information.

**quorum resource**

A crucial cluster resource that maintains the configuration data that is necessary for recovery of the cluster. The quorum resource is generally accessible to other cluster resources so that any cluster node has access to the most recent changes to the cluster configuration database.

This document provides information for clusters where the quorum resource is located on a single quorum device, as described in "single quorum device server cluster," earlier in this list.

**quorum log**

A log maintained on the quorum resource to store cluster state and configuration changes during times when a node is down. The quorum log ensures that even if all nodes go down and the cluster must be formed again, those changes will not be lost. Also known as the *recovery log* or *change log*.

# Verifying Permissions, Hardware, and Software Before Troubleshooting the Quorum Resource

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you begin troubleshooting, you should verify permissions, hardware, and software updates, as described in the following list:

- Make sure that you have administrative rights on the computer you are troubleshooting.

  You cannot modify quorum resource settings unless you are a member of the Administrators group on the computer that you are administering.

  To verify that you are a member of the Administrators group on a computer, open the Computer Management snap-in. In the console tree, double-click **Local Users and Groups**, and then click **Groups**. In the details pane, double-click **Administrators** and verify that the account that you logged in with appears in the **Members** list.

- Confirm that your hardware is compatible with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. For more information, see the following pages on the Microsoft Web site:

  - Windows Server Catalog

  - The Microsoft support policy for server clusters, the Hardware Compatibility List, and the Windows Server Catalog

- Confirm that cluster hardware is not disconnected or damaged. For example, check the cables to the cluster storage. If you use SCSI, check that the SCSI bus is properly terminated.

- Set aside time to review the software updates and service pack level on each node. Consider whether the latest service pack, critical updates, and security updates need to be tested and deployed on the cluster, and if so, choose a time to do so. Carry out this testing and deployment using standard methods for your organization.

  If you have not already planned for the testing and deployment of the latest service pack for Windows Server 2003, we strongly recommend that you plan for this. The service pack might enable the cluster to automatically correct future problems with the quorum resource — for example, corruption of a cluster configuration file on the quorum resource. For information about how to install service packs in a cluster, see article 174799 in the Microsoft Knowledge Base.

- Set aside time to review the drivers and software, including non-Microsoft drivers and software, on each node. Consider whether updated drivers and software need to be tested and deployed on the cluster, and if so, choose a time to do so. Carry out this testing and deployment using standard methods for your organization.

# Configuring a Computer for Troubleshooting the Quorum Resource in a Server Cluster

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and fix quorum troubleshooting problems, we recommend that you obtain the following tool:

- **Clusterrecovery.exe**, available from Windows Server 2003 Resource Kit Tools on the Microsoft Web site.

  Clusterrecovery is especially useful for helping you to:

  - Replace a failed disk or recover from disk signature changes.
  - Move a disk resource (for example, the quorum resource) to a different disk in the cluster storage.
  - Restore registry checkpoints and cryptographic key checkpoints for cluster resources.

# Troubleshooting Quorum Resource Problems

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides troubleshooting information about a server cluster for which all of the following are true:

- The cluster uses a single quorum device (storage that is attached to all nodes of the cluster). In other words, the cluster is not a single node cluster and is not a majority node set cluster.
- The Cluster service will not start on any node.

  Note that in some situations, the Cluster service might start despite a problem with the quorum resource, and you can use this guide for troubleshooting in those situations. For example, a cluster in which the latest service pack has been applied might have repeated instances of Event ID 1147 related to the quorum, yet the Cluster service might be able to start on the nodes.
- The problem seems as if it might be related to the quorum resource. For more information, see Distinguishing Quorum Problems from Other Problems.

If you already have some understanding of the problem with the quorum resource, use the following topics to begin troubleshooting. If not, use the flowchart and other information in this topic to begin to determine which of the following topics apply to your situation.

- Files on the Cluster Quorum Might be Missing, Inaccessible, or Corrupt
- The Quorum Resource is on an Inaccessible or Nonfunctioning Disk
- The Cluster Configuration File on a Node is Corrupt

**Sections in This Topic**

This topic provides the following sections to help you begin troubleshooting:

- Distinguishing Quorum Problems from Other Problems
- Flowchart for Troubleshooting the Quorum Resource
- Understanding the Fixquorum Option for Starting the Cluster Service

**Distinguishing Quorum Problems from Other Problems**

It can be challenging to analyze a problem with starting the Cluster service and determine whether it is related in some way to the quorum resource. To try to distinguish different types of problems, review the following table:

| Area | Explanation |
|---|---|
| **Cluster service account**: On the nodes on which you are trying to start the Cluster service, are there problems with the Cluster service account?<br><br>Also, if you have Windows Server 2003 with the latest service pack, does Event ID 7041 appear in the system event log? This event was added in Windows Server 2003 Service Pack 1 and indicates that the Cluster service account does not have all the necessary user rights, such as the **Log on as a service** user right. | If no domain controller is available to authenticate the Cluster service account, the Cluster service cannot start. Other problems with the account can also prevent the Cluster service from starting, for example, if the password was allowed to expire or the account does not have the necessary rights, possibly as a result of a Group Policy setting.<br><br>To check for this type of problem, try to log on to the computer with the Cluster service account, or check the system event log for messages that indicate that the Cluster service account cannot log on. Also, review the Cluster service account to make sure that it has the permissions and rights described in Change the Account Under Which the Cluster Service Runs at the Microsoft Web site. |

| | |
|---|---|
| **Cluster log**: Is the cluster log read-only? Alternatively, is a policy preventing the cluster log from being modified? | If the cluster log cannot be modified, the Cluster service cannot start.<br><br>By default, the cluster log is called **Cluster.log** and is located in *systemroot***Cluster**. The default name of this log can be changed by changing the system environment variable called **ClusterLog**. |
| **Events in event log**: Do event log messages appear to be consistent with a quorum resource problem? | Specific events can indicate that a problem with the quorum is preventing cluster startup. However, an event can indicate a symptom rather than a root cause, so all events should be interpreted in context.<br><br>See the next section for information about some events that can indicate problems with the quorum resource. |

For more information about troubleshooting problems with starting the Cluster service, see article 266274, "How to Troubleshoot Cluster Service Startup Issues" in the Microsoft Knowledge Base.

If your startup issue appears to be related in some way to the quorum resource, see Flowchart for Troubleshooting the Quorum Resource.

**Event Messages That are Consistent with Quorum Resource Problems**
The following list describes some common event log messages that are consistent with quorum resource problems.

| **Important** |
|---|
| If your event log contains any of the messages in the following list, be sure to check that the cables for the storage are not damaged or disconnected. Also, follow the other recommendations in Verifying Permissions, Hardware, and Software Before Troubleshooting the Quorum Resource. |

### Event Messages That Are Consistent with Quorum Resource Problems

- **1034**: The disk associated with cluster disk resource *DriveLetter* could not be found. The expected signature of the disk was *DiskSignature*.

  This error can result when the disk signature of the quorum disk has been inadvertently changed. This can happen when you make changes through a disk or storage utility, or when you recreate the LUN containing the quorum resource. Note that the cluster identifies the quorum resource and other disk resources by disk signature, not just drive letter.

  Follow the flowchart in this topic, and see if The Quorum Resource is on an Inaccessible or Nonfunctioning Disk applies to your situation. Consider whether Clusterrecovery.exe, which is described in Configuring a Computer for Troubleshooting the Quorum Resource in a Server Cluster, would be useful for your situation.

- **1035**: Cluster disk resource *DriveLetter* could not be mounted.

  Follow the flowchart in this topic, and see if The Quorum Resource is on an Inaccessible or Nonfunctioning Disk applies to your situation.

- **1066**: Cluster disk resource *DriveLetter* is corrupt. Run **ChkDsk /F** to repair problems.

  This error might indicate that the volume used for the quorum resource has a file system corruption problem, possibly a transient problem. Other events in the logs might help with diagnosis.

  Follow the flowchart in this topic, and see if The Quorum Resource is on an Inaccessible or Nonfunctioning Disk applies to your situation.

- **1069**: Cluster disk resource *DriveLetter* failed.

  This error might indicate that the disk used for the quorum resource has a problem. Other events in the logs might help with diagnosis.

  Follow the flowchart in this topic, and see if The Quorum Resource is on an Inaccessible or Nonfunctioning Disk applies

to your situation.

- **1147** or **1148**:

  The Microsoft Clustering Service encountered a fatal error. The vital quorum log file 'q:\MSCS\quolog.log' could not be found. (Additional text is provided in this event.)

  If you have Windows Server 2003 with the latest service pack, you might see this event and yet find that the Cluster service started. When you apply the latest service pack, if the quorum log and cluster configuration files are missing from the quorum resource, the operating system can replace these files with information from a node.

  Follow the flowchart in this topic, and see if Files on the Cluster Quorum Might be Missing, Inaccessible, or Corrupt applies to your situation.

If you want to find out more details about a specific event that relates to the cluster, one source of information is the cluster log. The cluster log may be easiest to use when you already have a general sense of a problem and are looking for details. By default, the cluster log is called **Cluster.log** and is located in *systemroot***Cluster**. The log might have a different name, because the default name can be changed by changing the system environment variable called **ClusterLog**.

**Flowchart for Troubleshooting the Quorum Resource**

Use the following flowchart and the topics to which it refers to troubleshoot quorum resource problems. For information about the **/fixquorum** option mentioned in the flowchart, see Understanding the Fixquorum Option for Starting the Cluster Service, later in this topic.

**Understanding the Fixquorum Option for Starting the Cluster Service**

The troubleshooting techniques shown in the flowchart in this topic use the **/fixquorum** option for starting the Cluster service. It is useful to understand the following details about the **/fixquorum** option:

- When the **/fixquorum** option is used on a particular node, the Cluster service starts on that node, but the resources in the group that contains the quorum disk (usually the Cluster Group) remain offline. This allows you to attempt bringing the quorum resource online manually so that you can more easily diagnose problems with the quorum. Note that if this attempt to bring the quorum resource online fails, the Cluster service will stop again, even though it was started with the **/fixquorum** option.

- Only one node at a time can be started with the **/fixquorum** option. You cannot join any other nodes to the node that was started with this option. When you have corrected the problem that you were having with the quorum resource, stop the Cluster service and restart it without options.

- You can start the Cluster service with the **/fixquorum** option by opening a command prompt and typing:

  **net start clussvc /fixquorum**

  Or by typing:

  **net start clussvc /fq**

  You can also start the Cluster service with the **/fixquorum** option when using Services in Computer Management. To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**. On a cluster node, the Cluster service will appear in the list of services. Right-click the service, click **Properties**, type **/fixquorum** in **Start parameters**, and then click **Start**.

# Files on the Cluster Quorum Might be Missing, Inaccessible, or Corrupt

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To understand this topic in context, see the flowchart in Troubleshooting Quorum Resource Problems.

If you can start the Cluster service only when you use the **/fixquorum** option but then you succeed at bringing the quorum resource online (with Cluster Administrator), there is probably a problem with the configuration files on the quorum resource, as described in the "Cause" description in this topic. You can examine the files on the quorum resource and replace them if necessary.

**Cause**

There are a variety of possible causes. Like any files, the cluster configuration files on the quorum resource can become corrupted. Also, the files might be missing or they might be impossible to write to, for example, because of incorrect permissions or because the disk is full.

**Solution**

Use Windows Explorer to examine the files on the quorum resource. The files will be in a folder, almost always called MSCS, and in subfolders of that folder. Check the permissions on the files and the folder, and check whether the quorum disk is full. Then use the following tables to help you determine if any files are missing or corrupt. The procedures later in this topic can help you replace files as appropriate.

**Files That Should be Present on the Quorum Resource**

| File | Description |
|---|---|
| Chk*xxx*.tmp | Copy of the cluster configuration database (also known as a checkpoint file, but not to be confused with registry checkpoints for resources). If the file contains 0 bytes, it is definitely corrupt. Even if it contains more than 0 bytes, it could be corrupt.<br><br>If you have the original release of Windows Server 2003, the Cluster service will not start if the Chk*xxx*.tmp file is missing or corrupt. However, if you have Windows Server 2003 with SP1, in many situations the Cluster service can automatically re-create this file if it is missing or corrupt. |
| Quolog.log | The quorum log, which records changes to the cluster configuration database, but only those changes that occur while one or more nodes are down. The file exists even when all nodes are functioning, but information is added to it only when a node is offline. Information in the log is carefully marked according to sequence and timing so that it can be used correctly when nodes go down and come back up.<br><br>If you have the original release of Windows Server 2003, the Cluster service will not start if Quolog.log is missing or corrupt. However, if you have Windows Server 2003 with SP1, in many situations the Cluster service can automatically re-create this file if it is missing or corrupt. |

**Folders and Files That Might be Present on the Quorum Resource**

| File | Description |
|---|---|
| Folder called {*GUID*} | Folder for each resource that is configured with registry checkpoints or cryptographic key checkpoints. The resource GUID is the name of the folder. |
| {*GUID*}*.cpt | Checkpoint files for resources configured with registry checkpoints. |
| {*GUID*}*.cpr | Checkpoint files for resources configured with cryptographic key checkpoints. |

Use the following procedures to replace a missing or corrupted file.

**To replace a missing or corrupt Chkxxx.tmp file or quorum log or both on the quorum resource**

1. If the Cluster service is running (with the **/fixquorum** option), stop it by typing:

   **net stop clussvc**

2. On a node that was functioning correctly when problems with the quorum resource appeared, restart the Cluster service

with the **/resetquorumlog** option by typing:

**net start clussvc /rq**

This re-creates the Chk*xxx*.tmp file based on the cluster configuration information on that node.

You can accomplish the same action through Computer Management by opening Services and then, for the Cluster service, opening the **Properties** dialog box. From the **General** tab, stop the Cluster service if needed, specify **/resetquorumlog** in **Start parameters**, and then start the service with that parameter. (The parameter is used only once and does not persist.)

3. If the previous steps are not workable for you, and you have a backup containing quorum information (that is, a recent System State backup created on a node while the Cluster service was running), start Backup on a node. Before restoring the System State, in the **Confirm Restore** dialog box, click **Advanced**, and then click **Restore the Cluster Registry to the quorum disk and all other nodes**.

| **Important** |
| --- |
| Be sure to click this advanced option, or information will not be restored to the quorum resource, only to the node. |

4. If you have resources that are configured to use registry checkpoints or cryptographic key checkpoints and you think that these checkpoint files are also corrupt, see the next procedure.

**To replace corrupt registry checkpoint files or cryptographic key checkpoint files on the quorum resource**

1. Correct other problems with the quorum resource and start the Cluster service without options.
2. Run Clusterrecovery.exe, which is described in Configuring a Computer for Troubleshooting the Quorum Resource in a Server Cluster. Use Clusterrecovery to recover the resource checkpoint files, referring to Clusterrecovery Help as needed.
3. If the previous steps are not workable for you, and you have a recent backup of your registry checkpoint files or cryptographic key checkpoint files (that is, *.cpt or *.cpr files), restore from backup. To do this:
   a. Correct other problems with the quorum resource and start the Cluster service without options. Identify the resources that are configured to use registry checkpoints or cryptographic key checkpoints and take them offline.
   b. Identify the node that currently owns the quorum resource. On that node, restore the *.cpt or *.cpr files to the correct folder on the quorum resource. Refer to the table earlier in this topic for information about where the files should be restored.

# The Quorum Resource is on an Inaccessible or Nonfunctioning Disk

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To understand this topic in context, see the flowchart in Troubleshooting Quorum Resource Problems.

If you can start the Cluster service with the **/fixquorum** option and can use Cluster Administrator to bring nonquorum disk resources online, but cannot bring the quorum resource online, the disk used for the quorum resource might be inaccessible or might have failed. Note that when the quorum resource cannot be brought online in this way, the Cluster service will stop again, even though it was started with the **/fixquorum** option.

**Cause**
A disk might be inaccessible because of incorrectly configured hardware or software, for example, multipath I/O (MPIO) software. There are multiple causes for failure of a hard disk.

**Solution**
For further diagnosis, you can study events in the system log for indications of hardware errors. Then, use Device Manager to review the condition of the disk that the quorum resource is on. If there is a disk signature problem but the quorum disk can function otherwise, correct the disk signature problem. If the disk will not function, use either Clusterrecovery or Cluster Administrator to use a different disk for the quorum resource.

**To use Device Manager to review the condition of the disk that the quorum resource is on**

1. On the node on which you have started the Cluster service with the **/fixquorum** option, click **Start**, click **Programs** or **All Programs**, click **Administrative Tools**, and then click **Computer Management**.

2. Click **Device Manager**.

3. In the Details pane, click **Disk drives** and then try to view the disk that the quorum resource is on.

   If you cannot view the disk and want to further diagnose its condition, see diagnostic tools or information provided by the disk manufacturer, or contact the disk manufacturer for assistance.

   If you can view the disk, look in the event log for an instance of Event ID 1034 related to the quorum resource, and record the disk signature expected by the Cluster service for the quorum resource. Then use one of the following procedures to correct problems with the disk.

**To use Clusterrecovery to correct problems with the quorum being on a nonfunctioning disk**

- On the node on which you have started the Cluster service with the **/fixquorum** option, run Clusterrecovery.exe, which is described in Configuring a Computer for Troubleshooting the Quorum Resource in a Server Cluster. Use Clusterrecovery to substitute a new disk for the disk that has been having problems, referring to Clusterrecovery Help as needed.

  Clusterrecovery makes it relatively easy to configure a new disk to replace the disk that has developed a problem.

**To use a different disk for the quorum resource without using Clusterrecovery**

1. After starting the Cluster service with the **/fixquorum** option, from the disks available on the cluster storage, choose the disk that you will use for the quorum resource. If the disk has two or more NTFS partitions, ensure that all partitions on the disk are assigned drive letters.

2. Using Cluster Administrator, create a Physical Disk resource or other storage-class resource for the new disk (unless one has already been created).

3. In the console tree, click the **Resources** folder.

4. In the details pane, click the resource that you will use for the quorum resource. If the resource is online, on the **File** menu, click **Take Offline**.

5. In the console tree, click the cluster name and then on the **File** menu, click **Properties**.

6. On the **Quorum** tab, click **Quorum resource**, and then select the disk or storage-class resource you want to use as the

quorum resource for the cluster.

7. In **Partition**, if the disk has more than one partition, click the partition to be used for the quorum resource.
8. In **Root path**, type the path to the folder on the partition. For example:

   \MSCS\

9. In the console tree, click the **Resources** folder and then, in the details pane, click the new quorum resource.
10. On the **File** menu, click **Bring Online** to confirm that you can bring the new quorum resource online.
11. Stop the Cluster service by typing:

    **net stop clussvc**

12. On the same node on which you performed the preceding steps, restart the Cluster service by typing:

    **net start clussvc**

| **Important** |
| --- |
| You must perform this step, which forms the cluster, from the node on which you performed the preceding steps. This is because the new information that you configured on this node does not exist yet on the other nodes. After the other nodes have joined the cluster, they will receive the new information about the location of the quorum resource and will be able to form the cluster as needed. |

# The Cluster Configuration File on a Node is Corrupt

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To understand this topic in context, see the flowchart in Troubleshooting Quorum Resource Problems.

If you try to start the Cluster service with the **/fixquorum** option on one node at a time and discover that this fails on one node although it succeeds on another, the cluster configuration file on the node from which you cannot start the Cluster service might be corrupt. This is a separate problem from problems with the quorum resource, but it is covered here because you might discover it while troubleshooting a problem with the quorum resource.

**Cause**
There are a variety of possible causes. Like any files, the cluster configuration file (CLUSDB) on a node can become corrupted.

**Solution**
First, correct any problems with the quorum resource and get the cluster running again (without the problem node). Analyze the local disk on the problem node and take appropriate corrective steps, as described in the procedure that follows. If the local disk on the node appears to be free of problems or has been fixed, try to join the cluster from that node. In some cases, the node will be able to join, and the cluster configuration file on the node will be re-created automatically. However, if it appears that a corrupt cluster configuration file is preventing the node from joining the cluster, use the procedure in this section to get a good copy of the cluster configuration database from the quorum resource and copy it to the node.

**To analyze the state of the local disk on a node that cannot be started with the /fixquorum option**

1. On the node on which you cannot start the Cluster service with the **/fixquorum** option, try to load and unload the cluster registry hive (collection of keys, subkeys, and values) by carrying out the following steps:

   a. At a command prompt, type:

      **regedit**

   b. Click HKEY_LOCAL_MACHINE and make sure it is selected.

   c. On the **File** menu, click **Load Hive**.

   d. Browse to the *Systemroot***Cluster** folder, and then double-click **CLUSDB**. When you are prompted for a key name, type **cluster**.

   e. If you can successfully load the hive, under HKEY_LOCAL_MACHINE, make sure that **Cluster** is selected and then, on the **File** menu, click **Unload Hive**. When prompted for confirmation, click **Yes**. At this point, you might need to perform additional troubleshooting. One step to take is to compare the cluster hive on this node with the cluster hive on another node. Another step is to make sure the cluster hive is unloaded and then try starting the Cluster service again on the node. A third step is to check the system event log for errors that indicate that incorrect permissions or user rights are preventing the Cluster service account from accessing or loading the local registry hive.

   f. If you cannot load the hive, it is corrupt. Continue to the next step.

2. If **CLUSDB** is corrupt, or if you want to check the condition of the local disk, run a disk utility that provides preliminary information about whether the disk appears to have problems. For example, to find out whether the dirty bit is set on the disk (indicating the file system may be in an inconsistent state), you can type the following at a command prompt:

   **fsutil dirty query** *d* **:**

   where *d***:** is the disk you are interested in. Another option is to use the Vrfydsk.exe utility, which is available from Windows Server 2003 Resource Kit Tools at the Microsoft Web site. Using information from the previous step along with information about the age and previous history of the local disk, assess whether the disk probably contains errors and needs to be fixed. To fix the disk, at a command prompt, type:

   **chkdsk** *d* **: /f**

or

**chkdsk** *d* **: /f /r**

where *d***:** is the disk you want to fix. Note that on a large disk volume, this command will take a long time to run, especially if the **/r** option is used.

3. If information from the previous steps and other disk symptoms indicate that the local disk is failing, replace the disk, restore from backup, and assess whether further troubleshooting is needed.

If the local disk on the node appears to be free of problems or has been fixed, try to join the cluster from that node. In some cases, the node will be able to join, and the cluster configuration file on the node will be re-created automatically. However, if it appears that a corrupt cluster configuration file is preventing the node from joining the cluster, use the following procedure to get a good copy of the cluster configuration database from the quorum resource and copy it to the node.

**To replace a corrupt cluster configuration file on a cluster node**

1. In Cluster Administrator, view the functioning nodes in the cluster, and find the node that owns the quorum resource.
2. From the node that owns the quorum resource, view the files on the quorum resource, and locate the Chk*xxx*.tmp file.
3. On the problem node, which is not joined to the cluster at the moment, in the *systemroot***\cluster** folder, locate the CLUSDB file (which you have determined is corrupt) and then rename it.
4. Copy the Chk*xxx*.tmp file to the *systemroot***\cluster** folder on the problem node, and then rename that file **CLUSDB**.

   If the problem has been corrected on the node, you will be able to start the Cluster service with no start parameters.

# Additional Resources for Troubleshooting the Quorum Resource in a Server Cluster

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For specific information about troubleshooting server clusters, see the following resources on the Microsoft Web site:

- Windows Server 2003 Clustering Services Technology Center
- Change the Account Under Which the Cluster Service Runs
- How to Install Service Packs in a Cluster
- How to Troubleshoot Cluster Service Startup Issues

For information about best practices for server clusters, see the following resources:

- Server Cluster Best Practices
- Backing Up and Restoring Server Clusters
- Server Clusters: Network Configuration Best Practices for Windows 2000 and Windows Server 2003
- Server Clusters: Security Best Practices for Windows 2000 and Windows Server 2003
- Server Clusters: Storage Best Practices for Windows 2000 and Windows Server 2003

For general information about how server clusters work, see the following resources:

- Planning Your Server Cluster
- Using Server Clusters
- How a Server Cluster Works

# Terminal Server Licensing Operations Guide

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Terminal Server Licensing Operations Guide provides troubleshooting information for Terminal Server licensing processes in the Windows Server 2003, Windows Server 2003 with Service Pack 1 (SP1) and Windows 2000 Server operating systems.

**In this guide**

- Troubleshooting Terminal Server Licensing

# Troubleshooting Terminal Server Licensing

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides troubleshooting information for Terminal Server Licensing in the Microsoft Windows Server 2003 and Windows 2000 operating systems.

# Introduction to Troubleshooting Terminal Server Licensing

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are using this guide for the first time, review the following sections of this introduction:

When to Use This Guide

How to Use This Guide

**When to Use This Guide**
You should use this guide when:

- You have a problem that you believe is related to Terminal Server Licensing, but you do not know how to resolve it.
- You have configured Terminal Server Licensing settings, but Terminal Server Licensing does not behave the way you anticipated.
- A program is not working properly and you believe that Terminal Server Licensing is causing the problem.

This guide assumes a basic understanding of Terminal Server Licensing, how it works, and why your organization uses it to provide, catalog, and enforce license policy among Terminal Server clients. You should also have a thorough understanding of how Terminal Server Licensing is deployed and managed in your organization. This includes an understanding of the mechanism your organization uses to configure and manage Terminal Server Licensing settings.

**How to Use This Guide**
This guide is divided into five sections. Each section addresses a type of problem, ranging from less complex to more complex.

Verifying Computer Settings for Troubleshooting Terminal Server Licensing

This section provides a list of prerequisites and settings that must be verified before you troubleshoot. Read this section first.

Quick Fixes for Terminal Server Licensing

This section provides quick solutions to the most common Terminal Server Licensing problems. Read this section if you have verified your computer settings, but your problem persists.

Configuring a Computer for Troubleshooting Terminal Server Licensing

This section describes how to configure your computer for troubleshooting. Read this section if you cannot find a solution in the Quick Fixes section.

Troubleshooting Terminal Server Licensing Problems

This section provides step-by-step diagnostic procedures and possible solutions that help you identify and fix Terminal Server Licensing problems.

Additional Resources for Troubleshooting Terminal Server Licensing

See this section for a comprehensive list of resources available to help you troubleshoot Terminal Server Licensing.

# Verifying Computer Settings for Troubleshooting Terminal Server Licensing

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Settings to Verify Before You Troubleshoot**
Before you begin troubleshooting, verify that your computer is configured properly and that Terminal Server Licensing is set up and running correctly. Following are important general questions to consider before you begin more specific troubleshooting:

- Which operating system is the client running (the client that is attempting to connect to the terminal server)?
- Which operating system is the terminal server running (the terminal server to which the client is attempting to connect)?
- Do you have a computer that is running the Terminal Server Licensing service?
- Which operating system is the license server running?
- How many licenses are available on the license server?

After you have answered these questions, you can proceed with the following more specific troubleshooting steps:

Verify that you have administrative rights on the computer you are troubleshooting

Install all critical security updates for Windows 2000 or Windows Server 2003

Update all of your software, including non-Microsoft software

Verify that the operating system of the Terminal Server license server is compatible with the operating system of the terminal server

Review additional configuration requirements and considerations for implementing Terminal Server Licensing in different environments

Verify that Terminal Server Licensing is correctly installed on the license server

Verify that the Terminal Server Licensing service is started and that the startup type is set to Automatic

Verify that the license server is activated

Verify that the license server has a sufficient number of CALs for clients

Verify that the Terminal Server Licensing mode on the terminal server matches the type of CALs on the license server (applicable to Windows Server 2003 only)

Verify that the Authenticated Users group on the terminal server has the appropriate rights

Verify the value of the RestrictAnonymous registry key

Verify that the TS-License-Server object exists in Active Directory, if the license server is an Enterprise license server

**Verify that you have administrative rights on the computer you are troubleshooting**
You cannot modify Terminal Server Licensing settings unless you are a member of the Administrators group on the computer that you are administering.

**To verify that you are a member of the Administrators group**

1. Open the Computer Management snap-in.
2. In the console tree, double-click **Local Users and Groups**, and then click **Groups**.
3. In the details pane, double-click **Administrators** and verify that your account name or a group in which your account is a

member appears in the **Members** list.

You can also tell if you have the appropriate administrative rights to configure Terminal Server Licensing by opening the Terminal Server Licensing tool. If you do not have administrative rights, all of the controls in the Terminal Server Licensing user interface (UI) will appear dimmed and a warning will appear telling you that you must be a computer administrator to change any settings.

### To open Terminal Server Licensing

- Click **Start**, point to **Control Panel**, **Administrative Tools**, and then click **Terminal Server Licensing**.

**Install all critical updates and security updates for Windows 2000 or Windows Server 2003**
Some updates might be required for Terminal Server Licensing to function properly.

### To verify that you have all critical updates and security patches

- Click **Start**, click **Windows Update**, and then follow the instructions that appear on your screen.

**Update all of your software, including non-Microsoft software**
Terminal Server Licensing might not function properly unless you update your operating system and programs with the most recent service pack or software updates. For example, if your license servers or terminal servers are running Windows 2000 Service Pack 3 (SP3) or earlier, you should install Service Pack 4 (SP4) on those servers. Newer versions of many programs, such as antivirus programs, might resolve any problems you have.

**Verify that the operating system of the Terminal Server license server is compatible with the operating system of the terminal server**
Note the following operating system compatibility requirements for Terminal Server Licensing.

- A license server running Windows Server 2000 cannot issue client access licenses (CALs) to terminal servers running Windows Server 2003 operating systems.

- A license server running a Windows Server 2003 operating system can issue CALs to terminal servers running Windows Server 2000 or Windows Server 2003, or to terminal servers running Windows Server 2000 and terminal servers running Windows Server 2003 in a mixed environment.

Verify that both the license server and the terminal server are running either the release version of Windows Server 2003 or a pre-release (evaluation) version of Windows Server 2003. A license server that is running a release version of Windows Server 2003 cannot communicate with a terminal server running an evaluation version of Windows Server 2003, and vice-versa.

| **Note** |
| --- |
| It is recommended that you do not install Terminal Server Licensing on a compressed drive. This can cause the license server database to become corrupted. The default location for the license server database is systemroot\System32\LServer. If the license server database is corrupted, then you must remove and then reinstall Terminal Server Licensing. If you encounter problems removing and reinstalling Terminal Server Licensing, you might need to contact the Microsoft Clearinghouse. For information about how to contact the Clearinghouse, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885). |

**Review additional configuration requirements and considerations for implementing Terminal Server Licensing in different environments**
To ensure that license server discovery works as expected, review configuration requirements and considerations, and verify that the requirements have been met for your environment. For information, see Understanding Troubleshooting Considerations for Specific Terminal Server Licensing Environments.

**Verify that Terminal Server Licensing is correctly installed on the license server**
For step-by-step instructions, see Verify that Terminal Server Licensing is correctly installed on the license server.

**Verify that the Terminal Server Licensing service is started and that the startup type is set to Automatic**
For step-by-step instructions, see Verify that the Terminal Server Licensing service is started and the startup type is set to Automatic.

**Verify that the license server is activated**
Windows Server 2003 Terminal Services supports the following licensing modes: Per Device and Per User. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL

gives one user the right to access a terminal server from an unlimited number of devices.

By default, when the Per Device licensing mode is used, after a client logs on and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. To issue clients permanent, Per Device licenses, a license server must be activated.

| **Note** |
| --- |
| If Per User licensing is used, after the terminal server discovers a license server, no further communication takes place between the servers, and client connections are allowed regardless of the number of licenses installed. Therefore, when Per User licensing is used, the license server does not need to be activated. |

To activate a license server, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**To verify that a license server is activated**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, point to **Control Panel**, **Administrative Tools**, and then click **Terminal Server Licensing**.
2. In the console tree, click the license server for which you want to verify the activation status.
3. In the details pane, verify that activation status is Activated.
4. If the status is Not Activated and you have Internet connectivity, right-click the server name, click **Activate Server**, select **Automatic connection (recommended)**, and then click **Next**.

   If you do not have Internet connectivity, see Activate a Terminal Server License Server (http://go.microsoft.com/fwlink/?LinkId=48888) for alternate license server activation procedures.
5. Follow the instructions in the wizard.

If necessary, at a later time you can change any license server properties, such as activation method and company information, that you set during the activation process.

**Verify that the license server has a sufficient number of CALs for clients**

You can use Terminal Server Licensing to verify whether a terminal server has a sufficient number of permanent, Per Device CALs to support the number of clients who require remote connections. When Per Device licensing is used, after a temporary license expires, a client can only connect to a terminal server if the license server can issue a permanent CAL, or if the terminal server is still within its licensing grace period. For step-by-step instructions on how to verify the number of CALs a license server has, see Verify that the license server has a sufficient number of CALs.

**Important** Per User CALs are not enforced by Terminal Server. As a result, client connections can occur regardless of the number of licenses installed. This does not remove administrators from End User License Agreement (EULA) requirements to have a valid terminal server CAL for each user, however. Failure to have a Per User CAL for each user, if Per Device CALs are not being used, is a violation of the EULA. To ensure that you are in compliance with the EULA, make sure that you track the number of Per User licenses being used in your organization and that you have a sufficient number of licenses to provide a Per User CAL for each user.

The following text is from the EULA for Windows Server 2003:

"Two different TS CALs are available to you: 'Device' and 'User.' Each TS Device CAL permits one Device (used by any User) to conduct Windows Sessions on any of your Servers. Each TS User CAL permits one User (using any Device) to conduct Windows Sessions on any of your Servers. You may use a mix of TS Device CALs and TS User CALs simultaneously with the Server Software in your environment. You can have a Terminal Server request Per User licenses or Per Device (default) but not both simultaneously."

| **Note** |
| --- |
| On license servers running Windows Server 2003 Service Pack 1 (SP1), the numeric values for Per User licenses in the Total and Available columns in the Terminal Server Licensing tool are no longer displayed. Instead, the phrase "Not applicable" appears in these columns, to remind administrators that Per User licenses are not enforced. This phase does not indicate a problem with the installation or operation of Terminal Server Licensing. |

**Verify that the Terminal Server Licensing mode on the terminal server matches the type of CALs on the license server (applicable to Windows Server 2003 only)**

For Terminal Server Licensing to function properly, you must ensure that the Terminal Server Licensing mode that you configure on the terminal server matches the type of CALs you have purchased and installed on the license server. You can verify whether the Terminal Server Licensing mode and type of CALs purchased match by doing one of the following:

Using Terminal Services Configuration (the most direct method)

Using Group Policy (in Windows Server 2003 Service Pack 1)

| **Note** |
| --- |
| If you use Group Policy to verify the Terminal Server Licensing mode and if the Group Policy setting is not properly applied to the Group Policy object (GPO) to which the terminal server is assigned, then the licensing mode that is displayed in Group Policy might not be valid. Therefore, using Terminal Services Configuration to verify the Terminal Server Licensing mode is a more direct method. |

**Using Terminal Services Configuration**

**To verify that the Terminal Server Licensing mode on the terminal server matches the type of CALs on the license server using Terminal Services Configuration**

1. On the terminal server, open **Terminal Services Configuration**. To open Terminal Services Configuration, click **Start**, point to **Control Panel**, **Administrative Tools**, and then click **Terminal Services Configuration**.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Licensing Mode**, and then click **Properties**. Note the licensing mode (**Per User** or **Per Device**), and then click **OK**.

   | **Note** |
   | --- |
   | A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. |

4. On the license server, open **Terminal Server Licensing**.
5. In the details pane, verify that the type of CALs installed on the license server match the Terminal Server Licensing mode that is configured on the terminal server.

**Using Group Policy**

**To verify that the Terminal Server Licensing mode on the terminal server matches the type of CALs on the license server using Group Policy**

1. On the terminal server, open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click **Set the Terminal Server licensing mode**.
3. If the setting is enabled, note the licensing mode (**Per Device** or **Per User**) that is selected in **Specify the licensing mode for the terminal server**.

   If the setting is disabled or not configured, the licensing mode that is specified during Setup or in Terminal Services Configuration is used.

   | **Note** |
   | --- |
   | A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. |

4. Click **OK**.
5. On the license server, open Terminal Server Licensing.
6. In the details pane, verify that the type of CALs installed on the license server match the Terminal Server Licensing mode

that is configured on the terminal server.

**Verify that the Authenticated Users group on the terminal server has the appropriate rights**

For Terminal Server Licensing to function correctly, the Authenticated Users group on the terminal server must have the following two rights: **Access this computer from the network** and **Bypass Traverse Checking**. By default, the only Group Policy object that has the **Access this computer from the network** right defined is the Default Domain Controllers policy. Member servers and servers in a workgroup environment have the **Access this computer from the network** right defined in their local security policy.

**To verify that the Authenticated Users group on the terminal server has the appropriate rights**

1. On the terminal server, open the appropriate policy (local policy or Group Policy).
2. In the console tree, navigate to Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment\.
3. In the details pane, right-click **Access this computer from the network**, and then click **Properties**.
4. If Authenticated Users is not in the list of users and groups that have been granted this right, click **Add User or Group**.
5. In **Select Users or Groups**, in **Enter the object name to select**, type Authenticated Users, click **OK**, and then click **OK** again to close the dialog box for this security setting.
6. In the console tree, right-click **Bypass Traverse Checking**, and then click **Properties**.
7. If **Authenticated Users** is not in the list of users and groups that have been granted this right, perform steps 5 and 6.

Additionally, users must also be members of the Remote Desktop Users group on the terminal server, as described in the following procedure, or you must assign the equivalent permissions manually. For more information, see Enabling users to connect remotely to the server (http://go.microsoft.com/fwlink/?LinkId=48887).

**To add users to the Remote Desktop Users group**

1. Open Computer Management. **T**o open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
2. In the console tree, click the **Local Users and Groups** node.
3. In the details pane, double-click the Groups folder.
4. Double-click **Remote Desktop Users**, and then click **Add**. By default, the Remote Desktop Users group is not populated. You must decide which users and groups should have permission to log on remotely, and then manually add them to the group.
5. On the **Select Users** dialog box, click **Locations...** to specify the search location.
6. Click **Object Types...** to specify the types of objects you want to search for.
7. Type the name you want to add in the **Enter the object names to select (examples):** box.
8. Click **Check Names**.
9. When the name is located, click **OK**.

**Verify the value of the RestrictAnonymous registry key**

If you are not using Windows Server 2003 terminal servers with Windows Server 2003-based license servers, verify that the **RestrictAnonymous** registry key value on the license server is set to **0** or **1**. In this scenario, if this registry key value is set to **2**, then the license server cannot issue CALS. When the **RestrictAnonymous** registry value is set to **2**, the access token built for non-authenticated users does not include the Everyone group, and because of this, the access token no longer has access to resources that grant permissions to the Everyone group.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To verify the value of the RestrictAnonymous registry key**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:
   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\RestrictAnonymous**
3. Verify the value of the **RestrictAnonymous**registry key.
4. The three valid registry key values for **Restrict Anonymous** are equivalent to the following security settings in Local Security Policy:

   **0** = None (rely on default permissions)

   **1** = Do not allow enumeration of SAM accounts and shares

   **2** = No access without explicit anonymous permissions
5. If the value of the registry key is set to **2**, then perform the following steps.
6. Open Local Security Policy, and then navigate to Security Settings\Local Policies\Security Options. To open Local Security Policy, click **Start**, point to **Settings**, Control Panel, click **Administrative Tools**, and then click **Local Security Policy**.
7. Double-click **Additional restrictions for anonymous connections**, and then click **No access without explicit anonymous permissions**.
8. Restart the server.

   If the license server is a member of an Active Directory domain and a conflicting security setting is configured for the license server in Group Policy, the Group Policy setting overrides the local security setting. Therefore, to ensure that the required setting changes take effect (if you must change the settings) this procedure describes how to configure the setting change in Group Policy.

   In Windows Server 2003, you cannot set **RestrictAnonymous** to a value of **2** to prohibit anonymous connections. If you need to prohibit anonymous users from being granted the same access that is granted to members of the Everyone group, you must use the new **Everyone Network access: Let Everyone permissions apply to anonymous users** setting in Local Security Policies.

**Verify that the TS-License-Server object exists in Active Directory, if the license server is an Enterprise license server**
To determine the license server role (whether the license server is an Enterprise license server or a Domain license server), check the **Role** registry key value.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To check the Role registry key value**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:
   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\TermServerLicensing\Parameters**

   If the registry key value is set to **0**, then the license server is a Domain license server.

   If the registry key value is set to **1**, then the license server is an Enterprise license server.

If the license server is an Enterprise License server, then the **TS-Enterprise-License-Server** object must exist in Active Directory.

**To verify that the TS-Enterprise-License-Server object exists in Active Directory**

1. Open Active Directory Sites and Services. To open Active Directory Sites and Services, click **Start**, click **Control Panel**, click **Performance and Maintenance**, click **Administrative Tools**, and then **double-click Active Directory Sites and Services**.

2. In the console tree, click **Sites**, and then click the site that contains the terminal server.
3. In the details pane, click **Licensing Site Settings**.
4. Right-click **TS-Enterprise-License-Server**, and then click **Properties**. The **SiteServer** attribute of the **TS-Enterprise-License-Server** object must specify the Distinguished Name (also known as DN) of the license server. For example: CN=TS-Enterprise-License-Server, CN=<**SiteName**>, CN=Configuration, DC=<**DomainName**>,DC=<**RootDomainName**>
5. On the **License Settings** tab, verify the name of the license server.

# Quick Fixes for Terminal Server Licensing

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a summary of the most common Terminal Server Licensing problems and the solutions to those problems. You can use the information in this section to resolve problems in the same way you would use a FAQ to find answers to common questions. Read this section before you begin any advanced troubleshooting.

**Common Terminal Server Licensing Problems**
Listed below are common Terminal Server Licensing problems and quick fixes:

The Terminal Server licensing mode on the terminal server is set to Per Device, but the license server is set to issue Per User CALs

Windows-Based Terminal devices (thin clients) cannot connect to terminal servers

Clients connecting to a Windows 2000 terminal server cannot obtain a permanent Windows 2000 Terminal Server CAL

**The Terminal Server licensing mode on the terminal server is set to Per Device, but the license server is set to issue Per User CALs**
When there is a mismatch between the Terminal Server Licensing mode configuration on the terminal server and the configuration on the license server, remote sessions can be disconnected prematurely. You can resolve this problem by making sure that the Terminal Server licensing mode on the terminal server matches the type of licenses installed on the license server. For more information, see Change the Terminal Server Licensing mode.

| **Note** |
| --- |
| If you are running a Windows Server 2003 terminal server, after you use the Windows Components Wizard in Add or Remove Programs to add or to remove a Windows component, an invalid registry value might be set in the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TerminalServer\Licensing Core\PolicyAcOn** subkey on the terminal server. This invalid value may unexpectedly change the Terminal Server Licensing mode and cause the terminal server to obtain only temporary licenses. To resolve this problem contact Microsoft Product Support Services to obtain the hotfix described in Knowledge Base article 834651, Terminal Services licensing mode changes from Per User or from Per Device to an invalid value after you add or remove a Windows component (http://go.microsoft.com/fwlink/?LinkId=48173) on the Microsoft Web site. This hotfix is applied to the terminal server. |

**Windows-based terminal devices (thin clients) cannot connect to terminal servers**
If you try to connect to connect to a terminal server from a Windows-based terminal device, the connection might be denied if:

- You update the electrically erasable programmable read-only memory (EEPROM) of the Windows-based terminal device
- You delete the following registry subkey: **HKEY_LOCAL_MACHINE\Software\Microsoft\MSLicensing\Store**
- The Windows-based terminal device has been issued a new temporary license
- You installed the hotfix described in Knowledge Base article 287687, Terminal Services Licensing Enhancements (http://go.microsoft.com/fwlink/?LinkId=48172) on the Microsoft Web site.

In such cases, the connection is denied because the license is treated as expired.

To resolve this problem, contact Microsoft Product Support Services to obtain the hotfix described in Knowledge Base article 287687 to apply to the terminal server, the license server, or both. For information about how to contact Microsoft Product Support Services, see Help and Support (http://go.microsoft.com/fwlink/?LinkId=48149) on the Microsoft Web site. If you are using a Citrix ICA client, you might also need to contact Citrix to obtain an appropriate fix.

**Clients connecting to a Windows 2000 terminal server cannot obtain a permanent Windows 2000 Terminal Server CAL**
In an environment with Windows 2000 terminal servers and Windows Server 2003 license servers, clients that connect to a Windows 2000 terminal server cannot obtain a permanent Windows 2000 client access license (CAL), even though Windows 2000 CALs are installed on the license server. Instead, the clients receive a Windows Server 2003 Terminal Server temporary license. This problem might occur because the CAL was not upgraded or renewed correctly.

To resolve this problem, do the following:

1. Install CALs automatically on the license server. Client computers can successfully upgrade from a temporary Windows Server 2003 Terminal Server license to a permanent Windows Server 2003 Terminal Server CAL.

2. Verify whether the clients can receive the new temporary licenses. If the clients cannot receive the new licenses, the terminal server might not be able to locate the license server. For troubleshooting procedures to resolve this issue, see The terminal server cannot locate the license server.

3. If the clients can connect to the terminal server, and if licenses are available on the license server and this problem still occurs, then contact Microsoft Product Support Services to obtain the hotfix described in Knowledge Base Article 837211, Client computers cannot obtain a permanent Windows 2000 Terminal Services Client Access License (CAL) from a Windows Server 2003 Terminal Services Licensing server (http://go.microsoft.com/fwlink/?LinkId=48146) on the Microsoft Web site, and then apply this hotfix to the license server. For information about how to contact Microsoft Product Support Services, see Help and Support (http://go.microsoft.com/fwlink/?LinkId=48149) on the Microsoft Web site.

# Configuring a Computer for Troubleshooting Terminal Server Licensing

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and fix Terminal Server problems, it is helpful to configure your computer for troubleshooting. In addition, you need a basic understanding of troubleshooting concepts, procedures, and tools.

**Using Terminal Server Licensing Troubleshooting Tools**
Using the following tools can help you monitor Terminal Server Licensing status and diagnose the cause of Terminal Server licensing issues.

**Terminal Server Licensing**
You can use Terminal Server Licensing to do the following:

- View the list of discoverable license servers on your network.
- Connect to any discoverable license server on your network and view information about the licenses on that server.

  Using the Terminal Server Licensing tool, you can view the following information: the list of installed client license key packs, the total number of licenses in each client license key pack, and the number of available and issued licenses in each key pack; the date a CAL was issued to each computer; the name of the computer to which each CAL is issued; the issue and expiration dates of each temporary license; and the name of the computer to which the license was issued.

  | **Note** |
  | --- |
  | If you are running a Windows 2000 license server, expiration dates for temporary licenses are displayed only if you have Service Pack 3 (SP3) or later installed. |

- Manage Terminal Server licenses.
- Perform the following management tasks: activate a license server, install CALs, reactivate a license server, deactivate a license server, repeat the installation of CALs, and change the properties of a license server.

This tool is included with Windows Server 2003. You can access this tool on any Terminal Server license server. For more information, see Terminal Server Licensing administrative tool (http://go.microsoft.com/fwlink/?LinkId=48896).

**Terminal Services Licensing Reporter (Lsreport.exe)**
You can use Terminal Services Licensing Reporter (Lsreport.exe) to create a report with information about the CALs that are installed on license servers.

Lsreport.exe exports information from the license server's database into LSreport.txt, a tab-delimited text file. You can use this data to track license consumption and usage trends within your organization. This tool has been updated to include the client hardware ID, information that is useful for tracking the CALs that are issued to particular client devices.

To download Lsreport.exe, see Windows Server 2003 Resource Kit Tools (http://go.microsoft.com/fwlink/?LinkID=16721) on the Microsoft Download Center Web site.

**Terminal Services License Server Viewer (Lsview.exe)**
You can use Terminal Services License Server Viewer (Lsview.exe) to do the following:

- Display the name of each license server in the current domain and site, the type (enterprise or domain) of each license server in the domain, and the date and time that each license server is available.
- Create a log file with advanced diagnostic information about the discovery process.

To download Lsview.exe, see Windows Server 2003 Resource Kit Tools (http://go.microsoft.com/fwlink/?LinkID=16721) on the

Microsoft Download Center Web site.

**Terminal Server Client License Test tool (Tsctst.exe)**
You can use the Terminal Server Client License Test tool to display information about CALs that reside on client devices. By default, this tool displays information in the following fields: Issuer, Scope, Issued to computer, Issued to user, License ID, Type/Version, Valid From, and Expires On.

To download Tsctst.exe, see Windows Server 2003 Resource Kit Tools (http://go.microsoft.com/fwlink/?LinkID=16721) on the Microsoft Download Center Web site.

**Terminal Services Diagnostic Utility (Tstst.exe)**
You can use the Terminal Services Diagnostic Utility to display configuration information for terminal servers. This tool provides a grace period check to determine whether terminal servers are still within the licensing grace period, and it enumerates available license servers.

To download Tstst.exe, see Windows Server 2003 Resource Kit Tools (http://go.microsoft.com/fwlink/?LinkID=16721) on the Microsoft Download Center Web site. Note that there are eight specialty tools, each corresponding to a specific support scenario. The specialty tool that contains Tstst.exe is MPSRPT DirSrvc.exe.

# Troubleshooting Terminal Server Licensing Problems

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Terminal Server Licensing issues can result in client connection failures, license server activation failures, and license issuance and upgrade problems. The following topics provide troubleshooting steps to resolve these problems. Additionally, important updates for Terminal Server Licensing in Windows Server 2003 are described, including updates for Service Pack 1. Understanding these updates can help you prevent or minimize problems with Terminal Server Licensing.

**In this section**

- Understanding Windows Server 2003 updates for Terminal Server Licensing
- Understanding Troubleshooting Considerations for Specific Terminal Server Licensing Environments
- Fixing Client Connectivity Problems
- Fixing CAL Issuance and Upgrade Problems
- Fixing License Server Activation Problems and Other Licensing Problems

# Understanding Windows Server 2003 updates for Terminal Server Licensing

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Following are important changes for Terminal Server Licensing in Windows Server 2003, including updates for Service Pack 1 (SP1).

**Per Device Licenses Available in Windows Server 2003**
In Windows Server 2003, two types of client access licenses (CALs) are available: Per User and Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device.

By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs, however, are not enforced by Terminal Server. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.

**Important**

For Terminal Server Licensing to function correctly you must ensure that the Terminal Server Licensing mode that you configure on the terminal server matches the type of CALs you have purchased and installed on the license server. You can verify whether the Terminal Server Licensing mode and type of CALs purchased match by using Terminal Services Configuration, or in Windows Server 2003 SP1, Group Policy. For more information, see Verifying Computer Settings for Troubleshooting Terminal Server Licensing.

**Note**

On license servers running Windows Server 2003 SP1, the numeric values for Per User licenses in the Total and Available columns in the Terminal Server Licensing tool are no longer displayed. Instead, the phrase "Not applicable" appears in these columns, to remind administrators that Per User licenses are not enforced. This phrase does not indicate a problem with the installation or operation of Terminal Server Licensing.

**Required Licenses for Terminal Server in Windows Server 2003**
For Windows Server 2003 Terminal Server to function correctly there must be at least one Windows Server 2003 license server in your environment. Although Terminal Server provides a licensing grace period during which no license server is required, after the grace period ends, clients must obtain a valid Windows Server 2003 Terminal Server CAL to log onto a Windows Server 2003 terminal server. This includes Windows Server 2003 clients. Currently, all Terminal Server CALs that are available for purchase are Windows Server 2003 Terminal Server CALs.

If you are running Windows 2000 terminal servers with Windows Server 2003 license servers, the Windows 2000 terminal server can use can use Windows Server 2003 Per Device CALs or Windows 2000 CALs. You can downgrade these CALs by calling the Microsoft Clearinghouse and requesting that the CALs be downgraded to Windows 2000. For more information, see Windows Server 2003 Downgrade Rights (http://go.microsoft.com/fwlink/?LinkId=48210) on the Microsoft Web site and Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkID=48885).

Note that a Windows 2000 license server cannot install or issue Windows Server 2003 Terminal Server CALs.

**Terminal Server Licensing Grace Period Increased in Windows Server 2003**
In Windows 2000, the Terminal Server Licensing grace period was 90 days. In Windows Server 2003, the licensing grace period has increased to 120 days. The licensing grace period begins the first time a terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first.

**New Group Policy Settings for Windows Server 2003 Service Pack 1**
Windows Server 2003 SP1 includes the following new Group Policy settings for Terminal Services Licensing:

- **Set the Terminal Server licensing mode**

  This new Group Policy setting determines the type of Terminal Server CAL a device or user requires to connect to a Terminal Server.

  When this setting is enabled, you can choose one of the following two licensing modes:

  - Per User. Each user connecting to the terminal server requires a Per User Terminal Server CAL.
  - Per Device. Each device connecting to the terminal server requires a Per Device Terminal Server CAL.

  If you enable this policy setting, the licensing mode that you specify overrides the licensing mode specified during Setup, or in Terminal Services Configuration (TSCC.msc).

  If you disable or do not configure this policy setting, Terminal Services uses the licensing mode specified during Setup or in Terminal Services Configuration.

- **Use the specified Terminal Server license servers**

  This new Group Policy setting determines whether terminal servers must first attempt to locate Terminal Server license servers that are specified in this policy setting before attempting to locate license servers elsewhere on the network.

  Specifying the name of a preferred licensing server in Group Policy saves time and helps eliminate roadblocks to successful configuration of your terminal servers. With the name of a specific licensing server added to Group Policy, Terminal Services does not need to search the network for a licensing server.

  During the automatic discovery process, terminal servers attempt to contact license servers in the following order:

1. Enterprise license servers or domain license servers that are specified in the**LicenseServers** registry key
2. Enterprise license servers that are specified in Active Directory
3. Domain license servers
4. Servers running Terminal Server Licensing in the same subnet
5. The local license server (if the terminal server is also running the Terminal Server Licensing service)

   If you enable this policy setting, terminal servers attempt to locate license servers that are specified in this setting, before following the automatic license server discovery process.

   If you disable or do not configure this policy setting, terminal servers follow the automatic license server discovery process.

| **Note** |
| --- |
| You are also prompted to specify a preferred license server during Setup, or you can specify the license server in Terminal Services Configuration, if the terminal server is running Windows Server 2003 SP1.<br><br>If you are upgrading a terminal server from Windows 2000 to Windows Server 2003, the compatibility report will now display a warning if a Windows Server 2003 license server is not located. |

**Show ToolTips for Licensing Problems on Terminal Server**
This new Group Policy setting allows you, after successfully logging on to a terminal server as an administrator, to display ToolTips that show any licensing problems with the terminal server, and also to display the expiration date of the terminal server's licensing grace period. If this Group Policy setting is not configured, ToolTips display is defined by registry settings.

Using ToolTips to view Terminal Server license statistics at a glance speeds administration tasks. By configuring Group Policy to show ToolTips for Terminal Server licenses, you do not need to open the Properties dialog box for specific licenses to view status and expiration information.

Allowing administrators to configure a global Terminal Server licensing mode makes it possible for them to implement unified license policies regardless of the configuration of Terminal Services client computers. With the new Group Policy setting, differences in configuration between terminal servers and clients can be resolved by defining a global policy that overrides other settings.

# Understanding Troubleshooting Considerations for Specific Terminal Server Licensing Environments

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To ensure that license server discovery works as expected, review the following configuration requirements and considerations, and verify that the requirements have been met for your environment.

Windows 2000 domain: Windows 2000 terminal servers and Windows 2000 license servers

Windows 2000 domain: Windows 2000 terminal servers and Windows Server 2003 license servers

Windows Server 2003 domain: Windows 2000 terminal servers and Windows 2000 license servers

Windows Server 2003 domain: Windows 2000 terminal servers and Windows Server 2003 license servers

Windows Server 2003 domain: Windows Server 2003 terminal servers and Windows Server 2003 license servers

Down level Windows clients, thin clients, and Macintosh clients

**Important**

The following two configurations will not function because a Windows 2000 license server cannot issue CALs to terminal servers running Windows Server 2003 operating systems:

- Windows 2000 domain: Windows Server 2003 terminal servers and Windows 2000 license servers
- Windows Server 2003 domain: Windows Server 2003 terminal servers and Windows 2000 license servers

Therefore, if you have an environment that includes Windows Server 2003 terminal servers, you must install a Windows Server 2003 license server. For more information, see Verify that Terminal Server Licensing is correctly installed on the license server.

**Windows 2000 domain: Windows 2000 terminal servers and Windows 2000 license servers**

- In this environment, you must install Terminal Server Licensing on a domain controller. Although you do not need to explicitly specify a license server, it is recommended that you do so. For more information, see Set a preferred license server.
- If the license server and the terminal server are not already running Windows 2000 Service Pack 4 (SP4), install this service pack on both computers. To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkId=48213), on the Microsoft Web site.
- Also on the license server, apply the hotfix described in article 837321, You cannot connect to a Windows 2000 Terminal server if your Windows Server 2003 Terminal Services license is expired (http://go.microsoft.com/fwlink/?LinkId=48215), on the Microsoft Web site.
- On the terminal server, apply the hotfix described in article 829395, The Terminal server does not automatically shut down when the TSShutdn.exe command is invoked in Windows 2000 (http://go.microsoft.com/fwlink/?LinkId=48216), on the Microsoft Web site.
- Terminal Server licenses that are issued by license servers running Windows 2000 Service Pack 3 or later have an expiration date. Licenses are either reissued or returned to the Terminal Server CAL pool at a random interval between 52 and 89 days. Note that this setting cannot be configured, and that licenses are renewed seven days before they expire. Any Terminal Server licenses that are issued by license servers running earlier versions of Windows 2000 do not have an expiration date. To return these licenses to the CAL pool, you must remove the license certificate from the clients, and then call the Microsoft Clearinghouse to recover the license. To remove the license certificates from the client, delete the following registry key: **HKEY_LOCAL_MACHINE \Software\Microsoft\MSLicensing**. Licenses for clients that do not have a registry are stored in the registry of the terminal server.

| ⚠Caution |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**Windows 2000 domain: Windows 2000 terminal servers and Windows Server 2003 license servers**

- You can install Terminal Server Licensing on a Windows Server 2003 domain controller or a Windows Server 2003 member server. If you install Terminal Server Licensing on a domain controller, you do not need to explicitly specify a license server for the terminal server to discover. However, it is recommended that you do this to help ensure that license server discovery works as expected. For information about how to do this, see Set a preferred license server.

- If the terminal server is not already running Windows 2000 SP4, install this service pack. To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkId=48213), on the Microsoft Web site.

- If you have thin clients in this environment, on the Windows Server 2003 license server, apply the hotfix described in article 88450, Event ID 1004 is logged when a thin client tries to obtain a license (http://go.microsoft.com/fwlink/?LinkId=48217) on the Microsoft Web site.

- If you have clients running Windows 2000 or Windows XP Professional in this environment, the license server issues a "free" Terminal Services CAL from its built-in pool to enable these clients to access the Windows 2000 terminal server. The use of this license is permitted under the Windows 2000 EULA. To issue these licenses, however, the license server must first be activated.

  **Note**

- For Windows Server 2003 terminal servers, there is no built-in pool of free licenses. You must install the appropriate number of CALs on the license server to enable all clients to connect to these terminal servers.

**Windows 2003 domain: Windows 2000 terminal servers and Windows 2000 license servers**

- If the license server and the terminal server are not already running Windows 2000 SP4, install this service pack on both computers. To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkId=48213), on the Microsoft Web site.

- On the Windows 2000 license server, apply the hotfix described in article 837321, You cannot connect to a Windows 2000 Terminal server if your Windows Server 2003 Terminal Services license is expired (http://go.microsoft.com/fwlink/?LinkId=48215), on the Microsoft Web site.

- On the Windows 2000 terminal server, apply the hotfix described in article 829395, The Terminal server does not automatically shut down when the TSShutdn.exe command is invoked in Windows 2000 (http://go.microsoft.com/fwlink/?LinkId=48216), on the Microsoft Web site.

**Windows 2003 domain: Windows 2000 terminal servers and Windows Server 2003 license servers**

- If the terminal server is not already running Windows 2000 SP4, install this service pack. To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkId=48213), on the Microsoft Web site.

- If you have thin clients in this environment, on the Windows Server 2003 license server, apply the hotfix described in article 88450, Event ID 1004 is logged when a thin client tries to obtain a license (http://go.microsoft.com/fwlink/?LinkId=48217) on the Microsoft Web site.

- If you have clients running Windows 2000 or Windows XP Professional in this environment, the license server issues a "free" Terminal Services CAL from its built-in pool to enable these clients to access the Windows 2000 terminal server. The use of this license is permitted under the Windows 2000 EULA. To issue these licenses, however, the license server must first be activated.

**Note**

- For Windows Server 2003 terminal servers, there is no built-in pool of free licenses. You must install the appropriate number of CALs on the license server to enable all clients to connect to these terminal servers.

**Windows 2003 domain: Windows Server 2003 terminal servers and Windows Server 2003 license servers**

- You can install Terminal Server Licensing on a Windows Server 2003 domain controller or a Windows Server 2003 member server. If you install Terminal Server Licensing on a domain controller, you do not need to explicitly specify a license server for the terminal server to discover. However, it is recommended that you do this to help ensure that license server discovery works as expected. For information about how to do this, see Set a preferred license server.

- If you have thin clients in this environment, on the Windows Server 2003 license server, apply the hotfix described in article 88450, Event ID 1004 is logged when a thin client tries to obtain a license (http://go.microsoft.com/fwlink/?LinkId=48217) on the Microsoft Web site.

**Down level Windows clients, thin clients, and Macintosh clients**
In addition to supporting clients that run Windows Server 2003, Windows 2000, and Windows XP Professional, Windows Server 2003 Terminal Server and Windows 2000 Terminal Server support clients running the following platforms:

- Windows XP Home Edition
- Windows XP Embedded Edition
- Windows Millennium Edition
- Windows 98
- Windows 95
- Windows NT 4.0
- Windows-based Terminal devices (embedded)
- Macintosh

To connect to a terminal server, these clients must have Terminal Server CALs available. Therefore, you should Verify that the license server has a sufficient number of CALs for clients.

# Fixing Client Connectivity Problems

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a description of client connectivity problems that you might experience when Terminal Server is enabled.

When troubleshooting client connectivity problems, it is most useful to first determine whether there are server configuration issues or problems with network connectivity. Keep in mind that all communication during the Terminal Server Licensing process occurs between the client and the terminal server, and between the terminal server and the license server. The Terminal Server client never communicates directly with the license server. Although Terminal Server Licensing issues often result in error messages appearing on clients, these issues are most frequently caused by problems with the Terminal Server license server or the terminal server.

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- The terminal server cannot locate the license server.
- The remote computer disconnected the session because of an error in the licensing protocol.
- The remote session was disconnected because there were network problems during the license protocol.
- A licensing error occurred while the client was attempting to connect. (Licensing timed out).
- The remote session was disconnected because there are no Terminal Server license servers available to provide a license.
- The remote session was disconnected because there are no Terminal Server client access licenses available for this computer.
- The remote session was disconnected because the local computer's client access license could not be upgraded or renewed.
- Because of a security error, the client could not connect to the terminal server.
- Event ID 26: Your terminal services temporary client license will expire in N days.
- Event ID 1011: The terminal services client has been disconnected because its temporary license has expired.
- Event ID 1026: The terminal server could not locate a license server in the domain.
- Event ID 1028: The terminal server client has been disconnected because its license could not be renewed.

# The terminal server cannot locate the license server

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The process of locating a license server is called license server discovery. If you open Terminal Server Licensing and are prompted for the name of the license server, license server discovery is not working.

**Solution**

1. Review configuration requirements and considerations for implementing Terminal Server Licensing in different environments.
2. Verify that the client, the terminal server, and the license server can communicate.
3. Set a preferred license server.
4. Attempt again to verify whether the terminal server can discover the license server.

If the terminal server still cannot discover the license server, then perform the following steps.

1. Verify RDP-tcp connection settings.
2. Verify the license server role.
3. Verify that the Remote Registry service is started on the license server and that the startup type is set to Automatic.
4. Verify permissions on the Domain Controllers organizational unit.
5. Verify the value of the RestrictAnonymous registry key.
6. Verify that the administrative shares are shared on the license server.
7. Verify that File and Printer Sharing is bound to the network adapter and that the internal network adapter is at the top of the binding order.
8. Verify that the Terminal Server Licensing service is started on the license server and that the startup type is set to Automatic.
9. Verify that Terminal Server Licensing is correctly installed on the license server.
10. Verify that the license server is activated.
11. Remove the MSLicensing registry key on the client and verify permissions on the rebuilt key.

**Review Configuration Requirements and Considerations for Implementing Terminal Server Licensing in Different Environments**
To ensure that license server discovery works as expected, you must configure the terminal servers and license servers correctly. Keep in mind that configuration requirements vary by environment. For information about environment-specific configuration requirements and considerations, see Understanding Troubleshooting Considerations for Specific Terminal Server Licensing Environments.

**Verify that the Client, the Terminal Server, and the License Server Can Communicate**
If the terminal server and license server are installed on separate computers, ensure that there is no firewall on both servers or between them that blocks necessary ports. Terminal Server Licensing uses Remote Procedure Call (RPC) over port 135, and a dynamically assigned port above 1024. To enhance security, you can control which ports RPC is using so that your firewall router can be configured to forward traffic only to these Transmission Control Protocol (TCP) ports. For information, see How to configure RPC dynamic port allocation to work with firewalls (http://go.microsoft.com/fwlink/?LinkId=48218) on the Microsoft Web site.

Additionally, to ensure that clients can establish remote connections to terminal servers, verify that TCP port 3389 is open and listening on the terminal server and on the client. To do this, you can use commands such as Telnet (http://go.microsoft.com/fwlink/?LinkID=48891), Netstat (http://go.microsoft.com/fwlink/?LinkID=48892), or Portqry.

**To verify that the client, the terminal server, and the license server can communicate**

1. At the command prompt, run the **ping** command from each computer to each computer by using:
   - Fully qualified domain name (for example, Server1.contoso.com)
   - NetBIOS name (Server1)
   - The IP address (for example, 206.73.118.1)
2. If any of the **ping** commands fails, verify the DNS configuration on the network.

**Set a Preferred Licensing Server**
By default, terminal servers communicate with license servers in the same domain. This behavior might force them to use wide area network (WAN) connections to find a license server, even if there is a license server from another domain located within the same site. By explicitly specifying a license server, you enable the crossing of domains for license tracking and accounting purposes. For information about how to do this, see Set a preferred license server.

**Verify Whether the Terminal Server Can Discover the License Server**
To verify whether the terminal server can discover the license server, you can use Terminal Server Licensing, as described in the following procedures.

Using Terminal Server Licensing (on Windows Server 2003)

Using Terminal Server Licensing (on Windows 2000)

**Using Terminal Server Licensing (on Windows Server 2003)**
To connect to a license server, a terminal server must have the **Access this computer from the network** logon right for the target license server. Additionally, if the License Server Security Group setting in Group Policy is enabled, the terminal server computer account must be a member of this group. Enabling this Group Policy setting and applying it to your license server creates a local group called Terminal Server Computers. The license server issues licenses only to the terminal servers in this group. You must add the terminal servers for which you need to provide licenses to this group for each license server.

**To verify whether the terminal server can discover the license server (on Windows Server 2003)**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, click **Control Pane**l, double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**.

   When Terminal Server Licensing opens, it discovers all license servers in your workgroup or domain (and searches Active Directory for Enterprise License Servers) and it displays the names of those servers in the console tree. If no license servers are automatically displayed in the console tree, you are prompted to specify the name of a server as noted in the following steps.
2. On the **Action** menu, click **Connect**.
3. In **Server**, type the name of the license server to which you want to connect, and then click **OK**.

**Using Terminal Server Licensing (on Windows 2000)**
In addition to supporting clients that run Windows Server 2003, Windows 2000, and Windows XP Professional, Windows 2000 Terminal Server supports clients running the following platforms: Windows XP Home Edition, Windows XP Embedded Edition, Windows Millennium Edition, Windows 98, Windows 95, Windows NT 4.0, Windows-based Terminal devices, and Macintosh. These clients must have Terminal Server CALs available to connect to a Windows 2000 terminal server.

If you have clients running Windows 2000 or Windows XP Professional, the license server issues a "free" Terminal Services CAL from its built-in pool to enable these clients to access the Windows 2000 terminal server. The use of this license is permitted under the Windows 2000 Server EULA. To issue these licenses, however, the license server must first be activated.

For Windows Server 2003 terminal servers, there is no built-in pool of free licenses. You must install the appropriate number of CALs on the license server to enable all clients to connect to these terminal servers.

**To verify whether the terminal server can discover the license server (on Windows 2000)**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Terminal Services Licensing**.

2. Navigate to **All Servers**, and then click the name of the terminal server to which you want to connect.

   A list of installed CALs appears in the details pane. Verify that **Windows 2000 Terminal Services Client Access License** appears in the list.

3. If it does not appear, purchase and install the appropriate number of CALs to support your clients.

**Verify RDP-tcp Connection Settings**

Use Group Policy or Terminal Services Configuration to verify that RDP-tcp connection settings are configured as follows:

- The RDP-tcp connection is enabled.

- The **Maximum connections** setting on the **Network Adapter** tab of the **RDP-tcp Properties** dialog box is set to **Unlimited**.

- Verify whether the level encryption being used for the RDP-TCP connection is set to **High**. If the encryption level is set to **High**, keep in mind that this level encrypts data sent from client to server and from server to client by using strong 128-bit encryption. Clients that do not support this level of encryption cannot connect to a terminal server.

- Verify that the user attempting to log on to the terminal server over the RDP-tcp connection has the appropriate rights and permissions. Users must either be members of the Remote Desktop Users group, or you must assign the equivalent rights and permissions manually (users must have the Allow log on through Terminal Services (http://go.microsoft.com/fwlink/?LinkID=48894) right and User Access permissions). For more information, see Enabling users to connect remotely to the server (http://go.microsoft.com/fwlink/?LinkID=48887). If users are running the Citrix ICA client, they must have the appropriate permissions for the ICA-TCP connection.

For instructions on how to verify and modify RDP-tcp connection settings, see Configure Terminal Services Connections (http://go.microsoft.com/fwlink/?LinkId=48219).

**Verify the License Server Role**

**Caution** Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**To To verify the license server role**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

2. Locate, and then click, the following key in the registry:

   **HKLM\System\CurrentControlSet\Services\TermServLicensing\Parameters\Role**

   Where

   **0** = Domain license server

   **1** = Enterprise license server

**Verify that the Remote Registry Service is Started on the License Server and that the Startup Type is Set to Automatic**

- You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

If you enable or disable a service and you encounter a problem starting the computer, you might be able to start the computer in Safe Mode. Then you can change the service configuration or restore the default configuration.

**Important** If you stop, start, or restart a service, any dependent services are also affected.

**To verify that the Remote Registry service is enabled on the license server and that the startup type is set to**

**Automatic**

1. On the license server, open **Services**. To open Services, click **Start**, click Control Panel, click **Performance and Maintenance**, click **Administrative Tools**, and then double-click **Services**.
2. In the list of services, right-click **Remote Registry**, and then click **Properties**.
3. On the **General** tab, verify that the service status is Started and that the startup type is Automatic.
4. If the status is not Started, click **Start** to start the service. If the startup type is not Automatic, click **Automatic** to ensure that the service will restart when the license server is restarted.

**Verify Permissions on the Domain Controllers OU**

For license server discovery to work in a Windows Server 2003 domain with Windows 2000 terminal servers and Windows 2000 license servers, the following permissions must exist on the Domain Controllers OU.

- System = Full Control
- Authenticated Users = Read
- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as (http://go.microsoft.com/fwlink/?LinkID=48886) to perform this procedure.

**To verify permissions on the Domain Controllers OU**

1. Open Active Directory Users and Computers. To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. On the **View** menu, select **Advanced Features**.
3. Right-click the **Domain Controllers** OU, and then click **Properties**.
4. On the **Security** tab, click **Advanced** to view the permission entries that exist for the object.
5. In the list, click **Authenticated Users**.
6. In the **Permissions** box, make sure that the **Allow** check box is selected for **Read.**
7. In the list, click **System**.
8. In the **Permissions** box, make sure that the **Allow** check box is selected for Full Control.

**Verify the Value of the RestrictAnonymous Registry Key**

If you are using Windows 2000 servers, verify that the **RestrictAnonymous** registry key value on the license server is set to**0**or **1**. In this scenario, if this registry key value is set to**2**, then the license server cannot issue CALS. When the**RestrictAnonymous** registry value is set to **2**, the access token built for non-authenticated users does not include the Everyone group, and because of this, the access token no longer has access to resources that grant permissions to the Everyone group.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To verify the value of the RestrictAnonymous registry key**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\RestrictAnonymous**

3. Verify the value of the **RestrictAnonymous**registry key.

The three valid registry key values for **RestrictAnonymous** are equivalent to the following security settings in Local Security Policy:

**0** = None (rely on default permissions)

**1** = Do not allow enumeration of SAM accounts and shares

**2** = No access without explicit anonymous permissions

If the license server is a member of an Active Directory domain and a conflicting security setting is configured for the license server in Group Policy, the Group Policy setting overrides the local security setting.

4. If the value of the registry key is set to **2**, then set it to **1** or **0**.

   Also, verify that the equivalent value (**No access without explicit anonymous permissions**) is not enabled by Group Policy. To do this, open Local Security Policy, navigate to **Security Settings\Local Policies\Security Options\Additional restrictions for anonymous connections**, and then verify whether **No access without explicit anonymous permissions** is enabled. If it is, disable it. To open Local Security Policy, click **Start**, point to **Settings**, Control Panel, click **Administrative Tools**, and then click **Local Security Policy**.

5. Restart the server.

   In Windows Server 2003, if you need to prohibit anonymous users from being granted the same access that is granted to members of the Everyone group, use the new **Everyone Network access: Let Everyone permissions apply to anonymous users** setting in Local Security Policies.

#### Verify that the Administrative Shares are Shared on the License Server

**To verify that the administrative shares are shared on the license server**

1. At the command prompt, type **net share**, and then press ENTER.

2. Verify that the default shares, such as C$, Admin$, and IPC$, are returned.

   If you perform this procedure and the default administrative shares are not returned, verify that the Server service is started, that File and Print Sharing is enabled, and that the license server does not have a virus. Also, see HOW TO: Restore Administrative Shares That Have Been Deleted (http://go.microsoft.com/fwlink/?LinkId=48223) on the Microsoft Web site.

#### Verify that File and Printer Sharing is Bound to the Network Adapter and that the Internal Network Adapter is at the Top of the Binding Order

**To verify that File and Printer Sharing is bound to the internal network adapter and that the internal network adapter is at the top of the binding order**

1. Open Network and Dial-up Connections. To open Network and Dial-up Connections, click **Start**, point to **Settings**, and then click **Network and Dial-up Connections**.

2. Click the connection that you want to verify, and on the **Advanced**menu, click **Advanced Settings**.

3. On the **Adapters and Bindings** tab, in **Bindings for *AdapterName***, verify that the **File and Printer Sharing** check box is selected. If the check box is not selected, select it.

   To modify the protocol bindings order, you must be logged on as a member of the Administrators group.

4. Also in **Bindings for *AdapterName***, verify that the internal adapter is at the top of the list. If it is not at the top of the list, click the up and down arrows to move the internal adapter to the top of the list.

#### Verify that the Terminal Server Licensing Service is Started and that the Startup Type is Set to Automatic

For step-by-step instructions, see Verify that the Terminal Server Licensing service is started and the startup type is set to Automatic.

#### Verify that Terminal Server Licensing is Correctly Installed on the License Server

For step-by-step instructions, see Verify that Terminal Server Licensing is correctly installed on the license server.

#### Verify that the License Server is Activated

A license server that has been installed but not activated only issues temporary licenses. These temporary licenses allow clients to connect to the terminal server for 90 days.

**To verify that a license server is activated**

1. Open Terminal Server Licensing.
2. In the console tree, click the license server for which you want to verify the activation status.
3. In the details pane, verify that activation status is Activated.
4. If the status is Not Activated, right-click the server name, click **Activate Server**, and then follow the instructions in the wizard.

**Remove the MSLicensing Registry Key on the Client and Verify Permissions on the Rebuilt Key**

If all of the previous troubleshooting procedures fail, create a backup of the **MSLicensing**registry key and its subkeys on the client, and then remove the original key and subkeys.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To remove the MSLicensing registry key on the client and verify permissions on the rebuilt key**

1. On the client, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**
3. On the **Registry** menu, click **Export Registry File**.
4. In the **File name** box, type **mslicensingbackup**, and then click **Save**.
5. If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.
6. On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing**registry subkey.
7. Close Registry Editor, and then restart the computer (when the client is restarted, the missing registry key is rebuilt).
8. On the client, open Registry Editor.
9. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**
10. On the **Edit** menu, click **Permissions**. Users must have at least Read permissions.

# The remote computer disconnected the session because of an error in the licensing protocol

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

The terminal server might not be able to locate the license server.

**Solution**

To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# The remote session was disconnected because there were network problems during the license protocol

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
Perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# A licensing error occurred while the client was attempting to connect. (Licensing timed out)

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
If you are using Internet Protocol security (IPsec) to help protect traffic over TCP between clients and terminal servers, then packet fragmentation might occur. As a result, some packets might not reach their destinations, and client connections to terminal servers might fail.

**Solution**
Configure IPsec to help protect traffic over UDP rather than over TCP, as described in Define IPSec Policies (http://go.microsoft.com/fwlink/?LinkID=48889).

**Cause**
If there is a firewall between the clients and terminal servers, packets might be fragmented due to the size of the maximum transmission unit (MTU) that can be transmitted over the network. As a result, the packet fragments might be dropped or received out of order.

**Solution**
Verify that the maximum transmission unit (MTU) that can be transmitted over the network is sufficient by running the **ping** command with the **-f** (don't fragment) parameter as follows:

**ping -l 1472 -f <Destination_IP_Address>**

If the MTU is not sufficient, you can change the MTU on the router or you can configure the computers to use a smaller MTU by modifying the registry. You can configure the computers to use a smaller MTU by creating a new MTU registry key entry and setting the value to 576 (or a larger value if appropriate, if the MTU is larger) or by creating a new **EnablePTMUDiscovery** registry key entry and setting the value to **0**. However, note that Windows Server 2003 And Windows 2000 TCP/IP use PMTU detection by default and query the NIC driver to determine the local MTU that is supported. Therefore, modifying the MTU parameter is generally not necessary and might result in reduced performance.

| ⚠Caution |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**Create a new MTU registry key and set it to 576 (or a larger value)**

1. Open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:
   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Tcpip\Parameters\Interfaces\<Interface_GUID>**
3. Create a new DWORD registry entry called **MTU**.
4. Set the value to **576** (or a larger value, if appropriate).

**Create an EnablePMTUDiscovery registry key and set it to 0**

1. Open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:
   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Tcpip\Parameters**
3. Create a new DWORD registry entry called **EnablePMTUDiscovery**.
4. Set the value to **0**.

# The remote session was disconnected because there are no Terminal Server license servers available to provide a license

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
Perform the troubleshooting procedures described in The terminal server cannot locate the license server.

**Cause**
The client might have exceeded its Terminal Server Licensing grace period (http://go.microsoft.com/fwlink/?LinkID=48895), and a license server has not yet been installed or activated to issue the client a client access license (CAL). After a temporary license expires, a client can only connect to a terminal server if the license server can issue a permanent CAL.

**Solution**
Install Terminal Server Licensing, activate the license server, then purchase and install a sufficient number of CALs to support the clients in your organization. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886) to perform this procedure.

| **Note** |
| --- |
| If you are installing an Enterprise License server and your environment includes multiple trusted Active Directory sites, each of which hosts a terminal server, you can use a script to publish a single license server across all of these sites. Doing this can greatly simplify deployment because it eliminates the need to deploy a separate license server in each site, and it eliminates the need to distribute CALs to license servers across multiple sites. For a sample script that you can use to accomplish this task, see the Microsoft Script Center (http://go.microsoft.com/fwlink/?LinkID=48230) on the Microsoft Web site. Note that this sample script is not supported under any Microsoft standard support program or service. |

**To install Terminal Server Licensing**

1. Open Add/Remove Programs in **Control Panel**.
2. Double-click **Add/Remove Programs**.
3. Click **Add/Remove Windows Components**.
4. In Terminal Server Licensing Setup, do one of the following:
   - Click **Your entire enterprise** to choose an Enterprise license server. You can only install an Enterprise license server on a domain controller or a member server in a domain (if the member server is running Windows Server 2003), not on a stand-alone server. This role is published to Active Directory. If you are installing an Enterprise License Server, you must meet one of the following conditions: 1) You must be a member of the Enterprise Admins group in Active Directory or 2) You must have the right to create the TS-Enterprise-License-Server object in the same site in which the license server will reside in Active Directory.
   - Click **Your domain or workgroup** to choose a Domain license server. If you select this option, the computer on which you install the license server does not have to be a domain controller, if the computer is running Windows Server 2003. However, if the computer is running Windows 2000, the computer on which you install the license server must be a domain controller or a stand-alone server in a workgroup. If the computer on which you plan to install the license server is in a workgroup, it can only be automatically discovered by terminal servers on the same subnet. If you are installing a Domain license server, you must be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
5. Provide the file system location where the license server database should be installed on the Terminal Server license server, click **Next**, and then click **Finish**.

   The default location for the license server database is systemroot\System32\LServer.

You can activate a Terminal Server license server by using one of three methods: Automatic, Web Browser, or Telephone. It is recommended that you activate a license server automatically, as described in the following procedure.

| **Note** |
| --- |
| To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886). |

**To activate a license server automatically.**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, point to **Control Panel**, **Administrative Tools**, and then click **Terminal Server Licensing**.
2. In the console tree, right-click the license server that you want to activate, click **Activate Server**, and then follow the instructions in the wizard.
3. In the **Activation** method list, select **Automatic connection (recommended)**, and then click **Next**.
4. Follow the instructions in the wizard.
5. If necessary, at a later time you can change any license server properties, such as activation method and company information, that you set during the activation process.

Then, Purchase CALs as required and Install CALs automatically.

# The remote session was disconnected because there are no Terminal Server client access licenses available for this computer

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
The license server might not have any remaining Per Device CALs to issue.

**Solution**

1. Use Terminal Server Licensing to Verify that the license server has a sufficient number of CALs for clients requiring remote connections.

2. If the license server does not have a sufficient number of permanent CALs, Purchase CALs as needed, and then Install CALs automatically, as needed.

**Cause**
In the following two cases, either no licenses, or temporary licenses that cannot be upgraded, are issued from the available pool of client access licenses (CALs) on a license server:

1. If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per User, then no licenses are issued from the available pool of licenses, because Per User licensing is not managed.

2. If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

   Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**
Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode.

- Change the Terminal Server Licensing mode.

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# The remote session was disconnected because the local computer's client access license could not be upgraded or renewed

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After a temporary license expires, a client can only connect to a terminal server if the license server can issue a permanent CAL, or if the terminal server is still within its licensing grace period.

**Note**

If you are running Terminal Server Licensing in a Windows 2000 Service Pack 3 (SP3) or later environment, the client must connect to a terminal server and authenticate twice to obtain a permanent license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and is not yet issued, the terminal server issues the client a permanent, Per Device CAL.

**Cause**

If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**

Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

**Cause**

If you are running Terminal Server Licensing in a Windows 2000 (SP3) or earlier environment, expired temporary licenses might not be upgraded to permanent CALs.

**Solution**

1. On the terminal server and license server, install Service Pack 4 (SP4). To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkID=48213) on the Microsoft Web site.

2. Use Terminal Server Licensing to Verify that the license server has a sufficient number of CALs for clients requiring remote connections.

3. If the license server does not have a sufficient number of permanent CALs, Purchase CALs, and then Install CALs automatically.

# Because of a security error, the client could not connect to the terminal server

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

If you upgraded a Windows NT domain to Windows 2000 or Windows Server 2003, then the certificate on the terminal server might be corrupted. As a result, Windows 2000 Terminal Services clients might be repeatedly denied access to the terminal server.

**Solution**

On each terminal server, back up and then delete the **Certificate**, **X509 Certificate**, and**X509 Certificate ID** registry subkeys. Then, on each client, back up and then delete the **MSLicensing** registry key.

**Back Up and Then Delete the Certificate, X509 Certificate, and X509 Certificate ID Registry Subkeys**

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To back up and then delete the Certificate, X509 Certificate, and X509 Certificate ID registry subkeys**

1. On each terminal server, create a backup of the registry.
2. Navigate to the following registry subkey: **HKLM\SYSTEM\CurrentControlSet\Services\TermServices\Parameters.**
3. On the **Registry** menu, click **Export Registry File**.
4. In the **File name** box, type **exported-parameters**, and then click **Save**.
5. If you need to restore this registry subkey in the future, double-click **exported-parameters.reg**.
6. Under the **Parameters r**egistry subkey, right-click each of the following values:
   - **Certificate**
   - **X509 Certificate**
   - **X509 Certificate ID**
7. Click **Delete**, and then click **Yes** to confirm the deletion.
8. Close Registry Editor, and then restart each terminal server.

**Back Up and Then Delete the MSLicensing Registry Key**

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To back up and then delete the MSLicensing registry key**

1. On the client, navigate to the following registry subkey:
   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing.**
2. Click **MSLicensing**.
3. On the **Registry** menu, click **Export Registry File**.
4. In the **File name** box, type **mslicensingbackup**, and then click **Save**.

5. If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.
6. On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing** registry subkey.
7. Close Registry Editor, and then restart the client.

**Solution**

If the client still cannot connect to the terminal server, then perform the following procedures.

1. On the client, back up and then delete the MSLicensing registry key and its subkeys.
2. On each terminal server, back up and then delete the Certificate, X509 Certificate, and X509 Certificate ID registry subkeys.
3. Deactivate the license server.
4. Reactivate the license server by using the Telephone connection method in the Terminal Server License Server Wizard.

**Deactivate the License Server**

You might need to deactivate a Terminal Server license server when the certificate of the server has expired or becomes corrupted, or when the server is being redeployed. You will be prompted to reactivate the Terminal Server license server when its registration has expired. When you deactivate a Terminal Server license server, you will not be able to license additional clients from this server until it is reactivated.

You can deactivate a server by using doing one of the following:

1. Using the Automatic method
2. Using the Telephone method

- You cannot deactivate a Terminal Server license server by using the Web browser connection method.

**Using the Automatic method**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**To deactivate a license server using the Automatic method**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**.
2. In the console tree, right-click the Terminal Server license server you want to deactivate, point to **Advanced**, and then click **Deactivate Server**. The Terminal Server License Server Wizard starts.
3. In **Required Information**, confirm that your name, phone number, company, and country or region are correct, and then click **Next**.
4. Your request to deactivate the Terminal Server license server is sent to the Microsoft Clearinghouse for processing.
5. Click **Finish**.

**Using the telephone method**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**To deactivate a license server using the Telephone method**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, click **Control Panel**, double-click

**Administrative Tools**, and then double-click **Terminal Server Licensing**.

2. In the console tree, right-click the Terminal Server license server you want to deactivate, point to **Advanced**, and then click **Deactivate Server**. The Terminal Server License Server Wizard starts.
3. Select **Telephone**, and then click **Next**.
4. Specify your location, and then click **Next**.
5. Call the telephone number displayed in the wizard, and give the Customer Support representative the Product ID that is displayed below the telephone number.
6. In the boxes in the wizard, type the 35-digit confirmation code provided by the Customer Support representative, then click **Next**.
7. Click **Finish**.

**Reactivate the License Server**

When you activate Terminal Server Licensing by using the Telephone option, Terminal Server Licensing uses a different certificate. You will receive a telephone call from the Microsoft Clearinghouse confirming that the license server has been reactivated. When a license server is reactivated, a record of your licenses is retained. Licenses that were already issued remain valid, and any un-issued licenses are also valid, but must be reissued through the Microsoft Clearinghouse.

You must reactivate a license server when its registration has expired.

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**To reactivate a license server**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**.
2. In the console tree, right-click the Terminal Server license server you want to reactivate, point to **Advanced**, and then click **Reactivate Server**. The Terminal Server License Server Wizard starts.
3. In **Information Needed**, confirm that your name, phone number, and e-mail address are correct.
4. In **Reason**, select the appropriate reason for reactivating the license server, and click **Finish**.
5. Your request to reactivate the license server is sent to the Microsoft Clearinghouse for processing.

**Cause**

Windows XP-based clients might be attempting to connect to a Windows 2000 terminal server in a low-bandwidth network environment, in which client sessions are encrypted. In this case, IP packet fragmentation can cause encrypted frames that are sent by a client to be decrypted incorrectly.

**Solution**

- On the terminal server, install Windows 2000 Service Pack 4 (SP4). To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkID=28213) on the Microsoft Web site .

**Cause**

The Remote Desktop Protocol (RDP) encryption settings on the terminal server and the client might not be compatible. For example, the terminal server might be running 128-bit encryption with an encryption level set to **High.** When this occurs, "Event ID 50, Source: TermDD" appears in the system event log on the terminal server.

**Solution**

Change the RDP encryption level on the terminal server to **Medium** or **Low** (if the terminal server is running Windows 2000) or to **Client Compatible** or **Low** (if the terminal server is running Windows Server 2003).

You can change the RDP encryption level on the terminal server by doing one of the following:

- Using Terminal Services Configuration (Windows 2000)

- Using Group Policy (Windows Server 2003)
- Using Terminal Services Configuration (Windows Server 2003)

  When you change the encryption level, the new encryption level takes effect the next time a user logs on. If you require multiple levels of encryption on one server, install multiple network adapters and configure each adapter separately.

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**Using Terminal Services Configuration (Windows 2000)**

**To change the RDP encryption level Using Terminal Services Configuration (Windows 2000)**

1. Open Terminal Services Configuration. To open Terminal Services Configuration, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Terminal Services Configuration**.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection that you want to modify, and then click **Properties.**
4. On the **General** tab, in **Encryption level**, click **Low** or **Medium**:
   - The **Low** setting encrypts data sent from the client to the server by using either 40-bit or 56-bit encryption. A Windows 2000 terminal server uses 56-bit encryption when Windows 2000 clients connect to it and 40-bit encryption when earlier versions of the client connect to it.
   - The **Medium** level encrypts data sent from client to server and from server to client by using either 40-bit encryption or 56-bit encryption. A Windows 2000 terminal server uses 56-bit encryption when Windows 2000 clients connect to it and 40-bit encryption when earlier versions of the client connect.

**Using Group Policy (Windows Server 2003)**

Any encryption level settings that you configure in Group Policy override the configuration that you set by using the Terminal Services Configuration tool. Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on as an administrator. Then, you must open Group Policy by using the Active Directory Users and Computers snap-in.

| **Important** |
| --- |
| You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. |

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**To change the RDP encryption level using Group Policy (Windows Server 2003)**

1. Open Group Policy.
2. In Computer Configuration, Administrative Templates, Windows Components, Terminal Services, Encryption and Security, double-click the **Set client connection encryption level setting**, and verify that the setting is set to **Enabled**.
3. In the **Encryption Level** list, click **Client Compatible** or **Low Level**, and then click **OK**.
   - The **Client Compatible** setting encrypts data sent between the client and the server at the maximum key strength supported by the client.
   - The **Low** setting encrypts data sent from the client to the server using 56-bit encryption.

**Using Terminal Services Configuration (Windows Server 2003)**
Any encryption level settings that you configure in Group Policy override the configuration that you set by using the Terminal Services Configuration tool.

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886).

**To change the RDP encryption level using Terminal Services Configuration (Windows Server 2003)**

1. Open Terminal Services Configuration. To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection you want to modify, and then click **Properties**.
4. On the **General** tab, in **Encryption level**, click **Low** or **Client Compatible**.
   - The **Low** setting encrypts data sent from the client to the server using 56-bit encryption.
   - The **Client Compatible** setting encrypts data sent between the client and the server at the maximum key strength supported by the client.

Windows XP Clients Cannot Connect to a Windows 2000 Terminal Services Server

# Event ID 26: Your terminal services temporary client license will expire in N days

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**
Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# Event ID 1011: The terminal services client has been disconnected because its temporary license has expired

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**
Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# Event ID 1026: The terminal server could not locate a license server in the domain

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

The process of locating a license server is called license server discovery. If license server discovery is not functioning correctly, Event ID 1026, Source:TermServ, might appear in the application event log, with the following message: "The terminal server could not locate a license server in the <domain> domain. Confirm that all license servers on the network are registered in WINS/DNS, accepting network requests, and the Terminal Server Licensing Service is running."

**Solution**

Set a preferred license server.

If your terminal server is running Windows Server 2003 with Service Pack 1 (SP1), you can do this by using Group Policy settings or Terminal Services Configuration, or you can use the registry or a Windows Management Instrumentation (WMI) script. If your terminal server is running Windows 2000 or Windows Server 2003 without SP1, you must use the registry or a WMI script. For three scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see Preferred License Server WMI Scripts (http://go.microsoft.com/fwlink/?LinkID=26220) in Windows Server 2003 Terminal Server Licensing on the Microsoft Web site.

**Note**

The license servers and the terminal servers must either be in the same domain or in domains that trust each other.

**Solution**

If explicitly specifying a license server does not resolve this issue, perform additional troubleshooting steps, as described in The terminal server cannot locate the license server.

# Event ID 1028: The terminal server client has been disconnected because its license could not be renewed

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are running a Windows Server 2003 terminal server, after you use the Windows Components Wizard in Add or Remove Programs to add or to remove a Windows component, an invalid registry value might be set in the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TerminalServer\Licensing Core\PolicyAcOn** subkey on the terminal server. This invalid value might may unexpectedly change the Terminal Server Licensing mode and cause the terminal server to obtain only temporary licenses.

**Cause**

This problem might occur because the value of the **PolicyAcOn** registry entry changes from either **2** (the correct registry value for the Per Device licensing mode) or **4** (the correct registry value for the Per User licensing mode) to an invalid value of **0**. This behavior causes the terminal server to attempt to obtain temporary Per Device licenses. In this case, if you view Terminal Services Configuration to verify the licensing mode, the licensing mode appears as Per Device. Therefore, to verify whether this problem is causing the client disconnection, you must verify the value of the **PolicyAcOn** registry entry.

**Solution**

To resolve this problem contact Microsoft Product Support Services to obtain the hotfix described in Knowledge Base article 834651, Terminal Services licensing mode changes from Per User or from Per Device changes from Per User or from Per Device to an invalid value after you add or remove a Windows component, (http://go.microsoft.com/fwlink/?LinkID=48173) on the Microsoft Web site. This hotfix is applied to the terminal server. For information about how to contact Microsoft Product Support Services, see Help and Support (http://go.microsoft.com/fwlink/?LinkID=48149) on the Microsoft Web site.

# Fixing CAL Issuance and Upgrade Problems

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a description of client access license (CAL) issuance and upgrade problems that you might experience when Terminal Server Licensing is enabled.

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- The terminal server cannot locate the license server.
- The remote session was disconnected because there are no Terminal Server license servers available to provide a license.
- The remote session was disconnected because there are no Terminal Server client access licenses available for this computer.
- The remote session was disconnected because the local computer's client access license could not be upgraded or renewed.
- No licenses are being issued from the available pool of licenses.
- Event ID 26: Your terminal services temporary client license will expire in N days.
- Event ID 1011: The terminal services client has been disconnected because its temporary license has expired.
- Event ID 1026: The terminal server could not locate a license server in the domain.
- Event ID 1028: The terminal server client has been disconnected because its license could not be renewed.

# The terminal server cannot locate the license server

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The process of locating a license server is called license server discovery. If you open Terminal Server Licensing and are prompted for the name of the license server, license server discovery is not working.

**Solution**

1. Review configuration requirements and considerations for implementing Terminal Server Licensing in different environments.
2. Verify that the client, the terminal server, and the license server can communicate.
3. Set a preferred license server.
4. Attempt again to verify whether the terminal server can discover the license server.

If the terminal server still cannot discover the license server, then perform the following steps.

1. Verify RDP-tcp connection settings.
2. Verify the license server role.
3. Verify that the Remote Registry service is started on the license server and that the startup type is set to Automatic.
4. Verify permissions on the Domain Controllers organizational unit.
5. Verify the value of the RestrictAnonymous registry key.
6. Verify that the administrative shares are shared on the license server.
7. Verify that File and Printer Sharing is bound to the network adapter and that the internal network adapter is at the top of the binding order.
8. Verify that the Terminal Server Licensing service is started on the license server and that the startup type is set to Automatic.
9. Verify that Terminal Server Licensing is correctly installed on the license server.
10. Verify that the license server is activated.
11. Remove the MSLicensing registry key on the client and verify permissions on the rebuilt key.

**Review Configuration Requirements and Considerations for Implementing Terminal Server Licensing in Different Environments**
To ensure that license server discovery works as expected, you must configure the terminal servers and license servers correctly. Keep in mind that configuration requirements vary by environment. For information about environment-specific configuration requirements and considerations, see Understanding Troubleshooting Considerations for Specific Terminal Server Licensing Environments.

**Verify that the Client, the Terminal Server, and the License Server Can Communicate**
If the terminal server and license server are installed on separate computers, ensure that there is no firewall on both servers or between them that blocks necessary ports. Terminal Server Licensing uses Remote Procedure Call (RPC) over port 135, and a dynamically assigned port above 1024. To enhance security, you can control which ports RPC is using so that your firewall router can be configured to forward traffic only to these Transmission Control Protocol (TCP) ports. For information, see How to configure RPC dynamic port allocation to work with firewalls (http://go.microsoft.com/fwlink/?LinkId=48218) on the Microsoft Web site.

Additionally, to ensure that clients can establish remote connections to terminal servers, verify that TCP port 3389 is open and listening on the terminal server and on the client. To do this, you can use commands such as Telnet (http://go.microsoft.com/fwlink/?LinkID=48891), Netstat (http://go.microsoft.com/fwlink/?LinkID=48892), or Portqry.

**To verify that the client, the terminal server, and the license server can communicate**

1. At the command prompt, run the **ping** command from each computer to each computer by using:
   - Fully qualified domain name (for example, Server1.contoso.com)
   - NetBIOS name (Server1)
   - The IP address (for example, 206.73.118.1)
2. If any of the **ping** commands fails, verify the DNS configuration on the network.

**Set a Preferred Licensing Server**
By default, terminal servers communicate with license servers in the same domain. This behavior might force them to use wide area network (WAN) connections to find a license server, even if there is a license server from another domain located within the same site. By explicitly specifying a license server, you enable the crossing of domains for license tracking and accounting purposes. For information about how to do this, see Set a preferred license server.

**Verify Whether the Terminal Server Can Discover the License Server**
To verify whether the terminal server can discover the license server, you can use Terminal Server Licensing, as described in the following procedures.

Using Terminal Server Licensing (on Windows Server 2003)

Using Terminal Server Licensing (on Windows 2000)

**Using Terminal Server Licensing (on Windows Server 2003)**
To connect to a license server, a terminal server must have the **Access this computer from the network** logon right for the target license server. Additionally, if the License Server Security Group setting in Group Policy is enabled, the terminal server computer account must be a member of this group. Enabling this Group Policy setting and applying it to your license server creates a local group called Terminal Server Computers. The license server issues licenses only to the terminal servers in this group. You must add the terminal servers for which you need to provide licenses to this group for each license server.

**To verify whether the terminal server can discover the license server (on Windows Server 2003)**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, click **Control Pane**l, double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**.

   When Terminal Server Licensing opens, it discovers all license servers in your workgroup or domain (and searches Active Directory for Enterprise License Servers) and it displays the names of those servers in the console tree. If no license servers are automatically displayed in the console tree, you are prompted to specify the name of a server as noted in the following steps.
2. On the **Action** menu, click **Connect**.
3. In **Server**, type the name of the license server to which you want to connect, and then click **OK**.

**Using Terminal Server Licensing (on Windows 2000)**
In addition to supporting clients that run Windows Server 2003, Windows 2000, and Windows XP Professional, Windows 2000 Terminal Server supports clients running the following platforms: Windows XP Home Edition, Windows XP Embedded Edition, Windows Millennium Edition, Windows 98, Windows 95, Windows NT 4.0, Windows-based Terminal devices, and Macintosh. These clients must have Terminal Server CALs available to connect to a Windows 2000 terminal server.

If you have clients running Windows 2000 or Windows XP Professional, the license server issues a "free" Terminal Services CAL from its built-in pool to enable these clients to access the Windows 2000 terminal server. The use of this license is permitted under the Windows 2000 Server EULA. To issue these licenses, however, the license server must first be activated.

For Windows Server 2003 terminal servers, there is no built-in pool of free licenses. You must install the appropriate number of CALs on the license server to enable all clients to connect to these terminal servers.

**To verify whether the terminal server can discover the license server (on Windows 2000)**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Terminal Services Licensing**.

2. Navigate to **All Servers**, and then click the name of the terminal server to which you want to connect.

   A list of installed CALs appears in the details pane. Verify that **Windows 2000 Terminal Services Client Access License** appears in the list.

3. If it does not appear, purchase and install the appropriate number of CALs to support your clients.

**Verify RDP-tcp Connection Settings**

Use Group Policy or Terminal Services Configuration to verify that RDP-tcp connection settings are configured as follows:

- The RDP-tcp connection is enabled.

- The **Maximum connections** setting on the **Network Adapter** tab of the **RDP-tcp Properties** dialog box is set to **Unlimited**.

- Verify whether the level encryption being used for the RDP-TCP connection is set to **High**. If the encryption level is set to **High**, keep in mind that this level encrypts data sent from client to server and from server to client by using strong 128-bit encryption. Clients that do not support this level of encryption cannot connect to a terminal server.

- Verify that the user attempting to log on to the terminal server over the RDP-tcp connection has the appropriate rights and permissions. Users must either be members of the Remote Desktop Users group, or you must assign the equivalent rights and permissions manually (users must have the Allow log on through Terminal Services (http://go.microsoft.com/fwlink/?LinkID=48894) right and User Access permissions). For more information, see Enabling users to connect remotely to the server (http://go.microsoft.com/fwlink/?LinkID=48887). If users are running the Citrix ICA client, they must have the appropriate permissions for the ICA-TCP connection.

For instructions on how to verify and modify RDP-tcp connection settings, see Configure Terminal Services Connections (http://go.microsoft.com/fwlink/?LinkId=48219).

**Verify the License Server Role**

**Caution** Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**To To verify the license server role**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

2. Locate, and then click, the following key in the registry:

   **HKLM\System\CurrentControlSet\Services\TermServLicensing\Parameters\Role**

   Where

   **0** = Domain license server

   **1** = Enterprise license server

**Verify that the Remote Registry Service is Started on the License Server and that the Startup Type is Set to Automatic**

- You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

If you enable or disable a service and you encounter a problem starting the computer, you might be able to start the computer in Safe Mode. Then you can change the service configuration or restore the default configuration.

**Important** If you stop, start, or restart a service, any dependent services are also affected.

**To verify that the Remote Registry service is enabled on the license server and that the startup type is set to**

**Automatic**

1. On the license server, open **Services**. To open Services, click **Start**, click Control Panel, click **Performance and Maintenance**, click **Administrative Tools**, and then double-click **Services**.
2. In the list of services, right-click **Remote Registry**, and then click **Properties**.
3. On the **General** tab, verify that the service status is Started and that the startup type is Automatic.
4. If the status is not Started, click **Start** to start the service. If the startup type is not Automatic, click **Automatic** to ensure that the service will restart when the license server is restarted.

**Verify Permissions on the Domain Controllers OU**

For license server discovery to work in a Windows Server 2003 domain with Windows 2000 terminal servers and Windows 2000 license servers, the following permissions must exist on the Domain Controllers OU.

- System = Full Control
- Authenticated Users = Read
- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as (http://go.microsoft.com/fwlink/?LinkID=48886) to perform this procedure.

**To verify permissions on the Domain Controllers OU**

1. Open Active Directory Users and Computers. To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
2. On the **View** menu, select **Advanced Features**.
3. Right-click the **Domain Controllers** OU, and then click **Properties**.
4. On the **Security** tab, click **Advanced** to view the permission entries that exist for the object.
5. In the list, click **Authenticated Users**.
6. In the **Permissions** box, make sure that the **Allow** check box is selected for **Read.**
7. In the list, click **System**.
8. In the **Permissions** box, make sure that the **Allow** check box is selected for Full Control.

**Verify the Value of the RestrictAnonymous Registry Key**

If you are using Windows 2000 servers, verify that the **RestrictAnonymous** registry key value on the license server is set to**0**or **1**. In this scenario, if this registry key value is set to**2**, then the license server cannot issue CALS. When the**RestrictAnonymous** registry value is set to **2**, the access token built for non-authenticated users does not include the Everyone group, and because of this, the access token no longer has access to resources that grant permissions to the Everyone group.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To verify the value of the RestrictAnonymous registry key**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\RestrictAnonymous**

3. Verify the value of the **RestrictAnonymous**registry key.

The three valid registry key values for **RestrictAnonymous** are equivalent to the following security settings in Local Security Policy:

**0** = None (rely on default permissions)

**1** = Do not allow enumeration of SAM accounts and shares

**2** = No access without explicit anonymous permissions

If the license server is a member of an Active Directory domain and a conflicting security setting is configured for the license server in Group Policy, the Group Policy setting overrides the local security setting.

4. If the value of the registry key is set to **2**, then set it to **1** or **0**.

   Also, verify that the equivalent value (**No access without explicit anonymous permissions**) is not enabled by Group Policy. To do this, open Local Security Policy, navigate to **Security Settings\Local Policies\Security Options\Additional restrictions for anonymous connections**, and then verify whether **No access without explicit anonymous permissions** is enabled. If it is, disable it. To open Local Security Policy, click **Start**, point to **Settings**, Control Panel, click **Administrative Tools**, and then click **Local Security Policy**.

5. Restart the server.

   In Windows Server 2003, if you need to prohibit anonymous users from being granted the same access that is granted to members of the Everyone group, use the new **Everyone Network access: Let Everyone permissions apply to anonymous users** setting in Local Security Policies.

#### Verify that the Administrative Shares are Shared on the License Server

**To verify that the administrative shares are shared on the license server**

1. At the command prompt, type **net share**, and then press ENTER.

2. Verify that the default shares, such as C$, Admin$, and IPC$, are returned.

   If you perform this procedure and the default administrative shares are not returned, verify that the Server service is started, that File and Print Sharing is enabled, and that the license server does not have a virus. Also, see HOW TO: Restore Administrative Shares That Have Been Deleted (http://go.microsoft.com/fwlink/?LinkId=48223) on the Microsoft Web site.

#### Verify that File and Printer Sharing is Bound to the Network Adapter and that the Internal Network Adapter is at the Top of the Binding Order

**To verify that File and Printer Sharing is bound to the internal network adapter and that the internal network adapter is at the top of the binding order**

1. Open Network and Dial-up Connections. To open Network and Dial-up Connections, click **Start**, point to **Settings**, and then click **Network and Dial-up Connections**.

2. Click the connection that you want to verify, and on the **Advanced**menu, click **Advanced Settings**.

3. On the **Adapters and Bindings** tab, in **Bindings for *AdapterName***, verify that the **File and Printer Sharing** check box is selected. If the check box is not selected, select it.

   To modify the protocol bindings order, you must be logged on as a member of the Administrators group.

4. Also in **Bindings for *AdapterName***, verify that the internal adapter is at the top of the list. If it is not at the top of the list, click the up and down arrows to move the internal adapter to the top of the list.

#### Verify that the Terminal Server Licensing Service is Started and that the Startup Type is Set to Automatic

For step-by-step instructions, see Verify that the Terminal Server Licensing service is started and the startup type is set to Automatic.

#### Verify that Terminal Server Licensing is Correctly Installed on the License Server

For step-by-step instructions, see Verify that Terminal Server Licensing is correctly installed on the license server.

#### Verify that the License Server is Activated

A license server that has been installed but not activated only issues temporary licenses. These temporary licenses allow clients to connect to the terminal server for 90 days.

**To verify that a license server is activated**

1. Open Terminal Server Licensing.
2. In the console tree, click the license server for which you want to verify the activation status.
3. In the details pane, verify that activation status is Activated.
4. If the status is Not Activated, right-click the server name, click **Activate Server**, and then follow the instructions in the wizard.

**Remove the MSLicensing Registry Key on the Client and Verify Permissions on the Rebuilt Key**

If all of the previous troubleshooting procedures fail, create a backup of the **MSLicensing**registry key and its subkeys on the client, and then remove the original key and subkeys.

| ⚠**Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**To remove the MSLicensing registry key on the client and verify permissions on the rebuilt key**

1. On the client, open Registry Editor. To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
2. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**
3. On the **Registry** menu, click **Export Registry File**.
4. In the **File name** box, type **mslicensingbackup**, and then click **Save**.
5. If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.
6. On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing**registry subkey.
7. Close Registry Editor, and then restart the computer (when the client is restarted, the missing registry key is rebuilt).
8. On the client, open Registry Editor.
9. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**
10. On the **Edit** menu, click **Permissions**. Users must have at least Read permissions.

# The remote session was disconnected because there are no Terminal Server license servers available to provide a license

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
Perform the troubleshooting procedures described in The terminal server cannot locate the license server.

**Cause**
The client might have exceeded its Terminal Server Licensing grace period (http://go.microsoft.com/fwlink/?LinkID=48895), and a license server has not yet been installed or activated to issue the client a client access license (CAL). After a temporary license expires, a client can only connect to a terminal server if the license server can issue a permanent CAL.

**Solution**
Install Terminal Server Licensing, activate the license server, then purchase and install a sufficient number of CALs to support the clients in your organization. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886) to perform this procedure.

| **Note** |
| --- |
| If you are installing an Enterprise License server and your environment includes multiple trusted Active Directory sites, each of which hosts a terminal server, you can use a script to publish a single license server across all of these sites. Doing this can greatly simplify deployment because it eliminates the need to deploy a separate license server in each site, and it eliminates the need to distribute CALs to license servers across multiple sites. For a sample script that you can use to accomplish this task, see the Microsoft Script Center (http://go.microsoft.com/fwlink/?LinkID=48230) on the Microsoft Web site. Note that this sample script is not supported under any Microsoft standard support program or service. |

**To install Terminal Server Licensing**

1. Open Add/Remove Programs in **Control Panel**.
2. Double-click **Add/Remove Programs**.
3. Click **Add/Remove Windows Components**.
4. In Terminal Server Licensing Setup, do one of the following:
   - Click **Your entire enterprise** to choose an Enterprise license server. You can only install an Enterprise license server on a domain controller or a member server in a domain (if the member server is running Windows Server 2003), not on a stand-alone server. This role is published to Active Directory. If you are installing an Enterprise License Server, you must meet one of the following conditions: 1) You must be a member of the Enterprise Admins group in Active Directory or 2) You must have the right to create the TS-Enterprise-License-Server object in the same site in which the license server will reside in Active Directory.
   - Click **Your domain or workgroup** to choose a Domain license server. If you select this option, the computer on which you install the license server does not have to be a domain controller, if the computer is running Windows Server 2003. However, if the computer is running Windows 2000, the computer on which you install the license server must be a domain controller or a stand-alone server in a workgroup. If the computer on which you plan to install the license server is in a workgroup, it can only be automatically discovered by terminal servers on the same subnet. If you are installing a Domain license server, you must be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
5. Provide the file system location where the license server database should be installed on the Terminal Server license server, click **Next**, and then click **Finish**.

   The default location for the license server database is systemroot\System32\LServer.

You can activate a Terminal Server license server by using one of three methods: Automatic, Web Browser, or Telephone. It is recommended that you activate a license server automatically, as described in the following procedure.

| **Note** |
| --- |
| To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider Using Run as (http://go.microsoft.com/fwlink/?LinkID=48886). |

**To activate a license server automatically.**

1. Open Terminal Server Licensing. To open Terminal Server Licensing, click **Start**, point to **Control Panel**, **Administrative Tools**, and then click **Terminal Server Licensing**.
2. In the console tree, right-click the license server that you want to activate, click **Activate Server**, and then follow the instructions in the wizard.
3. In the **Activation** method list, select **Automatic connection (recommended)**, and then click **Next**.
4. Follow the instructions in the wizard.
5. If necessary, at a later time you can change any license server properties, such as activation method and company information, that you set during the activation process.

Then, Purchase CALs as required and Install CALs automatically.

# The remote session was disconnected because there are no Terminal Server client access licenses available for this computer

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
The license server might not have any remaining Per Device CALs to issue.

**Solution**

1. Use Terminal Server Licensing to Verify that the license server has a sufficient number of CALs for clients requiring remote connections.

2. If the license server does not have a sufficient number of permanent CALs, Purchase CALs as needed, and then Install CALs automatically, as needed.

**Cause**
In the following two cases, either no licenses, or temporary licenses that cannot be upgraded, are issued from the available pool of client access licenses (CALs) on a license server:

1. If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per User, then no licenses are issued from the available pool of licenses, because Per User licensing is not managed.

2. If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

   Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**
Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode.

- Change the Terminal Server Licensing mode.

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# The remote session was disconnected because the local computer's client access license could not be upgraded or renewed

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

After a temporary license expires, a client can only connect to a terminal server if the license server can issue a permanent CAL, or if the terminal server is still within its licensing grace period.

**Note**

If you are running Terminal Server Licensing in a Windows 2000 Service Pack 3 (SP3) or later environment, the client must connect to a terminal server and authenticate twice to obtain a permanent license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and is not yet issued, the terminal server issues the client a permanent, Per Device CAL.

**Cause**

If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**

Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

**Cause**

If you are running Terminal Server Licensing in a Windows 2000 (SP3) or earlier environment, expired temporary licenses might not be upgraded to permanent CALs.

**Solution**

1. On the terminal server and license server, install Service Pack 4 (SP4). To download SP4, see Windows 2000 Service Packs (http://go.microsoft.com/fwlink/?LinkID=48213) on the Microsoft Web site.

2. Use Terminal Server Licensing to Verify that the license server has a sufficient number of CALs for clients requiring remote connections.

3. If the license server does not have a sufficient number of permanent CALs, Purchase CALs, and then Install CALs automatically.

# No licenses are being issued from the available pool of licenses

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

In the following two cases, either no licenses, or temporary licenses that cannot be upgraded, are issued from the available pool of client access licenses (CALs) on a license server:

1. If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per User, then no licenses are issued from the available pool of licenses, because Per User licensing is not managed.

2. If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device while the license server is configured to issue only Per User CALs, then only temporary Per Device CALs are issued from the available pool of licenses. These CALs cannot be upgraded. When the temporary CALs are within several days of expiring, "Event ID 26, Source: Application Pop-up" appears in the application event log on the client. The event message indicates the number of days remaining before the temporary license expires. Similarly, "Event ID 1011, Source:TermService" appears in the application event log on the terminal server.

**Solution**

Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see "Locate the Microsoft Clearinghouse telephone number for your country or region" (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

# Event ID 26: Your terminal services temporary client license will expire in N days

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**
Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# Event ID 1011: The terminal services client has been disconnected because its temporary license has expired

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**
If you are running Terminal Server Licensing in a Windows Server 2003 environment and the licensing mode on the terminal server is set to Per Device but the license server is configured to issue only Per User CALs, then only temporary Per Device licenses are issued from the available pool of licenses. These licenses cannot be upgraded. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source:TermService appears in the application event log on the terminal server, with the following message: "The terminal services client has been disconnected because its temporary license has expired."

**Solution**
Do one of the following, based on the requirements of your environment and license agreement:

- Call the Microsoft Clearinghouse and reactivate the license server in the correct mode. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region (http://go.microsoft.com/fwlink/?LinkId=48885).

- Change the Terminal Server Licensing mode.

**Cause**
The terminal server might not be able to locate the license server.

**Solution**
To resolve this issue, perform the troubleshooting procedures described in The terminal server cannot locate the license server.

# Event ID 1026: The terminal server could not locate a license server in the domain

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

The process of locating a license server is called license server discovery. If license server discovery is not functioning correctly, Event ID 1026, Source:TermServ, might appear in the application event log, with the following message: "The terminal server could not locate a license server in the <domain> domain. Confirm that all license servers on the network are registered in WINS/DNS, accepting network requests, and the Terminal Server Licensing Service is running."

**Solution**

Set a preferred license server.

If your terminal server is running Windows Server 2003 with Service Pack 1 (SP1), you can do this by using Group Policy settings or Terminal Services Configuration, or you can use the registry or a Windows Management Instrumentation (WMI) script. If your terminal server is running Windows 2000 or Windows Server 2003 without SP1, you must use the registry or a WMI script. For three scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see Preferred License Server WMI Scripts (http://go.microsoft.com/fwlink/?LinkID=26220) in Windows Server 2003 Terminal Server Licensing on the Microsoft Web site.

**Note**

The license servers and the terminal servers must either be in the same domain or in domains that trust each other.

**Solution**

If explicitly specifying a license server does not resolve this issue, perform additional troubleshooting steps, as described in The terminal server cannot locate the license server.

# Event ID 1028: The terminal server client has been disconnected because its license could not be renewed

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are running a Windows Server 2003 terminal server, after you use the Windows Components Wizard in Add or Remove Programs to add or to remove a Windows component, an invalid registry value might be set in the **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\TerminalServer\Licensing Core\PolicyAcOn** subkey on the terminal server. This invalid value might may unexpectedly change the Terminal Server Licensing mode and cause the terminal server to obtain only temporary licenses.

**Cause**

This problem might occur because the value of the **PolicyAcOn** registry entry changes from either **2** (the correct registry value for the Per Device licensing mode) or **4** (the correct registry value for the Per User licensing mode) to an invalid value of **0**. This behavior causes the terminal server to attempt to obtain temporary Per Device licenses. In this case, if you view Terminal Services Configuration to verify the licensing mode, the licensing mode appears as Per Device. Therefore, to verify whether this problem is causing the client disconnection, you must verify the value of the **PolicyAcOn** registry entry.

**Solution**

To resolve this problem contact Microsoft Product Support Services to obtain the hotfix described in Knowledge Base article 834651, Terminal Services licensing mode changes from Per User or from Per Device changes from Per User or from Per Device to an invalid value after you add or remove a Windows component, (http://go.microsoft.com/fwlink/?LinkID=48173) on the Microsoft Web site. This hotfix is applied to the terminal server. For information about how to contact Microsoft Product Support Services, see Help and Support (http://go.microsoft.com/fwlink/?LinkID=48149) on the Microsoft Web site.

# Fixing License Server Activation Problems and Other Licensing Problems

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a description of terminal server license server activation problems, and other problems that you might experience when Terminal Server Licensing is enabled.

From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- The product ID generated by the Terminal Server License Server Activation Wizard doesn't work
- Event ID 43: Work Manager error can't startup work scheduler, Error code -1072167891

# The product ID generated by the Terminal Server License Server Activation Wizard doesn't work

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In a Windows Server 2003 environment, when you use the Terminal Server License Server Activation Wizard to activate a Terminal Services license server by telephone, you might not be able to use the product ID that appears on the License Server Activation page of the wizard to complete the activation of the license server.

**Cause**

This problem might occur when the Terminal Server License Server Activation Wizard incorrectly processes the product ID. When this problem occurs, Event ID 43 appears in the application event log on the license server, with the following message: "Work Manager error can't startup work scheduler, Error code -1072167891."

**Solution**

To resolve this problem, contact Microsoft Product Support Services to obtain a hotfix for this issue, as described in Knowledge Base article 832794, Terminal Server License Server Activation Wizard generates a product ID that does not work (http://go.microsoft.com/fwlink/?LinkId=48232) on the Microsoft Web site. For information about how to contact Microsoft Product Support Services, see Help and Support (http://go.microsoft.com/fwlink/?LinkId=48149) on the Microsoft Web site.

# Event ID 43: Work Manager error can't startup work scheduler, Error code -1072167891

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cause**

This behavior occurs because Microsoft Jet database engine transactions can use a significant amount of memory on a large database (a database that is larger than 80 megabytes [MB] in size). If a transaction hangs (runs for a long time before committing) or performs many modifications, Jet might consume the available version store.

**Solution**

In Windows Server 2003, you can use a new registry key to tune the default memory resources that are necessary for version store in Jet transactions. The version store maintains list of changes that are made to the database since the latest transaction began.

**To tune the memory resources that are necessary for version store in Jet**

1. On the license server, open Registry Editor. To open Registry Editor, click **Start**, click **Run,** type **regedit**, and then click **OK**.

2. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\TermServLicensing\Parameters**

3. On the **Edit** menu, click **Add Value**, and then add the following registry value:

   Value name: **MaxVerPages**

   Data type: REG_DWORD

   Radix: Decimal

   Value data: 1024

   The valid range for Value is 256 to 2048

4. **Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

# Additional Resources for Troubleshooting Terminal Server Licensing

Applies To: Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For additional information about troubleshooting Terminal Server Licensing in Windows Server 2003 and Windows 2000, see the following resources.

**Known Issues**

**Windows Server 2003 and Windows 2000**

- Because of a security error, the client could not connect to the Terminal Server (http://go.microsoft.com/fwlink/?LinkId=46818) on the Microsoft Web site
- Client computers cannot obtain a permanent Windows 2000 Terminal Services Client Access License (CAL) from a Windows Server 2003 Terminal Services Licensing server (http://go.microsoft.com/fwlink/?LinkId=48146) on the Microsoft Web site
-
- **Windows Server 2003**
- Windows Server 2003 Terminal Server licensing issues and requirements for deployment (http://go.microsoft.com/fwlink/?LinkId=26381) on the Microsoft Web site
- License Server Security Group setting does not work in Windows Server 2003 Terminal Server (http://go.microsoft.com/fwlink/?LinkId=46819) on the Microsoft Web site
- "No License Server" Error Message Appears When You Try to Connect to Terminal Server After Mode Change (http://go.microsoft.com/fwlink/?LinkId=46820) on the Microsoft Web site
- Terminal Services Licensing mode changes from Per User to Per Device after you add or remove a Windows component (http://go.microsoft.com/fwlink/?LinkId=46821) on the Microsoft Web site
- Event ID 43: Work Manager error can't startup work scheduler, Error code -1072167891
- Terminal Server License Server Activation Wizard generates a product ID that does not work (http://go.microsoft.com/fwlink/?LinkId=48232) on the Microsoft Web site
-

**Windows 2000**

- Windows XP Clients Cannot Connect to a Windows 2000 Terminal Services Server (http://go.microsoft.com/fwlink/?LinkId=46822) on the Microsoft Web site

**How To**

# Step-by-Step Guide for Configuring Group Policy for Terminal Services

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Terminal Services provides configuration operations on a per-computer basis. Group Policy combined with Terminal Services provides central administration of terminal servers and remote desktop clients.

The basic scenario of this guide provides a way to assign the same user settings to all users logging on to Terminal Services. When not logged on to Terminal Services, users should see their normal configuration settings. Group Policy uses the loopback mechanism to apply the same consistent desktop to all Terminal Services users.

The basic scenario is then extended to assign the same user settings to all users logging on to Terminal Services while exempting domain administrators from these settings. This approach makes remote administration possible for domain administrators while providing a consistent logon experience for Terminal Services users.

# Loopback Technology Review

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Understanding Group Policy loopback technology is essential for configuring a consistent desktop for all Terminal Services users. This section introduces the Group Policy loopback feature with application to terminal servers.

**Group Policy loopback feature**

Group Policy is applied to the user or computer, based upon where the user or computer object is located in Active Directory® directory service. However, when applying a consistent logon experience to all users logging on to a terminal server, users will need policy applied to them, based on the location of the terminal server, not the location of the user object. The Group Policy loopback feature gives the administrator the ability to apply user Group Policy, based upon the terminal server Active Directory location.

To illustrate the loopback feature, we will use an example. In this example, you have full control over the computers and users in this domain because you have been granted domain administrator privileges.

The following illustration shows the Contoso.com domain, which is used for the purposes of this example. The gold lines connecting the Active Directory objects (domain and OU containers) are shown as solid lines. The GPO links between Active Directory objects (site, domain, and OU containers) and individual GPOs are shown as arrows.

**Figure 1 The Contoso.com domain**

The Terminal servers OU in the Contoso domain contains only the terminal servers. Users from the Marketing OU have GPOs A3, A1, A2, and A5 applied (in that order), regardless of the desktop computer to which they log on. The terminal servers located in the Terminal servers OU will have the computer settings from GPOs A3, A1, A2, A4, A6, and A7 applied (in that order) during computer Group Policy processing.

Loopback can be configured into two modes: replace and merge. For Terminal Services configuration purposes, the replace mode of the loopback policy setting is relevant. In this mode, the user's list of GPOs is not gathered. Only the list of GPOs based on the computer object location in the Active Directory is used. The loopback policy setting will be configured to replace mode in GPO A6. GPO A7 will be configured with the desired user-based policy settings for the Terminal Services desktop. Both GPO A6 and A7 are linked to the Terminal servers OU. This illustrates a best practice to separate the computer-based policy settings from the user-based policy settings to make troubleshooting Group Policy application problems easier.

For the Contoso.com domain example, users from the Marketing OU, when logging on to their normal desktops, will apply

user policy settings from GPOs A3, A1, A2, and A5 (in that order). When logging on to any terminal server, the users from the Marketing OU will evaluate a different set of user policy settings from GPOs A3, A1, A2, A4, A6, and A7 (in that order). You can easily see the difference in the set of user's policy settings based on the computer's location when seen in a table.

| Computer | GPOs evaluated to user when logging on |
|---|---|
| Normal desktop computer | A3, A1, A2, A5 |
| Terminal server | A3, A1, A2, A4, A6, A7 |

**Note**

The list of GPOs evaluated for a user logging on to a terminal server will include A3, A1, A2, A4, A6, and A7 (in that order). However, A6 will be found to only include computer settings and will not apply to a user.

In summary, administrators can use the loopback feature in replace mode to override the normal processing of user Group Policy settings. The user portion of the GPOs linked to the Terminal servers OU will be used for all terminal server logons, instead of evaluating the user GPOs in Group Policy processing normally applied when logging on to their desktop computer.

**Loopback processing and security filtering**

With security filtering, you can apply a GPO with user-based policy settings to a specific domain group with only user members. The computer policy will not apply, but the user policy settings will apply to any user belonging to the security group used in filtering.

Using the Contoso domain example, you would want to use security filtering to limit application of the user policy settings of GPO A7 to the Remote Desktop Users group. In this case, the Remote Desktop Users group will have the user policy settings of GPOs A3, A1, A2, A4, A6, and A7 applied to them and in that order. All other users will have only the user policy settings of GPOs A3, A1, A2, A4, and A6 applied to them and in that order. This method of limiting application of GPOs through security filtering will come in handy for Scenario 2.

**Loopback processing best practices**

When using loopback processing in replace mode to control the user policy processing settings, it is best to create separate GPOs for the user and computer configuration settings. Doing so will decrease the amount of confusion involved with using security filtering on a GPO—whether to filter for the user or computer side. Creating separate GPOs also will help in troubleshooting any issues surrounding the processing of Group Policy settings with loopback processing enabled.

Technical Overview of Windows Server 2003 Terminal Services

# Requirements for Configuring Group Policy for Terminal Services

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This step-by-step guide assumes you understand the basic concepts of Group Policy and using Group Policy Management Console.

Before running the scenarios presented in this document, you must follow these steps in order:

1. Prepare your environment.
2. Enable users to connect remotely to a terminal server.
3. Centrally enable Remote Desktop using Group Policy.
4. Grant access to your terminal servers with the Remote Desktop Users Group.

| **Note** |
| --- |
| It is assumed the firewall on the terminal server is off. If you have configured a firewall on your terminal server, you must allow inbound Remote Desktop exceptions through the firewall on the terminal server. |

**Prepare your environment**

You must have at least one Active Directory domain. You must have Group Policy Management Console (GPMC) installed on an administration computer. The administration computer should contain all the tools for administrating the domain-based operations.

In your domain, create a separate organizational unit (OU) for terminal servers. Move all terminal servers into that OU. Do not move any users or other computers into that OU.

It is assumed that you understand the basics of creating, managing, and administering Group Policy Active Directory domains. See Implementing Common Desktop Management Scenarios with the Group Policy Management Console for more information about creating, managing, and administering Group Policy Active Directory domains.

**Enable users to connect remotely to a terminal server**

To enable users to connect remotely to a terminal server, you must ensure that:

- Remote Desktop is enabled on the terminal server.
- Users have the appropriate rights and permissions to log on remotely to the server.

| **Note** |
| --- |
| To perform these two tasks, you must be logged on as a member of the Administrators group. These properties are configured on a per-server basis. You can use Group Policy to manage these properties centrally. |

**Centrally enable Remote Desktop using Group Policy**

It is recommended as a best practice to centrally enable Remote Desktop for all your terminal servers. Group Policy will allow you to centrally configure all your terminal servers instead of configuring the properties for each terminal server.

### To centrally enable Remote Desktop using Group Policy

1. To open Group Policy Management Console (GPMC), click **Start**, click **Run**, and then type **GPMC.msc**.
2. Create and link a GPO to the terminal server OU.
3. Right-click the GPO linked to the terminal server OU, and then click **Edit**.

4. In Computer Configuration\Administrative Templates\Windows Components\ Terminal Services, double-click the **Allow users to connect remotely using Terminal Services** policy setting.
5. Click **Enabled**.
6. Click **OK**.

| **Important** |
| --- |
| When you enable Remote Desktop on a computer, you enable the capability for other users and groups to log on remotely to the computer. However, you must also decide which users and groups should be able to log on remotely, and then manually add them to the Remote Desktop Users group. Domain administrators automatically have the ability to log on remotely to the terminal server. Do not add domain administrators to the Remote Desktop Users group.<br><br>You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. |

| **Note** |
| --- |
| If the **Allow users to connect remotely using Terminal Services** policy setting is set to "Not Configured," the **Enable Remote Desktop on this computer** policy setting (on the **Remote** tab of the **System Properties** dialog box) on the target computers takes precedence. Otherwise, the **Allow users to connect remotely using Terminal Services** policy setting takes precedence. |

**Grant access to your terminal servers with the Remote Desktop Users group**

The Remote Desktop Users group is one of the built-in users groups available when you install one of the Microsoft Windows Server 2003 operating systems. When you enable Remote Desktop, members of the Remote Desktop Users group and domain administrators are automatically able to log on remotely to a terminal server.

By default, the Remote Desktop Users group is not populated. Therefore, you must decide which users and groups should have access to log on remotely to a terminal server, and then add them to this group. Instead of populating the Remote Desktop Users group on a per-server basis, as a best practice it is recommended to centrally grant access to users via the Remote Desktop Users group for all your terminal servers using Group Policy. This approach will allow all domain administrators to be able to indirectly add their users to the Remote Desktop Users group for all terminal servers using a domain group.

| **Note** |
| --- |
| This procedure does not show you how to restrict access to the Remote Desktop Users group. Do not add domain administrators to the domain group configured as a member of the Remote Desktop Users group. By default, domain administrators have remote access rights to any terminal server. |

**To add a domain group to the Remote Desktop Users group via Group Policy**

1. To open Group Policy Management Console, click **Start**, click **Run**, and then type **GPMC.msc**.
2. Create and link a GPO named Restricted Groups to the terminal server OU.
3. Right-click the Restricted Groups GPO linked to the terminal server OU, and then click **Edit**.
4. You can configure the Restricted Groups setting in the following location in Group Policy Object Editor:

   **Computer Configuration\Windows Settings\Security Settings\Restricted Groups**
5. Right-click **Restricted Groups** and then click **Add Group**.
6. Click **Browse**, click **Locations**, select the locations you want to browse, and then click **OK**.
7. Type **Remote Desktop Users** in the **Enter the object names to select** text box and then click **Check Names**. Or, click **Advanced**, and then click **Find Now** to list all available groups.
8. Click the **Remote Desktop Users** group and then click **OK**.
9. Click **OK** in the **Add Groups** dialog box to close it. The **Remote Desktop Users Properties** dialog box is then displayed.
10. Click **Add** in the **Members of this group** section of the dialog box.

11. Click **Browse**.
12. Type the name of the domain group in the **Select Users or Groups** dialog box. Click **Check Names,** and then click **OK** to close this dialog box.
13. Click **OK** to close this dialog box to finish adding the domain group to the Remote Desktop Users group.

# Group Policy Terminal Services Scenarios

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The following scenarios illustrate how Group Policy applies a consistent user desktop during logon through the Remote Desktop client while providing domain administrators full access for remote administration.

# Scenario 1: Administering Group Policy to Provide a Consistent Terminal Services Desktop

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Terminal Services client, called Remote Desktop Connection (RDC), provides a number of ways to configure the client. Some examples for which you may want to standardize the RDC clients in your organization for all user logons are:

- Client redirection features.
- Terminal Services profile path.
- Wallpaper during connection.
- Printing connection management.
- Other security related lockdown features.

In each of these examples, the desire is to configure all RDC clients to behave the same way on user logon.

**Administering Group Policy to Provide a Consistent Terminal Services Desktop**
You must have privileges delegated to you to create, link, and edit GPOs for a specific OU to perform the steps in this scenario. This scenario assumes that the requirements for these scenarios—as specified in Requirements for Configuring Group Policy for Terminal Services—have been fulfilled.

To configure Terminal Services desktop settings for a consistent user logon experience, you must perform the following tasks:

- Create a loopback GPO linked to the terminal server OU.
- Create user policy settings in a separate GPO linked to the terminal server OU.

**To create a loopback GPO linked to the terminal server OU**

1. To open Group Policy Management Console, click **Start**, click **Run**, and then type **GPMC.msc**.
2. Create and link a GPO to the terminal server OU. Use this GPO for setting the loopback policy setting in replace mode. Name this GPO appropriately for loopback capability.
3. Right-click the loopback GPO linked to the terminal server OU, and then click **Edit**.
4. In Computer Configuration\Administrative Templates\System\Group Policy, double-click the **User Group Policy loopback processing mode** setting.
5. In the **User Group Policy loopback processing mode** properties, click **Enabled**.
6. In the **User Group Policy loopback processing mode** properties, open the **Mode** drop-down list, and then click **Replace**.
7. Click **OK** to close the **User Group Policy loopback processing mode** properties.
8. Click **File,** and then click **Exit** to close Group Policy Object Editor.

**To create user policy settings in a separate GPO linked to the terminal server OU**

1. If Group Policy Management Console is not open, click **Start**, click **Run**, and then type **GPMC.msc**.
2. Create and link a GPO to the terminal server OU. Name this GPO, "User Settings for Terminal Services". Use this GPO for setting the user configuration settings for Terminal Services and other desktop configurations.
3. Right-click the User Settings for Terminal Services GPO linked to the terminal server OU, and then click **Edit**.

4. Configure only user-based policy settings in this GPO. Do not configure any machine-based policy settings in this GPO.
5. After configuring all the user-based policy settings, click **File** and then click **Exit** to close Group Policy Object Editor.

| **Note** |
| --- |
| This guide does not make recommendations about which Terminal Services configuration settings should be set for user logons. This guide makes recommendations only for setting the Terminal Services configuration settings to create a consistent user logon experience. |

# Scenario 2: Filtering Administrators from Terminal Services Group Policies

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Scenario 1 documented a procedure to administer Group Policy in order to configure all RDC clients to behave the same way on user logon. This creates a problem for administrators when the need arises to log on to a terminal server for remote administration. Domain administrators may not want Group Policy to configure their RDC client during remote administration, due to limitations that may be imposed by the Group Policy.

There are a number of ways to apply security filtering to exempt domain administrators from Group Policy application. This scenario presents one approach to applying security filtering to the User Settings for Terminal Services Group Policy object (GPO) from Scenario 1. The net effect of this scenario is to exempt domain administrators from having a specific desktop applied to them on logon through an RDC client.

**Filtering application of a Group Policy object (GPO)**
To perform the steps in this scenario, you must have privileges delegated to you to create, link, and edit GPOs for a specific OU.

This scenario assumes you have previously performed all the steps in Scenario 1: Administering Group Policy to Provide a Consistent Terminal Services Desktop, including creating the loopback processing and user policy settings for Terminal Services GPO.

This scenario will show you how to use security filtering to limit application of the User Settings for Terminal Services GPO to the user domain group when logging on to terminal server. The user domain group is the original group created to add Terminal Services users to the Remote Desktop Users group. The assumption is that no domain administrator has been added to the user domain group. By limiting the application of the user policy settings for the User Settings for Terminal Services GPO to the user domain group, you will have filtered out application to all domain administrators.

**To limit application of the user policy settings for Terminal Services GPO to the user domain group**

1. To open Group Policy Management Console, click **Start**, click **Run**, and then type **GPMC.msc**.
2. In the console tree, double-click **Group Policy Objects** to expand this folder displaying the GPOs for this domain.
3. Click the **User Settings for Terminal Services** GPO.
4. In the results pane, on the **Scope** tab, click **Add**.
5. In the **Enter the object name to select** box, type the name of the user domain group that you previously added to the Remote Desktop Users group. Click **OK**. GPMC will add the read permissions and "Apply Group Policy" permissions by default.
6. Click **Authenticated Users**.
7. Click **Remove** to *not* apply the User Settings for Terminal Services GPO to all other users, such as members of the Domain Administrators group.

| **Note** |
| --- |
| The user domain group is the original group created to add Terminal Services users to the Remote Desktop Users group. Do not add domain administrators to this group. |

# Introduction to Administering Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide explains how to administer Windows Firewall. These activities are part of the operating phase of the IT life cycle. If you are not familiar with the Windows Server 2003 administration guides, review the following sections of this introduction.

**When to Use This Guide**
You should use this guide when:

- You want to know how to perform a specific procedure.
- You want to learn about the scheduled and unscheduled maintenance tasks for administering Windows Firewall.
- You want to identify and understand the high-level operations objectives and tasks that are associated with Windows Firewall.

Do not use this guide to diagnose and solve Windows Firewall problems. Step-by-step troubleshooting information can be found in Troubleshooting Windows Firewall.

This guide can be used by organizations that have deployed Windows Server 2003 with Service Pack 1 (SP1). It includes information that is relevant to different roles within an IT organization, including IT administrators and managers who plan and implement the IT operations processes that are required to administer Windows Firewall in Windows Server 2003 SP1.

In addition, this guide provides more detailed procedures for operators who have varied levels of expertise and experience. Although the procedures provide operator guidance from start to finish, operators must have a basic proficiency with the Microsoft Management Console (MMC) and snap-ins, and know how to start administrative programs and access the command line.

**How to Use This Guide**
The operations areas are divided into the following types of content:

- **Objectives** are high-level goals for managing and securing Windows Firewall. Each objective consists of one or more high-level tasks that describe how to accomplish the objective. "Managing Windows Firewall" and "Optimizing Windows Firewall" are high-level objectives. Sometimes, to make the subject more clear, high-level objectives are broken down into lower-level objectives. For example, "Managing Windows Firewall" is an objective that contains several lower-level objectives, such as "Managing Resets, Startup, and Shutdown," "Managing Windows Firewall Profiles," and "Managing IPsec, Multicast, and ICMP Settings."
- **Tasks** are used to group related procedures and provide general guidance for achieving the goals of an objective. For example, "Enabling and Disabling Windows Firewall" and "Restoring Windows Firewall Default Settings" are tasks within an objective called "Managing Resets, Startup, and Shutdown."
- **Procedures** provide step-by-step instructions for completing the task. For example, "Turn Windows Firewall On or Off" and "Turn Windows Firewall On with No Exceptions" are procedures within a task called "Enabling and Disabling Windows Firewall."

If you are an IT manager or administrator who will be delegating tasks to operators within your organization, you will want to:

- Read through the objectives and tasks to determine how to delegate permissions and whether you need to install tools before operators perform the procedures for each task.
- Before assigning tasks to individual operators, ensure that you have all the tools installed where operators can use them.
- When necessary, create “tear sheets” for each task that operators perform within your organization. Cut and paste the task and its related procedures into a separate document and then either print these documents or store them online.

**Terminology Used in This Guide**

**Domain profile**

A set of Windows Firewall settings that are applied when a computer is connected to a network that contains the domain controllers for the domain in which its computer account resides. The domain profile is one of two profiles used by Windows Firewall to apply settings to a computer.

**Exception**

A port, program, or system service that is allowed to receive unsolicited traffic.

**Exceptions list**

A rules store that specifies which ports, programs, or system services are allowed to receive unsolicited traffic. To allow unsolicited incoming traffic through Windows Firewall, you add ports, programs, and system services to the exceptions list.

**Notification**

A **Windows Security Alert** dialog box that appears when a program that is not listed in the exceptions list attempts to listen for unsolicited traffic on a port. If you have administrative rights on a computer, the notification displays the option to add the program to the exceptions list, and thereby allow the program to receive unsolicited traffic. If you do not have administrative rights on a computer, the notification displays a warning that a program is attempting to listen on a port.

A **Windows Security Alert** dialog box does not appear when a system service attempts to listen for unsolicited incoming traffic; it appears only when a program attempts to listen for unsolicited incoming traffic.

**Port**

A logical communication endpoint representing a service or an application that listens for and receives IP packets. Ports are specified by a positive 16-bit decimal number and by the type of traffic (either UDP or TCP) that is expected to pass through the port. Most ports are predefined and considered "well-known" for specific services, such as DHCP and DNS. However, some ports are created dynamically by a server and assigned to the services and applications that need to listen for incoming traffic from clients.

**Program**

A software application that is usually started by a user and runs under the user's account. Programs run only while the user is logged on to a computer and usually consist of one or more executable (.exe) files and one or more dynamic-link library (.dll) files.

| **Note** |
| --- |
| Some system services run within their own .exe file and are started by a user (for example, the Telnet service, which runs in Tlntsvr.exe). Typically, these system services run under a privileged account, such as Local Service. They do not run under the user's account. In Windows Firewall, any system service that runs within its own .exe file is considered a program. |

**Scope**

A Windows Firewall setting that you configure for an exception. The scope setting controls from which addresses unsolicited traffic is allowed to originate. By default, the scope of an exception is any address, which includes any computer on the Internet. You can change the scope of an exception to locally reachable addresses or a list of individual Internet Protocol version 4 (IPv4) addresses or IPv4 address ranges.

**System service**

A software application that is usually not started by a user and runs under a privileged account, such as LocalSystem. System services run even when a user is not logged on to a computer and usually run as a separate process within Svchost.exe.

**Standard profile**

A set of Windows Firewall settings that are applied when a computer is not connected to a network that contains the domain controllers in which its computer account resides (for example, a public network, such as the Internet). The standard profile is one of two profiles used by Windows Firewall to apply settings to a computer.

# Managing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To implement a successful management plan for Windows Firewall, you must address the following objectives:

Managing Resets, Startup, and Shutdown

Managing Windows Firewall Profiles

Managing Program, Port, and System Service Firewall Rules

Managing IPsec, Multicast, and ICMP Settings

Managing Windows Firewall Notifications

# Best Practices for Managing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best Practices**

Use the following best practices when you administer Windows Firewall.

Use Security Configuration Wizard to configure Windows Firewall.

Use Group Policy to manage Windows Firewall.

Do not configure Windows Firewall settings on a computer-by-computer basis.

Do not configure per-connection settings.

Create program exceptions instead of port exceptions.

Open the minimum number of ports.

Use scope settings to limit the scope of an exception.

Turn off Windows Firewall if you are using a non-Microsoft host firewall.

**Use Security Configuration Wizard to configure Windows Firewall.**

Security Configuration Wizard (SCW) is the recommended method for configuring Windows Firewall settings in Windows Server 2003. Using SCW ensures that your computer is configured appropriately for the installed roles and enabled services and that no unnecessary ports are opened based on those roles and services. For more information, see Configuring Windows Firewall with SCW.

**Use Group Policy to manage Windows Firewall.**

If your organization uses Group Policy, use the Windows Firewall Group Policy settings to manage and configure Windows Firewall. This will ensure more consistency among your Windows Firewall configurations and will allow you to secure Windows Firewall so that administrators and users who are logged on locally cannot configure Windows Firewall settings. For more information, see Administering Windows Firewall with Group Policy on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43157).

**Do not configure Windows Firewall settings on a computer-by-computer basis.**

This can make your organization more accessible to attack because each computer has a different attack surface. When you configure Windows Firewall settings on a computer-by-computer basis, it becomes difficult to determine which computers are accessible to an attack by a worm or other malicious program that relies on unsolicited incoming traffic to spread.

**Do not configure per-connection settings.**

Per-connection settings (also called connection-specific settings or interface-specific settings) are applied without regard to the profile (standard or domain) used by the computer. This can make a computer more accessible to attack when it is connected to a public network, such as the Internet. You cannot restrict the scope of per-connection exceptions; these exceptions allow unsolicited traffic from any address. For more information, see Configuring Firewall Rules for Specific Connections.

**Create program exceptions instead of port exceptions.**

If you need to allow unsolicited incoming traffic through Windows Firewall, create a program exception instead of a port exception. When you create a program exception, Windows Firewall dynamically opens ports for the specified program and then closes those ports when the program is shut down. When you create a port exception, the specified port is open all of the time, which makes the computer more accessible to attack. For more information, see Configuring Program Firewall Rules.

**Open the minimum number of ports.**

If you have to open ports to allow unsolicited incoming traffic through Windows Firewall, be sure to open only those ports that you need. If a port handles intermittent or infrequent traffic, open and close the port as needed. If a computer configuration requires you to open numerous ports, you should evaluate the roles that are installed on the computer and the services that the computer is providing. This could indicate poor infrastructure design, and could make the computer a critical point of failure or attack.

**Use scope settings to limit the scope of an exception.**

If you create a program or port exception or enable a system service exception, be sure to configure the scope of the exception. The scope setting restricts an exception to computers that are directly reachable or to specific Internet Protocol version 4 (IPv4) addresses and address ranges. For more information about scope settings, see Configuring Scope Settings.

**Turn off Windows Firewall if you are using a non-Microsoft host firewall.**
Using Windows Firewall with another host firewall does not necessarily increase your security. In fact, it can cause your computer to behave erratically if the rules and policies of both firewalls are not complementary. You should turn off (disable) Windows Firewall if you are running a non-Microsoft host firewall.

# Managing Resets, Startup, and Shutdown

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Because Windows Firewall and the Windows Firewall/Internet Connection Sharing service are disabled by default on Windows Server 2003, you must manage the initial startup of these components. In addition, you might have to manage the shutdown of Windows Firewall and the restoration of Windows Firewall settings.

To help you manage these functions, review Best Practices for Managing Windows Firewall and Known Issues for Managing Resets, Startup, and Shutdown

The following tasks are described in this objective:

- Configuring Windows Firewall with SCW
- Enabling and Disabling Windows Firewall
- Restoring Windows Firewall Default Settings

# Known Issues for Managing Resets, Startup, and Shutdown

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you manage Windows Firewall resets, startup, and shutdown.

- Make sure the Windows Firewall/Internet Connection Sharing service is running before you start any programs or system services that are listed in the program exceptions list. If you start the Windows Firewall/Internet Connection Sharing service after you have started programs that are listed in the Windows Firewall exceptions list, restart your computer and then start your programs and system services. Windows Firewall cannot track the state of a program's traffic if the program is started before you start the Windows Firewall/Internet Connection Sharing service.

- Do not run Windows Firewall if you are running Routing and Remote Access. Routing and Remote Access uses a firewall that cannot be used with Windows Firewall. For more information, see Basic Firewall on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43159).

- Do not run Windows Firewall on a server that is running a perimeter firewall, such as Microsoft Internet Security and Acceleration (ISA) Server 2004. The protection that Windows Firewall provides in this situation is redundant and unnecessary. In addition, Windows Firewall can cause perimeter firewalls such as ISA Server to function improperly.

- Do not permanently run Windows Firewall on a domain controller. Instead, use Internet Protocol security (IPsec) to protect incoming traffic on a domain controller. You can use Windows Firewall on a temporary basis (for example, to protect a domain controller from attack while you install security updates, virus signatures, or security software).

- Do not use Windows Firewall on a computer that is running a non-Microsoft host firewall. Although it is possible to run two host firewalls on a single computer, it is not recommended that you do so. Host firewall implementations vary widely and there is no guarantee that a non-Microsoft host firewall and Windows Firewall will work well together.

- Do not change the Startup type or status of any service on which Windows Firewall relies. Changing the Startup type or status of a dependent service can prevent Windows Firewall from starting or running properly. For more information about these dependent services, see the section titled "How Windows Firewall Works" in the Windows Firewall Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42729).

- You might not be able to start Windows Firewall if Administrative Templates from the Windows XP Security Guide were applied to the computer before Windows XP with Service Pack 2 (SP2) was installed. For more information, see article ID 892199 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45337). The article describes why the Windows Firewall/Internet Connection Sharing service might not start and how you can configure the service so it behaves properly when you use Administrative Templates.

- When you reset Windows Firewall, the settings that you specified in Netfw.inf are reapplied to the computer; all existing Windows Firewall settings are deleted. Any Windows Firewall settings that you specified in an answer file, such as Unattend.txt, are deleted and are not restored. If you want to restore the Windows Firewall settings that you configured during installation with an answer file, you must configure the settings manually.

# Configuring Windows Firewall with SCW

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security Configuration Wizard (SCW) is a tool used to reduce the attack surface of computers running a member of the Windows Server 2003 family with Service Pack 1 (SP1). SCW is the preferred tool for configuring Windows Firewall. You can use SCW to turn on Windows Firewall and configure Windows Firewall exceptions.

SCW does not configure Windows Firewall directly. It helps you create a security policy based on the roles performed by a server. After a policy is created, it can be edited or applied to one or more similarly configured servers. Applied policies can be rolled back to undo changes that have caused problems. To edit, apply, or roll back a security policy, the policy must have been created with SCW.

**When to perform this task**

You should use SCW to configure Windows Firewall when you install Windows Server 2003 with SP1. This includes:

- Installations of SP1 on servers that are running Windows Server 2003.
- Slipstream installations of Windows Server 2003 with SP1 on new servers.
- Upgrades from older operating systems to Windows Server 2003 with SP1.

Do not use SCW to configure Windows Firewall if you use Netfw.inf or an answer file to configure Windows Firewall during an automated installation or if you use domain-based Group Policy settings to configure Windows Firewall.

**Task requirements**

SCW is an optionally installed component. You must install SCW before you can use it. SCW can be installed only on computers running a member of the Windows Server 2003 family with SP1. The server that you are configuring must be running a member of the Windows Server 2003 family with SP1. For more information, see Install Security Configuration Wizard on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43158).

**Task procedures**

To complete this task, perform the following procedure:

Use SCW to Configure Windows Firewall

**See Also**
**Concepts**
Enabling and Disabling Windows Firewall
Restoring Windows Firewall Default Settings
Known Issues for Managing Resets, Startup, and Shutdown

# Use SCW to Configure Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Security Configuration Wizard (SCW) is an optional component that must be installed through Add or Remove Programs in Control Panel. SCW guides you through the process of creating a security policy, based on the roles performed by a given server. Once a policy is created, it can be edited or applied to one or more similarly configured servers.

SCW displays different pages, depending on the configuration settings you choose. If, during the Role-Based Service Configuration portion of SCW, you choose Remote access/VPN server, Internet Connection Sharing server, or Microsoft Internet Security and Acceleration Server 2004, you will not be able to select the Network Security portion of SCW, which is where Windows Firewall settings are configured.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**To use SCW to configure Windows Firewall**

You must use the graphical user interface to perform this procedure; you cannot use the command prompt or Group Policy to perform this procedure.

**To use SCW to configure Windows Firewall**

1. Open SCW, and follow the steps in the wizard until you reach the **Network Security** page.
2. Clear the **Skip this section** check box, and click **Next**.
3. Under **Select the ports to open**, review the ports that SCW will add to the Windows Firewall exceptions list. To prevent SCW from adding a port to the exceptions list, clear the check box next to the port.

   If you want to add additional ports or applications to the Windows Firewall exceptions list, click **Add**, and do the following:

   - To add a port to the exceptions list, in **Port number**, enter the port number, select **TCP** or **UDP** or both, and click **OK**.
   - To add an application to the exceptions list, click the **Approve Application** tab, and in **Application path**, enter the application path and name of the executable (.exe) file, and then click **OK**. Try to use environment variables for paths so that the administrative templates can be applied to any computer.
4. Click **Next**.
5. On the **Confirm Port Configuration** page, verify the port settings that SCW will use to configure Windows Firewall, and click **Next**.
6. On the **Registry Settings** page, select the **Skip this section** check box, and click **Next**.
7. On the **Audit Policy** page, select the **Skip this section** check box, and click **Next**.
8. On the **Internet Information Services** page, select the **Skip this section** check box, and click **Next**.
9. On the **Save Security Policy** page, click **Next**.
10. Enter a name and description for the security policy, and click **Next**.
11. Click **Apply now** to apply the security policy and configure Windows Firewall, and click **Next**.
12. After SCW has applied the security policy, click **Next**, and then click **Finish**.

**Note**

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Configuring Windows Firewall with SCW

# Enabling and Disabling Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To protect your computer with Windows Firewall, you must turn on (enable) Windows Firewall and start the Windows Firewall/Internet Connection Sharing service. If the Windows Firewall/Internet Connection Sharing service is not running and you attempt to start Windows Firewall, in the graphical user interface, a dialog box will be displayed to ask if you want to start the service; if you are using the command prompt, a warning will appear to inform you that the service has not been started.

| **Note** |
| --- |
| The Windows Firewall/Internet Connection Sharing service does not stop when you turn off Windows Firewall. Although unsolicited incoming traffic will not be blocked, as long as the Windows Firewall/Internet Connection Sharing service is still running, Windows Firewall events will be written to the security event log. |

**Turning Windows Firewall on and off**

If you turn on the Windows Firewall/Internet Connection Sharing service after you have started any programs or system services that are listed in the program exceptions list, you should do the following:

- Restart your computer.
- Start the programs that are listed in the exceptions list.

Windows Firewall cannot track the state of a program's traffic or a system service's traffic if the program or system service is started before the Windows Firewall/Internet Connection Sharing service is started. This problem typically occurs when you stop the Windows Firewall/Internet Connections Sharing service to install and configure software, and then turn on the Windows Firewall/Internet Connection Sharing service after you start the software program.

**Turning Windows Firewall on with no exceptions**

When you turn on Windows Firewall, you can also configure a special setting that blocks all traffic that has been added to the exceptions list. This setting appears in the graphical user interface as the **Don't allow exceptions** check box. When you use this setting, all of the exceptions in the Windows Firewall exceptions list are disabled and all unsolicited incoming TCP/IP traffic is blocked.

Using the **Don't allow exceptions** setting will prevent the display a **Windows Security Alert** dialog box when a program or system service attempts to listen for incoming traffic. However, Windows Firewall will continue to write notification events to the security log.

**Turning Windows Firewall on or off for a specific connection**

By default, when you turn Windows Firewall on or off, you are enabling or disabling Windows Firewall on every network connection on the computer. However, you can also turn Windows Firewall on or off on a connection-specific or interface-specific basis. When you do this, Windows Firewall filters traffic for each connection based on the connection-specific settings you configure.

When you turn on Windows Firewall globally, Windows Firewall is turned on for every connection on your computer unless you explicitly turn it off on a per-connection basis. However, if you turn off Windows Firewall globally, Windows Firewall is turned off for every connection on your computer; you cannot turn on Windows Firewall on a per-connection basis. In short, to turn Windows Firewall on or off on a per-connection basis, you must turn on Windows Firewall globally and then turn Windows Firewall on or off for each individual connection. The following table shows how global and per-connection settings are combined.

| Global Setting | Per-Connection Setting | Resultant Per-Connection Setting |
| --- | --- | --- |
| On | On | On |
| On | Off | Off |
| Off | Off | Off |

| | | |
|---|---|---|
| Off | On | Off |

**When to perform this task**

You should turn on Windows Firewall after you install Windows Server 2003 with Service Pack 1 (SP1). This includes:

- Installations of SP1 on servers that are running Windows Server 2003.
- Slipstream installations of Windows Server 2003 with SP1 on new servers.
- Upgrades from older operating systems to Windows Server 2003 with SP1.

| **Note** |
|---|
| You should not turn on Windows Firewall when you are running Routing and Remote Access, a perimeter firewall, such as Microsoft Internet Security and Acceleration (ISA) Server 2004, or a non-Microsoft host firewall. |

When your computer is connected to a public network, such as the Internet, or a nonsecure private network, you can turn on Windows Firewall and use the **Don't allow exceptions** setting to disable all exceptions in the exceptions list. You can also use the **Don't allow exceptions** setting when your computer or organization is being attacked by a malicious program that relies on unsolicited incoming traffic to spread and you need to protect your computer while you install security updates, virus signatures, or security software.

After you have started and configured it, you rarely need to turn off Windows Firewall except to install software or perform troubleshooting.

You usually do not need to configure Windows Firewall on a connection-specific basis, but you might want to if you have a multihomed computer and you do not want Windows Firewall to protect every connection on your computer.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To complete this task, perform the following procedures:

Turn Windows Firewall On or Off

Turn Windows Firewall On or Off for a Specific Connection

Turn Windows Firewall On with No Exceptions

# Turn Windows Firewall On or Off

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to turn on (enable) or turn off (disable) Windows Firewall.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To turn Windows Firewall on or off**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To turn Windows Firewall on or off**

- Open Windows Firewall.

  To turn on Windows Firewall, click **On**, and then click **OK**.

  To turn off Windows Firewall, click **Off**, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To turn Windows Firewall on or off**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set opmode mode =** *mode*

Substitute values for the placeholder in italics. The following table lists possible values for the placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *mode* | enable, disable | Specifies whether to turn Windows Firewall on or off. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Turn Windows Firewall On or Off for a Specific Connection

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to turn on (enable) or turn off (disable) Windows Firewall on a per-connection basis. This is useful if your computer has multiple network connections (sometimes referred to as interfaces) and you do not want to protect every network connection with Windows Firewall.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To turn Windows Firewall on or off for a specific connection**

This procedure can be performed using the graphical user interface or the command prompt. You cannot use Group Policy to turn Windows Firewall on or off on a per-connection basis.

**Using the graphical user interface**

**To turn Windows Firewall on or off for a specific connection**

1. Open Windows Firewall.
2. Click the **Advanced** tab.

   To turn off Windows Firewall for a connection, in **Network Connection Settings**, clear the check box next to the connection that you do not want to protect with Windows Firewall, and then click **OK**.

   To turn on Windows Firewall for a connection, in **Network Connection Settings**, select the check box next to the connection that you want to protect with Windows Firewall, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To turn Windows Firewall on or off for a specific connection**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set opmode mode** = *mode* **interface = "** *interface* **"**

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *mode* | enable, disable | Specifies whether to turn Windows Firewall on or off. |
| *interface* | The name of any network connection that can exist on the computer, as displayed in the Network Connections folder. | Specifies the interface or connection on which you want to enable or disable Windows Firewall. You must enclose *interface* in quotation marks. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows

Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Turn Windows Firewall On with No Exceptions

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to turn on Windows Firewall and prevent all exceptions from taking effect. This procedure is useful when you are connected to a public network, such as the Internet, or a nonsecure private network. When you perform this procedure, all of the exceptions in the exceptions list are disabled and all unsolicited incoming TCP/IP traffic is blocked.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To turn on Windows Firewall with no exceptions**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To turn Windows Firewall on with no exceptions**

1. Open Windows Firewall.
2. Click **On**, select the **Don't allow exceptions** check box, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To turn Windows Firewall on with no exceptions**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set opmode mode = enable exceptions = disable**

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.

# Restoring Windows Firewall Default Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you restore Windows Firewall settings, all of the changes you have made to Windows Firewall are undone (deleted) and all Windows Firewall settings are reset to their original configuration. All of the exceptions in the Windows Firewall exceptions list are deleted. All optional settings, such as log file settings, Internet Control Message Protocol (ICMP) settings, and the notification setting, are reset to their default configuration. Restoring the default settings will turn on Windows Firewall for all network connections, which might cause some programs to stop working. This ensures that your computer is protected by Windows Firewall when you restore default settings. Restoring the default settings might also cause Internet Connection Sharing and Network Bridge to stop working correctly.

| **Note** |
| --- |
| If you used a Netfw.inf file to automate the configuration of Windows Firewall settings, the settings that you specified in Netfw.inf are reapplied to the computer when you restore Windows Firewall default settings. Any Windows Firewall settings that you specified in an answer file, such as Unattend.txt, are deleted and are not restored. If you want to restore the Windows Firewall settings that you configured during installation with an answer file, you must configure the settings manually. |

### When to perform this task

You might need to restore Windows Firewall default settings when you change a server's role or reconfigure a server. In this case, it might be easier to configure Windows Firewall from its default configuration instead of manually rolling back all of the configuration changes you have applied to the computer.

### Task requirements

No special tools are required to complete this task.

### Task procedures

To complete this task, perform the following procedure:

Restore Windows Firewall Default Settings

# Restore Windows Firewall Default Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to reset Windows Firewall to its default configuration.

| **Note** |
| --- |
| Windows Firewall will be turned on when you perform this procedure. This ensures that your computer is protected by Windows Firewall when you restore default settings. |

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

#### To restore Windows Firewall default settings

This procedure can be performed using the graphical user interface or the command prompt. You cannot use Group Policy to restore Windows Firewall default settings.

### Using the graphical user interface

### To restore Windows Firewall default settings

1. Open Windows Firewall.
2. Click the **Advanced** tab, click **Restore Defaults**, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

### Using the command prompt

### To restore Windows Firewall default settings

- Type the following at the command prompt, and press ENTER:

  **netsh firewall reset**

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

### Notes

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Managing Windows Firewall Profiles

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you are configuring Windows Firewall settings, you must know which profile (standard or domain) Windows Firewall is using and how to specify a Windows Firewall profile. Both profiles contain the same set of Windows Firewall settings. However, you typically configure standard profile settings to be more restrictive than domain profile settings because the standard profile settings do not need to include applications and services that are used in a managed domain environment.

When you configure Windows Firewall in Control Panel, you are configuring settings in the profile that is currently in use. You cannot use Windows Firewall in Control Panel to configure settings in the profile that is not currently in use. When you configure Windows Firewall Group Policy settings, you can configure individual policy settings in either the domain profile or the standard profile. The Group Policy Object Editor shows you which profile you are configuring. Likewise, when you use the **netsh firewall** commands to configure Windows Firewall settings, you can choose to configure settings in either the domain profile or the standard profile; however, if you do not specify a profile, the settings are applied to the profile that is currently in use.

| **Note** |
| --- |
| If you do not configure standard profile settings, the default values for standard profile settings are applied whenever Windows Firewall uses the standard profile. These settings might not be appropriate when a computer is connected to a public network like the Internet. It is highly recommended that you configure both domain and standard profile settings and enable Windows Firewall for both profiles. |

For more information about the way Windows Firewall determines which profile to use, see the section titled "How Windows Firewall Works" in the Windows Firewall Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42729).

### When to perform this task

You should determine which profile Windows Firewall is using whenever you configure Windows Firewall settings through the graphical user interface or command prompt.

You should specify which profile you are configuring whenever you use the command prompt or the Group Policy Object Editor.

### Task requirements

No special tools are required to complete this task.

### Task procedures

To complete this task, perform the following procedure:

Determine Which Profile Windows Firewall Is Using

Specify Which Profile You Are Configuring

# Known Issues for Managing Windows Firewall Profiles

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you manage Windows Firewall profiles:

- A Windows Firewall Setting Does Not Take Effect
- VPN and Remote Access Connections Fail

# Determine Which Profile Windows Firewall Is Using

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful when you are configuring settings with Windows Firewall in Control Panel and you need to know to which profile the settings will be applied. This procedure is also useful if you are configuring settings with the **netsh firewall** command and you have not specified to which profile the settings should be applied.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**To determine which profile Windows Firewall is using**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To determine which profile Windows Firewall is using**

- Open Windows Firewall.

  If Windows Firewall is using the domain profile, you will see **Windows Firewall is using your domain settings** displayed at the bottom of the **General** tab.

  If Windows Firewall is using the standard profile, you will see **Windows Firewall is using your standard settings** displayed at the bottom of the **General** tab.

**Using the command prompt**

**To determine which profile Windows Firewall is using**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall show currentprofile**

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Managing Windows Firewall Profiles
Specify Which Profile You Are Configuring
Known Issues for Managing Windows Firewall Profiles

# Specify Which Profile You Are Configuring

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful when you are configuring Windows Firewall settings and you want to configure the settings in a specific profile.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**To specify which profile you are configuring**

This procedure can be performed using the graphical user interface, the command prompt, and Group Policy.

**Using the graphical user interface**

**To specify which profile you are configuring**

1. Open Windows Firewall.
2. If Windows Firewall is not currently using the profile that you want to configure, do one of the following:

   If Windows Firewall is using the domain profile and you want to configure settings in the standard profile, remove the computer from the domain or disconnect the computer from the network. This will force Windows Firewall to use the standard profile.

   If Windows Firewall is using the standard profile and you want to configure settings in the domain profile, join your computer to the domain in which its computer account resides.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To specify which profile you are configuring**

- Use the following **netsh firewall** commands:

  **netsh firewall set allowedprogram profile =** *profile*

  **netsh firewall set icmpsetting profile =** *profile*

  **netsh firewall set multicastbroadcastresponse profile =** *profile*

  **netsh firewall set notifications profile =** *profile*

  **netsh firewall set opmode profile =** *profile*

  **netsh firewall set portopening profile =** *profile*

  **netsh firewall set service profile =** *profile*

The *profile* parameter can have any of the following values:

| Value | Description |
|---|---|
| *current* | Specifies that you want to configure settings in the profile that Windows Firewall is currently using. |
| *domain* | Specifies that you want to configure settings in the domain profile. |

| | |
|---|---|
| *standard* | Specifies that you want to configure settings in the standard profile. |
| *all* | Specifies that you want to configure settings in the standard and domain profiles. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Using Group Policy**

**To specify which profile you are configuring**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, and then open **Windows Firewall**.
3. To configure settings in the domain profile, open **Domain Profile**. To configure settings in the standard profile, open **Standard Profile**.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Determine Which Profile Windows Firewall Is Using
Known Issues for Managing Windows Firewall Profiles

# Managing Program, Port, and System Service Firewall Rules

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Because Windows Firewall blocks all incoming unsolicited TCP/IP traffic by default, you might need to configure program, port, and system service exceptions for programs or system services that are acting as servers, listeners, or peers. Program, port, and system service exceptions must be managed on an ongoing basis as your server roles or configurations change.

To help you manage Windows Firewall program, port, and system service exceptions, review Best Practices for Managing Windows Firewall and Known Issues for Managing Firewall Rules.

The following tasks are described in this objective:

- Configuring Program Firewall Rules
- Configuring Port Firewall Rules
- Configuring System Service Firewall Rules
- Configuring Firewall Rules for Specific Connections
- Configuring Scope Settings

# Known Issues for Managing Firewall Rules

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you manage Windows Firewall exceptions.

- Do not use the **My network (subnet) only** scope setting unless you understand how this scope setting restricts the scope of an exception. For more information, see Configuring Scope Settings.

- Verify that you are configuring exceptions in the correct profile.

- You might have to enable Internet Control Message Protocol (ICMP) settings if you want to use the **ping** command. By default, Windows Firewall blocks all incoming ICMP traffic. For more information about enabling the **ping** command, see The Ping Command Times Out.

- Windows Firewall does not display a **Windows Security Alert** dialog box (notification) when a system service attempts to listen for unsolicited incoming traffic. You must use the security event log to identify system services that attempt to listen for unsolicited incoming traffic.

- If a computer is running Windows Server 2003 and the preconfigured Remote Desktop exception is enabled on a per-connection basis, the Remote Desktop exception will be enabled globally after you apply Service Pack 1 (SP1).

- You can use program exceptions to allow unsolicited incoming traffic through Windows Firewall only if the program uses Windows Sockets (Winsock) to create port assignments. If a program does not use Winsock to assign ports, you must determine which ports the program uses and add those ports to the exceptions list.

- You cannot use the **Custom list** scope setting to specify Internet Protocol version 6 (IPv6) addresses. You must use the **Any computer (including those on the Internet)** or **My network (subnet) only** settings to change the scope of an exception that receives IPv6 traffic.

- When you upgrade from Windows Server 2000 to Windows Server 2003, two shared fax folders, Faxclient$ and Fxssrvcp$, are created. The presence of these shared folders causes Windows Firewall to enable the File and Printer Sharing exception and the **Allow incoming echo request** setting.

- Some remote administration tools require you to configure exceptions on the server that is being managed and on the client that is being used to manage the server. For more information about remote administration tools and exceptions, see article ID 840634 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45342). This article describes why Windows Firewall might prevent you from remotely managing a computer and how you can configure Windows Firewall to overcome this problem.

- Some programs might stop working properly when you use Windows Firewall. For more information about the exceptions that are required for popular programs, see article ID 842242 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45343). The article describes why some program might not work properly with Windows Firewall and how you can configure Windows Firewall to overcome the problem.

- If you create an exception by modifying the registry, the exception might not show up in the Windows Firewall graphical user interface. In addition, you will need to stop and then start the Windows Firewall/Internet Connection Sharing service.

- If you modify the registry to create an exception and do not provide a name for the exception, the exception might not show up in the Windows Firewall graphical user interface. To see all exceptions, use the **netsh firewall show state verbose=enable** command. For more information, see article ID 897663 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=47734). The article describes why an exception might not show up in the graphical user interface and how you can configure the registry to overcome the problem.

# Configuring Program Firewall Rules

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you turn on Windows Firewall for the first time or restore Windows Firewall default settings, all unsolicited incoming TCP/IP traffic is blocked on all network connections. This means that any program or system service that attempts to listen for traffic on a TCP or UDP port will be unable to receive traffic. To allow programs and system services to receive unsolicited traffic through these ports, you must add the program or system service to the Windows Firewall exceptions list.

| **Note** |
| --- |
| In some cases, if you cannot add a program or system service to the exceptions list, you must determine which port or ports the program or system service uses and add the port or ports to the Windows Firewall exceptions list. |

To add a program or system service to the exceptions list, you must specify the executable (.exe) file used by the program or system service. A system service that runs within its own unique .exe file and is not hosted by a service container, such as Svchost.exe, is considered to be a program and can be added to the exceptions list. In the same way, a program that behaves like a system service and runs no matter if a user is logged on to the computer is also considered a program as long as it runs within its own unique .exe file. You cannot add a system service to the exceptions list unless the system service runs within its own unique .exe file. Also, you should not add service containers or programs that host services, such as Svchost.exe, Dllhost.exe, and Inetinfo.exe, to the exceptions list.

When you add a program to the exceptions list, Windows Firewall dynamically opens (unblocks) and closes (blocks) the ports required by the program. When the program is running and listening for incoming traffic, Windows Firewall opens the required ports; when the program is not running or is not listening for incoming traffic, Windows Firewall closes the ports. Because of this dynamic behavior, adding programs to the exceptions list is the recommended method for allowing unsolicited incoming traffic through Windows Firewall.

| **Note** |
| --- |
| You can use program exceptions to allow unsolicited incoming traffic through Windows Firewall only if the program uses Windows Sockets (Winsock) to create port assignments. If a program does not use Winsock to assign ports, you must determine which ports the program uses and add those ports to the exceptions list. |

In addition to adding program exceptions, you can also edit and delete program exceptions. Editing a program exception allows you to change the path or file name that is associated with the program and configure scope settings for the exception. Deleting a program exception removes the exception from the exceptions list and prevents the program from receiving unsolicited incoming traffic (unless a port exception or some other exception allows unsolicited incoming traffic to reach the program).

**Mitigating the Risks Associated with Exceptions**

Each time you add a program to the exceptions list, you make your computer more accessible to attack. A common form of network attack uses port scanning software to identify computers that have open and unprotected ports. By adding numerous programs to the exceptions list, you defeat the purpose of a firewall and increase the attack surface of your computer. This problem typically occurs when you configure a server for several different roles and you must open numerous ports to accommodate each of the server roles. You should closely evaluate the design of any server that requires you to open numerous ports. Servers that are configured for numerous roles or to provide numerous services can be a critical point of failure in your organization and might indicate poor infrastructure design.

To decrease your security risk, follow these guidelines when you configure program exceptions:

- **Create an exception only when you need it.** If you think a program might require a port for unsolicited incoming traffic, do not add the program to the exceptions list until you verify that the program attempted to listen for unsolicited traffic. By default, Windows Firewall displays a notification when a program attempts to listen for unsolicited traffic.

- **Never create an exception for a program that you do not recognize.** If Windows Firewall notifies you that a program has attempted to listen for unsolicited traffic, verify the name of the program and the .exe file before you add the program to the exceptions list.

- **Remove an exception when you no longer need it.** If you add a program to the exceptions list on a server and then change the server's role or reconfigure the services and applications on the server, be sure to update the exceptions list and remove exceptions that are no longer required.

### When to perform this task

You should configure a program exception when you can identify the .exe file for a program and you know that a program must receive unsolicited incoming traffic. You typically perform this task on an ongoing basis as your server roles and server configurations change.

### Task requirements

No special tools are required to complete this task.

### Task procedures

You can create most program exceptions by using the Windows Firewall notification feature. By default, Windows Firewall displays a **Windows Security Alert** dialog box (notification) whenever a program attempts to listen for incoming traffic and the incoming traffic is blocked. If you are a member of the Administrators group (or a member of a group that is a member of the Administrators group), the **Windows Security Alert** dialog box provides a **Keep Blocking** option, which adds the program to the exceptions list but does not enable the exception and an **Unblock** option, which adds the program to the exceptions list and enables the exception so that unsolicited incoming traffic can reach the program. If you are not a member of the Administrators group, a notification appears, but it does not display the options to unblock or continue to block the program. The notification is informational only.

| **Note** |
| --- |
| Many program exceptions are also created programmatically through the Windows Firewall application programming interfaces (APIs). Programs that use the Windows Firewall APIs can add themselves to the exceptions list without any user notification or input. |

The notification feature is useful if you do not know which programs are acting as servers, listeners, or peers (that is, are listening for unsolicited incoming traffic). However, you might have to use other methods to configure program exceptions if:

- You disable the notification feature.
- You are not logged on to a computer as an administrator when you see the **Windows Security Alert** dialog box.
- A program runs as a system service even though it runs within its own .exe file.
- You turn on Windows Firewall with the **Don't allow exceptions** option.

If you know that a program acts as a server, listener, or peer and you know the program's .exe file name and the path to the .exe file, use this procedure to add the program to the exceptions list:

Add a Program to the Firewall Rules List

If you know that a program acts as a server, listener, or peer, but you do not know the program's .exe file name, you might be able to find this information in the Windows Firewall Settings Technical Reference. For more information, see Windows Firewall Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43155).

If you do not know which programs act as servers, listeners, or peers, use the following procedure to identify programs that listen for unsolicited incoming traffic, and then add the program to the exceptions list:

Identify Blocked Servers, Listeners, and Peers

To edit or delete an existing program exception, use the following procedure:

Edit or Delete a Program Firewall Rule

# Add a Program to the Firewall Rules List

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful when a program or system service runs within an executable (.exe) file and you want the program or system service to receive unsolicited incoming traffic.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should configure scope settings for any exceptions that you create or enable. For more information about scope settings, see Configuring Scope Settings.

**To add a program to the exceptions list**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To add a program to the exceptions list**

1. Open Windows Firewall.
2. Click the **Exceptions** tab, and then click **Add program**.

   If the program that you want to add to the exceptions list appears in **Programs**, click the program, and then click **OK**.

   If the program that you want to add to the exceptions list does not appear in **Programs**, click **Browse**, and then do the following:

   In the **Browse** dialog box, find the .exe file for the program that you want to add to the exceptions list, click **Open**, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To add a program to the exceptions list**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set allowedprogram program =** *program* **name =** *name* **mode = enable**

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *program* | Path and file name for the .exe file. | Specifies the program to add to the exceptions list. |

| | | |
|---|---|---|
| *name* | Any string less than 256 characters. | Specifies the friendly name for the exception, which is displayed in the graphical user interface. You must enclose *name* in quotation marks. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Edit or Delete a Program Firewall Rule

# Edit or Delete a Program Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful when you change or delete the ports used by a program or system service and when you want to update the program settings in Windows Firewall.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should verify scope settings for any exceptions that you change. For more information about scope settings, see Configuring Scope Settings.

**To edit or delete a program exception**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To edit or delete a program exception**

1. Open Windows Firewall.
2. Click the **Exceptions** tab, and then click the program exception that you want to edit or delete.

   If you want to delete the program exception, click **Delete**, and then click **Yes**.

   If you want to edit the program exception, click **Edit**, make the changes you want to the program exception settings, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To edit or delete a program exception**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set allowedprogram program =** *program* **name =** *name* **mode = enable**

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *program* | Path and file name for the executable (.exe) file. | Specifies the program to add to the exceptions list. |
| *name* | Any string less than 256 characters. | Specifies the friendly name for the exception, which is displayed in the graphical user interface. You must enclose *name* in quotation marks. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows

Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Identify Blocked Servers, Listeners, and Peers

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful when you do not know which programs act as servers, listeners, or peers, and you want to add those programs to the exceptions list.

**Administrative Credentials**

You do not need administrative credentials to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should verify scope settings for any exceptions that you change. For more information about scope settings, see Configuring Scope Settings.

**To identify programs that are listening for but cannot receive incoming traffic**

This procedure can be performed using the graphical user interface or the command prompt. The graphical user interface method will help you identify programs that have attempted to listen for incoming traffic. The command prompt method will help you identify programs that are currently listening for incoming traffic.

**Using the graphical user interface**

You can use the security log in Event Viewer to identify programs and system services that attempted to listen for unsolicited incoming traffic but whose incoming traffic was blocked by Windows Firewall. You must first configure auditing so that Windows Firewall events are written to the security log.

Use the following procedure to configure auditing:

Enable Auditing of Windows Firewall Events

After you configure auditing, use the following procedure to view Windows Firewall events in the security log:

View Windows Firewall Events in Event Viewer

Programs that attempted to listen for but were unable to receive incoming traffic have the following attributes:

Type: Failure Audit

Event ID: 861

**Using the command prompt**

You can use the **netsh firewall** command to identify programs that are currently listening for but cannot receive incoming traffic because Windows Firewall is blocking it.

**To identify programs that are listening for but cannot receive incoming traffic**

1. Type the following at the command prompt, and press ENTER:

   **netsh firewall show state verbose = enable**

2. Search the output text for **Ports on which programs want to receive incoming connections**.

   If this section does not appear in the output text, then there are no easily recognizable programs currently listening for unsolicited incoming traffic.

3. For each program listed in **Ports on which programs want to receive incoming connections**, determine whether the program's ports are already open. To do this, search the command line output text for **Ports currently open on all**

**network interfaces**. If the open ports and protocols match the ports and protocols used by the program, then the program is already able to receive unsolicited incoming traffic.

4. If the ports associated with a program are not already open, then the program is listening for but cannot receive unsolicited incoming traffic.

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

**See Also**
**Concepts**
Configuring Program Firewall Rules
Known Issues for Managing Firewall Rules
Identify Unblocked Servers, Listeners, and Peers

# Identify Unblocked Servers, Listeners, and Peers

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful when you want to determine which programs are able to receive unsolicited incoming traffic and which ports do not block unsolicited incoming traffic.

**Administrative Credentials**

You do not need administrative credentials to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should verify scope settings for any exceptions that you change. For more information about scope settings, see Configuring Scope Settings.

**To identify unblocked servers, listeners, and peers**
This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To identify unblocked servers, listeners, and peers**

1. Open Windows Firewall.
2. Click the **Exceptions** tab.
3. In **Programs and Services**, identify the program and port exceptions that are enabled. Enabled exceptions have a check mark next to the program or port exception name and indicate unblocked programs and ports.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

| **Note** |
| --- |
| If you create an exception by modifying the registry, the exception might not show up in the Windows Firewall graphical user interface. |

**Using the command prompt**

**To identify unblocked servers, listeners, and peers**

1. Type the following at the command prompt, and press ENTER:

   **netsh firewall show state verbose = enable**

2. Search the output text for **Ports currently open on all network interfaces**. The ports and programs listed in this section are unblocked and represent enabled program or port exceptions.

   If this section does not appear in the output text, then there are no easily recognizable program or port exceptions currently enabled.

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**Prompt**.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Configuring Port Firewall Rules

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you turn on Windows Firewall for the first time or restore Windows Firewall default settings, all unsolicited incoming TCP/IP traffic is blocked on all network connections. This means that any program or system service that attempts to listen for traffic on a TCP or UDP port will be unable to receive traffic. To allow programs and system services to receive unsolicited traffic through these ports, you must add the program or system service to the Windows Firewall exceptions list. In some cases, if you cannot add a program or system service to the exceptions list, you must determine which port or ports the program or system service uses and add the port or ports to the Windows Firewall exceptions list.

| **Note** |
| --- |
| A system service that runs within its own unique executable (.exe) file and is not hosted by a service container is considered to be a program. Such a system service can be added to the exceptions list. In the same way, a program that behaves like a system service and runs no matter if a user is logged on to the computer is also considered a program as long as it runs within its own unique .exe file. Do not add service containers or programs that host services, such as Svchost.exe, Dllhost.exe, and Inetinfo.exe, to the exceptions list. |

When you add a port to the exceptions list, you must specify the protocol (TCP or UDP) and port number. You cannot specify protocols other than TCP or UDP and you cannot add a port number without specifying either TCP or UDP. (For example, you cannot exclude traffic based on protocol alone.) When you add a TCP or UDP port to the exceptions list, the port is open (unblocked) whenever Windows Firewall is running and no matter if there is a program or system service listening for incoming traffic on the port. For this reason, if you need to allow unsolicited incoming traffic through Windows Firewall, you should create a program exception instead of a port exception. When you add a program to the exceptions list, Windows Firewall dynamically opens and closes the ports required by the program. When the program is running and listening for incoming traffic, Windows Firewall opens the required ports; when the program is not running or is not listening for incoming traffic, Windows Firewall closes the ports.

In addition to adding port exceptions to the exceptions list, you can edit and delete port exceptions. Editing a port exception allows you to change the port name, protocol, port number, and scope settings for the exception. Deleting a port exception closes (blocks) the port and prevents the port from receiving unsolicited traffic (unless another port exception or some other exception allows unsolicited incoming traffic to reach the program).

**Mitigating the Risks Associated with Exceptions**

Each time you add a program, system service, or port to the exceptions list, you make your computer more accessible to attack. A common form of network attack uses port scanning software to identify computers that have open and unprotected ports. By adding numerous programs, system services, and ports to the exceptions list, you defeat the purpose of a firewall and increase the attack surface of your computer. This problem typically occurs when you configure a server for several different roles, and you need to open numerous ports to accommodate each of the server roles. You should closely evaluate the design of any server that requires you to open numerous ports. Servers that are configured for numerous roles or configured to provide numerous services can be a critical point of failure in your organization and might indicate poor infrastructure design.

To decrease your security risk, follow these guidelines when you configure port exceptions:

- **Create an exception only when you need it.** If you think a program might require a port for unsolicited incoming traffic, do not add a port to the exceptions list until you verify that the program attempted to listen for unsolicited traffic. By default, Windows Firewall displays a notification when a program attempts to listen for unsolicited traffic. You can also use the security event log to determine whether a system service has attempted to listen for unsolicited incoming traffic.

- **Never create an exception for a program or system service that you do not recognize.** If Windows Firewall notifies you that a program has attempted to listen for unsolicited incoming traffic, verify the name of the program and the .exe file before you add a port to the exceptions list. Likewise, if you use the security event log to determine that a system service attempted to listen for unsolicited incoming traffic, verify that the system service is a valid component before you add a port to the exceptions list.

- **Remove an exception when you no longer need it.** If you add a port to the exceptions list on a server and then change the server's role or reconfigure the services and applications on the server, be sure to update the exceptions list

and remove port exceptions that are no longer required.

### When to perform this task

You should configure a port exception when you cannot configure a program exception and you know that a program or system service must receive unsolicited incoming traffic. You typically perform this task on an ongoing basis as your server roles and server configurations change.

### Task requirements

No special tools are required to complete this task.

### Task procedures

If you know that a program or system service acts as a server, listener, or peer and you know which ports are used by the program or system service, use this procedure to add the ports to the exceptions list:

Add a Port to the Firewall Rules List

If you know that a program or system service acts as a server, listener, or peer, but you do not know the ports that the program or system service uses, you might be able to find this information in the Windows Firewall Settings Technical Reference. For more information, see Windows Firewall Settings on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43155).

If you do not know which programs or system services act as servers, listeners, or peers, use the following procedure to identify the ports used by programs and system services to listen for unsolicited incoming traffic:

Identify Blocked Servers, Listeners, and Peers

To edit or delete an existing program exception, use the following procedure:

Edit or Delete a Port Firewall Rule

# Add a Port to the Firewall Rules List

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to add a TCP or UDP port to the Windows Firewall exceptions list. When you add a port to the exceptions list, the port is always open; unsolicited incoming traffic is always allowed to pass through the port unless you select the **Don't allow exceptions** option when you turn on Windows Firewall. This procedure is useful when you know the port on which a program or service listens for incoming traffic and you want to run the program or service on your computer.

| **Note** |
| --- |
| Adding a port to the exceptions list can reduce the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program to the exceptions list. |

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should configure scope settings for any exceptions that you create or enable. For more information about scope settings, see Configuring Scope Settings.

#### To add a port to the exceptions list

This procedure can be performed using the graphical user interface or the command prompt.

### Using the graphical user interface

### To add a port to the exceptions list

1. Open Windows Firewall.
2. Click the **Exceptions** tab, and then click **Add Port**.
3. In **Name**, type a name for the port exception. This name will appear in the exceptions list.
4. In **Port number**, type the number of the port that you want to add to the exceptions list.
5. Click either **TCP** or **UDP**, depending on the type of traffic, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

### Using the command prompt

### To add a port to the exceptions list

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set portopening protocol** = *protocol* **port** = *port* **name** = *name* **mode** = **enable**

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *protocol* | TCP, UDP, All | Specifies the protocol for the port. Use All to specify both TCP and UDP. |
| *port* | Any number from 1 to 65,535 | Specifies the port number. |
| *name* | Any string less than 256 characters | Specifies the friendly name of the port exception, which is displayed in the graphical user interface. You must enclose *name* in quotation marks. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Edit or Delete a Port Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to change or delete a port exception in the Windows Firewall exceptions list. This procedure is useful when you change or delete the ports used by a program or system service and you want to update the port settings in Windows Firewall.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should verify scope settings for any exceptions that you change. For more information about scope settings, see Configuring Scope Settings.

**To edit or delete a port exception**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To edit or delete a port exception**

1. Open Windows Firewall.
2. Click the **Exceptions** tab, and then click the port exception that you want to edit or delete.

   If you want to delete the port exception, click **Delete**, and then click **OK**.

   If you want to edit the port exception, click **Edit**, make changes to the port exception settings, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To edit or delete a port exception**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set portopening protocol** = *protocol* **port** = *port* **name** = *name* **mode** = *mode*

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *protocol* | TCP, UDP, All | Specifies the protocol for the port. Use All to specify both TCP and UDP. |
| *port* | Any number from 1 to 65,535 | Specifies the port number. |
| *name* | Any string less than 256 characters | Specifies the friendly name of the port exception, which is displayed in the graphical user interface. You must enclose *name* in quotation marks. |

| | | |
|---|---|---|
| *mode* | enable, disable | Specifies whether to allow incoming traffic into the port. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Configuring System Service Firewall Rules

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you turn on Windows Firewall for the first time or restore Windows Firewall default settings, all unsolicited incoming TCP/IP traffic is blocked on all network connections. This means that any program or system service that attempts to listen for traffic on a TCP or UDP port will be unable to receive traffic. To allow programs and system services to receive unsolicited traffic through these ports, you must add the program or system service to the Windows Firewall exceptions list.

| **Note** |
| --- |
| If you cannot add a program or system service to the exceptions list, you must determine which port or ports the program or system service uses and add the port or ports to the Windows Firewall exceptions list. However, adding programs and system services to the exceptions list is the recommended way to control the traffic that is allowed through Windows Firewall. |

Windows Firewall provides four preconfigured system service exceptions that you can enable or disable. When you enable a preconfigured exception, Windows Firewall adds the appropriate programs and ports to the exceptions list so that the system service can receive unsolicited incoming traffic. When you disable a preconfigured system service, Windows Firewall deletes the programs and ports from the exceptions list. The following table lists the preconfigured exceptions you can configure in Windows Server 2003.

| Exception | Description |
| --- | --- |
| File and Printer Sharing | Adds TCP ports 139 and 445 and UDP ports 137 and 138 to the exceptions list. This setting allows a computer to receive unsolicited traffic to shared files, folders, and printers. |
| Remote Desktop | Adds TCP port 3389 to the exceptions list. This setting allows a computer to be managed remotely with the Remote Desktop Connection feature. |
| UPnP Framework | Adds TCP port 2869 and UDP port 1900 to the exceptions list. This setting allows a computer to receive UPnP discovery requests from other computers and devices. |
| Remote Administration | Adds TCP ports 135 and 445 to the exceptions list. Also adds Svchost.exe and Lsass.exe to the exceptions list to allow hosted services to open additional, dynamically-assigned ports, typically in the range of 1024 to 1034. This setting allows a computer to be remotely managed with administrative tools, such as the Microsoft Management Console (MMC) and Windows Management Instrumentation (WMI). It also allows a computer to receive unsolicited incoming Distributed Component Object Model (DCOM) and remote procedure call (RPC) traffic. |

| **Note** |
| --- |
| There is no predefined Remote Assistance exception in Windows Server 2003. If you want to use Remote Assistance on Windows Server 2003, you must enable the Remote Desktop exception or add TCP port 3389 to the Windows Firewall exceptions list. |

In most scenarios, all of the preconfigured exceptions are disabled by default. However, the File and Printer Sharing exception might be enabled by default after you perform an upgrade from an older operating system that has shared folders or printers. The Remote Desktop exception might be enabled by default after you perform an upgrade from an older operating system that has Remote Desktop Connection enabled.

In addition to enabling and disabling preconfigured exceptions, you can edit the File and Printer Sharing, Remote Desktop, and UPnP Framework exceptions. Editing a preconfigured exception allows you to enable and disable the programs and ports that are associated with the preconfigured exception. This is useful for troubleshooting and for those cases in which you want to modify a preconfigured exception to suit a specific server configuration but do not want to add additional exceptions to the exceptions list. You cannot delete any of the preconfigured exceptions; disabling a preconfigured exception does not remove it from the exceptions list.

| Note |
| --- |
| You cannot edit the Remote Administration exception nor can you enable or disable it in the graphical user interface. You must use the **netsh firewall** command or Group Policy to enable or disable the Remote Administration exception. |

**Mitigating the Risks Associated with Exceptions**

Each time you add a program, system service, or port to the exceptions list, you make your computer more accessible to attack. A common form of network attack uses port scanning software to identify computers that have open and unprotected ports. By adding numerous programs, system services, and ports to the exceptions list, you defeat the purpose of a firewall and increase the attack surface of your computer. This problem typically occurs when you configure a server for several different roles, and you need to open numerous ports to accommodate each of the server roles. You should closely evaluate the design of any server that requires you to open numerous ports. Servers that are configured for numerous roles or are configured to provide numerous services can be a critical point of failure in your organization and might indicate poor infrastructure design.

To decrease your security risk, follow these guidelines when you configure preconfigured exceptions:

- **Enable an exception only when you need it.** If you think a program might require a port for unsolicited incoming traffic, do not enable a preconfigured exception until you verify that the program attempted to listen for unsolicited traffic and that the ports it uses are those that are opened by the preconfigured exception.

- **Never enable an exception for a program or system service that you do not recognize.** If Windows Firewall notifies you that a program has attempted to listen for unsolicited incoming traffic, verify the name of the program and the executable (.exe) file before you enable a preconfigured exception. If you use the security event log to determine that a system service attempted to listen for unsolicited incoming traffic, verify that the system service is a valid component before you enable a preconfigured exception.

- **Disable preconfigured exceptions when you no longer need them.** If you enable a preconfigured exception on a server, and then change the server's role or reconfigure the services and applications on the server, be sure to update the exceptions list and disable the preconfigured exceptions that are no longer required.

### When to perform this task

You should configure the File and Printer Sharing, Desktop Connection, and UPnP Framework exceptions when your server provides or uses file and printer sharing, Remote Desktop Connection, or UPnP discovery. These exceptions are preconfigured for these services and features and are not meant to be used in any other way.

You should configure the Remote Administration exception on a server when you want to administer the server with a remote administration tool that uses RPC and DCOM. Malicious users often attempt to attack networks and computers using RPC and DCOM. You should contact the manufacturer of your remote administration tool to determine if it requires RPC and DCOM communication. If it does not, do not enable this exception.

### Task requirements

No special tools are required to complete this task.

### Task procedures

To complete this task, perform the following procedures:

Enable or Disable the File and Printer Sharing Firewall Rule

Enable or Disable the Remote Desktop Firewall Rule

Enable or Disable the UPnP Framework Firewall Rule

Enable or Disable the Remote Administration Firewall Rule

# Enable or Disable the File and Printer Sharing Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to open (enable) or close (disable) the TCP and UDP ports that are required for file and printer sharing. This procedure is useful when you share a folder or printer that you want other users to access.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should configure scope settings for any exceptions that you create or enable. For more information about scope settings, see Configuring Scope Settings.

**To enable or disable the File and Printer Sharing exception**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To enable or disable the File and Printer Sharing exception**

1. Open Windows Firewall.
2. Click the **Exceptions** tab.

   To enable the File and Printer Sharing exception, in **Programs and Services**, select the **File and Printer Sharing** check box, and click **OK**.

   To disable the File and Printer Sharing exception, in **Programs and Services**, clear the **File and Printer Sharing** check box, and click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To enable or disable the File and Printer Sharing exception**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set service type = fileandprint mode =** *mode*

Substitute values for the placeholder in italics. The following table lists possible values for the placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *mode* | enable, disable | Specifies whether to enable or disable the exception. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Enable or Disable the Remote Desktop Firewall Rule

Updated: July 9, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to open (enable) or close (disable) the TCP port required for Remote Desktop connections. This procedure is useful when you want to use Remote Desktop to connect to another computer.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should configure scope settings for any exceptions that you create or enable. For more information about scope settings, see Configuring Scope Settings.

**To enable or disable the Remote Desktop exception**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To enable or disable the Remote Desktop exception**

1. Open Windows Firewall.
2. Click the **Exceptions** tab.

   To enable the remote desktop exception, in **Programs and Services**, select the **Remote Desktop** check box, and click **OK**.

   To disable the remote desktop exception, in **Programs and Services**, clear the **Remote Desktop** check box, and click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To enable or disable the Remote Desktop exception**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set service type = remotedesktop mode =** *mode*

Substitute values for the placeholder in italics. The following table lists possible values for the placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *mode* | enable, disable | Specifies whether to enable or disable the exception. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Enable or Disable the UPnP Framework Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to open (enable) or close (disable) the TCP and UDP ports required for UPnP discovery requests from other computers and devices. This procedure is useful when you want to facilitate the discovery and control of networked devices and services.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should configure scope settings for any exceptions that you create or enable. For more information about scope settings, see Configuring Scope Settings.

**To enable or disable the UPnP Framework exception**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To enable or disable the UPnP Framework exception**

1. Open Windows Firewall.
2. Click the **Exceptions** tab.

   To enable the File and Printer Sharing exception, in **Programs and Services**, select the **UPnP Framework** check box, and click **OK**.

   To disable the File and Printer Sharing exception, in **Programs and Services**, clear the **UPnP Framework** check box, and click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To enable or disable the UPnP Framework exception**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set service type = upnp mode =** *mode*

Substitute values for the placeholder in italics. The following table lists possible values for the placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *mode* | enable, disable | Specifies whether to enable or disable the exception. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Configuring System Service Firewall Rules
Known Issues for Managing Firewall Rules

# Enable or Disable the Remote Administration Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to open (enable) or close (disable) the ports that are used by many remote administration tools, including tools that use Windows Management Instrumentation (WMI), remote procedure calls (RPC), and Distributed Component Object Model (DCOM). This procedure is useful when you are remotely administering a computer and your remote administration tool uses WMI, RPC, or DCOM.

| **Important** |
| --- |
| You should enable the Remote administration exception only if your remote administration tools require RPC and DCOM. Malicious users often attempt to attack networks and computers using RPC and DCOM. It is recommended that you contact the manufacturer of your remote administration tool to determine if it requires RPC and DCOM communication. If it does not, do not enable this exception. |

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should configure scope settings for any exceptions that you create or enable. For more information about scope settings, see Configuring Scope Settings.

#### To enable or disable the Remote administration exception

This procedure can be performed using the command prompt or Group Policy. You cannot perform this procedure using the graphical user interface.

### Using the command prompt

### To enable or disable the Remote administration exception

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set service type = remoteadmin mode =** *mode*

Substitute values for the placeholder in italics. The following table lists possible values for the placeholder.

| Placeholder | Possible Values | Description |
| --- | --- | --- |
| *mode* | enable, disable | Specifies whether to enable or disable the exception. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

### Using Group Policy

### To enable or disable the Remote administration exception

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.

2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then open either **Domain Profile** or **Standard Profile**, depending on which profile you want to

configure.

3. In the details pane, double-click **Windows Firewall: Allow remote administration exception**.
4. In the **Windows Firewall: Allow remote administration exception properties** dialog box, on the **Settings** tab, click **Enabled** or **Disabled**.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Configuring Firewall Rules for Specific Connections

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you turn on Windows Firewall for the first time or restore Windows Firewall default settings, all unsolicited incoming TCP/IP traffic is blocked on all network connections. This means that any program or system service that attempts to listen for traffic on a TCP or UDP port will be unable to receive traffic. To allow programs and system services to receive unsolicited traffic through these ports, you must add the program or system service to the Windows Firewall exceptions list. In some cases, if you cannot add a program or system service to the exceptions list, you must determine which port or ports the program or system service uses and add the port or ports to the Windows Firewall exceptions list. However, adding programs and system services to the exceptions list is the recommended way to control the traffic that is allowed through Windows Firewall.

| **Note** |
| --- |
| A system service that runs within its own unique .exe file and is not hosted by a service container is considered to be a program and can be added to the exceptions list. In the same way, a program that behaves like a system service and runs no matter if a user is logged on to the computer is considered a program as long as it runs within its own unique .exe file. Do not add service containers or programs that host services, such as Svchost.exe, Dllhost.exe, and Inetinfo.exe, to the exceptions list. |

You usually configure Windows Firewall on a global basis. For example, when you turn on Windows Firewall, Windows Firewall is enabled on all of the network connections on your computer and all network connections that you create on your computer. Likewise, when you create an exception, the exception applies to all network connections on the computer and all network connections that you create on the computer.

You can also configure Windows Firewall on a connection-specific (per-connection) or interface-specific basis. When you configure Windows Firewall on a per-connection basis, you can configure Windows Firewall differently for every network connection on your computer. This is useful if your computer has multiple network adapters or multiple network connections and you do not want Windows Firewall enabled on all connections or you want to open different ports for each network connection.

The most commonly configured per-connection exception is a port exception. Per-connection port exceptions are cumulative (between the global and per-connection exceptions). Be sure you understand how global and per-connection exceptions work before you use them.

When you open a port on a global basis, the port is open on every network connection on your computer; you cannot close the port on a per-connection basis. To open a port on a specific connection only, you must close the port globally and then open the port on the specific connection. To close a port on a specific connection, you must close the port globally and make sure that the port is not open on the connection you are configuring. The following table shows how global and per-connection port exceptions are combined.

| Global Port Exception | Per-Connection Port Exception | Resultant Per-Connection Port Exception |
| --- | --- | --- |
| Enabled (port open) | Enabled (port open) | Enabled (port open) on every connection |
| Enabled (port open) | Disabled (port closed) | Enabled (port open) on every connection |
| Enabled (port open) | Not configured (no per-connection port exception) | Enabled (port open) on every connection |
| Disabled (port closed) | Enabled (port open) | Enabled (port open) |
| Disabled (port closed) | Disabled (port closed) | Disabled (port closed) |
| Disabled (port closed) | Not configured (no per-connection port exception) | Disabled (port closed) |

As with global exceptions, when you add a port to the exceptions list on a per-connection basis, you must specify the protocol (TCP or UDP) and the port number. You cannot specify protocols other than TCP or UDP, and you cannot add a port number without specifying either TCP or UDP. (For example, you cannot exclude traffic based on just a protocol.) When you add a TCP

or UDP port to the exceptions list, the port is open (unblocked) whenever Windows Firewall is running and no matter if there is a program or system service listening for incoming traffic on the port.

In addition, per-connection port exceptions are created and applied without regard to which Windows Firewall profile a computer is using. For example, if your computer is using the domain profile and you configure a port exception for a specific connection, the port exception will be applied when the computer is using the domain profile and when the computer is using the standard profile. Furthermore, you cannot configure scope settings for a per-connection port exception. The scope of a per-connection port exception includes any computer that has access to the specific network connection.

In addition to adding port exceptions to the exceptions list, you can edit and delete port exceptions on a per-connection basis. Editing a port exception allows you to change the exception name, protocol, and port number. Deleting a port exception closes (blocks) the port and prevents the port from receiving unsolicited incoming traffic (unless a port exception or some other exception exists to allow unsolicited incoming traffic to reach the program).

**Mitigating the Risks Associated with Exceptions**
Each time you add a program, system service, or port to the exceptions list, you make your computer more accessible to attack. A common form of network attack uses port scanning software to identify computers that have open and unprotected ports. By adding numerous programs, system services, and ports to the exceptions list, you defeat the purpose of a firewall and increase the attack surface of your computer. This problem typically occurs when you configure a server for several different roles, and you need to open numerous ports to accommodate each role. You should closely evaluate the design of any server that requires you to open numerous ports. Servers that are configured for numerous roles or to provide numerous services can be a critical point of failure in your organization and might indicate poor infrastructure design.

To decrease your security risk, follow these guidelines when you configure port exceptions:

- **Create an exception only when you need it.** If you think a program might require a port for unsolicited incoming traffic, do not add a port to the exceptions list until you verify that the program attempted to listen for unsolicited traffic. You can use the security event log to determine whether a program has attempted to listen for unsolicited incoming traffic.

- **Remove an exception when you no longer need it.** If you add a port to the exceptions list on a server and then change the server's role or reconfigure its services and applications, be sure to update the exceptions list and remove those port exceptions that are no longer required.

### When to perform this task

You should configure a per-connection port exception when you want to allow unsolicited incoming traffic through Windows Firewall on a specific connection. You should do this only if you know that a program or system service must receive unsolicited traffic. You typically perform this task on an ongoing basis as your server roles and server configurations change.

### Task requirements

No special tools are required to complete this task.

### Task procedures

To complete this task, perform the following procedure:

Add a Port to the Firewall Rules List for a Specific Connection

Configuring Scope Settings

# Add a Port to the Firewall Rules List for a Specific Connection

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to add a TCP or UDP port to the Windows Firewall exceptions list on a per-connection basis. This is useful if your computer has multiple network connections (sometimes referred to as interfaces) and you want to open different ports on each network connection. When you add a port to the exceptions list, the port is always open; unsolicited incoming traffic is always allowed to pass through the port unless you select the **Don't allow exceptions** option when you turn on Windows Firewall.

| **Note** |
| --- |
| Adding a port to the exceptions list can reduce the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program (.exe file) to the exceptions list. |

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

#### To add a port to the exceptions list for a specific connection

This procedure can be performed using the graphical user interface or the command prompt. You cannot use Group Policy to configure per-connection port exceptions.

### Using the graphical user interface

#### To add a port to the exceptions list for a specific connection

1. Open Windows Firewall, and then click the **Advanced** tab.
2. In **Network Connection Settings**, click the connection that you want to configure, and click **Settings**.
3. Click **Add**.
4. In the **Service Settings** dialog box, in **Description of service**, type a display name for the port exception. The display name appears in the exceptions list.
5. In **Name or IP address of the computer hosting this service on your network**, type the name or IP address of the local computer.
6. In **External port number for this service**, type the port number to add to the exceptions list.
7. In **Internal port number for this service**, type the port number to add to the exceptions list.
8. Click either **TCP** or **UDP**, depending on the type of traffic, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

### Using the command prompt

#### To add a port to the exceptions list for a specific connection

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set portopening protocol** = *protocol* **port** = *port* **name** = *name* **mode** = *mode* **interface** = " *interface* "

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *protocol* | TCP, UDP, All | Specifies the protocol for the port. Use All to specify both TCP and UDP. |
| *port* | Any number between 1 and 65,535 | Specifies the port number for which you want to create an exception. |
| *name* | Any string less than 256 characters | Specifies the friendly name of the port exception. You must enclose *name* in quotation marks. |
| *mode* | enable, disable | Specifies whether to enable or disable the exception. |
| *interface* | The name of any network connection that can exist on the computer, as displayed in the Network Connections folder | Specifies the connection, or interface, on which to enable or disable the exception. You must enclose *interface* in quotation marks. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Edit or Delete a Connection-Specific Port Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to edit or delete a TCP or UDP port that is in the Windows Firewall exceptions list on a per-connection basis. This is useful if your computer has multiple network connections (sometimes referred to as interfaces) and you have opened different ports (created specific exceptions) on each network connection.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**To edit or delete a connection-specific port exception**

This procedure can be performed using the graphical user interface or the command prompt. You cannot use Group Policy to configure per-connection port exceptions.

**Using the graphical user interface**

**To edit or delete a connection-specific port exception**

1. Open Windows Firewall, and click the **Advanced** tab.
2. In **Network Connection Settings**, click the connection that the system service uses to communicate, and then click **Settings**.
3. Click the system service that you want to edit or delete.

   If you want to delete the system service exception, click **Delete**, and then click **OK**.

   If you want to edit the system service exception, click **Edit**, make changes to the system service exception settings, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To edit or delete a connection-specific port exception**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set portopening protocol** = *protocol* **port** = *port* **name** = *name* **mode** = *mode* **interface** = **"** *interface* **"**

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *protocol* | TCP, UDP, All | Specifies the protocol for the port. Use All to specify both TCP and UDP. |
| *port* | Any number between 1 and 65,535 | Specifies the port number for which you want to create an exception. |
| *name* | Any string less than 256 characters | Specifies the friendly name of the port exception. You must enclose *name* in quotation marks. |
| *mode* | enable, disable | Specifies whether to enable or disable the exception. |

| | | |
|---|---|---|
| *interface* | The name of any network connection that can exist on the computer, as displayed in the Network Connections folder | Specifies the connection, or interface, on which to enable or disable the exception. You must enclose *interface* in quotation marks. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- You cannot change the name of a per-connection port exception by clicking **Edit**. To rename a per-connection port exception, delete the exception and create a new exception with the new name.

Configuring Port Firewall Rules

# Configuring Scope Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

When you configure a program, port, or system service exception, you should also configure scope settings for the exception. Scope settings define from which addresses incoming traffic is allowed to originate, which defines the set of computers that are allowed to send traffic for an exception. There are three scope options:

**Any computer (including those on the Internet)**

This setting allows traffic from any Internet Protocol version 4 (IPv4) or Internet Protocol version 6 (IPv6) address through the exception. This setting might make your computer more accessible to malicious users or programs on the Internet.

**My network (subnet) only**

This setting allows traffic only from IPv4 or IPv6 addresses that can be reached directly by your computer. Windows Firewall determines whether the source IPv4 or IPv6 address of the incoming packet can be reached directly by querying the IPv4 and IPv6 routing tables. You can see all destinations that are considered directly reachable by typing the **route print** command at a command prompt. For the IPv4 routing table, all IPv4 addresses that match the routes in which the IPv4 address of the **Gateway** column equals the IPv4 address of the **Interface** column are considered directly reachable. For the IPv6 routing table, all IPv6 addresses that match routes in which the **Gateway** column is set to **On-link** are considered directly reachable. Therefore, the set of directly reachable addresses depends on your networking configuration, as specified by the IPv4 and IPv6 configuration of LAN-based connections (such as Ethernet and 802.11 wireless), dial-up connections, and broadband Internet connections. In some Internet configurations, all destinations are considered directly reachable.

For example, for a computer that is directly connected to a private home network only, the set of directly reachable unicast addresses is confined to those that match the IPv4 network ID of the private subnet. If the network connection is configured with an IPv4 address of 192.168.0.99 with a subnet mask of 255.255.0.0, only traffic from IPv4 addresses in the range 192.168.0.0 to 192.168.255.255 is allowed.

In another example, for a computer that is directly connected to both a private home network and the Internet through a cable modem, the set of directly reachable unicast addresses are those that match either the network ID of the private subnet or the cable modem provider subnet. For example, if the private network connection is configured with an IPv4 address of 192.168.0.1 and a subnet mask of 255.255.0.0 and the cable modem connection is configured with an IPv4 address of 131.107.17.211 and a subnet mask of 255.255.255.0, traffic received by either network connection is allowed from IPv4 addresses in ranges from 192.168.0.0 to 192.168.255.255 and from 131.107.17.0 to 131.107.17.255.

| **Important** |
| --- |
| The use of the **My network (subnet) only** option can make your computer more accessible than you expect. Make sure that you clearly understand how this option restricts scope before you use it. |

**Custom list**

This setting allows you to specify one or more IPv4 addresses or IPv4 address ranges separated by commas (with no spaces). IPv4 address ranges typically correspond to subnets. For IPv4 addresses, type the IPv4 address in dotted decimal notation. For IPv4 address ranges, you can specify the range using a dotted decimal subnet mask or a prefix length. When you use a dotted decimal subnet mask, you can specify the range as an IPv4 network ID (such as 10.47.81.0/255.255.255.0) or by using an IPv4 address within the range (such as 10.47.81.231/255.255.255.0). When you use a network prefix length, you can specify the range as an IPv4 network ID (such as 10.47.81.0/24) or by using an IPv4 address within the range (such as 10.47.81.231/24). The following is an example custom list:
10.91.12.56,10.7.14.9/255.255.255.0,10.116.45.0/255.255.255.0,172.16.31.11/24,172.16.111.0/24

You cannot specify a custom list for IPv6 traffic.

| **Important** |
| --- |

When you configure and enable an exception, you are instructing Windows Firewall to allow specific unsolicited incoming traffic sent from the specified scope (from any address, from an address that can be reached directly, or from a custom list). For any scope, enabling an exception makes the computer accessible to attacks based on incoming unsolicited traffic from computers that are assigned the allowed addresses and from malicious computers that spoof traffic. There is no way to prevent spoofed attacks from the Internet on connections assigned public IPv4 addresses except to disable the exception. Therefore, you should try to configure scope options so that the number of computers that are allowed to send unsolicited traffic through an exception is kept to a minimum. This will reduce, but not eliminate, the likelihood of a spoof attack.

**When to perform this task**

You should perform this task whenever you add, enable, or edit an exception. You typically perform this procedure on an ongoing basis as your server configurations and server roles change and your network architecture changes.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To complete this task, perform the following procedures:

Change the Scope of a Firewall Rule

Configuring Firewall Rules for Specific Connections

# Change the Scope of a Firewall Rule

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to configure the scope of an exception when you add or change a port, program, or system service exception. This procedure is useful when you want to create an exception but you want to make the exception less accessible, particularly to malicious users.

You cannot configure scope settings for port exceptions that are configured on a per-connection basis. The scope of a per-connection port exception includes any IP address. Also, you cannot configure scope settings for Internet Control Message Protocol (ICMP) exceptions. The scope of an ICMP exception includes any IP address.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

Using the **My network (subnet) only** option can make your computer more accessible than you expect. Make sure that you clearly understand how this option restricts scope before you use it.

**To change the scope of an exception**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To change the scope of an exception**

1. Open Windows Firewall, and click the **Exceptions** tab.
2. In **Programs and Services**, click the exception that you want to configure, and click **Edit**.
3. Click **Change scope**, and do one of the following:

   If you want to enable the exception for all computers, click **Any computer (including those on the Internet)**, and then click **OK**.

   If you want to enable the exception for computers that can be reached directly by your computer, click **My network (subnet) only**, and then click **OK**.

   If you want to enable the exception for specific IPv4 IP addresses or IPv4 IP address ranges, click **Custom list**, enter the specific IP addresses or IP address ranges, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To change the scope of an exception**

- If you are changing the scope of a program exception, type the following at the command prompt, and press ENTER:

  **netsh firewall set allowedprogram program =** *program* **name =** *name* **mode =** *mode* **scope =** *scope* **addresses =** *addresses*

- If you are changing the scope of a system service exception, type the following at the command prompt, and press ENTER:

  **netsh firewall set service type** = *type* **mode** = *mode* **scope** = *scope* **addresses** = *addresses*

- If you are changing the scope of a port exception, type the following at the command prompt, and press ENTER:

  **netsh firewall set portopening protocol** = *protocol* **port** = *port* **name** = *name* **mode** = *mode* **scope** = *scope* **addresses** = *addresses*

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *program* | Path and file name for the .exe file. | Specifies the program to add to the exceptions list. |
| *protocol* | TCP, UDP, All | Specifies the protocol for the port. Use All to specify both TCP and UDP. |
| *port* | Any number from 1 to 65,535 | Specifies the port number. |
| *type* | Fileandprint, Remoteadmin, Remotedesktop, Upnp, All | Specifies the service to configure. Use All to specify all services. |
| *name* | Any string less than 256 characters | Specifies the friendly name for the exception, which is displayed in the graphical user interface. You must enclose *name* in quotation marks. |
| *mode* | enable, disable | Specifies whether the exception is enabled or disabled. |
| *scope* | All, Subnet, Custom | Specifies the scope setting. |
| *addresses* | Comma-separated list of IPv4 addresses or ranges of IPv4 addresses | Specifies the IPv4 addresses or IPv4 address ranges if you use the **Custom scope** setting. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.

- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Known Issues for Managing Firewall Rules

# Managing IPsec, Multicast, and ICMP Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Firewall provides special settings for managing multicast and Internet Control Message Protocol (ICMP) traffic, as well as traffic protected by Internet Protocol security (IPsec).

To help you manage this type of traffic, review Best Practices for Managing Windows Firewall and Known Issues for Managing IPsec, Multicast, and ICMP Settings.

The following tasks are described in this objective:

Configuring ICMP Settings

Configuring IPsec Settings

Configuring Multicast Settings

# Known Issues for Managing IPsec, Multicast, and ICMP Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you manage Internet Protocol (IPsec), multicast, and Internet Control Message Protocol (ICMP) settings.

- Your computer might not be able to connect to multicast streams if you have Windows Firewall enabled. For more information about this issue, see article ID 883831 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45388). The article describes why Windows Firewall might prevent you from using Windows Media Player to connect to multicast and UDP streams and how you can configure Windows Firewall to overcome the problem.

- You might experience problems with ICMP traffic if you also use IPsec to secure traffic. For more information, see article ID 889527 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=45389). This article describes why you might have problems with ICMP traffic when you use IPsec to secure traffic and it provides information about how you can overcome the problem.

- The Ping Command Times Out.

# Configuring ICMP Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can configure Windows Firewall so that ICMP version 4 (ICMPv4) and ICMP version 6 (ICMPv6) traffic is either blocked or allowed. The following table describes the ICMPv4 and ICMPv6 messages that you can control with Windows Firewall.

| ICMP message | Description |
|---|---|
| Allow incoming echo request | Corresponds to ICMPv4 Type 8 (Echo) and ICMPv6 Type 128 (Echo Request) messages. |
| Allow incoming timestamp request | Corresponds to ICMPv4 Type 13 (Timestamp) messages. |
| Allow incoming mask request | Corresponds to ICMP Type 17 (Address Mask Request) messages. |
| Allow incoming router request | Corresponds to ICMP Type 9 (Router Solicitation) messages. |
| Allow outgoing destination unreachable | Corresponds to ICMPv4 Type 3 (Destination Unreachable) and ICMPv6 Type 1 (Destination Unreachable) messages. |
| Allow outgoing source quench | Corresponds to ICMP Type 4 (Source Quench) messages. |
| Allow outgoing parameter problem | Corresponds to ICMP Type 12 (Parameter Problem) and ICMPv6 Type 4 (Parameter Problem) messages. |
| Allow outgoing time exceeded | Corresponds to ICMP Type 11 (Time Exceeded) and ICMPv6 Type 3 (Time Exceeded) messages. |
| Allow redirect | Corresponds to ICMP Type 5 (Redirect) and ICMPv6 Type 137 (Neight Discovery Redirect) messages. |
| Allow outgoing packet too big | Corresponds to ICMPv6 Type 2 (Packet Too Big) messages. |

If you do not enable the **Allow incoming echo requests** setting, commands that use the ICMP Echo message (also known as the ICMP Echo Request message), such as **ping** or **tracert**, will not work. If you are running network management software that uses ICMP Destination Unreachable messages, you need to enable the **Allow outbound destination unreachable** setting.

If you configure Windows Firewall so that traffic is allowed through TCP port 445, Windows Firewall will allow incoming ICMP Echo messages automatically. This is true even if you disable the **Allow incoming echo requests** setting, or you disable the **Windows Firewall: Allow ICMP exceptions** Group Policy setting, or you use the **netsh firewall set icmpsetting 8 disable** command. For example, there are two predefined service exceptions that allow traffic through TCP port 445: the File and Printer Sharing exception and the Remote Administration exception. If you enable either of these exceptions, and you allow unsolicited incoming traffic to pass through TCP port 445, other computers will be able to access your computer with the **ping** command.

**When to perform this task**

You should use these settings if your organization uses the **ping** or **tracert** commands for troubleshooting. Usually, you configure these settings only once or on an as-needed basis.

**Task requirements**

No special tools are required to perform this task.

**Task procedures**

To complete this task, perform the following procedure:

Block and Unblock ICMP Messages

**See Also**
**Concepts**
Known Issues for Managing IPsec, Multicast, and ICMP Settings

# Block and Unblock ICMP Messages

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to block or unblock Internet Control Message Protocol (ICMP) messages. This procedure is useful if you want to allow other computers to access your computer with the **ping** command or **tracert** command.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To block and unblock ICMP messages**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To block and unblock ICMP messages**

1. Open Windows Firewall.
2. Click the **Advanced** tab.
3. In **ICMP**, click **Settings**.
4. In the **ICMP Settings** dialog box, do one of the following:

   To unblock an ICMP message (allow the ICMP message to pass through Windows Firewall), select the check box next to the ICMP message and then click **OK**.

   To block an ICMP message (prevent the ICMP message from passing through Windows Firewall), clear the check box next to the ICMP message and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To block and unblock ICMP messages**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set icmpsetting type =** *type* **mode =** *mode*

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *type* | 2,3,4,5,8,9,11,12,13,17, All | Specifies the ICMP message type. All specifies that you want to configure all ICMP message types. |

| | | |
|---|---|---|
| *mode* | Enable, Disable | Specifies whether to enable (allow the ICMP message to pass through Windows Firewall) or disable (prevent the ICMP message from passing through Windows Firewall). |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

### Notes

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

**Concepts**
Known Issues for Managing IPsec, Multicast, and ICMP Settings
Configuring ICMP Settings

# Configuring IPsec Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can configure Windows Firewall so that all incoming authenticated traffic protected by Internet Protocol security (IPsec) completely bypasses Windows Firewall processing on specific computers. To do this, you must enable the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting. To specify which computers allow incoming IPsec-protected traffic to bypass Windows Firewall, you must provide a Security Descriptor Definition Language (SDDL) string that corresponds to the group accounts for the computers to which this policy applies.

| **Important** |
| --- |
| This information applies only to IPsec in Windows Server 2003 with Service Pack (SP) 1 and Windows XP with SP2. It does not apply to Microsoft Windows Vista® or Windows Server® 2008, or later versions of Windows. For information about using authenticated bypass on Windows Vista or Windows Server 2008, see How to Enable Authenticated Bypass or "Allow if Secure" at http://go.microsoft.com/fwlink/?linkid=111313 in the Windows Server 2008 Technical Library. |

The format of the SDDL string for a single group is:

**O:DAG:DAD:(A;;RCGW;;;** *SID* **)**

Where *SID* is the Security Identifier (SID) of a group account.

Use the Getsid.exe tool to obtain the SID of a group account. Getsid.exe is typically used to compare the SIDs of two accounts on different domain controllers, but you can also use it to obtain the SID of a specified user or group account.

To obtain a SID for a group account, use the following syntax:

**getsid ** *domain_controller group_account* **** *domain_controller group_account*

Where *domain_controller* is the computer name of a domain controller and *group_account* is the group account name.

The following example uses the Getsid.exe tool with a domain controller named EXAMPLE2 in the example.com domain and a group account named IPsecComputers:

```
C:\>getsid \\example2 IPsecComputers \\example2 IPsecComputers
The SID for account EXAMPLE\IPsecComputers matches account EXAMPLE\IPsecComputers
The SID for account EXAMPLE\IPsecComputers is
S-1-5-21-3575094098-3669797271-991787341-1127
The SID for account EXAMPLE\IPsecComputers is
S-1-5-21-3575094098-3669797271-991787341-1127
```

Although redundant, it provides the information you need. To allow computers in the IPsecComputers group to bypass Windows Firewall, use the following string to configure the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting:

O:DAG:DAD:(A;;RCGW;;;S-1-5-21-3575094098-3669797271-991787341-1127)

If you have more than one group, then the syntax for the SDDL string is:

O:DAG:DAD:(A;;RCGW;;;*SID1*) (A;;RCGW;;;*SID2*) (A;;RCGW;;;*SID3*)...

If you enable the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting, and a computer that is a member of one of the security groups on the SDDL list receives an IPsec-protected packet, Windows Firewall does not process it to determine whether it is allowed.

If you disable or do not configure this Group Policy setting, incoming IPsec-protected traffic is processed by Windows Firewall. If you enable this Group Policy setting and configure an SDDL list, upon disabling this setting, Windows Firewall deletes the list.

**When to perform this task**

You can use this setting if your organization uses both IPsec and Windows Firewall, and you assume that traffic protected by IPsec is safe. If you enable the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting, you might need to modify the SDDL list to include additional security groups on an ongoing basis.

**Task requirements**

Getsid.exe. For more information, see Windows Support Tools at the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43235).

**Task procedures**

To complete this task, perform the following procedure:

Configure Authenticated IPsec Bypass

**See Also**
**Concepts**
Known Issues for Managing IPsec, Multicast, and ICMP Settings

# Configure Authenticated IPsec Bypass

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to allow authenticated traffic protected by Internet Protocol security (IPsec) to bypass Windows Firewall. When you perform this procedure, you must provide a Security Descriptor Definition Language (SDDL) string that contains a list of the computers or groups of computers that you want to bypass Windows Firewall. If you enable the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting, and a computer that is a member of one of the security groups on the SDDL list receives an IPsec-protected packet, Windows Firewall does not process it to see whether it is allowed. This setting is useful if you use Windows Firewall and IPsec in your organization and assume that any computer using IPsec is protected and that its traffic should be allowed to pass through Windows Firewall.

**Important**

This information applies only to IPsec in Windows Server 2003 with Service Pack (SP) 1 and Windows XP with SP2. It does not apply to Microsoft Windows Vista® or Windows Server® 2008, or later versions of Windows. For information about using authenticated bypass on Windows Vista or Windows Server 2008, see How to Enable Authenticated Bypass or "Allow if Secure" at http://go.microsoft.com/fwlink/?linkid=111313 in the Windows Server 2008 Technical Library.

For information about creating SDDL strings, see Managing IPsec, Multicast, and ICMP Settings.

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

If you perform this procedure and enable the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting, and then later disable the **Windows Firewall: Allow authenticated IPSec bypass** Group Policy setting, the SDDL strings that you entered will be deleted. Therefore, you should save the SDDL strings that you use to perform this procedure in case you need to perform this procedure again in the future.

#### To allow traffic protected by IPsec through Windows Firewall

This procedure can be performed through Group Policy only. You cannot use the graphical user interface or the command prompt to perform this procedure.

#### To allow traffic protected by IPsec through Windows Firewall

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, and then click **Windows Firewall**.
3. In the details pane, double-click **Windows Firewall: Allow authenticated IPSec bypass**.
4. In the **Windows Firewall: Allow authenticated IPSec bypass properties** dialog box, on the **Settings** tab, click **Enabled**.
5. In **Define IPSec peers to be exempted from firewall policy**, type the SDDL string that corresponds to the group accounts for the computers to which this policy applies, and then click **OK**.

**Note**

- The IPsec bypass only applies to computers that are the responder to an IPsec SA negotiation. The initiator of the session does not set the bypass flag for the connection, so the firewall on the initiator still inspects the packets. If the responder uses the same IPsec SA to connect back to the initiator, the packets are filtered out by the firewall on the initiator.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Group Policy settings must be refreshed before they take effect.

**See Also**
**Concepts**
Configuring IPsec Settings
Known Issues for Managing IPsec, Multicast, and ICMP Settings

# Configuring Multicast Settings

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can configure Windows Firewall so that Windows Firewall blocks all unicast responses to outgoing multicast or broadcast traffic. When you enable this setting, and your computer sends multicast or broadcast messages to other computers, Windows Firewall blocks the unicast responses sent by those other computers.

If you disable or do not configure this setting, and this computer sends a multicast or broadcast message to other computers, Windows Firewall waits as long as three seconds for unicast responses from the other computers and then blocks all later responses.

This setting has no effect if the unicast message is a response to a Dynamic Host Configuration Protocol (DHCP) broadcast message sent by this computer. Windows Firewall always permits those DHCP unicast responses. However, this setting can interfere with the NetBIOS messages that detect name conflicts.

**When to perform this task**

You should perform this task if your computer sends broadcast or multicast messages and you want Windows Firewall to block all unicast responses.

**Task requirements**

No special tools are required to perform this task.

**Task procedures**

To complete this task, perform the following procedure:

Block Unicast Responses to Multicast Traffic

**See Also**
**Concepts**
Known Issues for Managing IPsec, Multicast, and ICMP Settings

# Block Unicast Responses to Multicast Traffic

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to block unicast response traffic that is received in response to multicast or broadcast traffic.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To block unicast responses to multicast traffic**
This procedure can be performed using the command prompt or Group Policy. You cannot perform this procedure in the graphical user interface.

**Using the command prompt**

**To block unicast responses to multicast traffic**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set multicastbroadcastresponse mode = enable**

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Using Group Policy**

**To block unicast responses to multicast traffic**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, and then click **Windows Firewall**.
3. In the details pane, double-click **Windows Firewall: Prohibit unicast response to multicast or broadcast requests**.
4. In the **Windows Firewall: Prohibit unicast response to multicast or broadcast requests properties** dialog box, on the **Settings** tab, click **Enabled**.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Managing Windows Firewall Notifications

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By default, Windows Firewall displays a **Windows Security Alert** dialog box (referred to as a notification) when a program attempts to listen for unsolicited incoming traffic and the incoming traffic is blocked. If you are a member of the Administrators group on the computer (or you are a member of a group that is a member of the Administrators group), the notification provides you with the following options:

**Unblock**. This adds the program to the exceptions list in the profile that Windows Firewall is currently using and enables the program exception. If you choose this option, the **Windows Security Alert** dialog box will not be displayed again for the program even if you disable the program exception. The **Windows Security Alert** dialog box might appear again if the program attempts to listen for incoming traffic when Windows Firewall is using the other profile.

**Keep Blocking**. This adds the program to the exceptions list in the profile that Windows Firewall is currently using, but does not enable the exception. If you choose this option, the **Windows Security Alert** dialog box will not be displayed again for the program because the program is in the exceptions list. The **Windows Security Alert** dialog box might appear again if the program attempts to listen for incoming traffic when Windows Firewall is using the other profile.

**Ask Me Later**. No action is taken (that is, the program is not added the exceptions list). If you choose this option, the **Windows Security Alert** dialog box will appear the next time the program attempts to listen for unsolicited incoming traffic.

If you are not a member of the Administrators group on the computer, you will still see a **Windows Security Alert** dialog box when a program attempts to listen for unsolicited incoming traffic and the incoming traffic is blocked; however, the notification is informational only. You are not given the ability to take any action; the **Unblock**, **Keep Blocking**, or **Ask Me Later** options are not displayed.

Windows Firewall does not display a notification in the user interface (UI) when a system service attempts to listen for incoming traffic on a port and the incoming traffic is blocked. This is also true for any program that runs like a system service (that is, a program that runs under an account that has higher privilege than a user account, for example, the Local System account, or a program that runs even when there is no user logged on to the computer). You can use the security event log to determine whether a system service, or a program that runs like a system service, attempts to listen for incoming traffic. To do this, you must enable **Audit process tracking** and **Audit policy change** settings in Group Policy. When you do this, Windows Firewall will write a Failure Audit with Event ID 861 to the security event log any time a program or system service attempts to listen for incoming traffic. For more information about Windows Firewall events, see Using the Security Log.

In addition, there are two other instances when Windows Firewall might not display notifications:

- Windows Firewall does not display notifications if you select the **Don't allow exceptions** check box in Windows Firewall in Control Panel, or if you enable the **Do not allow exceptions** setting in Group Policy, or if you use the **netsh firewall set opmode exceptions = disable** command. There are no Windows Firewall settings that allow you to override this behavior.

- Windows Firewall does not display notifications for programs that rely on the Winsock driver to dynamically bind to a UDP port. If a program uses this method (sometimes referred to as wildcard binds) to bind to a UDP port, you might be able to use the **netstat** command and other troubleshooting tools to determine which UDP port is being used, and then add that port to the exceptions list.

You can disable the notification feature, which prevents Windows Firewall from displaying a **Windows Security Alert** dialog box. This might be necessary on remotely managed servers.

**When to perform this task**

You should manage Windows Firewall notifications as the notifications are displayed. If you do not want notifications to appear, you only have to disable notifications once unless you enable notifications or reset Windows Firewall settings.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To enable or disable the notification feature, use the following procedure:

Enable or Disable Windows Firewall Notifications

**See Also**
**Concepts**
Known Issues for Managing Windows Firewall Notifications

# Known Issues for Managing Windows Firewall Notifications

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you manage Windows Firewall notifications.

- Windows Firewall does not display notifications if you select the **Don't allow exceptions** check box in Windows Firewall in Control Panel, or if you enable the **Do not allow exceptions** policy setting in Group Policy, or if you use the **netsh firewall set opmode exceptions = disable** command. There are no Windows Firewall settings that allow you to override this behavior.

- Windows Firewall does not display notifications for programs that rely on the Winsock driver to dynamically bind to a UDP port. If a program uses this method (sometimes referred to as wildcard binds) to bind to a UDP port, you might be able to use the **netstat** command and other troubleshooting tools to determine which UDP port is being used, and then add that port to the exceptions list.

- Windows Firewall does not display a notification when a system service attempts to listen for incoming traffic on a port and the incoming traffic is blocked. This is also true for any program that runs like a system service (that is, a program that runs under an account that has higher privilege than a user account, for example, the Local System account, or a program that runs even when there is no user logged on to the computer).

# Enable or Disable Windows Firewall Notifications

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure to enable or disable the notification feature in Windows Firewall. This is useful on remotely managed servers or on servers that are managed or monitored infrequently. The notification feature is enabled by default.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To enable or disable Windows Firewall notifications**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To enable or disable Windows Firewall notifications**

1. Open Windows Firewall.
2. Click the **Exceptions** tab, and do one of the following:

   To enable notifications, select the **Display a notification when Windows Firewall blocks a program** check box, and click **OK**.

   To disable notifications, clear the **Display a notification when Windows Firewall blocks a program** check box, and click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To add a port to the exceptions list**

- To enable notifications, type the following at the command prompt, and press ENTER:

  **netsh firewall set notifications mode = enable profile =** *profile*

- To disable notifications, type the following at the command prompt, and press ENTER:

  **netsh firewall set notifications mode = disable profile =** *profile*

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *profile* | Current, Domain, Standard, All | Specifies the profile that you want to configure. All indicates that you want to configure both the standard profile and the domain profile. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- You can also use Group Policy settings to perform this procedure and configure other Windows Firewall settings.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Windows Firewall does not display notifications if you select the **Don't allow exceptions** check box in Windows Firewall in Control Panel, or if you enable the **Do not allow exceptions** policy setting in Group Policy, or if you use the **netsh firewall set opmode exceptions = disable** command. There are no Windows Firewall settings that allow you to override this behavior.
- Windows Firewall does not display notifications for programs that rely on the Winsock driver to dynamically bind to a UDP port. If a program uses this method (sometimes referred to as wildcard binds) to bind to a UDP port, you might be able to use the **netstat** command and other troubleshooting tools to determine which UDP port is being used, and then add that port to the exceptions list.

Known Issues for Managing Windows Firewall Notifications

# Optimizing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To optimize Windows Firewall, see the following:

Best Practices for Optimizing Windows Firewall

Known Issues for Optimizing Windows Firewall

# Best Practices for Optimizing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

As a best practice, you should upgrade your networking hardware on your server computers so you are using network adapters that support checksum offloading. Checksum offloading allows the network adapter to perform the checksum processing that is usually performed below the TCP/IP stack, which will reduce the load on your computer's processor.

| **Note** |
| --- |
| Checksum offloading will not usually impact the performance on a client computer. |

# Known Issues for Optimizing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Running Windows Firewall can affect your computer's network performance by reducing the throughput, or bandwidth, that can be handled by your computer. The impact is usually minimal, unless your server handles a large amount of network traffic. In addition, if your computer primarily handles unsolicited incoming TCP traffic, the performance impact is usually minimal; however, if your computer primarily handles unsolicited incoming UDP traffic, the performance impact can be substantial. This is because short-lived connections like UDP connections require more processing than long-lived connections like TCP connections.

For example, the optimal type of connection would be a large file download that requires some early processing by Windows Firewall, but little or no processing as soon as the connection is established and the file transfer occurs. The impact of Windows Firewall on file servers and Web servers is minimal because these servers typically use TCP. In contrast, Windows Firewall can have a significant impact on a streaming media server that uses unicast broadcasts to deliver media. This is because streaming media servers typically use UDP to create a new connection to the media encoder each time a client connects to the live content stream and each of those connections must pass through Windows Firewall. Servers that are connected to the Internet and handle a high number of unsolicited incoming messages might also experience impact on network performance because although most of the messages will be blocked, Windows Firewall must still process each incoming message.

Even if your computer primarily handles UDP traffic, the impact on performance will not be that significant unless your computer's processor and network adapter are operating at close to maximum capacity. If your computer handles a substantial amount of incoming traffic when Windows Firewall is not turned on, and the network traffic is putting a high load on your processor, then Windows Firewall will impact your computer's network performance. However, this is often a symptom of poor network or infrastructure design; a problem like this one should be addressed no matter which firewall solution you use.

# Monitoring Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can monitor Windows Firewall activity by using the Windows Firewall log file and the security log. Both tools are useful for troubleshooting Windows Firewall problems and temporarily monitoring the behavior of Windows Firewall.

To help you monitor Windows Firewall activity, review Best Practices for Monitoring Windows Firewall, Known Issues for Using the Windows Firewall Log and Known Issues for Using the Security Log.

The following tasks are described in this objective:

- Using the Windows Firewall Log
- Using the Security Log

# Best Practices for Monitoring Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for monitoring Windows Firewall**
Use the following best practices when you monitor Windows Firewall.

Enable the Windows Firewall log file only when you need to.

Enable auditing of Windows Firewall events when you first turn on Windows Firewall.

**Enable the Windows Firewall log file only when you need to.**
You should enable the Windows Firewall log file only when you need to troubleshoot Windows Firewall problems or monitor Windows Firewall behavior over short periods of time. Permanently enabling the Windows Firewall log file makes your log files difficult to manage and uses disk space.

**Enable auditing of Windows Firewall events when you first turn on Windows Firewall.**
You should audit Windows Firewall events when you first turn on Windows Firewall. This will help you identify programs and services that are acting as servers, peers, or listeners. When you have identified servers, peers, or listeners and configured Windows Firewall exceptions, you should disable auditing of Windows Firewall events because auditing can impact the performance of servers that handle a large amount of network traffic.

# Using the Windows Firewall Log

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the Windows Firewall log file to monitor TCP and UDP connections and packets that are blocked by Windows Firewall. The log file provides source and destination IP addresses, port numbers, and protocols. For more information about log file structure, including descriptions of each log file parameter, see the section titled "Windows Firewall Tools and Settings" in the Windows Firewall Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42729).

By default, the log file is disabled, which means that no information is written to the log file. To use the log file, you must enable the logging of dropped packets, successful connections, or both. You can also configure other log file settings, including the name, location, and maximum size of the log file.

**When to perform this task**

Enable the Windows Firewall log file when you need to troubleshoot a Windows Firewall problem or you need to temporarily monitor Windows Firewall behavior.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To complete this task, use the following procedures:

- Enable or Disable the Windows Firewall Log
- View the Windows Firewall Log File
- Change the Name and Location of the Windows Firewall Log File
- Change the Size of the Windows Firewall Log File

**See Also**

# Known Issues for Using the Windows Firewall Log

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you use the Windows Firewall log file.

- Logging is available only on connections for which Windows Firewall is turned on. This applies if you configure per-connection settings because no information is written to the log file for connections that are not protected with Windows Firewall.
- Outgoing traffic that successfully reaches its destination is not logged. In addition, outbound traffic that is not blocked is not logged.
- The default size of the Windows Firewall log file is 4,096 kilobytes (KB); the maximum size is 32,767 KB.
- When the Windows Firewall log reaches the size that you set in **Size limit (KB)**, the log file is renamed and a new log file is created.

# Enable or Disable the Windows Firewall Log

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to turn on (enable) or turn off (disable) the Windows Firewall log file. This is useful if you are troubleshooting Windows Firewall problems or you are temporarily monitoring Windows Firewall behavior.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To enable or disable the Windows Firewall log**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To enable or disable the Windows Firewall log**

1. Open Windows Firewall, and click the **Advanced** tab.
2. In **Security Logging**, click **Settings**.

   To enable the log file, select the **Log dropped packets** check box or the **Log successful connections** check box or both check boxes, and click **OK**.

   To disable the log file, clear the **Log dropped packets** check box and the **Log successful connections** check box, and click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To enable or disable the Windows Firewall log**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set logging droppedpackets =** *droppedpackets* **connections =** *connections*

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *droppedpackets* | enable, disable | Specifies whether to turn on (enable) or turn off (disable) the logging of dropped packets. |
| *connections* | enable, disable | Specifies whether to turn on (enable) or turn off (disable) the logging of successful connections. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# View the Windows Firewall Log File

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to view the data that has been written to the Windows Firewall log. This is useful if you are troubleshooting Windows Firewall problems or you are temporarily monitoring Windows Firewall behavior.

**Administrative Credentials**

No special administrative credentials are required to perform this task.

**Special Considerations**

No special considerations are required to perform this task.

**To view the Windows Firewall log**
This procedure can be performed using the graphical user interface.

**Using the graphical user interface**

**To view the Windows Firewall log**

1. Open Windows Firewall, and click the **Advanced** tab.
2. In **Security Logging**, click **Settings**.
3. In the **Log Settings** dialog box, click **Save As**.
4. Right-click the log file name, and then click **Open**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- By default, the Windows Firewall log file is named Pfirewall.log and is saved in the systemroot folder.
- You must enable the Windows Firewall log file for it to appear in the systemroot folder.

# Change the Name and Location of the Windows Firewall Log File

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to change the name and location of the Windows Firewall log file. This is useful if you do not want users to easily find the log file or you want to have the log file written to a central location.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To change the name and location of the Windows Firewall log**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To change the name and location of the Windows Firewall log**

1. Open Windows Firewall, and click the **Advanced** tab.
2. In **Security Logging**, click **Settings**.
3. Click **Save As**, and navigate to the location where you want to save the log file.
4. In **File name**, type the new log file name, or leave it blank to accept the default name of pfirewall.log.
5. Click **Save**, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To change the name and location of the Windows Firewall log**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set logging filelocation = "** *filelocation* **"**

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *filelocation* | Any string that includes a valid path and file name for a text file. | You must enclose *filelocation* in quotation marks if there are spaces in the path or file name. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

Change the Size of the Windows Firewall Log File

# Change the Size of the Windows Firewall Log File

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to change the size of the Windows Firewall log file. This is useful if you need to increase the size of the log file because you are logging substantial network activity or you want to log activity over a long period of time.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

**To change the size of the Windows Firewall log**

This procedure can be performed using the graphical user interface or the command prompt.

**Using the graphical user interface**

**To change the size of the Windows Firewall log**

1. Open Windows Firewall, and click the **Advanced** tab.
2. In **Security Logging**, click **Settings**.
3. In **Size limit (KB)**, enter the maximum size of the log file, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

**Using the command prompt**

**To change the size of the Windows Firewall log**

- Type the following at the command prompt, and press ENTER:

  **netsh firewall set logging maxfilesize =** *maxfilesize*

Substitute values for the placeholders in italics. The following table lists possible values for each placeholder.

| Placeholder | Possible Values | Description |
|---|---|---|
| *maxfilesize* | Any number between 1 and 32,767 kilobytes (KB). | Specifies the maximum size of the log file, in KB. |

If you get an "Access Denied" message when you run a command, you do not have administrative rights to configure Windows Firewall. If you get an "Ok" message but the command does not take effect, the setting might be managed by Group Policy.

**Notes**

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

- The default size of the Windows Firewall log file is 4,096 KB.

# Interpreting the Windows Firewall Log

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Windows Firewall log file is useful for determining if Windows Firewall is the cause of program failures. It can also be used to help identify malicious activity, although it does not provide the information needed to track down the source of the activity. The Windows Firewall log file is not useful for analyzing the overall security of your network.

The Windows Firewall log is a plaintext file that can be viewed through any text editor. Notepad is the default text editor for the Windows Firewall log file. Depending on the size limit set for the file and the duration of the logging event, a single log file can contain thousands of text entries. To improve its readability in Notepad, disable word wrapping. This will preserve the column formatting. For more information, see View the Windows Firewall Log File.

The following is an example of a Windows Firewall log file:

```
#Version: 1.5
#Software: Microsoft Windows Firewall
#Time Format: Local
#Fields: date time action protocol src-ip dst-ip src-port dst-port size tcpflags tcpsyn
tcpack tcpwin icmptype icmpcode info path
2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - -

```

| **Note** |
| --- |
| The preceding log file example has been truncated. Many dropped broadcast packets, which are the most common type of entry, have been removed from this example. |

The log file has two sections: the header and the body. The header displays information about Windows Firewall and provides a column heading for the entries that appear in the body section.

The following table lists the information contained in the header of the log file:

| Item | Description |
| --- | --- |
| #Version: | Displays which version of the Windows Firewall security log is installed.<br><br>`#Version: 1.5` |
| #Software: | Displays the name of the software creating the log.<br><br>`#Software: Microsoft Windows Firewall` |
| #Time: | Indicates that all of the timestamps in the log are in local time.<br><br>`#Time Format: Local` |

| | |
|---|---|
| #Fields: | Displays a static list of fields that are available for security log entries, if data is available. These fields are listed in the following table.<br><br>**Note**<br>The hyphen (-) is used for fields for which no information is available. |

The body is the report of information gathered about traffic or attempts to pass through Windows Firewall. The body of the security log is a dynamic list; new entries appear at the bottom of the log.

The following table lists the information contained in the body of the log file:

| Item | Description |
|---|---|
| date | Displays the year, month, and day that the recorded transaction occurred. Dates are recorded in the following format:<br><br>YYYY-MM-DD<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| time | Displays the hour, minute, and seconds at which the recorded transaction occurred. Times are recorded in the following 24-hour format:<br><br>HH:MM:SS<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| action | Displays which operation was observed by Windows Firewall. The options available are OPEN, OPEN-INBOUND, CLOSE, DROP, and INFO-EVENTS-LOST. An INFO-EVENTS-LOST action indicates the number of events that occurred but were not recorded in the log.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| protocol | Displays the protocol that was used for the communication. The options available are TCP, UDP, ICMP, and a protocol number for packets that are not TCP, UDP, or ICMP.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| src-ip | Displays the source IP address (the IP address of the computer attempting to establish communication).<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| dst-ip | Displays the destination IP address of a communication attempt.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| src-port | Displays the source port number of the sending computer. Only TCP and UDP display a valid src-port entry. All other protocols display a src-port entry of -.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| dst-port | Displays the port number of the destination computer. Only TCP and UDP display a valid dst-port entry. All other protocols display a dst-port entry of -.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |

| | |
|---|---|
| size | Displays the packet size, in bytes.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |
| tcpflags | Displays the TCP control flags found in the TCP header of an IP packet:<br><br>• **A**ck Acknowledgment field significant<br>• **F**in No more data from sender<br>• **P**sh Push function<br>• **R**st Reset the connection<br>• **S**yn Synchronize sequence numbers<br>• **U**rg Urgent Pointer field significant<br><br>`2005-04-11 08:06:27 DROP TCP 123.45.678 90 123.456.78.90 80 1726 54 AP 123456789 987654321 12345 - - - RECEIVE` |
| tcpsyn | Displays the TCP sequence number in the packet.<br><br>`2005-04-11 08:06:278 DROP TCP 123.45.678 90 123.456.78.90 80 1726 54 AP 123456789 987654321 12345 - - - RECEIVE` |
| tcpack | Displays the TCP acknowledgement number in the packet.<br><br>`2005-04-11 08:06:27 DROP TCP 123.45.678 90 123.456.78.90 80 1726 54 AP 123456789 987654321 12345 - - - RECEIVE` |
| tcpwin | Displays the TCP window size, in bytes, in the packet.<br><br>`2005-04-11 08:06:27 DROP TCP 123.45.678 90 123.456.78.90 80 1726 54 AP 123456789 987654321 12345 - - - RECEIVE` |
| icmptype | Displays a number that represents the Type field of the ICMP message.<br><br>`2005-04-11 08:06:27 DROP ICMP 123.45.678.90 123.456.78.90 7 7 78 - - - - 8 0 - RECEIVE` |
| icmpcode | Displays a number that represents the Code field of the ICMP message.<br><br>`2005-04-11 08:06:27 DROP ICMP 123.45.678.90 123.456.78.90 7 7 78 - - - - 8 0 - RECEIVE` |
| info | Displays an entry that depends on the type of action that occurred. For example, an INFO-EVENTS-LOST action will result in an entry of the number of events that occurred but were not recorded in the log from the time of the last occurrence of this event type.<br><br>`2005-04-11 08:52:26 INFO-EVENTS-LOST - - - - - - - - - - - - 59 -` |
| path | Displays the direction of the communication. The options available are SEND, RECEIVE, FORWARD, and UNKNOWN.<br><br>`2005-04-11 08:05:57 DROP UDP 123.45.678.90 123.456.78.255 137 137 78 - - - - - - - RECEIVE` |

**When to perform this task**

- When attempting to determine if program failure is a result of your Windows Firewall configuration.
- When searching for malicious activity on your network.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

- Identify Program Failures
- Identify Malicious Activity

**See Also**
**Concepts**
Enable or Disable the Windows Firewall Log
Known Issues for Using the Windows Firewall Log
Change the Name and Location of the Windows Firewall Log File
Change the Size of the Windows Firewall Log File

# Identify Program Failures

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to determine if Windows Firewall is the source of your program failures. This procedure is useful if you are troubleshooting.

| **Note** |
| --- |
| If the failing program is a service and it is running as a driver, it is not possible to determine from the log file if the failure is related to Windows Firewall. For information about troubleshooting this type of issue, see A System Service Runs in Svchost.exe and Cannot Be Added to the Exceptions List. |

### Administrative Credentials

No special administrative credentials are required to perform this task.

### Special Considerations

No special considerations are required to perform this task.

#### To identify program failures

You can use this procedure to find any of the following, which can be useful for identifying the source of your problem:

- Disabled port openings.
- Dynamic port openings.
- Dropped packets with push and urgent flags.
- Dropped packets on the send path.

This method will verify if disabled ports remain closed.

#### To identify disabled port openings

1. With the Windows Firewall log file open in Notepad, press **Ctrl** + **F**, type the number of port that you know to be disabled, and then click **Find Next**.
2. Make sure each log entry corresponding to the port number in the **dst-port** field does not have OPEN in the **action** field.
3. If you find entries corresponding to the port number in which OPEN appears in the action field, write down the source IP address (**srcip**) and the destination IP address (**dstip**), and then see Fixing Program Problems for information about troubleshooting the issue.

This method will verify if Windows Firewall is allowing dynamic port openings for programs that use them.

#### To identify dynamic port openings

1. With the Windows Firewall log open in Notepad, scroll to the bottom of the file.
2. Launch the program and watch the log while it is running.
3. Look at the entries for the port used by the program. If those entries have OPEN-INBOUND in the action field, then Windows Firewall is not the source of the problem. If the port is not opening, see Fixing Program Problems for information about troubleshooting the issue.

The presence of dropped packets that are flagged with push or urgent might indicate that there is a problem with one of your programs.

#### To identify dropped packets with push and urgent flags

1. With the Windows Firewall log file open in Notepad, press **Ctrl** + **F**, type [space]U[space] or [space]PU[space], and then

click **Find Next**.

2. Make sure each log entry with U or UP in the **tcpflags** field does not have DROP in the **action** field.

3. If you find entries with U or PU and DROP together, write down the source IP address (**srcip**), the destination IP address (**dstip**), and the source port (**srcport**), and then see Fixing Program Problems for information about troubleshooting the issue.

The presence of dropped packets on the send path is rare, but might indicate that there is a problem with one of your programs.

**To identify dropped packets on the send path**

1. With the Windows Firewall log file open in Notepad, press **Ctrl** + **F**, type SEND, and then click **Find Next**.

2. Ensure each log entry with SEND in the **path** field does not have DROP in the **action** field.

3. If you find entries with SEND and DROP together, write down the source IP address (**srcip**) and source port (**srcport**), and then see Fixing Program Problems for information about troubleshooting the issue.

Interpreting the Windows Firewall Log
View the Windows Firewall Log File

# Identify Malicious Activity

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to confirm that malicious activity is occurring within your network. This procedure is useful if you suspect such activity is taking place and you want to identify the targets of the attacks.

**Administrative Credentials**

No special administrative credentials are required to perform this task.

**Special Considerations**

No special considerations are required to perform this task.

**To identify malicious activity**

| **Note** |
| --- |
| Broadcast packets have destination IP addresses that end in 255. Disregard those packets when you search the Windows Firewall log file for malicious activity. |

**To identify malicious activity**

1. With the Windows Firewall log file open in Notepad, scroll through the file from beginning to end.
2. Look at each log entry with DROP in the **action** field and note whether the destination IP address (**dstip**) ends with a number other than 255.
3. If you find many such entries, take note of the destination IP addresses of the packets.
4. If those destination IP addresses are all the same, similar, or systematic, write down the source IP addresses (**srcip**) and the destination IP addresses. These dropped packets can be considered suspicious. Suspicious dropped packets often have systematic port hit entries as well.

# Using the Security Log

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can use the security log to track Windows Firewall events. The security log provides information about Windows Firewall activity, such as changes to Windows Firewall settings, Windows Firewall startup status, and notifications sent when programs and system services attempt to listen for incoming traffic and are blocked. For more information about the specific events that are written to the security log, see the section titled "Windows Firewall Tools and Settings" in the Windows Firewall Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42729).

By default, Windows Firewall events are not written to the security log. You must enable auditing in Group Policy to use the security log to track Windows Firewall events.

**When to perform this task**

You should enable the auditing of Windows Firewall events when you turn on Windows Firewall for the first time, when you need to troubleshoot Windows Firewall problems, or when you need to temporarily monitor Windows Firewall behavior.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To complete this task, use the following procedures:

- Enable Auditing of Windows Firewall Events
- View Windows Firewall Events in Event Viewer

**See Also**
**Concepts**
Using the Windows Firewall Log
Best Practices for Monitoring Windows Firewall

# Known Issues for Using the Security Log

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you use the Windows Firewall log file.

- You must enable the **Audit process tracking** and **Audit policy change** settings in Group Policy to have Windows Firewall events written to the security event log.

# Enable Auditing of Windows Firewall Events

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to enable auditing so that Windows Firewall events are written to the security log. This is useful for troubleshooting Windows Firewall problems or when you are configuring Windows Firewall for the first time and you want to monitor Windows Firewall behavior.

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

No special considerations are required to perform this procedure.

**To enable auditing of Windows Firewall events**
This procedure can be performed using Group Policy.

### Using Group Policy

### To enable auditing of Windows Firewall events

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Group Policy settings in your organization.
2. Open **Computer Configuration**, open **Windows Settings**, open **Security Settings**, open **Local Policies**, and then click **Audit Policy**.
3. Double-click **Audit process tracking**, select the **Success** and **Failure** check boxes, and then click **OK**.
4. Double-click **Audit policy change**, select the **Success** and **Failure** check boxes, and then click **OK**.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

### Notes

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

**See Also**
**Concepts**
Using the Security Log

# View Windows Firewall Events in Event Viewer

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use this procedure when you want to view Windows Firewall events that have been written to the security log. This is useful if you are troubleshooting Windows Firewall problems or you are configuring Windows Firewall for the first time and you want to monitor Windows Firewall behavior.

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

There are no special considerations to perform this procedure.

**To view Windows Firewall events in Event Viewer**
This procedure can be performed using the graphical user interface.

### Using the graphical user interface

### To view Windows Firewall events in Event Viewer

1. Open Event Viewer.
2. Click **Security**, and then look for event IDs 848 through 861.

If a Windows Firewall setting appears dimmed in the graphical user interface, and on the **General** tab, you see **For your security, some settings are controlled by Group Policy**, the setting might be managed by Group Policy. If all Windows Firewall settings appear dimmed, and on the **General** tab, you see **You must be a computer administrator to change these settings**, you do not have administrative rights to configure Windows Firewall.

### Notes

- To start Windows Firewall, click **Start**, point to **Control Panel**, and then click **Windows Firewall**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Securing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Firewall can be configured only by users who are members of the Administrators group or members of a group that is a member of the Administrators group. You can configure Windows Firewall so that local administrators are prevented from enabling or disabling Windows Firewall or configuring Windows Firewall settings. This is useful if you have a centrally managed environment and you want to strictly enforce your Windows Firewall configuration throughout your organization.

To help you secure Windows Firewall, review Best Practices for Securing Windows Firewall and Known Issues for Securing Windows Firewall.

The following tasks are described in this objective:

- Preventing Administrators from Turning Windows Firewall On or Off
- Preventing Administrators from Creating Exceptions

# Best Practices for Securing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Use the following best practice when you secure Windows Firewall.

**Do not let users configure Windows Firewall settings.**

Do not grant users local administrative rights so they can configure Windows Firewall. By default, you must be a member of the Administrators group (or a member of a group that is a member of the Administrators group) to configure Windows Firewall. Giving users the ability to configure Windows Firewall is not recommended because it can result in individualized configurations that are difficult and costly to troubleshoot. It can also increase your organization's attack surface.

**See Also**
**Concepts**
Best Practices for Managing Windows Firewall
Best Practices for Optimizing Windows Firewall
Best Practices for Monitoring Windows Firewall

# Known Issues for Securing Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Review the following known issues before you secure Windows Firewall.

- If you do not configure the **Windows Firewall: Allow local program exceptions** Group Policy setting, the ability of administrators to define local program exceptions depends on the configuration of the **Windows Firewall: Define program exceptions** Group Policy setting. If the **Windows Firewall: Define program exceptions** Group Policy setting is not configured, administrators can define local program exceptions. If it is enabled or disabled, administrators cannot define local program exceptions.

- If you do not configure the **Windows Firewall: Allow local port exceptions** Group Policy setting, the ability of administrators to define local port exceptions depends on the configuration of the **Windows Firewall: Define port exceptions** Group Policy setting. If the **Windows Firewall: Define port exceptions** Group Policy setting is not configured, administrators can define local port exceptions. If it is enabled or disabled, administrators cannot define local port exceptions.

- If the **Prohibit use of Internet Connection Firewall on your DNS domain network** setting is enabled and the **Windows Firewall: Protect all network connections** Group Policy setting is enabled, then Windows Firewall is enabled when connected to the network from which the Group Policy object (GPO) was obtained with new Windows Firewall settings.

# Preventing Administrators from Turning Windows Firewall On or Off

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By default, you must be a member of the Administrators group (or a member of a group that is a member of the Administrators group) to enable or disable Windows Firewall. This prevents users from inadvertently turning Windows Firewall on or off, which can result in individualized configurations that are difficult to troubleshoot and can reduce your organization's overall security.

You can secure Windows Firewall even further by preventing local administrators from enabling or disabling Windows Firewall. This is useful if you rely on Windows Firewall and you always want it enabled, or you use a non-Microsoft host firewall and you always want Windows Firewall disabled. Preventing local administrators from turning Windows Firewall on or off is also useful in a centrally-managed environment, such as a Group Policy environment or an environment in which you want to strictly enforce Windows Firewall configuration and policy settings.

**When to perform this task**

You should perform this task when required by your organization's security plan or when you want to strictly enforce Windows Firewall configuration and policy settings.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To complete this task, perform the following procedures:

Prevent Local Administrators from Turning Windows Firewall On or Off

**See Also**
**Concepts**
Best Practices for Securing Windows Firewall
Known Issues for Securing Windows Firewall
Preventing Administrators from Creating Exceptions

# Prevent Local Administrators from Turning Windows Firewall On or Off

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful if you want to prevent local administrators from turning Windows Firewall on or off.

**Administrative Credentials**

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Special Considerations**

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should verify scope settings for any exceptions that you change. For more information about scope settings, see Configuring Scope Settings.

**To prevent local administrators from turning Windows Firewall on or off**
This procedure can be performed using Group Policy. You cannot perform this procedure from the command prompt with the **netsh firewall** command or in the graphical user interface with Windows Firewall in Control Panel.

**Using Group Policy**

**To prevent local administrators from turning Windows Firewall on or off**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then open either **Domain Profile** or **Standard Profile**, depending on which profile you want to configure.
3. In the details pane, double-click **Windows Firewall: Protect all network connections**.
4. Do the following if you want to turn off Windows Firewall and prevent local administrators from turning on Windows Firewall:

   In the **Windows Firewall: Protect all network connections** properties dialog box, on the **Settings** tab, click **Disabled**, and then click **OK**.
5. Do the following if you want to turn on Windows Firewall and prevent local administrators from turning off Windows Firewall:

   In the **Windows Firewall: Protect all network connections** properties dialog box, on the **Settings** tab, click **Enabled**, and then click **OK**.

**Notes**

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Group Policy settings must be refreshed before they take effect.

**See Also**
**Concepts**
Preventing Administrators from Turning Windows Firewall On or Off
Known Issues for Securing Windows Firewall

# Preventing Administrators from Creating Exceptions

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By default, you must be a member of the Administrators group (or a member of a group that is a member of the Administrators group) to configure Windows Firewall exceptions. This prevents users from inadvertently configuring program and port exceptions, which can result in individualized configurations that are difficult to troubleshoot and can reduce your organization's overall security.

You can secure Windows Firewall even further by preventing local administrators from configuring Windows Firewall exceptions. This is useful if you have a centrally-managed environment, such as a Group Policy environment or an environment in which you want to strictly enforce Windows Firewall configuration and policy settings.

**When to perform this task**

You should perform this task when required by your organization's security plan or when you want to strictly enforce Windows Firewall configuration and policy settings.

**Task requirements**

No special tools are required to complete this task.

**Task procedures**

To complete this task, perform the following procedures:

Prevent Local Administrators from Creating Program Exceptions

Prevent Local Administrators from Creating Port Exceptions

**See Also**
**Concepts**
Best Practices for Securing Windows Firewall
Known Issues for Securing Windows Firewall
Preventing Administrators from Turning Windows Firewall On or Off

# Prevent Local Administrators from Creating Program Exceptions

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This procedure is useful if you want to prevent local administrators from using Windows Firewall in Control Panel or the **netsh firewall** command to configure program exceptions.

### Administrative Credentials

To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

### Special Considerations

You can configure Windows Firewall settings in the standard profile or the domain profile. The domain profile is used when a computer is connected to a network in which the computer's domain account resides. The standard profile is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network or the Internet. Make sure Windows Firewall is using the correct profile when you perform this procedure.

For more information about Windows Firewall profiles, see Managing Windows Firewall Profiles.

You should verify scope settings for any exceptions that you change. For more information about scope settings, see Configuring Scope Settings.

**To prevent local administrators from creating program exceptions**
This procedure can be performed using Group Policy. You cannot perform this procedure from the command prompt with the **netsh firewall** command or in the graphical user interface with Windows Firewall in Control Panel.

### Using Group Policy

### To prevent local administrators from creating program exceptions

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then open either **Domain Profile** or **Standard Profile**, depending on which profile you want to configure.
3. In the details pane, double-click **Windows Firewall: Allow local program exceptions**.
4. In the **Windows Firewall: Allow local program exceptions** properties dialog box, on the **Settings** tab, click **Disabled**, and then click **OK**.

### Notes

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Group Policy settings must be refreshed before they take effect.

**See Also**
**Concepts**

# Additional Resources for Administering Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For general information about how Windows Firewall works, see the following resources:

- Manually Configuring Windows Firewall in Windows XP Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=33763).
- New Networking Features in Microsoft Windows XP Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=33684).
- Windows Firewall Technical Reference on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=42729).

For specific information about troubleshooting Windows Firewall problems, see the following resources:

- Troubleshooting Windows Firewall
- Troubleshooting Windows Firewall Settings in Windows XP Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43102).
- Article ID 842242 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43103). This article describes why some programs might stop working after you install Windows XP with Service Pack 2 (SP2) and what you can do to overcome the problem.
- Article ID 884130 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43104). This article contains a list of programs that are known to experience loss of functionality when they run on Windows XP SP2.

# Troubleshooting Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This guide provides troubleshooting information for Windows Firewall in Microsoft® Windows Server™ 2003 with Service Pack 1 (SP1). It is designed to help you identify and resolve problems that are caused by Windows Firewall, including network access problems, problems running programs, and configuration and management problems.

**In this guide**

- Introduction to Troubleshooting Windows Firewall
- Verifying Computer Settings for Windows Firewall
- Windows Firewall Quick Fixes
- Configuring a Computer for Windows Firewall Troubleshooting
- Troubleshooting Windows Firewall Problems

# Introduction to Troubleshooting Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

If you are using this guide for the first time, review the following sections of this introduction.

**When to Use This Guide**
You should use this guide when:

- You have a problem that you believe is related to Windows Firewall, but you do not know how to resolve it.
- You have configured Windows Firewall settings, but Windows Firewall does not behave the way you anticipated.
- A program is not working properly and you believe that Windows Firewall is causing the problem.

Do not use this guide to find out how to perform a task, such as enabling Windows Firewall or adding a program or port to the Windows Firewall exceptions list. Information about how to perform tasks and configure settings can be found in Administering Windows Firewall.

This guide assumes a basic understanding of what Windows Firewall is, how it works, and why your organization uses it to enhance network security. You should also have a thorough understanding of how Windows Firewall is deployed and managed in your organization. This includes an understanding of the mechanism your organization uses to configure and manage Windows Firewall settings.

**How to Use This Guide**
This guide is divided into four sections. Each section addresses a type of problem, ranging from less complex to more complex.

Verifying Computer Settings for Windows Firewall

This section provides a list of prerequisites and settings that must be verified before you troubleshoot. Read this section first.

Windows Firewall Quick Fixes

This section provides quick solutions to the most common Windows Firewall problems. Read this section if you have verified your computer settings, but your problem persists.

Configuring a Computer for Windows Firewall Troubleshooting

This section describes how to configure your computer for troubleshooting. Read this section if you cannot find a solution in the Quick Fixes section.

Troubleshooting Windows Firewall Problems

This section provides step-by-step diagnostic procedures and possible solutions that help you identify and fix Windows Firewall problems.

Additional Resources for Windows Firewall Troubleshooting

**Terminology Used in This Guide**
**Domain profile**
A set of Windows Firewall settings that are applied when a computer is connected to a network that contains the domain controllers for the domain in which its computer account resides. The domain profile is one of two profiles that Windows Firewall uses to apply settings to a computer.

**Exception**
A port, program, or system service that is allowed to receive unsolicited traffic.

**Exceptions list**
A special type of rules store that specifies which ports, programs, or system services are allowed to receive unsolicited traffic. To allow unsolicited incoming traffic through Windows Firewall, you add ports, programs, and system services to the exceptions list.

**Notification**

A **Windows Security Alert** dialog box that appears when a program that is not listed in the exceptions list attempts to listen for unsolicited traffic on a port. If you have administrative rights on a computer, the notification displays an option to add the program to the exceptions list, and thereby allow the program to receive unsolicited traffic. If you do not have administrative rights on a computer, the notification displays a warning that a program is attempting to listen on a port. A **Windows Security Alert** dialog box does not appear when a system service attempts to listen for unsolicted incoming traffic; it only appears when a program attempts to listen for unsolicited incoming traffic.

**Port**
A logical communication endpoint representing a service or an application that listens for and receives IP packets. Ports are specified by a positive 16-bit decimal number and the type of traffic that is expected to pass through the port--either UDP traffic or TCP traffic. Most ports have been predefined and are considered "well-known" for specific services, such as DHCP and DNS. However, some ports are created dynamically by a server and assigned to the services and applications that need to listen for incoming traffic from clients.

**Program**
A software application that is usually started by a user and runs under the user's account. Programs run only while the user is logged on to a computer and usually consist of one or more executable (.exe) files and one or more dynamic-link library (.dll) files.

| **Note** |
| --- |
| Some system services run within their own .exe file and are started by a user. However, these system services typically run under a priviledged account, such as Local Service, and do not run under the user's account. An example of this is the Telnet service, which runs in Tlntsvr.exe. |

**Scope**
A Windows Firewall setting that you configure for an exception. The scope setting controls which addresses unsolicited traffic is allowed to originate from. By default, the scope of an exception is any address, which includes any computer on the Internet. You can change the scope of an exception to locally reachable addresses or a list of individual Internet Protocol version 4 (IPv4) addresses or IPv4 address ranges.

**System service**
A software application that is usually not started by a user and runs under a privileged account, such as LocalSystem. System services run even when a user is not logged on to a computer and usually run as a separate process within Svchost.exe.

**Standard profile**
A set of Windows Firewall settings that are applied when a computer is not connected to a network that contains the domain controllers in which its computer account resides (for example, a public network, such as the Internet). The standard profile is one of two profiles that Windows Firewall uses to apply settings to a computer.

# Verifying Computer Settings for Windows Firewall

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you begin troubleshooting, you need to verify that your computer is configured properly and that Windows Firewall is set up and running properly.

**Settings to Verify Before You Troubleshoot**
Verify all of the following items:

Make sure you have administrative rights on the computer you are troubleshooting.

Install all critical updates and security updates for Windows Server 2003.

Update all of your software, including non-Microsoft software.

Make sure that Windows Firewall is enabled when you experience the problem.

Verify that the Group Policy setting, Prohibit use of Internet Connection Firewall on your domain network, is either disabled or not configured.

Make sure that Windows Firewall/Internet Connection Sharing service, Network Connections service, Remote Procedure Call service, and Windows Management Instrumentation service are started.

Restart the computer if you are running a server operating system.

**Make sure you have administrative rights on the computer you are troubleshooting.**
You cannot modify Windows Firewall settings unless you are a member of the Administrators group on the computer that you are administering.

### To verify that you are a member of the Administrators group

1. Open the Computer Management snap-in.
2. In the console tree, double-click **Local Users and Groups**, and then click **Groups**.
3. In the details pane, double-click **Administrators** and verify that your account name or a group to which your account is a member appears in the **Members** list.

You can also tell if you have the appropriate administrative rights to configure Windows Firewall by opening Windows Firewall in Control Panel. If you do not have administrative rights, all of the controls in the Windows Firewall user interface (UI) will appear dimmed and a warning will appear telling you that you need to be a computer administrator to change any settings.

**Install all critical updates and security updates for Windows Server 2003.**
Some updates might be required for Windows Firewall to function properly.

### To verify that you have all critical updates and security patches

- Click **Start**, click **Windows Update**, and then follow the instructions that appear on your screen.

**Update all of your software, including non-Microsoft software.**
Windows Firewall might not function properly with some programs unless you update the programs with the most recent service pack or software update. Newer versions of many applications, such as antivirus programs, will automatically configure Windows Firewall and might resolve any problems you have.

**Make sure that Windows Firewall is enabled when you experience the problem.**
If Windows Firewall is not enabled when you experience your problem, then Windows Firewall cannot be causing your problem.

### To verify that Windows Firewall is enabled

1. In Control Panel, open **Windows Firewall**.
2. In the **Windows Firewall** dialog box, verify that **On** is selected.

If **On** appears dimmed, you do not have administrative rights on the computer or your Windows Firewall settings are managed

through Group Policy.

**Verify that the Group Policy setting, Windows Firewall: Prohibit use of Internet Connection Firewall on your domain network, is either disabled or not configured.**
If enabled, this setting prevents anyone, including administrators, from enabling or configuring Windows Firewall. To change this policy setting, use the Group Policy Object Editor snap-in to edit the Group Policy objects (GPOs) that are used to manage Windows Firewall settings in your organization.

### To modify the Prohibit use of Internet Connection Firewall on your domain network setting

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.
2. Click **Computer Configuration**, click **Administrative Templates**, click **Network**, and then click **Network Connections**.
3. In the details pane, double-click the **Windows Firewall: Prohibit use of Internet Connection Firewall on your domain network** policy setting.
4. Select either the **Disabled** or **Not Configured** check box.

If this policy setting is enabled and you cannot configure it, you do not have administrative rights to configure Group Policy settings.

**Make sure that Windows Firewall/Internet Connection Sharing service, Network Connections service, Remote Procedure Call service, and Windows Management Instrumentation service are started.**

### To verify that a system service is started

1. Open the Services snap-in.
2. In the details pane, double-click the system service that you want to verify, and then check the **Service status**.

**Restart the computer if you are running a server operating system.**
If you turned on the Windows Firewall/Internet Connection Sharing service after you started a program or a system service that is listed in the program exceptions list, you should do the following:

- Restart your computer.
- Start the programs that are listed in the exceptions list.

Windows Firewall cannot track the state of a program's traffic or a system service's traffic if the program or system service is started before the Windows Firewall/Internet Connection Sharing service is started. This problem typically occurs when you stop the Windows Firewall/Internet Connections Sharing service to install and configure software, and then turn on the Windows Firewall/Internet Connection Sharing service after you start the software program.

# Windows Firewall Quick Fixes

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Most Windows Firewall problems do not require extensive troubleshooting and can be fixed by making a simple configuration change. This section provides the most common Windows Firewall problems and their solutions. You can use the information in this section to resolve problems in the same way you would use a FAQ to find answers to common questions. Read this section before you begin any advanced troubleshooting.

**Common Windows Firewall Problems**
Listed below are common Windows Firewall problems and quick fixes:

I turned on Windows Firewall, but the programs in the exceptions list are not working properly.

Windows Firewall displays a Windows Security Alert when a program attempts to listen on a port, but the alert tells me to contact my system administrator and does not prompt me to unblock the program.

Windows Firewall does not display a Windows Security Alert when a program or system service attempts to listen on a port.

No one can ping my computer with the ping command.

I disabled ping by blocking incoming echo traffic, but other computers can still ping my computer.

I cannot access shared folders or printers on a computer that has Windows Firewall enabled.

I cannot use Remote Desktop to access another computer.

I cannot use remote administration tools to manage my servers.

I cannot get my FTP program to work with Windows Firewall.

I added a program to the exceptions list in Windows Firewall in Control Panel, but the program does not show up in the exceptions list when I take the computer off the managed network.

Some or all of the settings in Windows Firewall appear dimmed.

I added a program to the exceptions list in Group Policy, but the program does not behave as though it's in the exceptions list.

I used the My network (subnet) only scope option, but traffic originating beyond my subnet is getting through Windows Firewall.

I used the My network (subnet) only option to change the scope of a program exception, but some computers in my subnet are being blocked by Windows Firewall.

**I turned on Windows Firewall, but the programs in the exceptions list are not working properly.**
This can happen on a server if you turn on Windows Firewall after you have started a program (for example, if you have started a Web server or an e-mail server and then start Windows Firewall). Windows Firewall might not be able to track the state of a program's network traffic if the program is started before you start Windows Firewall. This is true no matter how you start Windows Firewall (through Control Panel, Group Policy, or the command prompt).

**Windows Firewall displays a Windows Security Alert when a program attempts to listen on a port, but the alert tells me to contact my system administrator and does not prompt me to unblock the program.**
There are two conditions under which you might see this Windows Security Alert (referred to throughout this documentation as a notification).

Windows Firewall displays this notification when a program attempts to listen on a port and the user who started the program is not a member of the Administrators group. If you are not a member of the Administrators group, you cannot configure the exceptions list, so Windows Firewall does not prompt you to unblock the program by adding the program to the exceptions list. To change the notification so that you are prompted to unblock a program, you must log on to the computer using an account that is a member of the Administrators group. You can then either wait for the notification to appear and click **Unblock**, or you can use Windows Firewall to add the program to the exceptions list.

**To add a program to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.

2. On the **Exceptions** tab, click **Add Program**, and then follow the instructions that appear on your screen.

Windows Firewall also displays this notification if the **Windows Firewall: Allow local program exceptions** policy setting is disabled or if the **Windows Firewall: Allow local program exceptions** policy setting is not configured and the **Windows Firewall: Define program exceptions** policy setting is either disabled or enabled. Windows Firewall displays this notification under these conditions even if you are a member of the Administrators group. To change the notification so that you are prompted to unblock a program, you must either enable the **Windows Firewall: Allow local program exceptions** policy setting or, if this policy setting is not configured, change the **Windows Firewall: Define program exceptions** policy setting to **Not Configured**.

**To enable the Allow local program exceptions policy setting**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. Double-click **Windows Firewall: Allow local program exceptions**, and on the **Settings** tab, click **Enabled**.

**To set the Define program exceptions policy setting to Not Configured**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. Double-click **Windows Firewall: Define program exceptions**, and on the **Settings** tab, click **Not Configured**.

**Windows Firewall does not display a Windows Security Alert when a program or system service attempts to listen on a port.**
There are several reasons Windows Firewall might not display a Windows Security Alert (notification) when a program or system service attempts to listen on a port.

- Notifications are displayed only if you enable the display notification option and have disabled or not configured the **Windows Firewall: Prohibit notifications** policy setting.

**To enable notifications**

1. Open Windows Firewall.
2. On the **Exceptions** tab, select the **Display a notification when Windows Firewall blocks a program** check box.

**To disable the Prohibit notifications policy setting**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. Double-click **Windows Firewall: Prohibit Notifications**, and on the **Settings** tab, select either **Not Configured** or **Disabled**.

- Windows Firewall will not display notifications for system services or programs that run when there is no user logged on to the computer. Most system services run this way, as do many server programs. However, Windows Firewall does write an event (Event ID 861) to the security event log for any system service or program that attempts to listen on a port, no matter if a notification is displayed. You must enable auditing for Windows Firewall events for Windows Firewall events to appear in the security event log.

**To enable auditing of Windows Firewall events**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.

2. Open **Windows Settings**, open **Security Settings**, open **Local Policies**, and then click **Audit Policy**.
3. Double-click **Audit process tracking**, select the **Success** and **Failure** check boxes, and then click **OK**.
4. Double-click **Audit policy change**, select the **Success** and **Failure** check boxes, and then click **OK**.

| **Note** |
| --- |
| The only way to determine when a system service listens on a port is to enable auditing and view security event log entries. |

**To view Windows Firewall notification events in Event Viewer**

1. Open Event Viewer.
2. Click **Security**, and then look for Event ID 861.

- Windows Firewall cannot display notifications if you select the **Don't allow exceptions** check box in Windows Firewall in Control Panel or if you enable the **Windows Firewall: Do not allow exceptions** policy setting in the Group Policy Object Editor. There are no Windows Firewall settings that allow you to override this behavior. To display notifications, you must clear the **Don't allow exceptions** check box or set the **Windows Firewall: Do not allow exceptions** policy setting to **Disabled** or **Not Configured**; however, doing so lessens the level of security that Windows Firewall provides when you are connected to a public network, such as the Internet. Instead of allowing exceptions through Windows Firewall so notifications are displayed, it is recommended that you use Event Viewer to identify programs and system services that attempt to listen on a port.

**To configure Windows Firewall to allow exceptions**

1. Open Windows Firewall in Control Panel.
2. On the **General** tab, clear the **Don't allow exceptions** check box.

**To configure Group Policy so Windows Firewall allows exceptions**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. Double-click **Windows Firewall:Do not allow exceptions**, and on the **Settings** tab, click either **Not Configured** or **Disabled**.

- Windows Firewall does not display notifications for programs that rely on the Winsock driver to dynamically bind to a UDP port (sometimes referred to as wildcard binds). If a program uses this method to bind to a UDP port, you might be able to use the **netstat** command and other troubleshooting tools to determine which UDP port is being used. For more information, see Fixing Program Problems.

**No one can ping my computer with the ping command.**

This happens because, by default, Windows Firewall blocks all Internet Control Message Protocol (ICMP) traffic. When someone pings your computer, an ICMP Echo message (also known as an Echo Request message) is sent to your computer; your computer sends back an ICMP Echo Reply message to the computer that sent the ICMP Echo message. By default, Windows Firewall discards the incoming ICMP Echo message. To configure your computer so that it does not discard ICMP Echo messages and can respond with ICMP Echo Reply messages, you must configure Windows Firewall to allow incoming echo traffic.

**To allow incoming echo request traffic**

1. Open Windows Firewall, and then click the **Advanced** tab.
2. In **ICMP**, click **Settings**.
3. In the **ICMP Settings** dialog box, select the **Allow incoming echo request** check box.

**I disabled ping by blocking incoming echo traffic, but other computers can still ping my computer.**

This happens when TCP port 445 is added to the exceptions list. By default, TCP port 445 is added to the exceptions list when you enable **File and Printer Sharing** in the Windows Firewall exceptions list or when you enable the **Windows Firewall: Allow remote administration exception** policy setting in Group Policy. To disable ping, you must remove TCP port 445 from the exceptions list. You can do this by disabling **File and Printer Sharing** in the Windows Firewall exceptions list or by editing **File and Printer Sharing** in the exceptions list settings so that TCP port 445 is disabled. You can also do this by disabling the **Windows Firewall: Allow remote administration exception** policy setting.

**To disable the File and Printer Sharing exception so ping is disabled**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Clear the **File and Printer Sharing** check box.

| **Note** |
| --- |
| Disabling the File and Printer Sharing exception will prevent users from accessing shared files, folders, and printers on your computer. |

**To edit the File and Printer Sharing exception so ping is disabled**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **File and Printer Sharing**, and then click **Edit**.
3. In the **Edit a Service** dialog box, clear the **TCP 445** check box.

| **Note** |
| --- |
| Editing the File and Printer Sharing exception can prevent other computers from accessing your shared folders, files, and printers. Be sure to test for the impact these changes might have on file and printer sharing functionality. |

**To disable the Allow remote administration exception so ping is disabled**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. In the details pane, double-click **Windows Firewall: Allow remote administration exception**, and then click either **Not Configured** or **Disabled**.

| **Note** |
| --- |
| Disabling or not configuring the **Windows Firewall: Allow remote administration exception** policy setting can cause your remote administration tools and other programs to stop running properly. |

**I cannot access shared folders or printers on a computer that has Windows Firewall enabled.**
This happens when Windows Firewall blocks incoming traffic through UDP ports 137 and 138 and TCP ports 139 and 445. To allow access to shared folders and printers, you must enable the predefined exception for file and printer sharing, which will dynamically allow incoming traffic on UDP ports 137 and 138 and TCP ports 139 and 445.

**To enable the File and Printer Sharing exception**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Select the **File and Printer Sharing** check box.

**I cannot use Remote Desktop to access another computer.**
This happens when Windows Firewall blocks incoming traffic through TCP port 3389 on the computer you are trying to access. To use Remote Desktop to communicate with a remote computer, you must enable the predefined exception for Remote Desktop on the remote computer, which will dynamically allow incoming traffic on TCP port 3389.

**To enable the Remote Desktop exception**

1. On the remote computer, open Windows Firewall, and then click the **Exceptions** tab.
2. Select the **Remote Desktop** check box.

**I cannot use remote administration tools to manage my servers.**
This happens when Windows Firewall blocks incoming remote procedure call (RPC) or DCOM traffic on your servers. Remote administration tools, such the Microsoft Management Console (MMC) and Windows Management Instrumentation (WMI), use RPC and DCOM to communicate with servers. By default, Windows Firewall blocks communication through TCP ports 135 and 445. To fix this problem, you can enable the **Windows Firewall: Allow remote administration exception**policy setting on your servers. If you enable this policy setting, you must specify the Internet Protocol version 4 (IPv4) addresses or address ranges from which these incoming messages are allowed.

**To enable the Allow remote administration exception**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. In the details pane, double-click **Windows Firewall: Allow remote administration exception**, click **Enabled**, and then, in **Allow unsolicited incoming messages from**, type the IPv4 addresses or address ranges for this exception.

| **Important** |
| --- |
| You should enable the **Windows Firewall: Allow remote administration exception** policy setting only if your remote administrative tools require RPC or DCOM. Malicious users often attempt to attack networks and computers using RPC and DCOM. It is recommended that you contact the manufacturer of your remote administration tool to determine if it requires RPC and DCOM communication. If it does not, do not enable the **Windows Firewall: Allow remote administration exception** policy setting. |

**I cannot get my FTP program to work with Windows Firewall.**
This happens when your FTP program uses active FTP instead of passive (PASV) FTP. Windows Firewall uses the Application Layer Gateway (ALG) Service to process active FTP traffic. If the ALG Service is not running, try starting it.

**To start the Application Layer Gateway Service**

1. Open the Services snap-in.
2. Double-click **Application Layer Gateway Service**.
3. On the **General** tab, if the **Service status** is not **Started**, click **Start**.

If the ALG Service is running and you still cannot get your FTP program to work with Windows Firewall, try adding the FTP program to the exceptions list.

**To add a program to the Windows Firewall exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Program**, and then follow the directions that appear on your screen.

**I added a program to the exceptions list in Windows Firewall in Control Panel, but the program does not show up in the exceptions list when I take the computer off the managed network.**
This happens when you add a program to the exceptions list for one profile (for example, the domain profile), and the computer is using the exceptions list for the other profile (for example, the standard profile). An example of this occurs when a portable computer is running on your corporate domain and you add a program to the exceptions list by using Windows Firewall in Control Panel. In this case, the program is added to the exceptions list for the domain profile. If the portable computer is then used outside of the office and is not connected to the corporate domain, the exceptions list for the standard profile is used; the program will not show up in the exceptions list because it was added to the exceptions list for the domain profile only. To fix this problem, you must do the following:

- Determine to which exceptions list (domain profile or standard profile) the program was added.
- Add the program to the appropriate exceptions list.

**To determine to which exceptions list a program has been added**

- At the command prompt, type **netsh firewall show all**, and press ENTER.

**To add a program to the exceptions list for a specific profile**

1. To add a program to the domain profile, type the following:

   **netsh firewall set allowedprogram** *your_program_path\your_program your_program_name* **enable domain**

   Where *your_program_path* is the path to your program's executable (.exe) file, *your_program* is the name of your program's .exe file, and *your_program_name* is the friendly name that you want to show up in the exceptions list.

2. Press ENTER.

3. To add a program to the standard profile, type the following:

   **netsh firewall set allowedprogram** *your_program_path\your_program your_program_name* **enable standard**

   Where *your_program_path* is the path to your program's executable (.exe) file, *your_program* is the name of your program's .exe file, and *your_program_name* is the friendly name that you want to show up in the exceptions list.

4. Press ENTER.

**Some or all of the settings in Windows Firewall appear dimmed.**
This happens when you do not have the appropriate user rights on the computer you are trying to administer. It can also happen if your company uses Group Policy to manage Windows Firewall.

Windows Firewall dims all of the options in Windows Firewall if you are not a member of the Administrators group. To configure Windows Firewall options, have your domain administrator or accounts administrator add you to the Administrators group on the computer you want to administer.

Windows Firewall also dims any options that are configured through Group Policy. This includes options that are configured through Local Group Policy or through domain-based Group Policy. You can use the Resultant Set of Policy snap-in to determine which Windows Firewall policies are being applied to a computer as well as in which GPO the policies are stored.

**To determine which policies are being applied to the computer**

1. At the command prompt, type **rsop.msc**, and press ENTER.

2. In the console tree, open **Computer Configuration**, open **Administrative Templates**, open **Network**, and then click **Network Connections**.

3. In the console tree, click **Windows Firewall**, and double-click any policies that appear in the details pane to learn more about the policy.

4. In console tree, click **Domain Profile**, and double-click any policies that appear in the details pane to learn more about the policy.

5. In the console tree, click **Standard Profile**, and double-click any policies that appear in the details pane to learn more about the policy.

**I added a program to the exceptions list in Group Policy, but the program does not behave as though it's in the exceptions list.**
This can occur for several reasons. Attempt each of the following possible fixes in the order in which they appear.

Make sure that you used the correct profile when you added the program to the exceptions list. You can configure Windows Firewall policy settings in either a domain profile or a standard profile. Domain profile settings are applied when a computer is connected to a network that contains the domain controllers for the domain in which its computer account resides. Standard profile settings are applied when a computer is not connected to a network that contains the domain controllers for the domain in which its computer account resides, such as a public network.

**To verify Group Policy settings in the domain profile or standard profile**

1. Open the Group Policy Object Editor snap-in to edit the GPO that is used to manage Windows Firewall settings in your organization.

2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, and then open **Windows Firewall**.

3. In the console tree, click **Domain Profile** to see the Group Policy settings that are configured when the computer uses the domain profile.

4. In the console tree, click **Standard Profile** to see the Group Policy settings that are configured when the computer uses the standard profile.

Make sure that the Group Policy settings have been refreshed on the computer you are administering. Local policies take effect immediately, but domain-based Group Policies are refreshed every 90 minutes (unless the computer is a domain controller, in which case policies are refreshed every 5 minutes). If you are unsure whether any policy changes have been applied to the computer, you can force Group Policy to refresh the policies on a computer by running **gpupdate /force** at the command line.

Make sure that policies are being applied from the correct GPO. You can determine this by using the Resultant Set of Policy snap-in.

**To determine in which GPO a policy setting is stored**

1. At the command prompt, type **rsop.msc**, and press ENTER.

2. In the console tree, open **Computer Configuration**, open **Administrative Templates**, open **Network**, and then click **Network Connections**.

3. In the console tree, double-click any policies that appear in the details pane to determine in which GPO the policy is stored.

4. In the console tree, click **Windows Firewall**, and double-click any policies that appear in the details pane to determine in which GPO the policy is stored.

5. In console tree, click **Domain Profile**, and double-click any policies that appear in the details pane to determine in which GPO the policy setting is stored.

6. In the console tree, click **Standard Profile**, and double-click any policies that appear in the details pane to determine in which GPO the policy is stored.

Finally, make sure that you typed the path or program name correctly when you added it to the exceptions list. Windows Firewall does not check for errors, nor does it check whether the program exists. This allows you to add programs to the exceptions list before you install the program. Also, make sure that the path you used applies to the computer you are troubleshooting. If possible, use environment variables in the path so that the path is valid for multiple computer configurations.

**I used the My network (subnet) only scope option, but traffic originating beyond my subnet is getting through Windows Firewall.** This can happen because of the way in which Windows Firewall determines traffic that matches the **My network (subnet) only** scope option. When you use the **My network (subnet) only** scope option, Windows Firewall does not perform any IP configuration testing or subnet mask interpretation to determine whether the traffic is coming from a computer that is a neighbor on a locally attached subnet. Instead, Windows Firewall determines whether the traffic is originating from an address that is directly reachable based on routes in the IPv4 and Internet Protocol version 6 (IPv6) routing tables (which you can view with the **route print** command). If it is, this traffic is considered to match the **My network (subnet) only** scope. Because Windows Firewall defines traffic for the **My network (subnet) only** scope in this way, there are situations in which Windows Firewall allows unexpected or unanticipated traffic.

An example of this occurs when you have a multihomed server with two network interfaces: for example, one interface for the accounting department's subnet and one interface for the marketing department's subnet. If you use the **My network (subnet) only** scope option to restrict the scope of an exception on this computer, Windows Firewall will allow traffic originating from both subnets because the addresses for the address ranges of both subnets are directly reachable. To ensure that Windows Firewall allows only exceptions traffic from one subnet for IPv4 traffic, select the **Custom list** option and configure the IPv4 address range for the desired subnet. You cannot specify custom address ranges for IPv6 traffic.

Another example of this occurs when a computer is configured with a default route to the Internet for which all locations are directly reachable. This can occur when you use an ISP to directly connect a computer to the Internet through a high-speed connection. In this case, Windows Firewall sees all locations on the Internet as directly reachable when you use the **My network (subnet) only** scope option. You can restrict the scope of an exception by selecting the **Custom list** scope option and designating specific IPv4 addresses or IPv4 address ranges.

**To configure a scope with specific IPv4 addresses or IPv4 address ranges**

1. Open Windows Firewall, and then click the **Exceptions** tab.

2. If you are configuring the scope of a program or system service that is already in the exceptions list, click the program or system service, click **Edit**, and then do the following:

    a. Click the port that you want to configure, and then click **Change Scope**.

    b. Click **Custom list**, and then enter the comma-separated list of IPv4 addresses or IPv4 address ranges.

3. If you are adding a program or system service, click **Add Program**; if you are adding a port, click **Add Port**. Then do one of the following:

    a. In the **Add a Program** dialog box, click the program or system service that you want to configure, or click **Browse** and find the program or system service that you want to configure.

    b. In the **Add a Port** dialog box, type the exception name, type the port, and then select **TCP** or **UDP**.

4. Click **Change scope**.

5. In the **Change Scope** dialog box, click **Custom list**, and then enter the comma-separated list of IPv4 addresses and subnets.

| **Important** |
| --- |
| The **My network (subnet) only** or **Custom list** scope options do not necessarily increase your security. Malicious users can circumvent these scope restrictions by spoofing an IP address that appears to be directly reachable or part of the custom list. |

**I used the My network (subnet) only option to change the scope of a program exception, but some computers in my subnet are being blocked by Windows Firewall.**

This happens when a computer roams from one subnet to another. For example, if you create a shared folder on your computer, and then configure the **File and Printer Sharing** exception with the **My network (subnet) only** scope option, only directly reachable computers will be able to access your shared folder. But if one of the neighboring computers on your subnet is a portable computer, and a user moves the portable computer to a network segment outside your local subnet, the DHCP server will assign a new IP address configuration to the portable computer. When the portable computer attempts to access your shared folder, Windows Firewall determines that the computer is not directly reachable and discards the incoming connection requests.

To fix this problem, you can use the **Custom list** scope option to specify a list of IP addresses or IP address ranges from which traffic is allowed.

**To configure a scope with specific IPv4 addresses or IPv4 address ranges**

1. Open Windows Firewall, and then click the **Exceptions** tab.

2. If you are configuring the scope of a program or system service that is already in the exceptions list, click the program or system service, click **Edit**, and then do the following:

    a. Click the port that you want to configure, and then click **Change Scope**.

    b. Click **Custom list**, and then enter the comma-separated list of IPv4 addresses or IPv4 address ranges.

3. If you are adding a program or system service, click **Add Program**; if you are adding a port, click **Add Port**. Then do one of the following:

    a. In the **Add a Program** dialog box, click the program or system service that you want to configure, or click **Browse** and find the program or system service that you want to configure.

    b. In the **Add a Port** dialog box, type the exception name, type the port, and then select **TCP** or **UDP**.

4. Click **Change scope**.

5. In the **Change Scope** dialog box, click **Custom list**, and then enter the comma-separated list of IPv4 addresses and subnets.

**Important**

The **My network (subnet) only** or **Custom list** scope options do not necessarily increase your security. Malicious users can circumvent these scope restrictions by spoofing an IP address that appears to be directly reachable or part of the custom list.

**Note**

You cannot specify custom address ranges for IPv6 traffic.

# Configuring a Computer for Windows Firewall Troubleshooting

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Before you can use advanced troubleshooting techniques to identify and fix Windows Firewall problems, you need to configure your computer for troubleshooting. In addition, you need a basic understanding of troubleshooting concepts, procedures, and tools.

**Configuration Tasks for Troubleshooting**
To configure your computer for troubleshooting, perform the following tasks:

Enable Windows Firewall logging

Enable Windows Firewall auditing

Enable network tracing

**Enable Windows Firewall logging**
The Windows Firewall log file contains information about the network traffic processed by Windows Firewall. To effectively troubleshoot problems with Windows Firewall, you must enable logging for both dropped packets and successful connections.

### To enable Windows Firewall logging

1. Open Windows Firewall in Control Panel.
2. Click the **Advanced** tab.
3. Under **Security Logging**, click **Settings**.
4. In the **Log Settings** dialog box, select the **Log dropped packets** and **Log successful connections** check boxes.

**Enable Windows Firewall auditing**
You can configure the Windows Server 2003 audit log so it records information about Windows Firewall. Specifically, the audit log can track changes that are made to Windows Firewall settings and it can track information about which programs and system services attempt to listen on a port. To record Windows Firewall information in the audit log, you must enable both the **Audit policy change** and **Audit process tracking** policies.

### To enable Windows Firewall auditing

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. In the console tree, open **Windows Settings**, open **Local Policies**, and then click **Audit Policy**.
3. In the details pane, double-click **Audit policy change**, select the **Success** and **Failure** check boxes, and then click **OK**.
4. In the details pane, double-click **Audit process tracking**, select the **Success** and **Failure** check boxes, and then click **OK**.

**Enable network tracing**
The IPNathlp trace log stored in the systemroot\tracing folder provides useful information about the network traffic passing to and from Windows Firewall. Network tracing is most commonly used to solve difficult-to-diagnose network access problems and problems with programs.

### To enable network tracing for Windows Firewall

- At the command line, type **netsh ras set tracing ipnathlp enable**, and press ENTER.

| **Important** |
| --- |
| Changing log file settings for Windows Firewall logging, auditing, and network tracing can substantially increase the size of your log files and use up disk space. After you are finished troubleshooting Windows Firewall issues, it is recommended that you configure log file settings, auditing settings, and network tracing settings as they were before you performed your troubleshooting tasks. |

# Troubleshooting Windows Firewall Problems

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Firewall typically causes three types of problems.

**In this section**

Fixing Network Access Problems

Fixing Program Problems

Fixing Configuration and Management Problems

# Fixing Network Access Problems

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a description of some common network access problems that you might experience when Windows Firewall is enabled.

Typically, you encounter network access problems when you attempt to perform a task that uses the network or when you try to connect to a resource across a network, such as a printer, computer, or a shared folder or file. From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- File and Printer Sharing Does Not Work
- Computer Names Do Not Resolve When Used in a UNC Path
- VPN and Remote Access Connections Fail
- Remote Administration Tools Fail
- The Ping Command Times Out
- A Computer Receives Network Traffic Only from Its Local Subnet or Specific Computers

# File and Printer Sharing Does Not Work

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem typically occurs when someone attempts to access a resource on your computer, such as a shared folder or printer, and the person attempting to access the resource receives a "network path was not found" error.

**Cause**

File and printer sharing can fail when you turn on Windows Firewall because file and printer sharing requires your computer to respond to unsolicited incoming traffic on one or more of the following ports: TCP ports 139 and 445, and UDP ports 137 and 138. Windows Firewall blocks incoming traffic through these ports. To fix this problem, you need to unblock one or more TCP and UDP ports.

**Solution**

Make sure that you have enabled the File and Printer Sharing exception in the Windows Firewall exceptions list.

**To enable the File and Printer Sharing exception**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Select the **File and Printer Sharing** check box.

If file and printer sharing still does not work properly, verify that you are configuring **File and Printer Sharing** in the same profile that your computer is using. If you enable **File and Printer Sharing** in the domain profile, but your computer is using the standard profile, then **File and Printer Sharing** might not be enabled. You can use the Netsh tool to determine which profile your computer is currently using and which profile has **File and Printer Sharing** enabled.

**To determine which profile your computer is currently using**

- At the command prompt, type **netsh firewall show currentprofile**, and press ENTER.

**To determine which profile has File and Printer Sharing enabled**

- At the command prompt, type **netsh firewall show service**, and press ENTER.

If **File and Printer Sharing** is not enabled in the profile that your computer is using, you need to enable **File and Printer Sharing** in the appropriate profile.

**To enable File and Printer Sharing in a specific profile**

1. At the command prompt, type the following:

   **netsh firewall set service type = fileandprint mode = enable profile =** *your profile*

   Where *your profile* can be current, domain, standard, or all, depending on which profile must have **File and Printer Sharing** enabled.

2. Press ENTER.

If file and printer sharing still does not work properly, verify that the scope setting for the **File and Printer Sharing** exception is not preventing other computers from accessing your shared files and printers. The scope setting allows you to restrict an exception to a specific group of computers. Be sure that the scope setting for the **File and Printer Sharing** exception includes the computers that are trying to access the files and folders on your computer. There are three possible scope settings:

**Any computer (including those on the Internet)**, which does not restrict the exception.

**My Network (subnet) only**, which restricts the exception to computers that are directly reachable based on entries in the IP routing table.

**Custom list**, which restricts the exception to a list of Internet Protocol version 4 (IPv4) addresses or IPv4 address ranges. You cannot use the **Custom list** option for Internet Protocol version 6 (IPv6) traffic.

**To verify the scope of the File and Printer Sharing exception**

1. Open Windows Firewall, and then click the **Exceptions** tab.

2. Click **File and Printer Sharing**, and then click **Edit**.
3. Click **TCP 139**, and then click **Change Scope**.
4. Verify that the scope setting includes the computers that you want to access your computer. If it does not, change the scope so it is less restrictive.
5. Repeat steps 3 and 4 for **TCP 445**, **UDP 137**, and **UDP 138**.

| **Important** |
| --- |
| The **My network (subnet) only** or **Custom list** scope options do not necessarily increase your security. Malicious users can circumvent these scope restrictions by spoofing an IP address that appears to be directly reachable or is part of the custom list. |

If file and printer sharing still does not work properly and you are using a collaboration tool or a file-sharing tool, you might have to configure other exceptions to share files. If your vendor does not provide information about the settings that need to be configured for your collaboration or file sharing program, try adding the program to the exceptions list.

**To add a program or service to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click **Add Program**, and then follow the instructions that appear on your screen.

# Computer Names Do Not Resolve When Used in a UNC Path

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem typically occurs when you use **Run** to access a shared folder and you specify a path in the form *server name**shared folder name*. If the UNC path does not resolve, you will see a "...network resource not found" error. This can also happen when you use the **net use** command to map a network drive.

**Cause**

Usually, UNC path names cannot resolve because Windows Firewall is preventing access to a naming service, such as WINS or DNS. To solve this problem, you need to add a port or a service to the Windows Firewall exceptions list on the server that is running the naming service.

This can also be caused if you're using NetBIOS and you have enabled the **Prohibit unicast response to multicast or broadcast requests** policy setting. If this policy setting is enabled, and a computer broadcasts a NetBIOS name query request to resolve a name, the unicast response from the target computer will be dropped by Windows Firewall. To fix this, you need to disable the **Windows Firewall: Prohibit unicast response to multicast or broadcast requests**policy setting.

**Solution**

If your organization uses WINS for name resolution, add UDP port 137 to the Windows Firewall exceptions list on your WINS server.

**To add UDP port 137 to the Windows Firewall exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click **Add Port**.
3. In the **Add a Port** dialog box, in **Name**, type a friendly name for the port exception (for example, UDP port 137).
4. In **Port number**, type 137, and then click the **UDP** option button.

If your organization uses DNS for name resolution, add UDP and TCP port 53 to the Windows Firewall exceptions list on your DNS server.

**To add UDP port 53 and TCP port 53 to the Windows Firewall exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click **Add Port**.
3. In the **Add a Port** dialog box, in **Name**, type a friendly name for the port exception (for example, TCP port 53).
4. In **Port number**, type 53.
5. Click the **TCP** option button, and then click **OK**.
6. On the **Exceptions** tab, click **Add Port**.
7. In the **Add a Port** dialog box, in **Name**, type a friendly name for the port exception (for example, UDP port 53).
8. In **Port number**, type 53.
9. Click the **UDP** option button, and then click **OK**.

If you use NetBIOS and UNC path names cannot resolve after you open the appropriate ports on your WINS server or DNS server, then try disabling the **Windows Firewall: Prohibit unicast response to multicast or broadcast requests**policy setting.

**Disable the Prohibit unicast response to multicast or broadcast requests policy setting**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open

**Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.

3. Double-click **Windows Firewall: Prohibit unicast response to multicast or broadcast requests**, and on the **Settings** tab, click **Disabled** or **Not Configured**.

# VPN and Remote Access Connections Fail

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you encounter this problem when you try to connect to a corporate or private network using a virtual private network (VPN) or remote access connection and you are unable to connect or you receive an error message telling you that the connection failed.

**Cause**

This usually occurs when you configure VPN or remote access settings and exceptions in the Windows Firewall domain profile, but Windows Firewall uses the settings and exceptions that are in the standard profile. If you have not configured VPN or remote access settings and exceptions in the standard profile, the VPN and remote access connections will fail.

This happens because VPN and remote access connections are special connection types. A computer that connects through a VPN or remote access connection does not undergo any checks for domain membership when Windows Firewall determines the network on which a computer resides. For example, if your computer is connected to a public network, such as the Internet, and you attempt to create a VPN or remote access connection directly to a private network that contains the domain controllers of the domain in which your computer account resides, the VPN or remote access connection is ignored and Windows Firewall will determine that your computer is currently connected to a public network. Because your computer is connected to a public network, Windows Firewall uses the settings and exceptions in the standard profile instead of the settings in the domain profile.

**Solution**

To solve this problem, you need to configure VPN and remote access settings and exceptions in the standard profile. The following table lists some of the common ports that you might need to add to the exceptions list for your VPN configuration. It is not an exhaustive list. You might not need to add all of these ports to the exceptions list for your VPN configuration. For example, if you are allowing only Layer Two Tunneling Protocol (L2TP), you would not configure a filter for Point-to-Point Tunneling Protocol (PPTP).

| Service or Protocol | Port |
|---|---|
| PPTP | TCP 1723, UDP 1723 |
| L2TP | TCP 1701, UDP 1701 |
| Hypertext Transport Protocol (HTTP) | TCP 80 |
| Secure Hypertext Transport Protocol (HTTPS) | TCP 443 |
| Simple Mail Transfer Protocol (SMTP) | TCP 25, UDP 25 |
| Dynamic Host Control Protocol (DHCP). Required if the remote access server uses an external DHCP server. | TCP 67, UDP 67 |
| Post Office Protocol version 3 (POP3) | TCP 110 |
| Domain Name Service (DNS) | UDP 53 |
| IPsec | UDP 500 |
| IPsec with network address translation (NAT) | UDP 4500 |

# Remote Administration Tools Fail

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you encounter this problem when you try to connect to a remote server with an administration tool, such as a Microsoft Management Console (MMC) snap-in.

**Cause**

Remote administration tools often fail because the server you are trying to manage blocks the unsolicited incoming traffic from the remote administration tool. To remotely manage a server with a remote administration tool, you must configure Windows Firewall on the remote server to allow unsolicited traffic from the remote administration tool.

**Solution**

You can solve this problem by configuring Windows Firewall settings on the remote server you are trying to administer. Usually, you need to add a port, program, or service to the Windows Firewall exceptions list on the server you are trying to manage. To determine which Windows Firewall settings you need to configure on the remote server, see "Windows Firewall Settings" in the Windows Server 2003 Tools and Settings documentation. Windows Firewall Settings provides information about the specific Windows Firewall settings you need to configure to use every remote administration tool that is available on Windows Server 2003.

If you cannot find your remote administration tool in Windows Firewall Settings, or the settings do not fix your problem, try enabling the **File and Printer Sharing** exception on the remote server.

**To enable the File and Printer Sharing exception**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Select the **File and Printer Sharing** check box, and click **Edit**.
3. In the **Edit a Service** dialog box, click **Change Scope**.
4. In the **Change Scope** dialog box, do one of the following:

   Click **Any computer (including those on the Internet)** if you want this exception to apply to all computers.

   Click **Custom list** if you want this exception to apply to specific Internet Protocol version 4 (IPv4) addresses or IPv4 address ranges.

If you still cannot use your remote administration tool to administer a remote server, try enabling the **Windows Firewall: Allow remote administration exception** policy setting on the remote server.

**To enable the Allow remote administration exception policy setting**

1. Open the Group Policy Object Editor snap-in to edit the Group Policy object (GPO) that is used to manage Windows Firewall settings in your organization.
2. Open **Computer Configuration**, open **Administrative Templates**, open **Network**, open **Network Connections**, open **Windows Firewall**, and then click either **Domain Profile** or **Standard Profile**.
3. In the details pane, double-click **Windows Firewall: Allow remote administration exception**, and then click **Enabled**.

| **Important** |
| --- |
| You should enable the **Windows Firewall: Allow remote administration exception** policy setting only if your remote administrative tools require RPC or DCOM. Malicious users often attempt to attack networks and computers using RPC and DCOM. It is recommended that you contact the manufacturer of your remote administration tool to determine if it requires RPC and DCOM communication. If it does not, do not enable the **Windows Firewall: Allow remote administration exception** policy setting. |

# The Ping Command Times Out

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you see this problem occur when you use the **ping** command to test network connectivity or to see if another computer is on the network.

**Cause**

The **ping** command times out because the computer you are trying to reach is blocking incoming Internet Control Message Protocol (ICMP) echo traffic.

**Solution**

To fix this problem, you need to configure Windows Firewall ICMP settings on the computer you are trying to reach so that incoming ICMP echo traffic is allowed.

**To allow incoming echo request traffic**

1. Open Windows Firewall, and then click the **Advanced** tab.
2. In **ICMP**, click **Settings**.
3. In the **ICMP Settings** dialog box, select the **Allow incoming echo request** check box.

# A Computer Receives Network Traffic Only from Its Local Subnet or Specific Computers

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you see this problem occur when a computer beyond your local subnet tries to access a shared folder, printer, or file on your computer and the connection fails. You might also see this problem if you've added a port or program to the exceptions list and the port or program blocks traffic from beyond your local subnet, but does not block traffic from within your local subnet.

**Cause**

This usually occurs because the scope of one or more exceptions on your computer has been restricted to your local subnet or to a specific group of computers.

By default, exceptions are not restricted in scope (that is, an exception applies to any computer, including computers on the Internet). However, you can configure the scope of an exception to your local subnet or to specific Internet Protocol version 4 (IPv4) addresses.

**Solution**

To fix this problem, first determine whether any of the exceptions in your exceptions list have restricted scope. Next, if there any scope restrictions, you need to expand the scope restriction.

**To determine whether an exception has restricted scope**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click a program or port, and click **Edit**.
3. Click **Change scope**.

   If an exception has restricted scope, **My network (subnet) only** or **Custom list** will be selected.

You can customize a scope restriction by using the **Custom list** option. The **Custom list** option allows you to enter specific IPv4 addresses or a range of IPv4 addresses. You cannot use the **Custom list** option for Internet Protocol version 6 (IPv6) traffic.

**To configure a scope with specific IP addresses or IP address ranges**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. If you are configuring the scope of a program or system service that is already in the exceptions list, click the program or system service, click **Edit**, and then do the following:
   a. Click the port that you want to configure, and then click **Change Scope**.
   b. Click **Custom list**, and then enter the comma-separated list of IP addresses or IPv4 address ranges.
3. If you are adding a program or system service, click **Add Program**; if you are adding a port, click **Add Port**. Then do one of the following:
   a. In the **Add a Program** dialog box, click the program or system service that you want to configure, or click **Browse** and find the program or system service that you want to configure.
   b. In the **Add a Port** dialog box, type the exception name, type the port, and then select **TCP** or **UDP**.
4. Click **Change scope**.
5. In the **Change Scope** dialog box, click **Custom list**, and then enter the comma-separated list of IPv4 addresses and IPv4 address ranges.

**Important**

The **My network (subnet) only** or **Custom list** scope options do not necessarily increase your security. Malicious users can circumvent these scope restrictions by spoofing an IP address that appears to be directly reachable or part of the custom list.

# Fixing Program Problems

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a description of some common problems you might experience when you run a program with Windows Firewall enabled.

Typically, you encounter program problems when you try to run a program with Windows Firewall turned on or you turn Windows Firewall on while a program is running. From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- A Program in the Exceptions List Does Not Run Properly
- A Notification Says Windows Explorer Is Trying to Listen on a Port
- A User Cannot Determine What to Add to the Exceptions List
- A Program Removed from the Exceptions List Keeps Working
- There Is a Problem Running an Antivirus Program
- A System Service Runs in Svchost.exe and Cannot Be Added to the Exceptions List
- An Unexpected Program Appears in the Exceptions List

# A Program in the Exceptions List Does Not Run Properly

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, this problem occurs when you add a program's executable (.exe) file to the exceptions list and then try to run the program. Either the program will start, but then fail to run properly, or the program will not start at all.

**Cause**

Some programs depend on more than one .exe file. If this is the case, and the dependent .exe file is not in the exceptions list, the program will not run properly.

**Solution**

If you have already restarted your computer, but the problem persists, make sure that you added the correct .exe file to the exceptions list. If a program relies on more than one .exe file, you need to identify the .exe files that are associated with the program and add those .exe files to the exceptions list. You can use the **tasklist** command to determine whether a program relies on other .exe files.

**To determine whether a program relies on more than one .exe file**

1. Start the program that you want to evaluate.
2. At the command line, type **tasklist /m**, and press ENTER.
3. If a program relies on another .exe file, you will see it in the list of modules that are associated with the program.

If a program relies on other .exe files, add those files to the exceptions list.

**To add a program to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click **Add Program**, and then follow the instructions that appear on your screen.

If the program still does not work properly, you might have to add ports to the exceptions list.

First, you need to identify the ports used by the program.

**To determine the ports used by a program**

1. Start the program that you want to evaluate.
2. At the command line, type **tasklist**, and then press ENTER.
3. Look up the process ID (PID) that is associated with the program you are evaluating. If the program relies on more than one .exe file, be sure to look up the PID for each .exe file that the program is using.
4. At the command line, type **netstat -a -o -n**, and then press ENTER.
5. Use the program's PID to determine the ports on which the program is listening.

Next, you need to determine which ports are enabled in the exceptions list.

**To identify ports that are enabled in the exceptions list**

- At the command line, type **netsh firewall show state**, and then press ENTER.

  Ports that are designated as open are enabled in the Windows Firewall exceptions list.

If a program uses a port, and the port is not enabled in the exceptions list, try adding the port to the exceptions list.

**To add a port to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Port**.

3. In **Name**, type a friendly name for the port exception.
4. In **Port number**, type the port number used by the program.
5. Click either **TCP** or **UDP** to specify the type of port that corresponds to your port number.
6. Repeat steps 2 through 5 if your program uses multiple ports and the ports are not enabled in the exceptions list.

| **Important** |
| --- |
| Adding a port to the exceptions list can lessen the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program to the exceptions list. |

# A Notification Says Windows Explorer Is Trying to Listen on a Port

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, this problem occurs when you open Windows Explorer and see a **Windows Security Alert** dialog box (referred to throughout this documentation as a notification) that displays a message informing you that Explorer.exe is attempting to listen on a port. If you are a member of the Administrators group, the notification will ask if you want to unblock Explorer.exe. If you are not a member of the Administrators group, the notification will tell you to contact your Administrator if you want to unblock Explorer.exe.

**Cause**

When you see this notification, it usually means that Windows Explorer (Explorer.exe) is hosting a secondary program and the program it is hosting is trying to listen for incoming traffic on one or more ports. Because Explorer.exe is hosting the program, the program is running as a separate process within Explorer.exe. For this reason, Windows Firewall cannot determine the name of the program's executable (.exe) file. Instead, it can determine only that a process within Explorer.exe is attempting to listen for incoming traffic.

**Solution**

To fix this problem, trying using the **tasklist** command to identify the program that is attempting to listen for incoming traffic. If you can identify the program, try to add it to the exceptions list.

| **Important** |
| --- |
| Do not add Explorer.exe to the exceptions list. Doing so allows any program that is hosted by Explorer.exe to receive unsolicited incoming traffic, which can decrease the security of your computer. |

**To identify a program that is running within Windows Explorer**

1. Start Windows Explorer and wait for the Windows Firewall notification telling you that Explorer.exe is attempting to listen on a port.
2. At the command line, type **tasklist /m**, and press ENTER.
3. See if there is an .exe file listed with the modules that are running in Explorer.exe.

If there is an .exe file associated with Explorer.exe, try adding it to the exceptions list, and then shut down and restart Windows Explorer to see if you still get the Windows Firewall notification. If there is more than one .exe file, add the .exe files to the exceptions list one at a time and test Windows Explorer each time to determine which .exe files you need to add to the exceptions list. You might not need to add them all.

**To add a program to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click **Add Program**, and then follow the instructions that appear on your screen.

If there are no .exe files running in Explorer.exe, you can try to determine which ports the program is using and then add those ports to the exceptions list.

**To determine the ports that are being used by Windows Explorer**

1. Start Windows Explorer and wait for the Windows Firewall notification telling you that Explorer.exe is attempting to listen on a port.
2. At the command line, type **tasklist /m**, and press ENTER.
3. Look up the process ID (PID) that is associated with Explorer.exe.
4. At the command line, type **netstat -a -o -n**, and then press ENTER.
5. Use the program’s PID to determine the ports on which the program is listening.

After you determine the ports that Explorer.exe is using, try adding the ports to the exceptions list.

**To add a port to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Port**.
3. In **Name**, type a friendly name for the port exception.
4. In **Port number**, type the port number used by the program.
5. Click either **TCP** or **UDP** to specify the type of port that corresponds to your port number.
6. Repeat steps 2 through 5 if your program uses multiple ports and the ports are not enabled in the exceptions list.

| **Important** |
| --- |
| Adding a port to the exceptions list can lessen the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program to the exceptions list. |

# A User Cannot Determine What to Add to the Exceptions List

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you have this problem when you try to add a program to the exceptions list, but you cannot find the program's executable (.exe) file or the program relies on secondary .exe files and dynamic-link library (.dll) files and you do not know which files to add to the exceptions list.

**Cause**

Some programs run as a system service and might not have an .exe file that you can add to the exceptions list. In addition, some programs rely on secondary .exe files or .dll files to process incoming traffic. In this case, adding the program's primary .exe file to the exceptions list will not open the port that the program needs because the program uses a secondary .exe file or .dll to process incoming traffic.

**Solution**

To fix this problem, ask the program vendor or read the program documentation to see which .exe file the program uses to listen for unsolicited traffic, and then add the .exe file to the exceptions list.

**To add a program to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. On the **Exceptions** tab, click **Add Program**, and then follow the instructions that appear on your screen.

If you cannot determine which .exe file to add to the exceptions list, you might be able to use Event Viewer to determine which .exe file the program uses to listen for unsolicited traffic.

| **Note** |
| --- |
| You must configure audit policies to see Windows Firewall events. For more information, see Configuring a Computer for Windows Firewall Troubleshooting. |

**To view Windows Firewall notification events in Event Viewer**

1. Open Event Viewer.
2. Click **Security**, and look for the most recent **Failure Audit** event type that has an **Event** identifier of 861.
3. Double-click the event.
4. The path and the name of the .exe file should appear next to **Path**.
5. If there is no information next to **Path**, write down the number that appears next to **Process Identifier**.

If you know the process identifier (PID) for the .exe file that attempted to listen for unsolicited traffic, you can use the **tasklist** command to determine the name of the .exe file.

**To determine which .exe file is associated with a process identifier**

1. At the command line type **tasklist**, and then press ENTER.
2. Use the PID to identify the .exe file.

If you still cannot determine which .exe file is listening for unsolicited traffic, try using the **tasklist** and **netstat** commands to determine which ports the program uses, and then add those ports to the exceptions list.

**To determine the ports used by a program**

1. Start the program that you want to evaluate.
2. At the command line, type **tasklist**, and then press ENTER.
3. Look up the PID that is associated with the program you are evaluating. If the program relies on more than one .exe file, be sure to look up the PID for each .exe file.

4. At the command line, type **netstat -a -o -n**, and then press ENTER.
5. Use the program's PID(s) to determine the ports on which the program is listening.

**To add a port to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Port**.
3. In **Name**, type a friendly name for the port exception.
4. In **Port number**, type the port number used by the program.
5. Click either **TCP** or **UDP** to specify the type of port that corresponds to your port number.
6. Repeat steps 2 through 5 if your program uses multiple ports and the ports are not enabled in the exceptions list.

| **Important** |
| --- |
| Adding a port to the exceptions list can lessen the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program to the exceptions list. |

# A Program Removed from the Exceptions List Keeps Working

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you see this behavior when you remove a program from the exceptions list and then run the program. Although the program is not on the exceptions list, it runs as though it is still listed in the exceptions list.

**Cause**

This can occur for several reasons.

- The program might not listen for unsolicited traffic all of the time. Some programs listen for unsolicited incoming traffic only when you enable certain options or use certain program features.
- There might be another exception on the exceptions list that opens a port used by the program. In this case, the program will still run normally even though it is not listed in the exceptions list.
- The program might use the Windows Firewall application programming interface (API) to add a required port to the exceptions list without notifying you.

**Solution**

You cannot prevent a program from using the Windows Firewall API to add a port to the exceptions list. If you need to prevent this, contact the program vendor or read the program documentation to see if there is a way to disable the feature that listens for incoming traffic. This might prevent the program from using the Windows Firewall APIs.

If the program consists of several components or features, and only one of those components or features is responsible for handling unsolicited incoming traffic, you can try to disable the feature or the component. The program vendor might be able to provide with a registry modification to do this.

If the program is using a port that is already listed in the exceptions list, contact the program vendor or read the program documentation to determine which ports the program uses. If you cannot determine this, run the program and then use the **tasklist** and **netstat** commands to determine which ports the program is using. To do this, you might need to contact the program vendor or read the program documentation to determine which program features you need to use or which program options you need to enable to force the program to listen on a port.

**To determine the ports used by a program**

1. Start the program that you want to evaluate.
2. At the command line, type **tasklist**, and then press ENTER.
3. Look up the process ID (PID) that is associated with the program you are evaluating. If the program relies on more than one .exe file, be sure to look up the PID for each .exe file that the program is using.
4. At the command line, type **netstat -a -o -n**, and then press ENTER.
5. Use the program's PID to determine the ports on which the program is listening.

After you identify the port that the program uses, see if the port is already listed on the exceptions list.

**To identify ports that are enabled in the exceptions list**

- At the command line, type **netsh firewall show state**, and then press ENTER.

  Ports that are designated as open are enabled in the Windows Firewall exceptions list.

Finally, if the port is in the exceptions list, you need to determine whether you can remove the port without causing other programs or system services to stop running. Removing a port from the exceptions list might prevent other programs and system services from running properly.

# There Is a Problem Running an Antivirus Program

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you see this problem occur when an antivirus program tries to automatically download a file--such as a virus definition file, a signature file, or a program update--either from the Internet or from a server on your corporate network. When this happens, you might see a **Windows Security Alert** dialog box (notification) that displays a message informing you that the application is trying to use a port that is blocked, or the application might stop responding or it might behave unpredictably.

**Cause**

If the download is initiated by a central server and "pushed" down to your computer, then the download traffic will be considered unsolicited incoming traffic and Windows Firewall will block the traffic. Many antivirus programs use the file transfer protocol (FTP) to transmit program updates, virus signatures, and virus definitions to a computer, and because Windows Firewall blocks the FTP ports by default, the program cannot process the download request. Although many antivirus programs have been updated and use the Windows Firewall application programming interface (API) to open the FTP ports, not all programs do this. If a program does not automatically open the proper ports to allow an unsolicited download, the program might fail when Windows Firewall is enabled.

**Solution**

To solve this problem, contact the program vendor or read the program documentation to see if you can configure the antivirus program so files cannot be "pushed" down to your computer. In some cases, you can configure an antivirus program so it "pulls" files down at specified intervals or when you manually initiate an update or download.

If this is not acceptable behavior in your organization, contact the program vendor or read the program documentation to see if the antivirus program uses FTP to download program updates, virus signature files, or virus definition files. If the program use FTP, make sure that the Application Layer Gateway (ALG) Service is started. Windows Firewall uses the ALG Service to process active FTP traffic.

**To start the Application Gateway Service**

1. Open the Services snap-in.
2. Double-click **Application Layer Gateway Service**.
3. On the **General** tab, if **Service status** is not **Started**, click **Start**.

If the ALG Service is running and you still cannot get your antivirus program to work with Windows Firewall, try adding the antivirus program to the exceptions list.

**To add a program to the Windows Firewall exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Program**, and then follow the directions that appear on your screen.

If this does not work, you need to determine which port(s) the antivirus program uses, and then add the port(s) to the exceptions list.

**To determine the ports used by a program**

1. Start the program that you want to evaluate.
2. At the command line, type **tasklist**, and then press ENTER.
3. Look up the process ID (PID) that is associated with the program you are evaluating. If the program relies on more than one .exe file, be sure to look up the PID for each .exe file that the program is using.
4. At the command line, type **netstat -a -o -n**, and then press ENTER.
5. Use the program's PID to determine the ports on which the program is listening.

After you identify the port that the antivirus program uses, try adding the port to the exceptions list.

**To add a port to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Port**.
3. In **Name**, type a friendly name for the port exception.
4. In **Port number**, type the port number used by the program.
5. Click either **TCP** or **UDP** to specify the type of port that corresponds to your port number.
6. Repeat steps 2 through 5 if your program uses multiple ports and the ports are not enabled in the exceptions list.

| **Important** |
| --- |
| Adding a port to the exceptions list can reduce the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program to the exceptions list. |

# A System Service Runs in Svchost.exe and Cannot Be Added to the Exceptions List

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Typically, you see this behavior when you need to add a service to the exceptions list, but the service runs within Svchost.exe, not within an executable (.exe) file that you can add to the exceptions list.

**Cause**

Most system services run within Svchost.exe. It is not recommended that you add Svchost.exe to the exceptions list. Doing so will allow any service running within Svchost.exe to receive incoming traffic through Windows Firewall.

**Solution**

If the service uses one or more fixed ports, you might be able to add the ports to the exceptions list. You can use the **netstat** and **tasklist** commands to determine whether a service uses fixed ports. First, run **tasklist** to identify the process identifier (PID) that is associated with the Scvhost.exe process in which the service is running. Then, run **netstat** to determine whether there are any fixed ports being established by the Svchost.exe process in which the service is running. You need to restart your computer several times and perform these procedures each time you restart your computer to verify that the same ports are being assigned each time.

**To determine the process identifier for a service**

1. At the command line, type **tasklist /svc**, and press ENTER.
2. Look up the PID that is associated with the Svchost.exe in which the service is running.

**To determine which ports a process is using**

1. At the command line, type **netstat -a -o -n**, and press ENTER.
2. Look up the port numbers that are assigned to the PID you are evaluating.

If, after restarting your computer several times, you can determine that the same ports are being assigned to Svchost.exe, try adding those ports to the exceptions list.

**To add a port to the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Add Port**.
3. In **Name**, type a friendly name for the port exception.
4. In **Port number**, type the port number used by the program.
5. Click either **TCP** or **UDP** to specify the type of port that corresponds to your port number.

| **Important** |
| --- |
| Adding a port to the exceptions list can lessen the security of your computer because the port will be open any time the computer is running. You should add ports to the exceptions list only when it is not possible to add a program to the exceptions list. |

If the service does not use static ports, but instead uses the RPC endpoint mapper (EPM) to allocate ports dynamically, you might be able to define the range of ports that the RPC EPM allocates and then add the defined ports to the exceptions list. For more information about defining a range ports that RPC assigns, see How to Configure RPC Dynamic Port Allocation to Work with Firewalls in the Microsoft Knowledge Base.

| **Important** |
| --- |
| Adding numerous ports to the exceptions list lessens the security of your computer and can increase the risk of attack. You should open numerous ports only as a last resort. |

# An Unexpected Program Appears in the Exceptions List

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can see this problem occur when you open Windows Firewall and click the **Exceptions** tab.

**Cause**
A program can use the Windows Firewall application programming interface (API) to automatically add itself and other programs, ports, and services to the Windows Firewall exceptions list without notifying you.

Group Policy might be applying policy settings that you are unaware of to your computer.

**Solution**
You cannot prevent a program from using the Windows Firewall API to add itself or other programs, ports, or system services to the exceptions list. You can, however, determine whether programs are being added to the exceptions list through Group Policy. To do this, you must run the Resultant Set of Policy snap-in.

**To determine which policies are being applied to a computer**

1. At the command prompt, type **rsop.msc**, and press ENTER.
2. In the console tree, open **Computer Configuration**, open **Administrative Templates**, open **Network**, and then click **Network Connections**.
3. In the console tree, click **Windows Firewall**, and double-click any policies that appear in the details pane to learn more about the policy.
4. In console tree, click **Domain Profile**, and double-click any policies that appear in the details pane to learn more about the policy.
5. In the console tree, click **Standard Profile**, and double-click any policies that appear in the details pane to learn more about the policy.

# Fixing Configuration and Management Problems

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section provides a description of some common problems that you might experience when you configure or manage Windows Firewall.

Typically, you encounter configuration and management problems when you are configuring Windows Firewall settings, either in the Windows Firewall user interface (UI) or through Group Policy. From the following list, choose the problem that best describes your situation, and then step through the suggested fix:

- A Program Named “Unspecified” Appears in the Exceptions List
- A Windows Firewall Setting Does Not Take Effect
- One or More Windows Firewall Settings Appear Dimmed

# A Program Named “Unspecified” Appears in the Exceptions List

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem most commonly occurs when you use the **netsh** command to add a program to the exceptions list.

**Cause**
When you use the **netsh** command to add programs to the exceptions list, you have the option of specifying the display name for the program. If you do not specify a display name, Windows Firewall uses “Unspecified” as the display name.

**Solution**
You can fix this problem by using the **netsh** command to add the application to the exceptions list with the proper display name. To do this, you need to know the name and path to the executable (.exe) file that is associated with the “unspecified” program.

**To identify the path and file name of a program in the exceptions list**

1. Open Windows Firewall, and then click the **Exceptions** tab.
2. Click **Unspecified**, and then click **Edit**.
3. Look in **Path** to see the path and file name of the .exe file.

After you identify the path and file name, you can change the display name of the program.

**To change the display name of a program in the exceptions list**

1. At the command prompt, type the following:

   **netsh firewall set allowedprogram program = *program path and file name* name = *display name***

   Where *program path and file name* is the path and file name of the executable file and *display name* is the display name that you want to use for the program.

2. Press ENTER.

# A Windows Firewall Setting Does Not Take Effect

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem most commonly occurs when you add a program or port to the exceptions list, but the program or port does not behave as though it's in the exceptions list. This problem can also occur when you configure other Windows Firewall settings, such as log file settings and notification settings, and the settings do not seem to take effect.

**Cause**

Usually this problem occurs because the exceptions and settings were configured in one profile and the computer is using another profile. Windows Firewall settings can be configured in two profiles: the domain profile, which is used when a computer is connected to a network in which the computer's domain account resides; and the standard profile, which is used when a computer is connected to a network in which the computer's domain account does not reside, such as a public network.

This problem can also occur if you add a program to the exceptions list, run the program, and then start Windows Firewall. In this case, Windows Firewall cannot track the ports that the program is using because they were assigned before Windows Firewall was started.

This problem can also occur when there is a Group Policy hierarchy problem. For example, if you configure Windows Firewall settings in a Group Policy Object (GPO) that inherits policy settings from another GPO, then your Windows Firewall settings might never get applied.

**Solution**

To see if you configured the Windows Firewall setting in the wrong profile, you must first determine which profile your computer is currently using.

**To determine which profile your computer is currently using**

- At the command prompt, type **netsh firewall show currentprofile**, and press ENTER.

Next, you need to verify your Windows Firewall settings in both the domain and standard profiles.

**To verify Windows Firewall settings in the domain and standard profiles**

- At the command line type **netsh firewall show config**, and then press ENTER.

  Windows Firewall configuration settings are displayed for both the standard and domain profiles.

If you configured a setting in a profile different from the one your computer is currently using, try configuring the setting in the appropriate profile.

If you still have a problem with the setting, try restarting your computer. Be sure to start Windows Firewall before you start any applications that are in the Windows Firewall exceptions list.

If you still have a problem with the setting, and your organization uses Group Policy to manage Windows Firewall settings, use the Resultant Set of Policy snap-in to determine how policy settings are being applied to the computer.

**To determine which policies are being applied to a computer**

1. At the command prompt, type **rsop.msc**, and press ENTER.
2. In the console tree, open **Computer Configuration**, open **Administrative Templates**, open **Network**, and then click **Network Connections**.
3. In the console tree, click **Windows Firewall**, and double-click any policies that appear in the details pane to learn more about the policy.
4. In console tree, click **Domain Profile**, and double-click any policies that appear in the details pane to learn more about the policy.
5. In the console tree, click **Standard Profile**, and double-click any policies that appear in the details pane to learn more about the policy.

# One or More Windows Firewall Settings Appear Dimmed

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This problem occurs when you open Windows Firewall in Control Panel and you cannot configure settings because they appear dimmed.

**Cause**

Windows Firewall settings appear dimmed when you do not have the appropriate administrative rights to configure Windows Firewall or Windows Firewall settings are being managed by Group Policy. You must be a member of the Administrators group to configure Windows Firewall settings. Domain-based policy settings override local Windows Firewall settings.

**Solution**

Make sure you are a member of the Administrators group on the computer you are trying to administer.

**To verify that you are a member of the Administrators group**

1. Open the Computer Management snap-in.
2. In the console tree, double-click **Local Users and Groups**, and then click **Groups**.
3. In the details pane, double-click **Administrators** and verify that your account name or a group to which your account is a member appears in the **Members** list.

You can also tell if you have the appropriate administrative rights to configure Windows Firewall by opening Windows Firewall in Control Panel. If you do not have administrative rights, all of the controls in the Windows Firewall user interface will appear dimmed and a warning will appear in the user interface (UI) telling you that you need to be a computer administrator to change any settings.

If you are a member of the Administrators group and some controls appear dimmed in the Windows Firewall UI, you can use the Resultant Set of Policy snap-in to determine which policy settings are being applied to the computer. Any controls that are managed by Group Policy will appear dimmed in the Windows Firewall UI.

**To determine which policies are being applied to a computer**

1. At the command prompt, type **rsop.msc**, and press ENTER.
2. In the console tree, open **Computer Configuration**, open **Administrative Templates**, open **Network**, and then click **Network Connections**.
3. In the console tree, click **Windows Firewall**, and double-click any policies that appear in the details pane to learn more about the policy.
4. In console tree, click **Domain Profile**, and double-click any policies that appear in the details pane to learn more about the policy.
5. In the console tree, click **Standard Profile**, and double-click any policies that appear in the details pane to learn more about the policy.

# Additional Resources for Windows Firewall Troubleshooting

Updated: March 28, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

For specific information about troubleshooting Windows Firewall problems, see the following resources:

- Troubleshooting Windows Firewall Settings in Windows XP Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43102).
- Article ID 842242 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43103). This article describes why some programs might stop working after you install Windows XP with Service Pack 2 (SP2) and what you can do to overcome the problem.
- Article ID 884130 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=43104). This article contains a list of programs that are known to experience loss of functionality when they run on Windows XP SP2.

For information about Windows Firewall known issues and best practices, see the following resources:

- Best Practices for Managing Windows Firewall
- Known Issues for Managing Resets, Startup, and Shutdown
- Known Issues for Managing Windows Firewall Profiles
- Known Issues for Managing Firewall Rules
- Known Issues for Managing IPsec, Multicast, and ICMP Settings
- Known Issues for Managing Windows Firewall Notifications
- Known Issues for Optimizing Windows Firewall
- Known Issues for Securing Windows Firewall

For general information about how Windows Firewall works and how to manage and configure Windows Firewall, see the following resources:

- Administering Windows Firewall
- Manually Configuring Windows Firewall in Windows XP Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=33763).
- New Networking Features in Microsoft Windows XP Service Pack 2 on the Microsoft Web site (http://go.microsoft.com/fwlink/?LinkId=33684).

# Windows Server 2003 PKI Operations Guide

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

By David B. Cross and Ayman AlRashed

Microsoft Corporation

This document provides a guide for administrators on how to configure and operate a Windows certification authority. Various operational scenarios, custom configuration information, sample commands, and best practices are provided.

Windows Server 2003 provides a flexible and low TCO solution for deploying a public key infrastructure. Due to the complexity of customer environments and various organization requirements, a Windows Server 2003 certification authority (CA) may require configuration changes. This white paper provides operational best practices and configuration walkthroughs for some of the more common scenarios. It is not intended to cover the entire scope of all operational scenarios and configuration parameters possible with the Windows Server 2003 CA.

**In This White Paper**

- Basic Administrative Tasks
- Migrating from a Stand-alone to an Enterprise CA
- Windows Server 2003 PKI and Role-Based Administration
- Role Separation
- CA Auditing
- Setting Up CA Auditing
- Auditing and Event Management
- CA Maintenance
- Custom CA Configuration
- Enrollment Processing
- Tuning CA Database Performance
- Viewing Extended Information
- Managing Subject Relative Distinguished Names in the Certificate Subject
- Enabling the Netscape Revocation Method
- Configuring the SMTP Exit Module
- Using SSL to Communicate with Exchange Server
- Related Links for Windows Server 2003 PKI Operations
- Appendix A for Windows Server 2003 PKI Operations

# Basic Administrative Tasks

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

For day to day tasks, it is usually preferable to create a standard procedure. A procedure is usually organization-dependent as the processes and people differ from organization to organization. There are usually common practices employed by most organizations when doing the common day to day administrative tasks.

**Adding Certificate Templates to a CA**

A certificate template profiles certificates based on their intended use. When requesting a certificate from a Microsoft certification authority (CA), depending on their access rights, the certificate requester will be able to select from a variety of certificate types that are based on certificate templates, such as User and Basic EFS. The certificate template saves users from low-level, technical decisions about the type of certificate that they need. Instead, they can rely on the judgment of their administrators and use the template name that indicates the purpose of the certificate. If none of the preset certificate templates meets your needs, you can create new certificate templates and customize them for a variety of different uses.

| **Note** |
| --- |
| In addition to assigning the correct permissions for enrollment on a certificate template in Active Directory; you also need to add the template to the list of certificate templates a CA can issue if you want your users to start enrolling for this template. |

| **Note** |
| --- |
| Only Windows Server 2003 and Windows 2000 Enterprise CAs can issue certificates based on certificate templates; stand-alone CAs cannot use certificate templates. |

| **Note** |
| --- |
| You need to be part of the Enterprise Admins or the Domain Admins, or you need to have enough permissions to write to the Certificate Templates container in Active Directory. |

**To change the permissions on a certificate template for user enrollment**

1. Right-click the Certificate Templates node in the Certification Authority snap-in and select Manage.
2. Double-click a certificate template.
3. On the Security tab, check the Allow boxes for the Read and Enroll permissions.

**To add a certificate template to a CA**

1. Right-click the Certificate Templates node in the Certification Authority snap-in, and on the New submenu, select Certificate Template to Issue.
2. Select the appropriate template and click OK.

| **Note** |
| --- |
| You need to be a CA Administrator to add templates to the CA. |

**Delegating Administration of Certificate Templates**

Although most of the CA-related tasks are achieved through the administration of the CA itself, certain tasks are controlled through Active Directory, such as administration of Certificate Templates.

**To delegate the administration of Certificate Templates**

1. Right-click the **Certificate Templates** node in the **Certification Authority** snap-in and select **Manage**.
2. Double-click a certificate template.

3. On the **Security** tab, check the **Allow** boxes for the **Read** and **Write** permissions.

**Issuing Certificates**

There are some questions you need to answer and document before issuing a certain certificate. These questions are more relevant to how the certificate is issued from an operational side rather than a technical side.

1. Does my organization currently employ a Certificate Practice Statement (CPS) for this CA? If it does, did the requester meet all the requirements for enrollment?

2. Are there special requirements that the person issuing the certificate (such as being an Officer) that I must fulfill as an administrator?

3. Are there any documented operational procedures for my organization that I must follow when issuing certificates (such as backup)?

4. Are there any special attributes that must be included in the certificate that are not included in the request (such as Certificate Policy)?

When these questions are answered, and all the requirements are fulfilled, issue the certificate by logging on as a user with Certificate Manager (CA Officer) permissions:

1. Left-click the **Pending Requests** node in the **Certification Authority** snap-in.

2. Right-click the request, then select **Issue** on the **All Tasks** submenu.

If one of the requirements is not met, you can either ensure that requirements are met (such as making the user supply more authentication information) then issuing the certificate, or you can deny the request.

**To deny the request**

1. Left-click the **Pending Requests** node in the **Certification Authority** snap-in.

2. Right-click the request, then select **Deny** on the **All Tasks** submenu.

In either case, make sure you document your actions and the answers to all four questions.

| **Important** |
| --- |
| The policy module will always re-process requests that are pended and if template, configuration, or user group information has changed after the request was originally submitted, the policy module will re-evaluate the request on the new information only. |

| **Note** |
| --- |
| To re-submit a failed request and issue the failed request, a user must have both the CA Officer and CA Admin permissions on the CA. Obviously, this capability will not be possible when role separation is enabled on the CA. |

**Revoking Certificates**

Although certificates are usually used to enhance the trust in an organization, removing the trust from a certain certificate is sometimes required. Before you revoke a certificate, make sure you answer and document the following questions:

1. What is the reason for revoking this certificate?

2. Who requested the revocation of this certificate?

3. Will I ever need this certificate again (such as verification of signatures or decryption of messages)? If yes, what is the need (that is, verification of signatures, decryption of messages, normal usage)?

4. Are there special requirements for the person revoking the certificate (such as being an Officer) that I must fulfill as an

administrator?

5. Are there any documented operational procedures for my organization that I must follow when revoking certificates (such as backup)?

When all of these questions are answered, and all the requirements are fulfilled, revoke the certificate.

**To revoke the certificate**

1. Left-click the Issued Certificates node in the Certification Authority snap-in.
2. Right-click the certificate and select **Revoke Certificate** on the **All Tasks** submenu.
3. Choose the correct reason for revocation and click **Yes**.

Make sure you document your actions and the answers to all five questions.

| **Note** |
| --- |
| If you answered yes to question 3, and the need will be full or normal usage, make sure you choose **Certificate Hold** as the reason. This is the only reason that could allow a revoked certificate to be unrevoked. |

If you revoke a certificate and the reason is Certificate Hold, and you decide later that you want to unrevoke the certificate, you need to answer and document the following questions:

1. Why am I revoking this certificate?
2. Who requested this task?
3. Are there special requirements from the person unrevoking the certificate (such as being an Officer) that I must fulfill as an administrator?
4. Are there any documented operational procedures for my organization that I must follow when revoking certificates (such as backup)?
5. Does my organization currently employ a Certificate Practice Statement (CPS) for this CA, and if it does, did the requester meet all the requirements for unrevoking the certificate?

When all of these questions are answered, and all the requirements are fulfilled, unrevoke the certificate.

**To unrevoke the certificate**

1. Left-click the Revoked Certificates node in the Certification Authority snap-in.
2. Right-click the revoked certificate, and select **Unrevoke Certificate** on the **All Tasks** submenu.

Make sure you document your actions and the answers to all four questions.

| **Note** |
| --- |
| Unrevoking a certificate is considered dangerous if misused. Ensure proper operations and documentation when you unrevoke a certificate. |

# Migrating from a Stand-alone to an Enterprise CA

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

Despite the best planning intentions, it may be necessary to change the configuration of a Windows-based certification authority from a stand-alone mode to an enterprise mode. It may also be necessary to change the configuration of a CA that was first installed as an NT 4.0 certification authority that was included in the NT 4.0 Option Pack. For example, an NT 4.0 CA may be upgraded in place to a stand-alone CA and later converted to an enterprise CA to work with Exchange 2000. For NT 4.0 upgrade procedures, see the help files in Windows 2000 or Windows Server 2003. This section provides a walkthrough of the steps required to convert a Windows Server 2003 stand-alone CA to an enterprise CA.

| **Note** |
| --- |
| It is not possible to convert a root CA to a subordinate CA, or vice versa. |

The first step in migrating the CA is backing up the existing key pairs used by the CA and its database. To backup the CA keys and database, right-click the CA node in the MMC and choose **Back up CA** under **All Tasks**.

Next, you must back up the certificate database, the CA certificate, and the CA private key. Select **Private key and CA certificate** and **Certificate database and certificate database log**, then choose the appropriate path for the backup files.

| **Note** |
| --- |
| The backup path should not contain old backup files. Use the command-line tool Certutil.exe if you want to overwrite old backup files. |

Enter a strong password. This password is used to protect the CA's private key.

| **Important** |
| --- |
| Do not lose this password or you will not be able to restore the keys on the new CA. |

Review the summary, and click **Finish** to complete the backup.

You have now successfully backed up the CA keys and database. Next, you should remove the stand-alone CA from the server by uninstalling it. Uninstall the CA by removing the **Certificate Services** from the Windows Components.

Join the computer to a domain in the forest if it is not already joined to one.

**Best Practice** The recommended best practice is to install CAs as a member of the root domain in the forest to provide centralized administration and control of the PKI services. For additional best practices, see the Windows Server 2003 Resource Kit.

Reinstall the CA by adding the **Certificate Services** to the Windows Components.

Select **Enterprise root CA** as the CA Type, and select custom settings for the key generation.

| **Note** |
| --- |
| You must be an Enterprise Admin to install an Enterprise CA. |

Choose the CSP that has access to the old CA keys, and choose the same keys and certificate used with the old CA.

| **Note** |
| --- |
| If your CA has multiple keys, choose the original key used by the old CA. This can be determined by the number appended to the key where no number means oldest. |

Select **Preserve existing certificate database** to use the old database. This enables the new Enterprise CA to keep track of any pending requests to the old stand-alone CA, as well as any certificates issued or revoked by it.

When prompted for stopping the IIS service, click **Yes** to finish the installation of the CA.

# Windows Server 2003 PKI and Role-Based Administration

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

Windows 2000 Server CA administration is changed significantly with Windows Server 2003 CA role-based administration. Windows 2000 Server administrators can perform any activity on a Windows 2000 Server CA, but once CA roles are assigned on a Windows Server 2003 CA, its administrators are subject to its roles. Administrators who could perform all tasks on a Windows 2000 Server CA will only be able to perform the tasks associated with their role on the Windows Server 2003 CA. After upgrading a Windows 2000 Server CA to a Windows Server 2003 CA, its administrators need to be assigned to the roles defined in the role-based administration for the Windows Server 2003 CA.

Windows Server 2003 was designed with the needs of organizations in mind to provide role-based administration of a public key infrastructure. Windows Server 2003 certification authorities were also designed to meet the role definitions defined in version 1.0 of Certificate Issuing and Management Components Family of Protection Profiles found at http://go.microsoft.com/fwlink/?LinkId=59668

Role-based administration can be used to organize CA Administrators into separate, predefined task-based roles, each with its own set of tasks. Roles are assigned using each user's security settings. Roles are assigned to a user by assigning that user the specific security settings that are associated with the role. A user who has one type of permission, such as Manage CA permission, may perform specific CA tasks that a user with another type of permission, such as Issue and Manage Certificates permission, may not perform. Role-based administration is supported by both Windows Server 2003 enterprise and stand-alone certification authorities.

Role-based administration involves CA roles users and groups. To assign a role to a user or group, you must assign the role's corresponding security permissions, group memberships, or user rights to the user or group. These security permissions, group memberships, and user rights are used to distinguish which users have which roles. The following table describes the CA roles of role-based administration and the groups relevant to role-based administration.

| Roles and Groups | Security Permission | Description |
|---|---|---|
| CA Administrator | **Manage CA** permission | Configure and maintain the CA. This is a CA role and includes the ability to assign all other CA roles and renew the CA certificate. This is a separate role from the local Administrator role. |
| Certificate Manager | Issue and Manage Certificates permission | Approve certificate enrollment and revocation requests. This is a CA Officer role. |
| Backup Operator | Back up files and directories and Restore files and directories permissions | Perform system backup and recovery. This is an operating system role. |
| Auditor | Manage auditing and security log permissions | Configure, view, and maintain audit logs. This is an operating system role. |
| Enrollees | Authenticated Users | Enrollees are clients who are authorized to request certificates from the CA. This is not a CA role for the purposes of administration. |
| Read | All (except Enrollees) | Allows an entity to read records from the database. |

With the default installation, all CA roles are assigned and modified by local Administrators on the computer, Enterprise Admins and Domain Admins (if joined to a domain). Local Administrators, Enterprise Admins and Domain Admins are CA Administrators by default on an Enterprise CA. Only local Administrators are CA Administrators by default on a stand-alone CA. If the stand-alone CA is joined to an Active Directory domain, Domain Admins are also CA Administrators.

The CA Administrator and Certificate Manager roles can be assigned to either Active Directory users or local users in the local Security Accounts Manager (SAM) database. As a best practice, it is recommended to assign roles to group accounts instead of individual user accounts. Only CA Administrator, Certificate Manager (as Officer in the CIMC), Auditor (as Auditor in the CIMC), and Backup Operator (as Operator in the CIMC) are CA roles. The other users described in the following table are relevant to

role-based administration and should be understood before assigning CA roles.

Only CA Administrators and Certificate Managers are assigned using the Certification Authority Microsoft Management Console (MMC) snap-in. Other roles, users, and groups are specified in their related consoles. To change the roles of a user, you must change the user's security permissions, group membership, or user rights.

When key archival is configured on an enterprise CA running Windows Server 2003 Enterprise Edition, the subject obtaining a certificate from a CA will provide their private key to the CA. The CA stores that private key in its database until key recovery is desired. Only a Certificate Manager can get the encrypted private key blob out of the CA database, which is then passed on to key recovery agents (KRAs). For more information, see the Key Archival and Management in Windows Server 2003 white paper.

**Roles and Activities**

Each CA role has a specific list of CA administration tasks associated with it. The following table lists all the CA administration tasks along with the roles in which they are performed. One of the most important distinctions is the local Administrator versus CA Administrator role. The local Administrator applies to the local operating system privilege which may be required to perform some tasks associated with the operations of the CA. The CA Administrator role applies only to specific tasks within the functionality of the CA. The local Administrator will always have full control of the system including the CA and cannot be blocked from taking control of the CA. Therefore, it is very important to keep this fact in mind when assigning operational and delegated roles to the CA for management purposes.

| **Activity** | **CA Administrator** | **Certificate Manager** | **Auditor** | **Backup Operator** | **Local Administrator** | **Notes** |
|---|---|---|---|---|---|---|
| Install CA | | | | | X | |
| Configure policy and exit module | X | | | | | |
| Stop and start the Certificate Services service | X | | | X (only stop) | | |
| Configure extensions | X | | | | | |
| Configure roles | X | | | | | |
| Renew CA keys and certificates | | | | | X | |
| Define key recovery agents | X | | | | | |
| Configure Certificate Managers restrictions | X | | | | | |
| Delete single row in database | X | | | | | |
| Delete multiple rows in database (bulk deletion) | | | | | X | |
| Enable role separation | | | | | X | |
| Issue and approve certificates | | X | | | | |
| Deny certificates | | X | | | | |

| | | | | | | |
|---|---|---|---|---|---|---|
| Revoke certificates | | X | | | | |
| Reactivate certificates placed on hold | | X | | | | |
| Enable, publish, or configure CRL schedule | X | | | | | |
| Recover archived key | | X | | | | Only a Certificate Manager can retrieve the encrypted key data structure from the database. The private key of a valid Key Recovery Agent is required to decrypt the key data structure and generate a PKCS#12 file. |
| Configure audit parameters | | | X | | | By default, the local Administrator holds the system audit privilege. |
| Audit logs | | | X | | | By default, the local Administrator holds the system audit privilege. |
| Back up system | | | | X | | By default, the local Administrator holds the system backup privilege. |
| Restore system | | | | X | | By default, the local Administrator holds the system restore (backup) privilege. |
| Read CA database | X | X | X | X | X | By default, the local Administrator holds the system audit and backup privileges. |
| Read CA configuration information | X | X | X | X | X | By default, the local Administrator holds the system audit and backup privileges. |

**Note**

By default, enrollees are allowed to read CA properties and certificate request lists (CRLs), and can request certificates. On an Enterprise CA, a user must also have Read and Enroll permissions on the certificate template to request a certificate. CA Administrators, Certificate Managers, the Auditor, and Backup Operators have implicit Read privileges on the CA. An Auditor is based on a user that holds the system audit privilege. The local Administrator by default on each machine always holds the system audit privilege. If role separation is enabled, a separate user must be configured to hold the system audit privilege.> A Backup Operator is based on a user that holds the system backup privilege. In addition, the Backup Operator has the ability to stop the Certificate Services service (but not start it). As many or as few roles may be configured and used. It is not necessary to define all roles if only one specific role is assigned to a security group. It is required to have both CA Administrator and CA Manager roles to do bulk deletion, so any person who has both the roles will be able to perform bulk deletion. If role separation is enabled, this feature is not available. For issuing failed requests, it is required to have both CA Administrator and CA Manager permissions. If role separation is enabled, this feature is not available.

**Assigning Roles**

The CA Administrator for a CA assigns users to the separate roles of role-based administration by giving each user the security settings required by a role. The CA Administrator can assign a user to more than one role, but the CA is more secure when each user belongs to one role only. When each CA role belongs to one user only, fewer CA tasks can be compromised if a user's account becomes compromised.

The default installation setting for a stand-alone CA is to have members of the local Administrators security group as CA Administrators. The default installation setting for an Enterprise CA is to have local Administrators, Enterprise Administrators, and Domain Administrators as CA Administrators. To limit the power of any of these accounts, they should be removed from the CA Administrator and Certificate Manager roles once all CA roles are assigned; and they should also be removed from the Administrators group on the CA computer if it is not a Domain Controller. To list the roles a current user holds with a given CA, see the sample script in Appendix A.

**Best Practice** As a best practice, group accounts that have been assigned CA Administrator or Certificate Manager roles should not be members of the local Admin security group. Also, CA roles should only be assigned to group accounts and not individual user accounts.

| **Note** |
| --- |
| Membership in the local Administrators group on the CA is required to renew the CA certificate. Members of this group are considered to be all powerful on the CA with administrative authority over all other CA roles. |

# Role Separation

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

The separation of CA roles can be enforced using role separation. Once enforced, role separation only allows a user to be assigned a single role. If a user is assigned to more than one role and attempts to perform an operation on the CA, the operation is denied. For this reason, before role separation is enabled, a user should be assigned only one CA role. This feature is valuable for large enterprises where the separation of roles ensures that the compromise of a user's account does not compromise the entire CA administered by the user.

| **Important** |
|---|
| Before role separation is enabled, each user assigned a CA role on the CA must only be assigned a single CA role on that CA. If a user is assigned more than one CA role, when role separation is enabled, the Certificate Services service will detect that a user has more than one role and deny the user's attempts to operate the CA. |

Only members of the local Administrators security group on a CA can enable and disable role separation. Enabling role separation requires editing the registry of the Windows Server 2003 Enterprise Edition running the Certificate Services service. Once this registry setting is edited to enable role separation, any assigned roles are in effect until the local Administrator of the server disables role separation through the registry. CA roles can be assigned and changed by the CA Administrator while role separation is enabled or disabled. While role separation is enabled, the CA Administrator cannot assign a user to more than one CA role. If the CA Administrator attempts to assign a user to a second CA role, the operation is refused.

| **Important** |
|---|
| It is possible for a user assigned a role to become locked out of administering a CA when role separation is enabled if the user is also assigned to a second CA role. If the CA Administrator is assigned to a second role, or assigns another role holder to a second role, the CA Administrator violates the rules of role separation by allowing a user to have two roles. Once the user is assigned to two roles, role separation will not allow that user to perform any activity on the CA, including, in the case of the CA Administrator, the activity of removing himself from one of the roles. |

To correct this configuration, the local Administrator of the server must disable role separation, remove the CA Administrator from the second role, and then restart the Certificate Services service. Following these steps, role separation can be enabled again.

**Windows 2000 and Windows Server 2003 Role-Based Administration**

During the upgrade from a Windows 2000 CA to a Windows Server 2003 CA, Windows 2000 CA permissions are upgraded to Windows Server 2003 CA roles according to the rules in the following table.

| Windows 2000 Permission | Windows Server 2003 Role or Permission |
|---|---|
| **Manage CA** permission | CA Administrator **and** Certificate Manager |
| Revoke Certificate permission | Certificate Manager |
| Approve/Issue Certificate permission | Certificate Manager |
| **Enroll** permission | **Enroll** permission |
| **Read** permission | **Read** permission |
| All other permissions listed in the Windows 2000 CA advanced security settings | **Read** permission |

| **Note** |
|---|
| You can assign certification authority roles for role-based administration on servers running any version of the Windows Server 2003 family, but you can only *enable* role separation on servers running Windows Server 2003 Enterprise Edition and Windows Server 2003 Datacenter, including the 64-bit version of Windows Server 2003 Enterprise Edition and 64-bit version of Windows Server 2003 Datacenter. |

To enable role separation, open a command prompt window and type

```
certutil -setreg ca\RoleSeparationEnabled 1
```

The Certificate Services service must now be stopped and started.

To stop and start the Certificate Services service, at the command prompt, type

```
net stop certsvc
net start certsvc
```

To disable role separation, open a command prompt and type

```
certutil -delreg ca\RoleSeparationEnabled
```

Again, the Certificate Services service must be stopped and started.

To display the role separation setting, at the command prompt, type

```
certutil -getreg ca\RoleSeparationEnabled
```

The following command will display all CA information including CA role separation status:

```
Certutil.exe –cainfo role
```

**Role Separation Validation**
All role operations are performed through the ICertAdminD DCOM interface once the CA is configured into role separation mode. Role separation may not be enabled nor enforced when role assignments are made. Role separation validation is only enforced when a person (administrator, operator, and so on) performs an action. Role separation enforcement rules are stored and read by the CA in the registry as binary blobs. Each role is defined as a bit (allow/deny). For more information about this interface, see the Platform SDK in MSDN.

**Certificate Managers**
The capability of Certificate Managers is supported to prevent a CA Officer from issuing certificates to everyone. This is implemented through an authorization callback and is stored in a virtual Security Descriptor in the registry of the CA. A second access check is performed on the Officer role to validate what user(s) and group(s) they manage (approve and revoke certificates). The GUI for each Certificate Manager has a list of users and groups that the Officer can approve, revoke, and so on.

If an Officer attempts to approve a request for a user to which the Officer is not authorized to manage, an access denied error will occur. This does not reject the request or remove it from the pending approval queue. In addition, a new user or group may be added to the Certificate Managers authorized list AFTER the certificate request has been made.

**Backup/Restore and Auditing under Role Separation**
When you enable Role Separation, members of the local Administrators group, including the local Administrator account, will not be able to back up or restore the CA, nor will they be able to enable auditing on the CA. Because Administrators have the permission to back up and restore the CA as well as enable auditing on the CA, the CA will not allow them to do any tasks because they are assigned multiple roles.

To assign the backup permission to another user, either add the user to the local Backup Operators group, or assign the user the Backup files and directories privilege in the Local Security Policy snap-in under User Rights Assignment. To assign the restore permission to another user, either add the user to the local Backup Operators group, or assign the user the Restore files and directories privilege in the Local Security Policy snap-in under User Rights Assignment. To give the permission needed to enable auditing, assign the user the Manage auditing and security log in the Local Security Policy snap-in under User Rights Assignment.

| **Note** |
| --- |
| You may need to refresh the local security policy by typing **gpupdate.exe** at the command prompt. To open the Local Security Policy, type **secpol.msc** at the command prompt. |

# CA Auditing

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

Auditing certification authority (CA) operations is supported for Windows Server 2003 Enterprise Edition. The audit events will be logged in the Security log and can be viewed using the Event Viewer utility. CA auditing is dependent on system object access auditing, and therefore, it is necessary for the system administrator to first enable object access auditing on the target system.

CA auditing is enabled by selecting which group of CA operations to audit in the MMC snap-in. The following sections describe each group of CA operations that can be audited.

**CA Audit Groups**
The following group of events can be configured to be audited:

- Back Up and Restore the CA Database
- Change CA Configuration
- Change CA Security Settings
- Issue and Manage Certificate Requests
- Revoke Certificates and Publish CRLs
- Store and Retrieve Archived Keys
- Start and Stop Certificate Services

**Back Up and Restore the CA Database**
By enabling auditing on this group, successful or failed attempts to back up the CA database will be logged to the system Security log. In addition, the CA service will detect on restart that the CA database has been restored. The restore events are logged to the system Security log.

**Change CA Configuration**
By enabling auditing on this group, successful or failed attempts to change CA configuration will be logged to the system Security log. This includes the following operations:

- Add/Remove Templates to the CA
- Configure the CRL Publication Schedule
- Modify Request Disposition for the Policy Module
- Modify Publish Cert Flags for the Exit Module
- Configure CRL Distribution Points (CDP)
- Configure Authority Information Access (AIA)
- Change the Policy Module
- Change the Exit Module
- Configure Key Archival and Recovery (KAR)

**Change CA Security Settings**
By enabling auditing for this group, successful or failed attempts to change CA security settings will be logged to the system Security log. This includes the following operations:

- Configure CA Roles for Role-Based Administration of the CA
- Configure Restrictions on Certificate Managers
- Configure CA Auditing

**Issue and Manage Certificate Requests**
By enabling auditing for this group, successful or failed attempts to issue and manage certificate requests will be logged to the system Security log. This includes the following operations:

- Incoming Certificate Requests
- Certificate Issuance
- Certificate Import
- Deletion of Rows in the CA Database

**Revoke Certificates and Publish CRLs**
By enabling auditing for this group, successful or failed attempts to revoke certificates and publish CRLs will be logged to the system Security log. This includes the following operations:

- Certificate Revocation
- CRL Publication

**Store and Retrieve Archived Keys**
By enabling auditing for this group, successful or failed attempts to store and retrieve archived keys will be logged to the system Security log. This includes the following operations:

- Archival of Subject Keys
- Retrieval of Subject Keys

**Start and Stop Certificate Services**
By enabling auditing for this group, successful or failed attempts to start and stop Certificate Services will be logged to the system Security log. This includes the following operations:

- Starting Certificate Services
- Stopping Certificate Services

# Setting Up CA Auditing

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

CA auditing depends on system object access auditing to be enabled. Therefore, to set up CA auditing for a system, a system administrator will have to

1. Enable Object Access Auditing on the system.

2. Enable auditing for the CA by selecting which group of events to audit in the MMC snap-in.

The following sections describe these steps in detail.

**Enabling Object Access Auditing**
**When the CA Is on a Domain Controller**
**To enable object access auditing when the CA is on a Domain Controller (DC)**

1. Select Start > Programs > Administrative Tools > Domain Controller Security Policy.
2. Expand Default Domain Controllers Security.
3. Expand Computer Configuration.
4. Expand Windows Settings.
5. Expand Security Settings.
6. Expand Local Policies.
7. Select Audit Policy.
8. Right-click Audit object access and select Properties.
9. Check Define these policy settings.
10. Check Success and Failure under Audit these attempts.
11. Click OK.

**When the CA Is on a Member or a Workgroup Server**
**To enable object access auditing when the CA is on a member or a workgroup server**

1. Select Start > Programs > Administrative Tools > Local Security Policy.
2. Expand Local Policies.
3. Select Audit Policy.
4. Right-click Audit object access and select Properties.
5. Check Success and Failure under Audit these attempts.
6. Click OK.

**Enabling Auditing on the CA**
**To enable auditing of the CA**

1. Open the MMC snap-in.
2. Right-click the CA and select Properties.
3. Click the Audit tab.
4. Check which groups of CA operations to audit.

5. Click OK.

# Auditing and Event Management

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

**Event IDs Used by Certificate Services**

The following event IDs are currently used by Certificate Services:

772. The Certificate Manager denied a pending certificate request.
773. Certificate Services received a resubmitted certificate request.
774. Certificate Services revoked a certificate.
775. Certificate Services received a request to publish the certificate revocation list (CRL).
776. Certificate Services published the certificate revocation list (CRL).
777. A certificate request extension changed.
778. One or more certificate request attributes changed.
779. Certificate Services received a request to shut down.
780. Certificate Services backup started.
781. Certificate Services backup completed.
782. Certificate Services restore started.
783. Certificate Services restore completed.
784. Certificate Services started.
785. Certificate Services stopped.
786. The security permissions for Certificate Services changed.
787. Certificate Services retrieved an archived key.
788. Certificate Services imported a certificate into its database.
789. The audit filter for Certificate Services changed.
790. Certificate Services received a certificate request.
791. Certificate Services approved a certificate request and issued a certificate.
792. Certificate Services denied a certificate request.
793. Certificate Services set the status of a certificate request to pending.
794. The Certificate Manager settings for Certificate Services changed.
795. A configuration entry changed in Certificate Services.
796. A property of Certificate Services changed.
797. Certificate Services archived a key.
798. Certificate Services imported and archived a key.
799. Certificate Services published the CA certificate to Active Directory.
800. One or more rows has been deleted from the certificate database.
801. Role separation enabled.

**Breakdown of Shared Event IDs**

**796:**
Property: 29

Index: 0

Type: 4

Adding/removing template to/from CA. Value is list of resulting

templates by name and object identifier.

Property: 26

Index: <KRA cert index>

Type: 3

Adding KRA cert to CA. Value is Base64 representation of the

certificate.

Property: 25

Index: 0

Type: 1

Removing KRA certificate from CA. Value is the total KRA certificate count. For example, you can add 7 KRA cert to CA but configure it to use 3 only. In this case, the property 25 (CR_PROP_KRACERTCOUNT) will be 7 and the property 24 (CR_PROP_KRACERTUSEDCOUNT) will be 3.

Property: 24

Index: 0

Type: 1

Adding/removing number of KRA certificates to use for key archival. Value is resulting number of certificates to use. A value of 0 indicates that KAR is disabled. For example, you can add 7 KRA cert to CA but configure it to use 3 only. In this case, the property 25 (CR_PROP_KRACERTCOUNT) will be 7 and the property 24 (CR_PROP_KRACERTUSEDCOUNT) will be 3.

**795:**
Node:

Entry: CRLPeriod or CRLPeriodUnits or CRLDeltaPeriod or

CRLDeltaPeriodUnits

Describe change in CRL publication schedule. Value of 0 for

CRLDeltaPeriodUnits means Delta CRL publishing disabled.

Node: PolicyModules\CertificateAuthority_MicrosoftDefault.Policy

Entry: RequestDisposition

Value: 1

Set CA to issue incoming requests unless specified otherwise.

Node: PolicyModules\CertificateAuthority_MicrosoftDefault.Policy

Entry: RequestDisposition

Value: 257

Set CA to keep incoming requests pending.

Node: ExitModules\CertificateAuthority_MicrosoftDefault.Exit

Entry: PublishCertFlags

Value: 1

Allow certificates to be published to the file system.

Node: ExitModules\CertificateAuthority_MicrosoftDefault.Exit

Entry: PublishCertFlags

Value: 0

Disallow certificates to be published to the file system.

Node: ExitModules

Entry: Active

Change in active Exit module. Value specifies name of new module. Blank

means none.

Node: PolicyModules

Entry: Active

Change in active Policy module. Value specifies name of new module.

Node:

Entry: CRLPublicationURLs

Change in CDPs or AIAs. Value specifies resultant set of CDPs.

Node:

Entry: CACertPublicationURLs

Change in AIAs or CDPs. Value specifies resultant set of AIAs.

**CA Audit Specification**

The following tables provide more information about the data contained in the CA audit events.

**Certificate Request Events**

| Audit Event | Audit Data |
|---|---|
| Certificate Request Submission | Request ID<br>UPN of Requestor |
| Certificate Request Processing | Request ID<br>Distinguished Name of Subject<br>Result of Processing (Issue, Pend, or Deny) |
| Certificate Issuance | Request ID<br>Certificate Serial No<br>Hash of Certificate<br>Certificate Template and Version<br>Sequence Number from CSP |
| Certificate Publication | Request ID<br>Distinguished Name of Object Updated<br>DC Name<br>Certificate Serial No |

| | |
|---|---|
| Certificate Revocation | Certificate Serial No<br>Time for Revocation<br>Reason for Revocation |
| Key Archived | Request ID<br>UPN of Requestor<br>List of Hashes of Recovery Agents Certificate(s) |

**Certificate Management Audit Events**

| **Audit Event** | **Audit Data** |
|---|---|
| Certificate Revocation Request | Issuer Name and Serial No of Signing Certificate (if signed)<br>Revocation Reason<br>UPN of Certificate Manager |
| Request Resubmission | Request ID<br>UPN of Certificate Manager |
| Denied Request | Request ID<br>UPN of Certificate Manager |
| Certificate Import | Request ID<br>UPN of Certificate Manager |

# CA Maintenance

Updated: March 4, 2013

Applies To: Windows Server 2003 with SP1

Setting up the PKI is a small step compared to the management and operational tasks that are associated with the public key infrastructure.

**CA Remote Maintenance**

A CA that is connected to the network can be maintained locally or through a remote connection; however, the CA maintenance and administration tools are best designed for local operation. This is because the CA administration is a sensitive operation and should be kept as secure as possible.

If the Certificate Services MMC Snap-In should be used for remote administration, see *Users Allowed to Manage the CA Cannot Access It Remotely* [271470] to take the appropriate steps to make the CA remotely accessible.

Even if it is technically possible, a CA should not be maintained through a Terminal Server session because it increases the attack spectrum, and because some administration tools—like certutil.exe—do not work properly if used in a Terminal Server session.

| **Note** |
| --- |
| A Windows 2000 CA may not be managed using the Windows Server 2003 version of the Certification Authority MMC snap-in, or vice-versa. |

**Publish the CRL of an Offline CA**

The actual offline CRL publication should be performed at a minimum of several days before the actual expiration of the previously issued CRL. This should be performed to provide a safety factor in case the offline root CA has a hardware or publication failure. Adequate time should be allotted to ensure that any errors or failures can be corrected and to enable actual publication and replication of the CRL to all CDP locations.

Once the CDP extensions have been updated on the CA, new CRL(s) should be published so that all clients who download the CRL have the latest download information (for example, Delta CRL URL).

**To manually publish a CRL on an offline CA**

1. Select the **Revoked Certificates** node of the certification authority MMC snap-in.
2. Right-click, select **All Tasks**, and then click **Publish**.

   A new base and delta (if configured) CRL will be published.

      

   A prompt will be displayed asking to confirm which type(s) of CRL(s) should be published with this request. Since only base CRLs are being published from the offline root CA, only the **New CRL** option will be available.

3. Click OK.

4. Root CA certificates may be published manually to Active Directory using the Windows Server 2003 version of the **certutil.exe –dspublish** command from the command line if logged in as an account that is a member of the Enterprise Admin Group or a domain admin from the root (first) domain in the forest.

   The equivalent command in Windows 2000 is called **dsstore.exe**. For more information about pushing CA certificates manually into Active Directory, see the following Knowledge Base article:

   - *HOW TO: Use the Directory Services Store Tool to Add a Non-Windows 2000 Certification Authority (CA) to the PKI in Windows 2000* [313197]

**CRL Re-Sign**

In some scenarios, it may not be possible to publish a CRL from an offline CA. In this case, with Windows Server 2003, the old CRL may be re-signed without using the certification authority. This process assumes the availability of the CA private key(s) outside of the CA to actually sign the CRL. To update an expiring CRL, the old CRL file will need to be retrieved first. It will be available in Active Directory if the CA is an Enterprise CA or if Active Directory was accessible when the CA was installed, or in the **%windir%\System32\CertSrv\CertEnroll** directory on the CA computer itself.

The simple syntax for re-signing a CRL is

```
certutil -sign <existing CRL file name> <resigned CRL file name>
```

You can also add or remove serial numbers, or remove extensions, or change the length of time the CRL will be valid through the certutil.exe –sign command.

The default is to re-sign the CRL to be valid starting 10 minutes prior to the signature (to allow for clock skew), and a lifetime (NextUpdate) equal to the old CRL. Use the following command to publish the CRL to Active Directory. Certutil will state whether the object in Active Directory was updated or if it was already up-to-date.

```
certutil -dspublish <resigned CRL file name>
```

Publishing to a file://, ftp:// or an http:// location can be done by copying the CRL file manually to that location. The following command executed on the CA computer should display the next time the CA expects to wake up and publish the next CRL:

```
certutil -getreg ca\CRLNextPublish
```

Dumping the CRL with the certutil command will display the 1.3.6.1.4.1.311.21.4 (Next CRL Publish) extension, which should be equivalent to the CRLNextPublish registry value (but the syntax of the two displays is different). Certutil -sign strips this extension out of re-signed CRLs, because the next issue date is misleading at best after re-signing. Dumping a certificate issued by the CA with the certutil command will display the ldap:///, http://, and file:// URLs where the CRL is stored.

**Administrative Process for Offline CRL Publication**

The following is a sample process outline that may be followed for publishing an offline CA's CRL:

Several days before the current CRL is due to expire, the offline Root CA system is removed from its protected location (usually in secured storage such as double-locked closet, combination safe, or other physically well-protected locations); normally two or more staff are present (for example, one IT administrator as well as a supervisory manager).

The root CA computer is powered up and logged on with an account with appropriate permissions.

The MMC is started and the CA's CRL is published to the local drive.

The CRL is copied to a disk or other removable media.

The offline Root CA server is logged out and shut down, and placed into a secured storage.

The removable media is taken to the publishing or staging servers, and the CRL is copied to the appropriate location(s), according to the current CDP locations published in non-expired certificates from the CA.

| **Important** |
| --- |
| It is extremely important for administrators to perform regular (test) restores of their offline CAs to see if the procedure for backup/restore performs as expected. Disaster recovery procedures and testing are paramount in operating a public key infrastructure. |

**Certification Authority Renewal**
**Best Practices for Renewing CAs**
Certification authorities are renewed or replaced for a multitude of reasons. The following are the most common reasons for CA renewal:

- Increase the lifetime of the CA
- Change the key used by the CA
- Increase the key size of the CA
- Add certificate policies to the CA (qualified subordination)
- CRL partitioning

The first three reasons may be performed by using a capolicy.inf file when renewing the CA. If renewing a root CA, it is important to understand that the root CA certificate will need to be re-distributed to all clients that will trust the root CA. Otherwise, existing clients will only be aware of the exiting root CA certificate and will have no mechanism for discovery of the renewal event.

When a CA is renewed, various objects and attributes will be updated or changed. If the CA is an Enterprise root or subordinate CA, the following objects in Active Directory will be updated:

The updated CA certificate (cACertificate) and cross-certificate (CrossCertificatePair if renewal with a new key pair is performed) will be published to the AIA container.

A new CRL will be published for every key pair the CA has used.

The new certificate will be published to the NTAUTH object.

The new certificate will replace the existing certificate in the enrollment services container.

| **Note** |
| --- |
| If the enrollment services container had been previously deleted, it will be replaced on renewal and the default templates will be re-installed as well, if they have been deleted. |

**CRL Partitioning**

CRL partitioning is another main reason why administrators often renew an issuing CA. When a CA is renewed with a new key, a new key and certificate are generated for that CA. When a new key and certificate are generated, the CA will use the new key as well as any unexpired previous keys corresponding to previous certificates when generating revocation information. Therefore, a CA may be using multiple keys at the same time and will publish multiple CRLs corresponding to those keys. This may be seen in the Certification Authority MMC snap-in by selecting the CA properties.

The renewal status of the CA may also be determined by examining the CA certificate itself. The CA version extension will identify how many times a CA has been renewed and how many times with a new key. In this case, the CA has been renewed three times and with each instance, a new key, hence the 3.3 version number as displayed in the following screen.

Once a CA has been renewed with a new key, only the new key will be used in signing new certificates. The unexpired previous key(s) will continue to be used to sign CRLs for certificates that were signed using the previous keys. Therefore, a CA may publish multiple CRLs at the same time, each using a different key. This method of CA renewal may be an ideal method for CRL size control and effective CRL partitioning using the Microsoft CA.

**Automatic RootCA Cross-Certificate Generation**

Windows Server 2003 has introduced the capability for Microsoft root certification authorities with access to Active Directory to automatically issue and publish a cross-certificate for a root CA that has been renewed. For example, when a Windows Server 2003 root CA is renewed with a new key, the root will cross-certify the renewed root CA certificate as being a qualified subordinate to the old root CA certificate. For more information about qualified subordination, see the Planning and Implementing Qualified Subordination for Using Windows Server 2003 Enterprise Server white paper.

This functionality is especially important to customers who have had an existing root CA trusted by other organizations, bridge CAs, or cross-certified by other organizations. To configure or disable this functionality, the following commands may be performed on the root CA.

- To force the root CA to use the CrossCA certificate template, the following command should be run. Otherwise, without this flag, the CA will never use the CrossCA certificate template (even if it is available), and will fall back to generating a certificate without the template, using predefined extensions:

  ```
  certutil -setreg ca\CRLFlags +CRLF_USE_CROSS_CERT_TEMPLATE
  ```

- To disable automatic CrossCA certificate generation, run the following command:

  ```
  certutil -setreg ca\CRLFlags +CRLF_DISABLE_ROOT_CROSS_CERTS
  ```

- To enable automatic CrossCA certificate generation again, run the following command:

  ```
  certutil -setreg ca\CRLFlags -CRLF_DISABLE_ROOT_CROSS_CERTS
  ```

- To force the root CA to use the CAExchange certificate template when generating CA encryption certificates on demand, run the following command. Without this flag, the CA will use the CAExchange cert template when available, and fall back to generating a certificate without the template, using predefined extensions.

  ```
  certutil -setreg ca\CRLFlags +CRLF_USE_XCHG_CERT_TEMPLATE
  ```

**Key Backup**

If you are using a smartcard or other hardware key and the computer fails, you will need to move the smartcard or key device to another computer, install the CA certificate, and possibly add the KeyProvInfo property to the CA certificate, so the private key's CSP and container name, and so on, will be available. This may be accomplished using the **certutil.exe –repairstore** command (see below). This is usually done automatically when a smart card is inserted into a reader.

If you are using a software-based CSP and the computer fails, it is necessary to use the **certutil -backupkey** command prior to the hardware failure to save the CA's keys and certificates in a PFX file (PKCS #12) encrypted with a password, and use **certutil -restorekey** on the second computer.

To add the KeyProvInfo property, use the following command. Include the **-user** option if the certificate may have been imported into the HKEY_CURRENT_USER personal store.

```
certutil -repairstore my CACertSHA-1Hash
```

or

```
certutil -repairstore -user my CACertSHA-1Hash
```

If necessary, dump the certificate with **certutil.exe –dump <file name>** to display the SHA-1 certificate hash.

**Backup/Recovery**
**Best practice** Backing up the certification authority database, the CA certificate, and the CA keys is essential to protect against the loss of critical data. The CA should be backed up on a regular basis (daily, weekly, monthly) based on the number of certificates issued over the same interval. The more certificates issued, the more frequently the CA should be backed up.

For additional information, see the Microsoft Knowledge Base:

Certificate Server Does Not Create Backups of Installed Keys [216922] *(This article applies to Windows 2000 only.)*

**Removing a CA from Active Directory**
Removing a CA from any public key infrastructure or Active Directory environment may have a significant impact on applications and services. Therefore, careful planning is always recommended before removing a CA. Always perform a complete backup and maintain that backup for a period of time should a restore be required at a later date.

**Uninstalling an Enterprise Certification Authority**
To decommission a root certification authority, all outstanding certificates issued by that CA should be revoked. After revocation, the Certificate Revocation List (CRL) should be published.

1. Revoke all issued certificates.

    - Start the Certification Authority MMC snap-in.
    - Click the Issued Certificates folder.
    - Highlight one of the issued certificates, and then press CTRL+A to select all issued certificates.
    - Right-click the highlighted certificates, select All Tasks, and then click Revoke Certificate.
    - In the Certificate Revocation dialog box, select Cease of Operation as the reason for revocation.
    - Click OK.

2. Increase the CRL publication interval.

    - In the Certification Authority MMC snap-in, right-click the Revoked Certificates folder.
    - Select Properties.
    - Increase the Publication Interval to a suitably long value (5 years).

      The lifetime of the CRL should be longer than the remaining lifetime of the certificates that have been revoked.

- Clear the Publish Delta CRLs check box if it is selected.
- Click OK.

3. Publish the new CRL.

   - In the Certification Authority MMC snap-in, right-click the Revoked Certificates folder.
   - Select All Tasks, and then select Publish.
   - Choose New CRL as the type of CRL to publish.
   - Click OK.

4. Stop Certificate Services.

   - At the command prompt, type

     ```
     certutil -shutdown
     ```

5. List all the key stores for the local computer.

   - At the command prompt, type

     ```
     certutil -key
     ```

   This will display the names of all the installed Cryptographic Service Providers (CSP) and the key stores associated with each provider. Among the listed key stores, you will see the name of your CA listed several times. The following is the sample output.

```
Microsoft Strong Cryptographic Provider:
  Enterprise Root CA
    AT_SIGNATURE
  Enterprise Root CA(11)
    AT_SIGNATURE
  Enterprise Root CA(13)
    AT_SIGNATURE
  Enterprise Root CA(4)
    AT_SIGNATURE
  Enterprise Root CA(14)
    AT_SIGNATURE
  Enterprise Root CA(9)
    AT_SIGNATURE
  Enterprise Root CA(7)
    AT_SIGNATURE
  Enterprise Root CA(6)
    AT_SIGNATURE
  MS IIS DCOM Server
    AT_SIGNATURE, AT_KEYEXCHANGE
  Enterprise Root CA(2)
    AT_SIGNATURE
  Enterprise Root CA(12)
```

```
    AT_SIGNATURE
  Enterprise Root CA(16)
    AT_SIGNATURE
  Enterprise Root CA(1)
    AT_SIGNATURE
  Microsoft Internet Information Server
    AT_SIGNATURE, AT_KEYEXCHANGE
  Enterprise Root CA-Xchg(7)
    AT_KEYEXCHANGE
  Enterprise Root CA(5)
    AT_SIGNATURE
  Enterprise Root CA(8)
    AT_SIGNATURE
  Enterprise Root CA(15)
    AT_SIGNATURE
  Enterprise Root CA(3)
    AT_SIGNATURE
```

6. Delete the private keys associated with the CA.

   - At the command prompt, type

     ```
     certutil -delkey <CA Name>
     ```

   If your CA name contains spaces, enclose it in quotation marks.

   | **Note** |
   | --- |
   | Repeat this step for all the key containers of your CA. You will need to do this if your CA has multiple certificates. |

7. List the key stores again to verify that the private key for your CA has been deleted.

8. Use Add or Remove Programs to uninstall Certificate Services.

**Active Directory Objects**

When Microsoft Certificate Services is installed on a server that is a member of a domain, several objects are created in the Configuration container in Active Directory. These objects are

- certificateAuthority object
  - Located in CN=AIA,CN=Public Key Services,CN=Services,CN=Configuration,DC=
  - Contains the CA certificate for the Certification Authority
  - Published Authority Information Access location
- crlDistributionPoint object
  - Located in CN=<servername>,CN=CDP,CN=Public Key Service,CN=Services,CN=Configuration,DC=
  - Contains the CRL periodically published by the certification authority
  - Published CRL Distribution Point location
- certificationAuthority object

    - Located in CN=Certification Authorities,CN=Public Key Services,CN=Services,CN=Configuration,DC=
    - Contains the CA certificate for the certification authority
- pKIEnrollmentService object
    - Located in CN=Enrollment Services,CN=Public Key Services,CN=Services,CN=Configuration,DC=
    - Created by Enterprise CAs. Contains information about the types of certificates the CA has been configured to issue. Permissions on this object can control which users are allowed to enroll against this CA.
- msPKI-PrivateKeyRecoveryAgent object
    - Located in CN=KRA,CN=Public Key Services,CN=Services,CN=Configuration,DC=
    - Contains the Key Recovery Agent certificate(s)

When the CA is uninstalled, only the pKIEnrollmentService object is removed. The other objects are left in place because there are likely still outstanding certificates issued by the CA. In order for clients to successfully process these outstanding certificates, they need to locate the AIA and CDP paths in Active Directory. Good practice is to revoke all outstanding certificates (Reason: Cease of Operation), extend the lifetime of the CRL, and publish it in Active Directory. When those outstanding certificates are processed by the various clients, validation should fail and those certificates will not be used.

If maintaining the CDP and AIA in Active Directory is not a priority, these objects can be safely removed.

**To remove all Certification Services objects from Active Directory**

1. Start Active Directory Sites and Services.
2. Click the View menu option, and select Show Services Node.
3. Expand the Services, and then expand Public Key Services.
4. Select the AIA node.
5. In the right-hand pane, locate the certificateAuthority object for your Certification Authority. Delete the object.
6. Select the CDP node.
7. In the right-hand pane, locate the Container object for the server where Certification Services is installed. Delete the container and the objects it contains.
8. Select the Certification Authorities node.
9. In the right-hand pane, locate the certificateAuthority object for your Certification Authority. Delete the object.
10. Select the Enrollment Services node.
11. In the right-hand pane, verify that the pKIEnrollmentService object for your Certification Authority was removed when Certificate Services was uninstalled. If not, delete it.
12. Select the Certificate Templates node.
13. In the right-hand pane, delete all the Certificate Templates.

    | ⚠**Caution** |
    | --- |
    | Delete all the Certificate Templates only if no other Enterprise CAs are installed in the forest. If the templates are inadvertently deleted, restore the templates from backup. |

14. Click the Public key Services node and locate the NTAuthCertificates object.
15. If there are no other Enterprise or Stand-alone CAs installed in the forest, delete the object, otherwise leave it alone.

**CA Database**
When Certification Services is uninstalled, the CA database is left intact in case the CA is to be recreated on another server.

**To remove the CA database**

- Delete the %systemroot%\system32\certlog folder.

**Domain Controller Cleanup**
Once the CA has been taken down, the certificates that have been issued to all the domain controllers need to be removed. This can be done quite easily using DSSTORE.EXE from the Resource Kit.

### To remove old domain controller certificates

1. At the command prompt on a domain controller, type

```
certutil -dcinfo deleteBad
```

2. Certutil.exe will attempt to validate all the DC certificates issued to the domain controllers. Certificates that fail to validate will be removed.

At this point, you can reinstall Certificate Services. After the installation is finished, the new root certificate will be published to Active Directory. When the domain clients refresh their security policy, they will automatically download the new root certificate into their trusted root stores.

### To force application of the security policy

- At the command prompt, type

```
gpupdate /target:computer
```

**Best Practices for CRLs**
**Certificate Revocation List Defaults**
Certificates that are revoked prior to expiration will remain in a published base CRL for one full base CRL period (defined by CA) after they expire. Certificates that expire will no longer be included in published CRLs after one additional base CRL is expired.

| **Note** |
| --- |
| The CRL table for the CA can be exported and converted to a tab-separated file for Microsoft Excel or other programs using the following commands: |

```
certutil -view <name of CRL file> > crl.txt
```

The following registry setting may be enabled on a CA to ensure that revoked certificates that have now expired are not removed from the CRL. Although most applications do not check CRLs for certificates that have expired, it is sometimes desirable in specific scenarios to maintain a public list of signing certificates that have been revoked.

To enable this option on the CA, use the following command:

```
certutil -setreg ca\CRLFlags +CRLF_PUBLISH_EXPIRED_CERT_CRLS
```

**Application Reliability**
Many applications rely on the availability of the certificate revocation list (CRL) and will fail completely should the CRL be inaccessible or out of date. One such example is the smartcard logon process. During smartcard logon, the client validates the domain controller certificate and the domain controller validates the user (client) certificate. If either validation fails, the smartcard logon process will fail. Therefore, it is highly desirable to keep the following best practices in mind when publishing CRLs:

1. The CRL should be valid for a reasonable period of time that would allow recovery of the CA should hardware or software failures occur. For example, a one-hour CRL publication period is most likely not adequate time to perform a hardware or software restoration in case of failure.

2. Set a reasonable CRL overlap period to dampen and overcome CRL publication or replication issues. For CRL overlap settings, see the next section. The CRL schedule for frequently publishing issuing CAs must be able to survive network and server downtime as well as take the replication latency of Active Directory into consideration. The CRL publication schedule must be longer than the maximum replication latency. In addition, the validity of a certificate must allow enough time to repair a broken network connection or to restore a down system. To enable this, the publication schedule must be shorter than the validity period of the CRL.

3. The private key of the CA and a copy of the CRL may be kept securely offline to manually sign and publish a valid CRL through certutil.exe when a catastrophic failure occurs.

4. For immediate denial of logon certificates, the account in Active Directory should be disabled. It is more efficient to delete or disable user accounts when a certificate should be revoked when a user should be denied access immediately.

5. CRLs should be published using Active Directory methods whenever possible for highest availability and best network performance. Always consider the expected propagation delay with a minimum replication time of 10 minutes.

6. CRLs should not be published to Active Directory when the CRL publication period is shorter than the replication convergence time for the Active Directory forest.

**Revoking Large Numbers of Certificates**

When a large number of certificates are revoked, such as during an employee layoff, the Delta CRL size may increase significantly due to the large number of entries, and almost all clients will refer to the older Base CRL. This situation will happen even if a new base CRL is published right after the revocation of the certificate until the new base is fully propagated.

To overcome this particular scenario where the Delta CRL is very large, perform the following steps on the CA:

1. Modify the registry values under the following registry key:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CertSvc\Configuration\<Name of CA>**

   - Set the **CRLOverLapPeriod** to minutes. The default is hours.

   - Set the **ClockSkewMinutes** to 1minute. The default is 10.

2. Restart the CA.

3. Publish a new Base CRL. The Base CRL will have a CRLPropagationComplete time that will be just two minutes and any subsequent Delta CRLs will refer to this base CRL.

Once this has been completed, you can then restore the **CRLOverLapPeriod** and **ClockSkew** to the default values.

**Controlling CRL Size**

Often, it may be necessary to perform CRL partitioning to control the size of a Base CRL that is published from the CA. This is especially important for controlling both the data size that is replicated to Active Directory as well as the size of the data object downloaded by clients when performing revocation checks on certificates. CRL partitioning may be performed through CA key renewal which effectively creates a partitioned CRL for all subsequently issued certificates. For more information about this process, see the section on CA renewal.

Depending on the revocation reason chosen, the CRL will grow linearly in size by 29 bytes for every certificate that is revoked and added to the CRL. Accordingly, revoked certificates will be removed from the CRL when the certificate reaches its original expiration date. CAs may consider renewing the CA with a new key every 100-125K certificates to maintain a reasonable CRL size. This issuance number is based on the assumption that approximately 10 percent of the issued certificates will be revoked prior to their natural expiration date. If the actual or planned revocation rate is higher or lower for your organization, adjust the key renewal strategy accordingly.

| **Important** |
| --- |
| The more keys and certificates used by a CA will affect its performance in service restarts as each certificate and key must be validated before the CA will be operational. |

**Note**

Windows 2000 and Windows Server 2003 do not support the issuance of the IDP extension for partitioned CRLs; however, Windows XP and Windows Server 2003 clients may use a partitioned CRL (using IDP extension). This is technically different from the method identified previously.

**Remove Expired CRLs**

By default, a CA will maintain an expired CRL in the database and will keep this CRL also in the directory at the last known CDP publication point for historical purposes. Once the key of a CA expires, the CRL is published one final time and no additional changes are made to that CRL. A best practice is to maintain this CRL in the CA database for long-term validation and audit purposes. However, it may be removed by using the following command:

```
certutil -setreg ca\CRLFlags + CRLF_DELETE_EXPIRED_CRLS
```

For more information about how CRL checking and revocation status works see Windows XP: Certificate Status and Revocation Checking and How Certificate Revocation Works

Large CRLs: What is added to a Certificate Revocation List (CRL)?

# Custom CA Configuration

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

This section highlights various custom configuration scenarios that may be employed with a Windows Server 2003 certification authority to achieve various operational environment requirements. Various scenarios may apply differently to stand-alone or enterprise CAs.

**Ignore Offline CRL Errors on the CA**
Normally, a Windows Server 2003 CA will always check revocation on all certificates in the PKI hierarchy (except the root CA certificate) before issuing an end-entity certificate. To disable this feature, use the following command on the CA, and then restart the CA service:

```
certutil -setreg ca\CRLFlags +CRLF_REVCHECK_IGNORE_OFFLINE
```

**Configure Serial Number Generation**
In a Windows 2000 CA, two types of fixed-length serial numbers are generated. The registry can be modified to generate one or the other type. The default serial number is (from high to low): a DWORD from GetTickCount() + a USHORT CA cert index (0 to start) + a DWORD RequestId (10 bytes/20 hexadecimal digits). The alternate form is: one byte derived from the registry + a DWORD RequestId + 8 bytes of CryptGenRandom output + a USHORT CA cert index + a DWORD RequestId (19 bytes/38 hexadecimal digits).

To enable the alternate form and set the byte derived from the registry, use the following command:

```
certutil -setreg ca\HighSerial 0x33
```

The byte value specified will be modified to clear the sign bit and to set a bit in the high nibble to work around serial number encoding ambiguity bugs in certain non-Microsoft PKI applications.

In a Windows Server 2003 CA, three types of fixed-length serial numbers are generated. The default and alternate forms are the same as in Windows 2000. The Windows 2000 alternate form uses a new random 8 bytes generated by CryptGenRandom for each serial number. The new alternate form for Windows Server 2003 uses a fixed random 8 bytes from CryptGenRandom, generated during the first attempt to issue a certificate, and saved in the registry as 8 bytes of fixed CryptGenRandom output + a USHORT CA cert index + a DWORD RequestId (14 bytes/28 hexadecimal digits).

To enable the new alternate form in the registry, use the following command:

```
certutil -setreg ca\HighSerial 0xffffffff
```

Since the fixed random 8 bytes from CryptGenRandom are encoded as a string and saved in the registry, you could set them directly and cause them to be used for new serial numbers. In fact, any length hexadecimal string could be set in the registry (but there must be an even number of digits). The number of bytes used from the registry will be reduced if it would overflow a total of 19 bytes for the serial number. The high byte is manipulated as described previously to avoid problems with certain non-Microsoft applications. The IETF standards specify a maximum of 20 byte serial numbers.

**CA Key Usage**
Normally, a stand-alone CA certificate will contain digital signature, Certificate Signing, and CRL Signing as key usage values. For a stand-alone CA to issue a subordinate CA certificate without the digital signature key usage value, the following command must be performed on the stand-alone CA and the CA service restarted before the subordinate CA request is issued:

```
certutil -setreg policy\EditFlags -EDITF_ADDOLDKEYUSAGE
```

| **Note** |
| --- |
| Enterprise CAs enforce the key usage based on the subordinate CA template settings. |

**Disable DN Length Enforcement**
The original CCITT spec for the OU field says it should be limited to 64 characters. Normally, the CA enforces x.500 name length standards on the subject extension of certificates for all requests. It is possible that deep OU paths may exceed normal length restrictions.

To disable name length enforcement, run the following command on the CA, and then restart the CA service:

```
certutil -setreg ca\EnforceX500NameLengths 0
```

To restore the default setting, run the following command on the CA, and then restart the CA service:

```
certutil -setreg ca\EnforceX500NameLengths 1
```

**Maintaining the CA Database**

Windows Server 2003 allows certificate records to be purged manually through certutil.exe should the need arise to remove expired certificate records. The **certutil.exe –deleterow** command may be used for this task. Only a local administrator may delete multiple rows from a CA database. Standard JET database tools such as **ESEUTIL.EXE** may also be used with the certificate server database to perform defragmentation maintenance, and so on. For additional information, see the Windows Server 2003 help files.

**Securing DCOM Interfaces**

The Windows Server 2003 CA does not enforce encryption on the ICertRequest or ICertAdmin DCOM interfaces by default. Normally, this setting is not required except in special operational scenarios and should not be enabled. Only Windows Server 2003 machines by default support DCOM encryption on these interfaces. For example, Windows XP clients will not by default enforce encryption on certificate request to a Windows Server 2003 CA.

To enable encryption to be forced, perform the following procedures from the command line:

```
certutil -setreg ca\InterfaceFlags [+|-]IF_ENFORCEENCRYPTICERTREQUEST
certutil -setreg ca\InterfaceFlags [+|-]IF_ENFORCEENCRYPTICERTADMIN
```

# Enrollment Processing

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

**Enabling Referrals Across Forests**
Windows Server 2003 native Active Directory domains now support Kerberos trust and referrals across forests. By default, a Windows Server 2003 CA will not chase a referral for user or computer information in a trusted forest. When referrals are not chased and the user information is not available, the request will be denied if the user is enrolling from another forest. Referral chasing is not enabled by default as unintended template enumeration and enrollment may occur in some scenarios.

To enable referral chasing, use the following command on the certification authority and stop and start the service:

```
certutil -setreg policy\EditFlags +EDITF_ENABLELDAPREFERRALS
```

| **Note** |
| --- |
| For this to work, you need to use Kerberos Forest Trust as opposed to normal External Domain Trust. For more information, see the Windows Server 2003 help files. |

**Enabling Netscape Browser Enrollment**
The following configuration change must be made to a Windows Server 2003 CA to permit Netscape 6.2.2 and later browsers to perform enrollment through the Web enrollment pages.

To enable the parsing of request attributes for subject information, which is required for Netscape browser enrollment, use the following command:

```
certutil -setreg ca\CRLFlags +CRLF_ALLOW_REQUEST_ATTRIBUTE_SUBJECT
```

The certification authority must be stopped and re-started for this change to take effect. If this is not enabled, Netscape clients will receive the following error in the event log when the enrollment fails: The request subject name is invalid or too long.

**Adding CRL Information in an Authority Revocation List**
Neither Windows clients nor Windows certification authorities use or process authority revocation lists. However, some manual steps may be followed to artificially create an ARL.

To place a CRL in the ARL attribute in the directory, use the following command where the CAName, MachineName, Domain information, and name of the CRL are specific to the PKI environment and must be specified by the administrator:

```
certutil -addstore "ldap:///CN=CAName(KeyIndex),CN=MachineName,CN=CDP,CN=Public Key
Services,CN=Services,CN=Configuration,DC=Domain2,DC=Domain1,DC=com?auth
orityRevocationList" <name of CRL file.crl>
```

To delete an old CRL from the same attribute, use the same command, but use the –delstore instead of –addstore flag and specify the hash of the CRL instead of the CRL file as the last parameter. To display all CRLs with that attribute, use the –store flag and no ending parameter.

**Allowing and Blocking Extensions in Certificate Requests**
The template extension processing takes place *__before__* the three object identifier lists in the registry are processed.

The following configuration change must be made to a Windows Server 2003 CA to configure the CA to allow custom extensions to be added or blocked in certificates issued by the CA. Due to the fact that custom extensions comprise custom ASN.1 data, the CA is unable to parse and validate the information contained in the extension. If the certificate request contains the custom extension information properly encoded, the CA can be configured to pass the extension into issued certificates without validating the information. The extension must exist in the request as the CA will not generate this information. The request should be evaluated by a Registration Authority process before processing such requests.

To enable custom extension passing by using the object identifier of the custom extension defined by the organization, use the following command:

**certutil -setreg** policy**EnableRequestExtensionList** +< object identifier of extension to be added>

The certification authority must be stopped and re-started for this change to take effect.

**Example** The Netscape certtype extension is not enabled by default on a Microsoft CA and must be enabled using the previous mechanism.

To accept the Netscape certtype revocation extension to be included in issued certificates, use the following command:

**certutil -setreg** policy**EnableRequestExtensionList** +2.16.840.1.113730.1.1

To add a custom extension during CA installation through a capolicy.inf file or to submit a request using certreq.exe and a policy.inf file, the following information can be added to the extensions section of the *.inf file as an example. The object identifier of the extension must be specified followed by the Base64 representation of the value to be included in the extension. For example, AwIBBg== is the Base64 representation of the ASN.1 value: 03 02 01 06.

[Extensions]

1.3.6.1.5.5.7.1.3= AwIBBg==

To disable a certificate extension from being added to a certificate that is included by default in certificates issued by an enterprise CA, such as the S/MIME capabilities extension, use the following command, and then re-start the CA:

```
certutil -setreg policy\DisableExtensionList +< object identifier of extension to be added>
```

| **Note** |
| --- |
| When encountering template extensions with conflicting object identifiers, an Enterprise CA will override the EnableRequestExtensionList and EnableEnrolleeRequestExtensionList registry value behavior. If the certificate request includes extensions whose object identifiers conflict with the template extensions, the template extensions will override the request extensions. The EnableRequestExtensionList and EnableEnrolleeRequestExtensionList registry values merely cause the disabled bit to be cleared for any extensions in the two registry object identifier lists that exist. Extensions supplied by the template will already have the disabled bit clear. The object identifier list in EnableEnrolleeRequestExtensionList is only processed for templates that are configured to allow the request supply subject information. The object identifier list in EnableRequestExtensionList is processed for all templates. The object identifier list in DisableExtensionList causes the disabled bit to be *__set__* for any extensions in the list that exist—without regard to the origin of the extension (request or template). This prevents the listed extensions from appearing in issued certificates. This object identifier list is also processed for all templates. |

**Adding an E-Mail Address to the SubjectAltName Extension**
The following configuration option applies to stand-alone CAs only. Enterprise CAs may add e-mail address information to certificates automatically (if specified in the template) based on the user account information in Active Directory. One of the few configuration options that may be set for subject naming on a stand-alone CA is the ability for the CA to place the e-mail address of the requestor (authenticated user making the request) in the SubjAltName extension of an issued certificate.

To set the policy module to allow this option, perform the following steps using regedit.exe on the stand-alone CA:

Set the following REG_SZ value to Email in the registry, and then restart the CA:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CertSvc\Configuration\<*CAName*>\PolicyModules\CertificateAuthority_MicrosoftDefault.Policy\SubjectAltName2

The <*CAName*> is the name of the local CA.

Set the e-mail request attribute to the users e-mail name by specifying the following request attribute string in the Web enrollment pages: email:joe@northwindtraders.com. As an alternative, set the e-mail name as part of the subject name E= email:joe@northwindtraders.com as part of the full subject distinguished name, or just joe@northwindtraders.com if there is a separate e-mail text box on the Web page.

The following is the syntax for specifying a Subject Alt Name 2 extension as a request attribute; it will only work on a Windows Server 2003 CA server and requires enabling the flag to process this attribute in the registry:

SAN:1.2.3.4=
{asn}Base64String&email=sample@bar.com&dns=sample.bar.com&dn="CN=xxx,OU=xxx,DC=xxx"&url="http://sample.com/default.htlm"&ipaddress=172.134.10.134&oid=1.2.3.4&upn=sample@bar.com&
b8ce-4fb4-aa58-3d1dc0e36b39

To set the Subject Alt Name 2 extension to a specific UPN value:

SAN:upn=sample@bar.com

To set it to a specific DNS name:

SAN:dns=sample.bar.com

To set both:

SAN:upn=sample@bar.com&dns=sample.bar.com

To enable the registry flag for a CA:

certutil –setreg policy\EditFlags +EDITF_ATTRIBUTESUBJECTALTNAME2

or certutil –setreg policy\EditFlags +0x40000

And restart the CA.

**How to Change the Validity Period for Certificates Issued from a CA**
Enterprise CAs set the validity of issued certificates through the settings on Active Directory-based templates. Stand-alone CAs enforce the validity period of issued certificates based on registry values. To change the default validity period intervals for all certificates that are issued by a stand-alone CA, set the following registry values:

HKLM\system\currentcontrolset\services\certsvc\configuration\<ca name>\validityperiod (=days/months/years)

HKLM\system\currentcontrolset\services\certsvc\configuration\<ca name>\validityperiodunits (=number of above)

# Tuning CA Database Performance

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

**Increasing CA Database Session Limit**

By default, the Windows Server 2003 certification authority allows only 20 concurrent sessions to the JET BLUE database, which is used for storing certificate information, and so on. The CA itself can use several connections as well as client enrollment requests or management tools that view the database. In general, the 20 concurrent session limit should be sufficient for most operations. To increase the max session limit, use the following command to increase the maximum number of sessions to 30, which is the highest limit tested with the Windows Server 2003 certification authority:

```
certutil -setreg DBSessionCount 30
```

The certification authority must be stopped and re-started for this change to take place.

# Viewing Extended Information

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

**Viewing Request Attributes**

Request Attributes are name-value string pairs that are passed to the certificate server and stored in the database for possible use by the policy module or exit module. They are intended to be used for customer-specific purposes to control the behavior of a custom policy or exit module. They do not directly affect the certificate content. They may be used by the policy module to affect certificate content, but that is determined by the custom policy module, not the default policy module. To review a Request Attribute for a specific request, use the following command, replacing nnnn with the Request ID of the request being examined:

```
certutil -view -restrict requested=nnnn -out attrib:all
```

**Removing CA Information from the Directory**

Enterprise CA information is stored in the configuration container of Active Directory, most specifically in the Enrollment Services container of the Public Key Services node. Various pieces of information stored in the Public Key Services node of the configuration partition in Active Directory can be viewed or removed with the PKI Health Tool.

# Managing Subject Relative Distinguished Names in the Certificate Subject

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

For the subject relative distinguished names in certificates issued by a Windows Server 2003 certification authority, the following list contains the object identifiers that are supported in the platform:

COUNTRY_NAME "2.5.4.6" "Country"

ORGANIZATION_NAME "2.5.4.10" "OrganizationalUnit"

ORGANIZATIONAL_UNIT_NAME "2.5.4.11" "Organization"

COMMON_NAME "2.5.4.3" "CommonName"

LOCALITY_NAME "2.5.4.7" "Locality"

STATE_OR_PROVINCE_NAME "2.5.4.8" "State"

TITLE "2.5.4.12" "Title"

GIVEN_NAME "2.5.4.42" "GivenName"

INITIALS "2.5.4.43" "Initials"

SUR_NAME "2.5.4.4" "SurName"

DOMAIN_COMPONENT "0.9.2342.19200300.100.1.25" "DomainComponent"

RSA_emailAddr "1.2.840.113549.1.9.1" "EMail"

STREET_ADDRESS "2.5.4.9" "StreetAddress"

RSA_unstructName "1.2.840.113549.1.9.2" "UnstructuredName"

RSA_unstructAddr "1.2.840.113549.1.9.8" "UnstructuredAddress"

DEVICE_SERIAL_NUMBER "2.5.4.5" "DeviceSerialNumber"

By default, the following relative distinguished names elements are allowed in the subject of certificates and in the following order when also specified in a version 2 template:

- 0: EMail
- 1: CommonName
- 2: OrganizationalUnit
- 3: Organization
- 4: Locality
- 5: State
- 6: DomainComponent
- 7: Country

The default list can be displayed on a CA by running the following command:

```
certutil -getreg ca\SubjectTemplate
```

A relative distinguished names component can be added to the allowable list by running the following command. In this

example, the title is added to the end of the list in the registry of the CA.

```
certutil -setreg ca\SubjectTemplate +title
```

Because the strings are ordered, using the "+title" parameter to add a string to the REG_MULTI_SZ registry value may not produce a certificate with the Subject RDNs in the desired order. You can also use regedit.exe to editing the registry directly may be easiest way to specify the desired order.

You can set the value to the Windows 2003 defaults via the following command:

```
certutil -setreg ca\SubjectTemplate
"EMail\nCommonName\nOrganizationalUnit\nOrganization\nLocality\nState\nDomainComponent\
nCountry"
```

Variations on this command can be used to specify any subset of the 16 supported RDNs in any desired order.

To remove the DC= component from the subject of a certificate issued by a subordinate stand-alone CA, run the following command:

```
certutil -setreg ca\SubjectTemplate -DomainComponent
```

# Enabling the Netscape Revocation Method

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

To enable a legacy Netscape (iPlanet) application certificate revocation service with a Windows Server 2003 CA, runs the following command on the CA:

```
certutil -SetReg Policy\RevocationType +AspEnable
```

If the IIS (ASP) pages are to be hosted on a separate computer or if the default URL to be used by the Netscape application server is different from the default, it may be reviewed by using the following command-line example:

certutil -getreg Policy\RevocationURL

Where the value is stored in the following registry key:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\CertSvc\Configuration\ <*CAName*> \PolicyModules\CertificateAuthority_MicrosoftDefault.Policy\RevocationURL:

RevocationURL REG_SZ = https://%1/CertEnroll/nsrev_%3.asp

The URL may be changed in the registry. Restart the CA after making a change. The following replacement variables may be used in the revocation URL:

SERVERDNSNAME "%1"

SERVERSHORTNAME %2"

SANITIZEDCANAME "%3"

CERTFILENAMESUFFIX "%4"

DOMAINDN "%5"

CONFIGDN "%6"

SANITIZEDCANAMEHASH "%7"

CRLFILENAMESUFFIX "%8"

CRLDELTAFILENAMESUFFIX "%9"

DSCRLATTRIBUTE "%10"

DSCACERTATTRIBUTE "%11"

DSUSERCERTATTRIBUTE "%12"

DSKRACERTATTRIBUTE "%13"

DSCROSSCERTPAIRATTRIBUTE "%14"

Note that for this revocation service to work, the application, service, or account connecting to this URL must have READ permissions in the certification authority MMC snap-in. If IIS is using a local account, follow the steps for enabling anonymous access in IIS and allowing Anonymous READ access to the CA.

| **Important** |
| --- |
| Allowing anonymous access to the CA may expose privacy or security concerns. |

# Configuring the SMTP Exit Module

Updated: December 13, 2010

Applies To: Windows Server 2003 with SP1

The following information can be applied to Windows Server 2003 with SP1 Enterprise and Datacenter versions only.

A Windows Server 2003 certification authority (CA) has the capability to send SMTP (e-mail) messages to users, administrators, and Certificate Managers regarding various operations on the CA. This function is enabled through the default exit module of the CA and is configured in the registry. By default, no messages are enabled for the CA.

**Sample Configuration Batch File**

The following batch file can be used as a sample to configure the SMTP exit module capabilities of the CA without editing the registry directly. The SMTP exit module can use various values stored in the CA database. BodyArg is a list of database columns to be defined and later called by variable names such as %%1, %%2, and so on. Variables must be called in sequential order as they are defined. The following text can be used in a batch file to configure the SMTP exit module options on a CA:

**Important**

Before using the batch file below, ensure that you replace:

- <ExchangeServerNameOrIP> with the actual name or IP address of the Exchange Server you want to use.
- <Account> with the administrative mailbox account you want to use.
- <EmailAddress> with the administrative email address you want to use.

```
@echo off
cd\
%systemdrive%
:Setup_SMTP_Server // Section for setting the name of the exchange
server to be used and type of authentication to be used. 1 means to use
Basic authentication, 2 means to use NTLM authentication, 0 is for Anonymous
authentication

:Certificate_Authority_Startup // Section for setting Startup parameters.
certutil -setreg exit\smtp\Startup\To "<EmailAddress>"
certutil -setreg exit\smtp\Startup\From "<EmailAddress>"
```

```
certutil -setreg exit\smtp\Startup\CC "<EmailAddress>"
:Stop_Start_CA // This is just a sub-routine for stopping and starting the CA.
net stop certsvc & net start certsvc
:Exit
echo Certificate Services SMTP Exit module has now been configured.
echo .
pause
exit
```

**Revocation Status**

The SMTP exit module allows for e-mail notification when a certificate has been revoked. However, one of the database columns, Request.RevokedReason, can only be used to return a revocation value to the user in the e-mail body, instead of the string. For example, "Key Compromise" would be displayed as a value of 1. The revocation values and their corresponding definitions as defined in RFC 2459 are as follows:

0 = Unspecified

1 = Key Compromise

2 = CA Compromise

3 = Change of Affiliation

4 = Superseded

5 = Cease of Operation

6 = Certificate Hold

It may be necessary to list the values in the body of the e-mail message to easily interpret the revocation reason.

# Using SSL to Communicate with Exchange Server

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

A best practice in using the SMTP exit module of a certification authority with a Microsoft Exchange 2000 Server is to configure the CA to communicate with the Exchange Server over SSL (SMTP Protocol). The following steps should be implemented to enable this enhanced security configuration once the SMTP exit module is already configured on the CA for operation:

Make sure the Root CA that issued the server certificate for the Exchange Server is trusted by the CA.

Configure the Exchange Server SMTP Protocol to use SSL by enrolling for a Server Certificate using the Wizard in the Exchange System Manager console.

Open the Exchange System Manager on the Exchange server by selecting Start >

Programs > Microsoft Exchange > System Manager.

In the left-pane view, expand Servers > SERVER_NAME > Protocols > SMTP > Default SMTP Virtual Server.

Right-click Default SMTP Virtual Server, and then select Properties.

Click the Access tab, and then select the Certificate button under Secure communication.

Follow the directions in the Wizard and when completed, go back to the Default SMTP Virtual Server Properties and select Communication.

Select the Require secure channel checkbox. It is recommended to set Require 128-bit encryption.

At a CMD prompt on the CA, type the following command:

```
certutil -setreg exit\smtp\http://schemas.microsoft.com/cdo/configuration/smtpusessl 1
```

| **Note** |
| --- |
| This will add a REG_SZ value: http://schemas.microsoft.com/cdo/configuration/smtpusessl with a value of 1 to the SMTP key in the registry. |

# Related Links for Windows Server 2003 PKI Operations

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

For the latest information about Windows Server 2003, see the Windows Server 2003 Web site at http://www.microsoft.com/windowsserver2003/default.mspx

# Appendix A for Windows Server 2003 PKI Operations

Updated: August 13, 2009

Applies To: Windows Server 2003 with SP1

The following basic VBScript can be run by an end user or administrator to enumerate all the enterprise CAs in the forest, list the individual CAs, and display the role(s) held by the current user for each of the CA(s) as appropriate:

```
on error resume next
dim certadm
dim configobj
dim config
dim index
dim roles(9)
roles(0) = "CAADMIN"
roles(1) = "OFFICER"
roles(2) = "AUDITOR"
roles(3) = "OPERATOR"
roles(8) = "READ"
roles(9) = "ENROLL"
set certadm = CreateObject("CertificateAuthority.Admin")
Call ExitOnError("Createobject CertificateAuthority.Admin")
set configobj = CreateObject("CertificateAuthority.Config")
Call ExitOnError("Createobject CertificateAuthority.Config")
index = 0
do while index <> -1
    config = ""
    config = configobj.GetField("config")
    if(config <> "") then
        wscript.echo "CA: ", config
        PrintRoles(config)
    end if
    index = configobj.Next()
    Call ExitOnError("ICertConfig::Next")
loop
sub PrintRoles(config)
    value = certadm.GetMyRoles(config)
    Call ExitOnError("GetMyRoles")
    wscript.echo "Roles: 0x" & hex(value)
    for count=0 to 9
        if((count<4 or count>7) and value mod 2) then
            wscript.echo "      ", roles(count)
        end if
        value = value \ 2
    next
End Sub
Sub ExitOnError(failedCall)
'    if err.number <> 0 then
 '   wscript.echo "Error calling " + failedCall + " : " + err.value
  '  end if
End Sub
```

# How to Use Windows Firewall with a Server Cluster

Updated: March 2, 2005

Applies To: Windows Server 2003 R2

If you enable Windows Firewall for a server cluster running Windows Server™ 2003 Service Pack 1, you must configure the firewall so that the cluster nodes can communicate as needed. To do this, run the Security Configuration Wizard, which is an optional component in Windows Server 2003 Service Pack 1 that can be installed through Control Panel.

| **Note** |
| --- |
| To perform the following procedures, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. |

**Using the Security Configuration Wizard to Configure Windows Firewall**

To use the Security Configuration Wizard to configure Windows Firewall on a server cluster node, you must do the following:

- Install the Security Configuration Wizard (an optional component).
- Use the Security Configuration Wizard to create a new security policy for a server cluster node.
- Turn on Windows Firewall (if you have not already turned it on) and apply the security policy you created to the appropriate server cluster nodes.

After turning on Windows Firewall and applying the security policy, confirm that the recovery action is set correctly for the Cluster service.

| **Important** |
| --- |
| In Windows Server 2003, Windows Firewall resets its TCP session mapping table whenever a significant IP addressing change occurs. This means that when failover occurs in a cluster, and the virtual IP address is moved to another node, any existing TCP session mappings are lost. Because of this, for the firewall on the new node, inbound traffic appears to be unsolicited and will be dropped. TCP eventually times out and renegotiates the sessions through the firewall on the new node, but the timeout can cause the affected programs to experience delays of up to two minutes. |

**To install the Security Configuration Wizard**

1. In Control Panel, open **Add or Remove Programs**.
2. Click **Add/Remove Windows Components**.
3. Select the **Security Configuration Wizard** check box, click **Next**, and then click **Finish**.

**To use the Security Configuration Wizard to create a new security policy for a server cluster node**

1. Make sure you have installed the server cluster nodes and have configured the clustered resources and resource groups.
2. Make sure you have installed the Security Configuration Wizard as described in the previous procedure.
3. In **Administrative Tools**, open **Security Configuration Wizard** and read the information on the first page of the wizard.
4. Click **Next** and then select **Create a new security policy**.
5. Click **Next** and then select a cluster node to use as a baseline for this security policy. Later, you can apply this policy to the selected server or to any other server with a similar configuration.

You must be logged on as an administrator of the selected server.

6. Click **Next** several times until you see the **Select Server Roles** page.

7. On the **Select Server Roles** page, for **View**, select **All roles**.

8. Select **Cluster server** and any server roles that correspond to the clustered resources on the server cluster nodes. For example, for a cluster with a File Share resource, select **Cluster server** and **File server**. Clear any roles that do not correspond to the clustered resources on server cluster nodes.

9. Click **Next**, select the client features that are necessary for the node to function, and clear any client features that are not necessary.

   Examples of client features are **Domain member**, **Microsoft networking client**, **DHCP client**, **DNS client**, and **WINS client**.

10. Click **Next** and, on the **Select Administration and Other Options** page, select **Join a cluster**.

11. Select or clear check boxes for other options as appropriate.

    Examples of options on this page include **Remote Windows administration** and **Time synchronization**.

12. Click **Next** and select additional services required for the node.

    The services that are available are listed. For example, if antivirus software is installed, the services it provides might be listed.

13. Click **Next** and choose an option for the handling of unspecified services.

    To learn more about unspecified services, click the link on this wizard page.

14. Click **Next** and review the service changes resulting from the selections you have made. If necessary, go back to previous pages and change your selections.

15. Click **Next**.

16. If needed, specify additional configuration details in the next three sections of the wizard, which cover Network Security, Registry Settings, and Audit Policy. You can probably skip those three sections if the following is true for your configuration:

    - You have already specified all the roles the servers will have, and there are no additional ports (beyond those needed for those server roles) that need to be opened.

    - The clients and servers that connect to your cluster nodes are running Windows Server 2003, Microsoft Windows® 2000, or Windows XP, and are not running operating systems earlier than these.

    - The cluster nodes do not require specialized auditing.

17. Use the remaining pages of the wizard to save and view the security policy and to specify whether to apply the policy now or later.

**To turn on Windows Firewall and apply the security policy to server cluster nodes**

As with any configuration change to a cluster, it is best to observe the cluster carefully as you make the following change. Apply the security policy to one node, then observe that node and make adjustments if necessary before applying the security

policy to the next node.

1. If you have not already turned on Windows Firewall, click **Start**, click **Control Panel**, and click **Windows Firewall**. If you are prompted to start the Windows Firewall/Internet Connection Sharing (ICS) service, click **Yes**. Click **On**, and then click **OK**.

2. In **Administrative Tools**, open **Security Configuration Wizard**, and then click **Next**.

3. Select **Apply an existing security policy**.

4. Specify the security policy that you created for cluster nodes, or click **Browse** and then select the security policy.

5. Click **Next** and select the server to which you want to apply the security policy.

6. Click **Next** twice.

   The wizard applies the security policy.

7. Click **Next**, and then click **Finish**.

8. As appropriate, test the cluster node to ensure that it functions correctly with Windows Firewall enabled and the security policy in effect.

   If the security policy does not work correctly, you can run the wizard again to roll it back, and then turn off Windows Firewall. At that point, you can run the wizard to edit the security policy as needed, and then repeat this procedure to apply the modified security policy.

9. Repeat steps 1 through 8 for each of the cluster nodes.

**Confirming the Recovery Action Setting for the Cluster Service**

After turning on Windows Firewall and applying a security policy to server cluster nodes, confirm that the recovery action is set correctly for the Cluster service.

**To confirm that the recovery action is set correctly for the Cluster service**

1. On a cluster node, in Control Panel, open **Administrative Tools**.

2. Open **Services**.

3. Double-click **Cluster service**.

4. On the **Recovery** tab, for **First failure**, make sure **Restart the Service** is chosen.

5. For **Second failure** and **Subsequent failures**, make sure **Restart the Service** is chosen.

Note that the preceding procedure will set the recovery action for the Cluster service, but will not immediately restart the Cluster service. If necessary, after completing the procedure, start the Cluster service, either in the Services snap-in or by opening a command prompt and typing **net start clussvc**.

# Using Windows Server 2003 with Service Pack 1 in a Managed Environment: Controlling Communication with the Internet

Applies To: Windows Server 2003 with SP1

This white paper provides information about the communication that flows between components in Windows Server 2003 with Service Pack 1 (SP1) and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users.

This white paper includes the following sections:

Introduction to Controlling Communication with the Internet for Windows Server 2003 with SP1

Activation, Registration, and Resulting Internet Communication in Windows Server 2003 with Service Pack 1

Certificate Support and Internet Communication

Device Manager, Hardware Wizards, and Internet Communication

Dynamic Update and Internet Communication

Event Viewer and Internet Communication

File Association Web Service and Internet Communication

Help and Support Center: Features That Communicate with the Internet

HyperTerminal and Internet Communication

Internet Explorer 6.0 and Resulting Internet Communication in Windows Server 2003 with Service Pack 1

Internet Information Services and Internet Communication

Internet Protocol Version 6 (IPv6) and Internet Communication

NetMeeting and Internet Communication

Online Device Help and Internet Communication

Outlook Express 6.0 and Resulting Internet Communication in Windows Server 2003 with Service Pack 1

Plug and Play and Internet Communication

Program Compatibility Wizard and Internet Communication

Remote Assistance and Internet Communication

Search Companion and Internet Communication

Terminal Server Licensing and Internet Communication

Windows Error Reporting and Internet Communication

Windows Media Player and Internet Communication

Windows Media Services and Internet Communication

Windows Time Service and Internet Communication

Windows Update, Automatic Updates, and Internet Communication

Appendix A: Resources for Learning About Automated Installation and Deployment

Appendix B: Resources for Learning About Group Policy

Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key

Appendix D: Differences in Windows Server 2003 Before and After Service Pack 1

Appendix E: Windows Firewall and Security Configuration Wizard

Appendix F: Internet Connection Sharing and Network Bridge

Appendix G: Message Queuing and Internet Communication

Appendix H: Connection Manager and Internet Communication

Appendix I: Passport Manager Administration

Appendix J: Online Ordering Wizards, Add Network Place Wizard, and New Connection Wizard

# Introduction to Controlling Communication with the Internet for Windows Server 2003 with SP1

Applies To: Windows Server 2003 with SP1

Products in the Microsoft® Windows Server™ 2003 family include a variety of technologies that communicate with the Internet to provide increased ease of use. Browser and e-mail technologies are obvious examples, but there are also technologies such as Automatic Updates that help you obtain the latest software and product information, including bug fixes and security patches. These technologies provide many benefits, but they also involve communication with Internet sites, which administrators might want to control.

Control of this communication can be achieved through a variety of options built into individual components, into the operating system as a whole, and into server components designed for managing configurations across your organization. For example, as an administrator, you can use Group Policy to control the way some components communicate. For some components, you can direct all communication to the organization's own internal Web site instead of to an external site on the Internet. In addition, in Windows Server 2003 with Service Pack 1 (SP1), you can use Windows Firewall and the Security Configuration Wizard to help you control aspects of your configuration such as which services are running and which ports are open.

This white paper provides information about the communication that flows between components in Windows Server 2003 with SP1 and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users. The white paper is designed to assist you, the administrator, in planning strategies for deploying and maintaining products in the Windows Server 2003 family with SP1 in a way that helps to provide an appropriate level of security and privacy for your organization's networked assets.

This white paper provides guidelines for controlling components in the following operating systems:

- Windows Server 2003 with SP1, Web Edition
- Windows Server 2003 with SP1, Standard Edition
- Windows Server 2003 with SP1, Enterprise Edition
- Windows Server 2003 with SP1, Datacenter Edition
- Windows Server 2003, Standard x64 Edition
- Windows Server 2003, Enterprise x64 Edition
- Windows Server 2003, Datacenter x64 Edition

For more information about the services and software available in each of the editions of Windows Server 2003, see the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46002

Note that when selecting an appropriate edition of the operating system, you can use the basic security principle of running only the services and software that a particular server requires. For example, if you have a server that requires only the operating-system services and software in Windows Server 2003 SP1, Web Edition, you might choose this edition instead of another edition for that server.

The white paper is organized around individual components found in the Windows Server 2003 family, so that you can easily find detailed information for any component you are interested in.

**What This White Paper Covers and What It Does Not Cover**

This section describes the following:

- Types of components covered in this white paper
- Types of components not covered in this white paper

- Security basics that are beyond the scope of this white paper, with listings of some other sources of information about these security basics

**Types of Components Covered in This White Paper**
This white paper provides:

- Information about components that in the normal course of operation send information to or receive information from one or more sites on the Internet. An example of this type of component is Windows Error Reporting. If you choose to use this component, it sends information to a site on the Internet.

- Information about components that routinely display buttons or links that make it easy for you to initiate communication with one or more sites on the Internet. An example of this type of component is Event Viewer; if you open an event in Event Viewer and click a link, you are prompted with a message box that says, "**Event Viewer will send the following information across the Internet. Is this OK?**" If you click **OK**, information about the event is sent to a Web site, which replies with any additional information that might be available about that event.

- Brief descriptions of Windows Firewall and the Security Configuration Wizard, which are designed to help you control certain settings related to network communication (and therefore are related to communication across the Internet). These components can help you control aspects of your configuration such as which services are running and which ports are open.

- Brief descriptions of components like Microsoft Internet Explorer and Internet Information Services (IIS) that are designed to communicate with the Internet. It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization running servers that communicate across the Internet. This white paper does, however, provide basic information about how components such as Internet Information Services work, and it provides suggestions for other sources of information about balancing your organization's requirements for communication across the Internet with your organization's requirements for protection of networked assets.

**Types of Components Not Covered in This White Paper**
This white paper does not provide:

- Information about managing or working with applications, scripts, utilities, Web interfaces, Microsoft ActiveX® controls, extensible user interfaces, the .NET Framework, and application programming interfaces (APIs). These are either applications, or are layers that support applications, and as such provide extensions that go beyond the operating system itself.

  Windows Installer is not covered in this white paper, although Windows Installer includes some technology that (if you choose) you can use for installing drivers or other software from the Internet. Such Windows Installer packages are not described here because they are like a script or utility that is created specifically for communication across the Internet.

  Note that among the applications not covered in this white paper are Web-based and server-based applications, for example, server-based applications for databases, e-mail, or instant messaging. You must work with your application software provider to learn what you can do to mitigate any risks that are part of using particular applications (including Web-based or server-based applications), scripts, utilities, and other types of software that run on products in the Windows Server 2003 family.

- Information about components that store local logs that could potentially be sent to someone or could potentially be made available to support personnel. This information is similar to any other type of information that can be sent through e-mail or across the Internet in other ways. You must work with your support staff to provide guidelines about the handling of logs and any other similar information you might want to protect.

**Security Basics That are Beyond the Scope of This White Paper**
This white paper is designed to assist you, the administrator, in planning strategies for deploying and maintaining Windows Server 2003 with SP1 in a way that helps provide an appropriate level of security and privacy for your organization's networked assets. The white paper does not describe security basics, that is, strategies and risk-management methods that provide a foundation for security across your organization. It is assumed you are actively evaluating and studying these security basics as a standard part of network administration.

Some of the security basics that are a standard part of network administration include:

- Monitoring. This includes using a variety of software tools, including tools to assess which ports are open on servers and clients.
- Virus-protection software.
- The principle of least privilege (for example, not logging on as an administrator if logging on as a user is just as effective).
- The principle of running only the services and software that are necessary—that is, stopping unnecessary services and keeping computers (especially servers) free of unnecessary software.
- Strong passwords -- that is, requiring all users and administrators to choose passwords that are not easily cracked.
- Risk assessment as a basic element in creating and implementing security plans.
- Software deployment and maintenance routines to help ensure that your organization's software is running with the latest security updates and patches.
- Defense-in-depth. In this context, defense-in-depth (also referred to as in-depth defense) means redundancy in security systems. An example is using firewall settings together with Group Policy to control a particular type of communication with the Internet.

**Other Sources of Information about Security Basics**

The following books and Web sites are a few of the many sources of information about the security basics described previously:

- Howard, Michael, et al. *Designing Secure Web-Based Applications for Microsoft Windows 2000*. Redmond, WA: Microsoft Press, 2000.
- Howard, Michael, and David LeBlanc. *Writing Secure Code*. Redmond, WA: Microsoft Press, 2002.
- Kaufman, C., R. Perlman, and M. Speciner. *Network Security: Private Communication in a Public World*. Upper Saddle River, New Jersey: Prentice-Hall Inc., 2002.
- Smith, B., B. Komar, and the Microsoft Security Team. *Microsoft® Windows® Security Resource Kit*. Redmond, WA: Microsoft Press, 2003.

  http://go.microsoft.com/fwlink/?LinkId=46004

# Activation, Registration, and Resulting Internet Communication in Windows Server 2003 with Service Pack 1

Applies To: Windows Server 2003 with SP1

This white paper provides information about the communication that flows between components in Windows Server 2003 with SP1 and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users.

This section of the white paper provides information about:

- The purposes of activation and registration associated with a new installation or an upgrade
- How a computer running Windows Server 2003 with SP1 communicates with sites on the Internet during activation and registration
- Choosing volume licensing so that product activation need not take place (to limit the flow of information to and from Internet sites)
- Using Group Policy to prevent a connection between a server running Windows Server 2003 with SP1 and the Microsoft Web site for online registration

**Purposes of Activation and Registration Associated with a New Installation or an Upgrade**
This subsection briefly describes the differences between product activation and registration, and then describes the purpose of each.

Product registration involves the provision of personally identifiable information, such as an e-mail address, to Microsoft for the purpose of receiving information about product updates and special offers. Registration is usually done on a per-product basis and is not required for Windows Server 2003. If registration is completed, all registration information is stored using a variety of security technologies. When you register, you can specify what kinds of communication you wish to receive and whether your information can be used in particular ways. For example, if you provide a mailing address during registration, you can specify whether your mailing address can be shared with other companies. Other than the uses you specify, your registration information is never loaned or sold outside Microsoft.

Product activation involves the authentication with Microsoft of nonpersonal information, including the product identifier for Microsoft Windows Server 2003 with Service Pack 1 (SP1) and a hardware hash representing the computer, for the purpose of reducing software piracy. (A hardware hash is a non-unique number generated from the computer's hardware configuration.) Activation of Windows Server 2003 is required in situations where the product is not purchased through a volume licensing program such as Microsoft Select License, Microsoft Enterprise Agreement, or Microsoft Open License. Many computer manufacturers can bypass activation on software preinstalled on a new computer by binding the software to the computer’s basic input/output system (BIOS). In this situation, no activation of that software is required. Detailed information about product activation can be found on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=29484

For more information about volume licensing, see "Choosing Volume Licensing So That Individual Product Activation Need Not Take Place," later in this section.

Activation is aimed at reducing software piracy as well as ensuring that Microsoft customers are receiving the product quality that they expect. Activation means that a specific product key becomes associated with the computer (the hardware) it is installed on. After that happens, that product key cannot be used for activation on other computers (unless you are enrolled in a special program that permits additional activations, for example, a program through the Microsoft Developer Network [MSDN]).

**Overview: Activation and Registration in the Context of a Managed Environment**
Product activation is an anti-piracy technology designed to verify that software products have been legitimately licensed. If you have software re-imaging rights granted under a Microsoft volume license agreement, and if you obtained Windows Server 2003 through a retail channel or preinstalled by the computer manufacturer, you can re-image it with the product that you licensed through one of the Microsoft volume licensing programs. With volume licensing, there is no need to perform product activation.

Product registration involves the provision of personally identifiable information, such as an e-mail address, to Microsoft for the purpose of receiving information about product updates and special offers. In a managed environment, you might want to prevent administrators from registering the product with Microsoft. You can use Group Policy to do this.

**How a Computer Communicates with Sites on the Internet During Activation and Registration**
Windows Server 2003 with SP1 can be activated through the Internet or by phone. When it is activated through the Internet, the operating system communicates with Web sites as follows:

- **Specific information sent or received**: During activation of Windows Server 2003 with SP1, the following information is sent to the activation server at Microsoft:

    - Request information, that is, protocol information necessary for successfully establishing communication with the activation server.

    - Product key information in the form of the product ID, plus the product key itself.

    - A hardware hash (a non-unique number generated from the computer's hardware configuration). The hardware hash does not represent anything about the software or any personal information (such as user name or e-mail address). It is based on the MD5 message-digest hash algorithm, and consists of a combination of partial MD5 hash values of various computer components. The hardware hash cannot be used to determine the make or model of the computer, nor can it be backward-calculated to determine the raw computer information.

    - Date and time.

    - The language being used on the system (so that any error message that is sent back can be in the correct language).

    - The operating system being activated (and the version number of the activation software).

  Depending on your preference, the preceding information is either sent over the Internet to the activation system at Microsoft, or the product key information and hardware hash (combined into one number) are called in by phone.

- **Default setting and ability to disable**: Product activation can only be disabled by installing the operating system with software acquired through one of the Microsoft volume licensing programs. Product activation can be bypassed by many computer manufacturers if they bind the product to the computer’s BIOS instead. In all other cases, product activation cannot be disabled.

- **Trigger and notification for activation**: When activation is required, the operating system provides a reminder each time you log on and at common intervals until the end of the activation grace period stated in the End-User License Agreement (thirty days is the typical grace period). With software acquired through one of the Microsoft volume licensing programs, there is no need for activation, and therefore there are no reminders that appear about activation.

- **Trigger and notification for registration**: Registration is optional for Windows Server 2003. You can register at activation time by choosing appropriate options on the Windows Product Activation interface. As an alternative, you can type **regwiz /r** to start the Registration Wizard for Windows Server 2003 with SP1. Before the wizard starts and in the first page of the wizard, brief explanations notify you that completing the wizard will cause the product to be registered.

- **Logging**: Entries that track the progress of activation and registration (for example, return codes and error codes) are logged into a text file, *systemroot***setuplog.txt**. This file can be used for troubleshooting if activation (or any part of setup) fails. If you choose to register the product, two entries are made in this text file. One entry records the country or region that was chosen for the operating system. A second entry records whether you chose to have Microsoft (or the computer manufacturer) send information about product updates and special offers. No other registration data is logged.

- **Privacy, encryption, and storage for activation data**: Customer privacy was a paramount design goal in building the product activation technology. No personal information, such as user name or e-mail address, is collected as part of activation. The data is encrypted (using HTTPS) during transmission and is stored on servers located in controlled facilities at Microsoft. The data is accessible to a restricted number of server and program support personnel who oversee and maintain the activation servers and the product activation program.

To review the Microsoft online privacy statement on activation, see the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=29923

- **Privacy, encryption, and storage for registration data**: When you register at activation time (through the Windows Product Activation interface), registration data is encrypted (using HTTPS) during transmission. When you register by using the Registration Wizard (which you start by typing **regwiz /r**), registration data is encrypted (using HTTPS) during transmission unless the wizard is unable to establish an HTTPS connection through port 443 with the Microsoft registration server. In this situation, registration data will be sent unencrypted, using HTTP through port 80.

  Registration data, which contains information that you choose to send to Microsoft, is stored on servers with restricted access that are located in controlled facilities. The data can be seen by customer service representatives and marketing personnel. To review the Microsoft online privacy statement on product registration, see the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29508

- **Transmission protocol and port**:

  - **For Windows Product Activation**: When the operating system is activated through the Internet and a modem is not used, the first transmission uses HTTP through port 80 and goes to wpa.one.microsoft.com/ to check the HTTP response code. A response code of less than 500 indicates that a product activation server is available. (With a modem, there is only a check to see whether the modem can currently be used to make a connection to the Internet.) If the product activation server can be reached (or for a modem, if a connection to the Internet can be made), any activation or registration data that is sent by Windows Product Activation uses HTTPS through port 443.

  - **For the Registration Wizard**: When you register by using the Registration Wizard (which you start by typing **regwiz /r**), HTTPS is used through port 443 unless the wizard is unable to establish an HTTPS connection through port 443 with the Microsoft registration server. In this situation, HTTP is used through port 80.

**Activation Improvements in Windows Server 2003 Compared to Windows XP**

After the original release of Windows XP, Microsoft introduced improvements to activation that are aimed at ensuring that customers receive the full benefits of purchasing valid licenses. Windows Server 2003 and Windows Server 2003 SP1 contain these improvements, as do Windows XP SP1 and Windows XP SP2. Some of the changes include:

- The addition of a three-day grace period, where re-activation is required because of a significant hardware change. (When Windows XP was originally released, there was no grace period for reactivation after a significant hardware change.)

- The ability for volume license customers to encrypt their volume license product keys in unattended installations.

For more information about the changes to activation that were made after the original release of Windows XP, see the Microsoft Web site at:

- http://go.microsoft.com/fwlink/?linkid=29225

- http://go.microsoft.com/fwlink/?linkid=29226

**Choosing Volume Licensing So That Individual Product Activation Need Not Take Place**

If you use the rights granted under a volume licensing agreement to purchase or re-image software, you cannot and need not perform activation on the individual computers that are installed under the volume license. Qualifying as a volume licensing customer is not difficult. Customers can qualify for a Microsoft volume license by purchasing as few as five licenses. For more information, see the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=29878

**Procedure for Preventing Online Product Registration with Microsoft**

Use the following procedure to configure Group Policy to prevent online registration with Microsoft.

1. See Appendix B: Resources for Learning About Group Policy for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.

3. In the details pane, double-click **Turn off Registration if URL connection is referring to Microsoft.com**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

# Certificate Support and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of the certificate functionality built into Microsoft Windows Server 2003 with Service Pack 1 (SP1), including the benefits of Update Root Certificates
- How the Update Root Certificates component in Windows Server 2003 with SP1 communicates with sites on the Internet
- How to control Update Root Certificates to limit the flow of information to and from the Internet

**Benefits and Purposes of Certificate Functionality**

Certificates, and the public key infrastructure of which they are a part, support authentication and encrypted exchange of information on open networks, such as the Internet, extranets, and intranets. A certificate securely binds a public key to the entity that holds the corresponding private key. With certificates, host computers on the Internet no longer have to maintain a set of passwords for individual subjects who need to be authenticated as a prerequisite to access. Instead, the host merely establishes trust in a certification authority that certifies individuals and resources that hold private keys. The host can establish this trust through a certificate hierarchy that is ultimately based on a root certificate, that is, a certificate from a certification authority that establishes a well-defined level of integrity and security for the hierarchy.

Examples of times that a certificate is used are when you:

- Use a browser to engage in a Secure Sockets Layer (SSL) session
- Accept a certificate as part of installing software
- Accept a certificate when receiving an encrypted or digitally signed e-mail message

When learning about public key infrastructure, it is important to learn not only about how certificates are issued, but about how certificates are revoked and how information about those revocations is made available to clients. This is because certificate revocation information is crucial for an application that is seeking to verify that a particular certificate is currently (not just formerly) considered trustworthy. Certificate revocation information is often stored in the form of a certificate revocation list, although this is not the only form it can take. Applications that have been presented with a certificate might contact a site on an intranet or the Internet not only for information about certification authorities, but also for certificate revocation information.

In an organization where servers run Windows Server 2003 with SP1, you have a variety of options in the way certificates and certification revocation lists (or other forms of certificate revocation information) are handled. For more information about these options, see the references listed in the next subsection, "Overview: Using Certificate Components in a Managed Environment."

The Update Root Certificates component in Windows Server 2003 with SP1 is designed to automatically check the list of trusted authorities on the Microsoft Windows Update Web site when this check is needed by an application. Specifically, if the application is presented with a certificate issued by a certification authority that is not directly trusted, the Update Root Certificates component (if present) will contact the Microsoft Windows Update Web site to see if Microsoft has added the certification authority to its list of trusted authorities. If the certification authority has been added to the Microsoft list of trusted authorities, its certificate will automatically be added to the trusted certificate store on the computer. Note that the Update Root Certificates component is optional, that is, it can be removed or excluded from installation on a computer running Windows Server 2003 with SP1.

**Overview: Using Certificate Components in a Managed Environment**

In an organization where servers run Windows Server 2003 with SP1, you have a variety of options in the way certificates are handled. For example, you can establish a trusted root authority, also known as a root certification authority, inside your organization. The first step in establishing a trusted root authority is to install the Certificate Services component. Another step that might be appropriate is to configure the publication of certificate revocation information to the Active Directory® directory service. When implementing public key infrastructure, we recommend that you also learn about Group Policy as it applies to certificates. Procedures for these steps are provided in the resources listed at the end of this subsection.

When you configure a certification authority inside your organization, the certificates it issues can specify a location of your choosing for retrieval of additional evidence for validation. That location can be a Web server or a directory within your organization. Because it is beyond the scope of this white paper to provide full details about working with certification authorities, root certificates, certificate revocation, and other aspects of public key infrastructure, this section provides a list of conceptual information and a list of resources to help you learn about certificates.

Some of the concepts to study when learning about certificates include:

- Certificates and the X.509 V3 standard (the most widely used standard for defining digital certificates) as well as the public key infrastructure for X.509 (PKIX). PKIX is described in RFC 3280, which you can search for on the Internet Engineering Task Force (IETF) Web site at:

  http://www.ietf.org/rfc.html

  You can also learn about PKIX on the Internet Engineering Task Force (IETF) Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29924

- Standard protocols that relate to certificates, for example, Transport Layer Security (TLS), Secure Sockets Layer (SSL), and Secure Multipurpose Internet Mail Extensions (S/MIME).

- Encryption keys and how they are generated.

- Certification authorities, including the concept of a certification authority hierarchy and the concept of an offline root certification authority.

- Certificate revocation.

- Ways that Active Directory and Group Policy can work with certificates.

The following list of resources can help you as you plan or modify your implementation of certificates and public key infrastructure:

- Help for products in the Windows Server 2003 family.

  You can view Help for products in the Windows Server 2003 family on the Web at:

  http://go.microsoft.com/fwlink/?linkid=29881

- The *Microsoft Windows Server 2003 Deployment Kit* and the *Microsoft Windows Server 2003 Technical Reference*.

  You can view links on the Windows Deployment and Resource Kits Web site at:

  http://www.microsoft.com/windows/reskits/

- "Troubleshooting Certificate Status and Revocation," a white paper on the Microsoft TechNet Web site at:

  http://go.microsoft.com/fwlink/?LinkId=27081

- Links to information about public key infrastructure for Windows Server 2003 on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=29886

In a medium-size to large organization, for the greatest control of communication with the Internet, it is recommended that you manage the list of certification authorities yourself.

**How Update Root Certificates Communicates with Sites on the Internet**

This subsection focuses on how the Update Root Certificates component communicates with sites on the Internet. The previous

subsection, "Overview: Using Certificate Components in a Managed Environment" provides references for the configuration choices that control the way other certificate components communicate with sites on the Internet.

If the Update Root Certificates component is installed on a server, and has not been disabled through Group Policy, and an application is presented with a certificate issued by a root certification authority that is not directly trusted, the Update Root Certificates component communicates across the Internet as follows:

- **Specific information sent or received**: Update Root Certificates sends a request to the Windows Update Web site, asking for the current list of root certification authorities in the Microsoft Root Certificate Program. If the untrusted certificate is named in the list, Update Root Certificates obtains that certificate from Windows Update and places it in the trusted certificate store on the server. No user authentication or unique user identification is used in this exchange.

  The Windows Update Web site is located at:

  http://windowsupdate.microsoft.com/

- **Default setting and ability to disable**: Update Root Certificates is installed by default in Windows Server 2003 with SP1. You can disable this component with Group Policy, or you can remove it or exclude it from installation on a server.

- **Trigger and user notification**: Update Root Certificates is triggered when the user is presented with a certificate issued by a root certification authority that is not directly trusted. There is no user notification.

- **Logging**: Events containing information such as the following will be logged:

  **For Event ID 7**:

  Description: Successful auto update retrieval of third-party root list sequence number from: *URL_for_Windows_Update_Web_Site*

  **For Event ID 8**:

  Description: Failed auto update retrieval of third-party root list sequence number from: *URL_for_Windows_Update_Web_Site* with error: *hexadecimal_error_value*

- **Encryption, privacy, and storage**: When requests or certificates are sent to or from Update Root Certificates, no encryption is used. Microsoft does not track access to the list of trusted authorities that it maintains on the Microsoft Windows Update Web site.

- **Transmission protocol and port**: The transmission protocol is HTTP and the port is 80.

**Controlling the Update Root Certificates Component to Prevent the Flow of Information to and from the Internet**
If you want to prevent the Update Root Certificates component in Windows Server 2003 with SP1 from communicating automatically with the Microsoft Windows Update Web site, you can disable this component with Group Policy, or you can remove it or exclude it from installation on servers. You can exclude the component during deployment by using standard methods for unattended installation or remote installation, as described in Appendix A, "Resources for Learning About Automated Installation and Deployment." If you are using an answer file, the entry is as follows:

```
[Components]
Rootautoupdate = Off
```

For information about how to disable Update Root Certificates through Group Policy, see "To Disable the Update Root Certificates Component by Using Group Policy," later in this section.

**How Disabling, Removing, or Excluding Update Root Certificates from Servers Can Affect Applications**
If a server is presented with a certificate issued by a root certification authority that is not directly trusted, and the Update Root Certificates component is not installed on that server, you (or your application) will be prevented from completing the action that required authentication. For example, you might be prevented from installing software, viewing an encrypted or digitally signed e-mail message, or using a browser to engage in an SSL session.

**Procedures for Preventing Root Certificates from Being Updated on an Individual Computer**
The following procedures describe:

- How to use Group Policy to disable the Update Root Certificates component.
- How to use Control Panel to remove the Update Root Certificates component from an individual computer running Windows Server 2003 with SP1.
- How to exclude the Update Root Certificates component during unattended installation of Windows Server 2003 with SP1 by using an answer file.

**To Disable the Update Root Certificates Component by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.
3. In the details pane, double-click **Turn off Automatic Root Certificates Update**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

**To Remove the Update Root Certificates Component from an Individual Computer Running Windows Server 2003 with SP1**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. Click **Add/Remove Windows Components** (on the left).
4. Scroll down the list of components to **Update Root Certificates**, and make sure the check box for that component is cleared.
5. Follow the instructions to complete the Windows Components Wizard.

**To Exclude the Update Root Certificates Component During Unattended Installation by Using an Answer File**

1. Using the methods you prefer for unattended installation or remote installation, create an answer file. For more information about unattended and remote installation, see Appendix A: Resources for Learning About Automated Installation and Deployment.
2. In the [Components] section of the answer file, include the following entry:

   **Rootautoupdate = Off**

# Device Manager, Hardware Wizards, and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Device Manager.
- How hardware wizards communicate with sites on the Internet.

  Device Manager provides an interface for viewing the configuration of hardware devices, and the wizards help with installing and configuring the correct driver for a device. Therefore, this section describes how the wizards communicate with the Internet, while providing background about Device Manager.

- How to control hardware wizards to limit the flow of information to and from the Internet.

For procedures related to disabling Windows Update, see Windows Update, Automatic Updates, and Internet Communication in this white paper.

**Benefits and Purposes of Device Manager**
Device Manager provides users and administrators with information about how the hardware on their computers is installed and configured, and how the hardware interacts with the computer's applications. With Device Manager, administrators can update the drivers (or software) for hardware devices, modify hardware settings, and troubleshoot problems.

| **Note** |
| --- |
| Only administrators or users with administrative credentials can install or update device drivers. |

**Overview: Using Device Manager in a Managed Environment**
In Microsoft Windows Server 2003, you access Device Manager through Administrative Tools\Computer Management. Administrators or users with administrative credentials will typically use Device Manager to check the status of hardware and to update device drivers. Administrators who have a thorough understanding of computer hardware might also use Device Manager's diagnostic features to resolve device conflicts and change resource settings.

Device Manager can work in conjunction with hardware wizards and Windows Update to deliver updated drivers for installed hardware. On a computer running Windows Server 2003 with SP1, when a driver is being upgraded, the person at the computer is prompted to find out whether to search the Windows Update Web site for an appropriate device driver. The same prompt is displayed if the person has attached a new Plug and Play device for which the driver is not included as part of Windows Server 2003 with SP1. As an administrator, you can prevent this, if you choose, by using Control Panel or Group Policy. The following subsection provides details about how hardware wizards interact with the Internet.

**How Hardware Wizards Communicate with Sites on the Internet**
Hardware wizards search for device drivers in slightly different ways, depending on the type of device for which a driver is needed:

- An existing device for which a new device driver is available.

  To update a device driver, a person logged on to Windows Server 2003 as an administrator opens Device Manager, selects a hardware device, and clicks **Update Driver** on the **Action** menu. Alternatively, the person can open Device Manager, right-click a hardware device, and click **Update Driver**. This activates the Hardware Update Wizard. If Windows Update device driver searching has not been disabled, by default, the Hardware Update Wizard prompts the person to find out whether to search the Windows Update Web site for an updated device driver.

- A new Plug and Play device for which the driver is not included as part of Windows Server 2003 with SP1.

  To install a new Plug and Play device, a person logged on to Windows Server 2003 as an administrator first attaches the device. In some instances, Windows Server 2003 then finds the appropriate driver locally and installs it without input

from the user. In other instances, Windows Server 2003 cannot find an appropriate driver locally, and the Found New Hardware Wizard starts. If Windows Update device driver searching has not been disabled, by default, the Found New Hardware Wizard prompts the person to find out whether to search the Windows Update Web site for an updated device driver.

- A device that is not Plug and Play.

  After a person logged on to Windows Server 2003 as an administrator attaches a device that is not Plug and Play, he or she can use Add Hardware in Control Panel to start the Add Hardware Wizard. This wizard does not connect to the Internet for device drivers.

When the person at the computer responds to a prompt by agreeing to the Internet search for a device driver, the Hardware Update Wizard or Found New Hardware Wizard communicate with the Windows Update Web site. Therefore, much of the information in this subsection is the same as for Windows Update. Additional details are as follows:

- **Specific information sent or received**: See the section Windows Update, Automatic Updates, and Internet Communication in this white paper. None of the communication between the computer and the Internet uniquely identifies the user.

- **Default settings**: By default, the hardware wizards prompt to find out whether to search Windows Update for a device driver.

- **Triggers**: A person logged on as an administrator starts the Hardware Update Wizard, or adds a new Plug and Play device for which Windows Server 2003 with SP1 cannot find an appropriate driver locally.

- **User notification**: By default, when the Hardware Update Wizard is started, it asks whether to search Windows Update for the device driver, and offers the following choices:

  - Yes, this time only

  - Yes, now and every time I connect a device

  - No, not this time

  Choosing the second choice, **Yes, now and every time I connect a device**, causes the Hardware Update Wizard to stop offering the preceding three prompts, but these prompts can be restored through System Properties (in Control Panel). To restore the three prompts, in System Properties, click the **Hardware** tab, click the **Windows Update** button, and choose **Ask me to search Windows Update every time I connect a new device.**

  To use System Properties to turn off Windows Update Device Driver searching, see "Procedures for Controlling Communication Between Hardware Wizards and Windows Update," later in this section.

- **Logging**: Errors that result from problems installing hardware devices without drivers are logged to the event log.

- **Encryption, access, privacy, transmission protocol, and port**: See the section Windows Update, Automatic Updates, and Internet Communication in this white paper. To view the privacy statement for Windows Update, go to the Web site and click **Windows Update Privacy Statement**:

  http://windowsupdate.microsoft.com/

- **Ability to disable**: You cannot disable Device Manager, but you can use Control Panel or Group Policy to prevent hardware wizards from searching for drivers on Windows Update. Alternatively, you can turn off all access to Windows Update.

**Controlling Hardware Wizards to Limit the Flow of Information to and from the Internet**

To prevent hardware wizards from searching Windows Update for device drivers, you can use either Control Panel or Group Policy. You can also turn off all access to Windows Update by using Group Policy.

If you turn off all access to Windows Update, users will still be able to use Device Manager to view information about their hardware devices. For administrators to be able to update drivers, there is the option for manually downloading driver updates from the Windows Update Catalog, or from an intranet server, whereby they can be distributed on your managed network as needed.

For more information about the Windows Update Catalog, see the Windows Update Web site at:

http://windowsupdate.microsoft.com/

**Procedures for Controlling Communication Between Hardware Wizards and Windows Update**
The procedures for turning off Windows Update device driver searching by using either Control Panel or Group Policy are included here. When you turn off Windows Update device driver searching, Windows Server 2003 does not search the Windows Update Web site for device drivers, regardless of any action taken through Device Manager or the hardware wizards.

For the procedure to turn off all access to Windows Update or configure automatic updating, see the section Windows Update, Automatic Updates, and Internet Communication in this white paper.

**To Turn Off Windows Update Device Driver Searching by Using Control Panel**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **System**.
3. In **System Properties**, click the **Hardware** tab.
4. Click **Windows Update**.
5. Click **Never search Windows Update for drivers**.

**To Turn Off Windows Update Device Driver Searching by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.
3. In the details pane, double-click **Turn off Windows Update device driver searching,** and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

# Dynamic Update and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Dynamic Update
- How Dynamic Update communicates with sites on the Internet
- How to control Dynamic Update to limit the flow of information to and from the Internet

**Benefits and Purposes of Dynamic Update**

With Dynamic Update, Setup for Microsoft Windows Server 2003 can check the Windows Update Web site for new Setup files, including drivers and other files, while the server operating system is being installed. In an interactive installation (in contrast to an unattended installation), the person installing Windows Server 2003 chooses whether to allow Dynamic Update to occur.

In a managed environment, if you are using Setup (Winnt32.exe) for unattended installation, you can create a shared folder on a server and deliver Dynamic Update files to destination computers from that shared folder (instead of downloading the files directly from the Windows Update Web site to the computer being installed). For additional information about how to do this, see "How Dynamic Update Communicates with Sites on the Internet" and "Controlling Dynamic Update to Limit the Flow of Information to and from the Internet," later in this section.

Whenever an important update is made to any crucial Setup file, that update is made available through Dynamic Update functionality built into the Windows Update Web site. Some of the updated files will be replacements (for example, an updated Setup file) and some will be additions (for example, a driver not available at the time that the Setup CD was created). All files on the Dynamic Update section of the Windows Update Web site are carefully tested, and only files that are important in ensuring that Setup runs well are made available.

Using Dynamic Update reduces the need to apply patches to recently installed systems, and makes it easier to run Setup with hardware that requires a driver that was recently added or updated on Windows Update. For example, if a new video adapter requires a driver that was recently added to Windows Update, with Dynamic Update, the video adapter is recognized and supported during Setup.

Dynamic Update downloads only the files that are required for a particular computer, which means that the Dynamic Update software briefly examines the computer hardware. No personal information, such as user name or e-mail address, is collected. The only purpose for examining the hardware is to select appropriate drivers for it. This keeps the download time as short as possible and ensures that only necessary drivers are downloaded to the hard disk.

**Overview: Using Dynamic Update in a Managed Environment**

If you do not want Dynamic Update to connect to the Windows Update Web site during the installation of Windows Server 2003, you have several options:

- **Creating a shared folder on a server and delivering Dynamic Update files to destination computers from that shared folder**: You can create a shared folder on a server in your organization, download Dynamic Update files to that server, and by using Winnt32.exe for unattended installations, ensure that when Setup for Windows Server 2003 is run in your organization, Dynamic Update uses the files you placed on the server and does not connect to the Internet.
- **Avoiding Dynamic Update**: You can avoid using Dynamic Update, which means Setup will use only the files and drivers provided on the CD for Windows Server 2003. For more information, see "Avoiding Dynamic Update," later in this section.

The subsections that follow provide more information about these options.

For additional sources of information about performing unattended installations, see Appendix A: Resources for Learning About Automated Installation and Deployment.

**How Dynamic Update Communicates with Sites on the Internet**

This subsection focuses on the communication that occurs between Dynamic Update and the Windows Update Web site during an interactive installation (or a pre-installation compatibility check) when the computer has access to the Internet. This

subsection also provides some description of the default behavior of Dynamic Update with unattended Setup.

For information about how you can control the behavior of Dynamic Update during unattended installations, see "Controlling Dynamic Update to Limit the Flow of Information to and from the Internet," later in this section.

- **Specific information sent or received**: When Dynamic Update contacts the Windows Update Web site, it sends only the information necessary for appropriate drivers to be selected. In other words, it collects only necessary information about the hardware (devices) on that particular computer. No personal information, such as user name or e-mail address, is collected.

  The Setup files and drivers downloaded by Dynamic Update consist only of files that are important in ensuring that Setup runs successfully. Files with minor updates that will not significantly affect setup are not made available through the Dynamic Update section of the Windows Update Web site. Some of the updated files will be replacements (for example, an updated Setup file) and some will be additions (for example, a driver not available at the time that the setup CD was created).

- **Default behavior and triggers**: Dynamic Update may connect to the Internet, depending on how Setup is run. The following two tables provide details. The first table provides contrasting scenarios to show the broad outlines of choices among command-line options and answer file entries. The second table provides details about additional scenarios.

**Three Contrasting Scenarios for Running or Preventing Dynamic Update**

| Scenario | Steps to Take and Effect on Dynamic Update | Does Dynamic Update Connect to the Internet? |
|---|---|---|
| Interactive installation in which you permit Dynamic Update to run | Start Setup from the CD or a network and run it interactively. You are offered the choice of running Dynamic Update or skipping Dynamic Update. | Yes, if you choose to run Dynamic Update. |
| Unattended installation in which you prevent Dynamic Update from running | Run Winnt32.exe with the **/unattend** and **/DUdisable** command-line options. If the **/DUdisable** option is used, Dynamic Update is not triggered, regardless of whether an answer file is used. | No. |
| Unattended installation in which you create a shared folder on a server and deliver Dynamic Update files to destination computers from that shared folder | Prepare a shared folder as outlined in "Creating a Shared Folder on a Server and Delivering Dynamic Update Files to Destination Computers from that Shared Folder," later in this section. Then choose one of two methods for handling installations:<br><br>One method is to run Winnt32.exe with **/DUShare** = *path_to_downloaded_files*. Dynamic Update uses the folder specified in the /DUShare option and does not connect to the Internet.<br><br>Another method is to create an answer file that includes an **[Unattended]** section with an entry that specifies **DUShare** = *path_to_downloaded_files*. Run the Winnt32.exe command with the **/unattend**:*answer_file* option. Dynamic Update uses the folder specified in the DUShare entry and does not connect to the Internet. | No, Dynamic Update uses the files in the shared folder that you created. |

**Additional Scenarios for Running or Preventing Dynamic Update**

| Scenario | Steps to Take and Effect on Dynamic Update | Does Dynamic Update Connect to the Internet? |
|---|---|---|

| | | |
|---|---|---|
| Pre-installation compatibility check | Insert the Setup CD and choose the appropriate options for checking system compatibility. You are offered the choice of running Dynamic Update or skipping Dynamic Update. | Yes, if you choose to run Dynamic Update. |
| Unattended Setup in which you do not use an answer file and you allow Dynamic Update to run | Run the Winnt32.exe command with the **/unattend** option, but do not provide the name of an answer file and do not specify **/DUdisable** or any other options that affect Dynamic Update. Dynamic Update is triggered under these conditions for both unattended installation and unattended upgrade. | Yes. |
| Unattended Setup in which you use an answer file and you allow Dynamic Update to run | Create an answer file that includes an **[Unattended]** section with an entry that specifies **DUDisable = No**. Run the Winnt32.exe command with the **/unattend**:*answer_file* option. Dynamic Update is triggered. (However, note that if you run Winnt32.exe from the command line with the **/DUdisable** option, Dynamic Update is always prevented from running.) | Yes. |
| Unattended Setup in which you prevent Dynamic Update by creating an answer file that does not specify any options that affect Dynamic Update | Run the Winnt32.exe command with the **/unattend**:*answer_file* command-line option. By default, if the answer file does not specify any options that affect Dynamic Update, Dynamic Update is disabled. | No. |

- **User notification**: During an interactive installation, the user is notified when the choice of whether to run Dynamic Update is offered. During an unattended installation, there is no notification (unattended installation by definition means that no user interaction is required).

- **Logging**: By default, the progress of Setup is logged in *systemroot*\Winnt32.log. By using command options for the Winnt32.exe command, you can control the name of the log and the level of detail it contains.

- **Encryption**: The data is transferred from Microsoft using HTTPS.

- **Access**: No information about the hardware (devices) on a particular computer is saved or stored, so no one can access this information. The information is used only to select appropriate drivers.

- **Privacy**: Dynamic Update is covered by the same privacy statement that covers Windows Update. To view the privacy statement for Windows Update, go to the Web site and click **Windows Update Privacy Statement**:

  http://windowsupdate.microsoft.com/

- **Transmission protocol and port**: The transmission protocol is HTTPS and the port is 443.

- **Ability to disable**: You can control the behavior of Dynamic Update by running Setup in specific ways, as shown in the previous table. (Of course, you can also disable Dynamic Update by preventing access to the Internet or by blocking HTTPS over port 443.)

If you do not want to disable Dynamic Update but only want to prevent it from communicating with an Internet site, as noted earlier you can create a shared folder on a server and deliver Dynamic Update files to destination computers from that shared folder.

**Controlling Dynamic Update to Limit the Flow of Information to and from the Internet**
As summarized in "Overview: Using Dynamic Update in a Managed Environment" earlier in this section, if you do not want Dynamic Update to connect to the Windows Update Web site during the installation of Windows Server 2003, you have several options. With the appropriate methods for unattended installation, you can create a shared folder on a server and deliver Dynamic Update files to destination computers from that shared folder. Another alternative is to avoid using Dynamic Update at all.

**Creating a Shared Folder on a Server and Delivering Dynamic Update Files to Destination Computers from that Shared Folder**
This subsection briefly describes the steps for creating a shared folder on a server and delivering Dynamic Update files to destination computers from that shared folder. The subsection also provides links to more detailed information. The steps can

be summarized as follows:

- Step 1: Determine what packages you need to download from the Windows Update Web site.
- Step 2: Download the packages and prepare them and the folder they are in for use with Dynamic Update. This step includes extracting files and placing them in folders, as well as running Winnt32.exe with the **/duprepare** option, which creates subfolders and copies appropriate files to those subfolders. This step also requires other actions, such as sharing the folder and setting permissions.
- Step 3: Configure the answer file and Winnt32.exe settings for Dynamic Update (and for any other configuration options you want).
- Step 4: Run the unattended installations.

For more detailed information about performing the preceding steps, see the *Microsoft Windows Server 2003 Deployment Kit*, specifically the book titled, *Automating and Customizing Installations*. To view the *Microsoft Windows Server 2003 Deployment Kit*, see the Microsoft Web site at:

http://go.microsoft.com/fwlink/?linkid=29887

For additional sources of information about performing unattended installations, see Appendix A: Resources for Learning About Automated Installation and Deployment.

**Avoiding Dynamic Update**

You can avoid using Dynamic Update, which means that Setup will use only the files and drivers provided on the CD for Windows Server 2003. The method by which you avoid using Dynamic Update depends on how you are performing the installation:

- **Interactive installation**: During interactive installation (not unattended installation), you can select **No** when offered the option to use Dynamic Update. As an alternative, you can ensure that the computer does not have Internet access.
- **Unattended Setup**: Dynamic Update is disabled when you run Setup in specific ways, as shown in the tables in "How Dynamic Update Communicates with Sites on the Internet," earlier in this section. As the tables show, the simplest way to ensure that Dynamic Update does not run during unattended Setup is to use the **/DUdisable** option in the command line. This ensures that Dynamic Update will not occur during the installation.

**How Avoiding Dynamic Update or Directing Dynamic Update to a Server on Your Network Can Affect Users and Applications**

Regardless of whether you use Dynamic Update, you can obtain updated system and driver files after installations are complete (for example, through Windows Update or a service pack). Allowing Dynamic Update to run during Setup, however, helps ensure Setup success.

If you create a shared folder on a server and deliver Dynamic Update files to destination computers from that shared folder (instead of downloading the files directly from Windows Update to the computers), you can control the exact set of updated files to be installed. By contrast, when you download the current set of Dynamic Update files directly from the Windows Update Web site to users' computers, you might introduce inconsistencies among your destination computers because the Windows Web Site is periodically updated, and you cannot control when these updates occur.

**Procedures for Controlling Dynamic Update**

For detailed descriptions of Dynamic Update and procedures for controlling it, see the *Microsoft Windows Server 2003 Deployment Kit*, specifically the book titled, *Automating and Customizing Installations*. To view the *Microsoft Windows Server 2003 Deployment Kit*, see the Microsoft Web site at:

http://go.microsoft.com/fwlink/?linkid=29887

# Event Viewer and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Event Viewer
- How Event Viewer communicates with sites on the Internet
- How to control Event Viewer to prevent the flow of information to and from the Internet

**Benefits and Purposes of Event Viewer**
Administrators can use Event Viewer to view and manage event logs. Event logs contain information about hardware and software problems and about security events on your computer. A computer running Microsoft Windows Server 2003 records events in at least three kinds of logs: application, system, and security. A computer running Windows Server 2003 which is configured as a domain controller records events in two additional logs, the Directory service log and the File Replication service log. A computer running Windows Server 2003 which is configured as a Domain Name System (DNS) server records events related to DNS in an additional log.

Other types of events and event logs might be available on a computer, depending on what services are installed.

**Overview: Using Event Viewer in a Managed Environment**
The Event Log service starts automatically when you start the operating system. Administrators access event logs for a server through **Administrative Tools\Event Viewer**. They can obtain detailed information about a particular event by either double-clicking the event or selecting the event and clicking **Properties** on the **Action** menu. The dialog box gives a description of the event, which can contain one or more links to Help.

Links can either be to Microsoft servers or to servers managed by the software vendor for the component that generated the event. On Windows Server 2003, most events that originate from Microsoft products will have standard text containing a URL at the end of the description ("For more information, see Help and Support Center at http://go.microsoft.com/fwlink/events.asp").

When you click the link, you are asked to confirm that the information presented can be sent over the Internet. If you click **Yes**, the information listed will be sent to the Web site named in the link. The parameters in the original URL will be replaced by a standard list of parameters whose contents are detailed in the confirmation dialog box. This list is provided in the next subsection under "Specific Information Sent or Received."

You may want to prevent users from sending this information over the Internet through this link and accessing a Web site. Alternatively, you may want to redirect the requests that result from users clicking links in Event Viewer so that the requests go to a Web server in your organization. In Windows Server 2003 with SP1, you can do either of these things through Group Policy.

**How Event Viewer Communicates with Sites on the Internet**
In order to access the relevant Help information provided by the link in the Event Properties dialog box, you must send the information listed about the event. The collected data is confined to what is needed to retrieve more information about the event from the Microsoft Knowledge Base. User names and e-mail addresses, names of files unrelated to the logged event, computer addresses, and other forms of personal information are not collected.

The exchange of information that takes place over the Internet is as follows:

- **Specific information sent or received**: Information about the event sent over the Internet includes the following:
    - Company name (software vendor)
    - Date and time
    - Event ID (for example, 1704)
    - File name and version (for example, userenv.dll, 5.2.3790.1830)

- Product name and version (for example, Microsoft Windows Operating System, 5. 2.3790.1830)
- Registry source (for example, Userenv)
- Type of event message (for example, Error)

The information the user receives is from the Web site named in the link.

- **Default settings**: Access to Event Viewer is enabled by default.
- **Triggers**: The user chooses to send information about the event over the Internet in order to obtain more information about the event.
- **User notification**: When a user clicks the link, a dialog box listing the information that will be sent is provided.
- **Logging**: This is a feature of Event Viewer.
- **Encryption**: The information may or may not be encrypted, depending on whether the link uses HTTP or HTTPS.
- **Access**: No information is stored.
- **Privacy**: For information about privacy, in Help and Support, type **Linking to Microsoft for Help and Support**.)
- **Transmission protocol and port**: Communication occurs over the standard port for the protocol in the URL, using either HTTP or HTTPS.
- **Ability to disable**: The ability to send information over the Internet or to be linked to a Web site can be prevented through a Group Policy setting.

**Controlling Event Viewer to Prevent the Flow of Information to and from the Internet**

You can prevent administrators from sending information across the Internet and accessing Internet sites through Event Viewer by configuring Group Policy. Alternatively, you can redirect the requests that result from a person clicking a link in Event Viewer so that the requests go to a Web server in your organization. You can do these things by configuring Group Policy.

These Group Policy settings affect only the flow of information to and from an intranet or the Internet through Event Viewer, not the other functions of Event Viewer.

**Procedures for Preventing the Flow of Information to and from the Internet Through Event Viewer**

The following procedures tell how to use Group Policy to prevent the flow of information to and from the Internet through Event Viewer.

**To Use Group Policy to Prevent the Flow of Information to and from the Internet Through Event Viewer**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.
3. In the details pane, double-click **Turn off Event Viewer "Events.asp" links**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

The following procedure tells how to use Group Policy to redirect the requests that result from users clicking links in Event Viewer so that the requests go to a Web server in your organization.

**To Use Group Policy to Redirect Links in Event Viewer to a Web Server in Your Organization**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Event Viewer**.

3. In the details pane, double-click **Events.asp URL**, click **Enabled**, and then type in the URL for the Web page that you want Event Viewer links to go to. Click **OK**.

4. In the details pane, double-click **Events.asp program**, click **Enabled**, and then type the path for the program that should be used for displaying the URL that you typed in the previous step. If you want the page to be displayed in the Web browser and the Web browser is in the system path, you can type the name of the Web browser executable alone, for example, **iexplore.exe**.

5. In the details pane, double-click **Events.asp program command line parameters**, click **Enabled**, and then type any command line parameters required for the program you typed in the previous step. If the program you typed in the previous step does not use parameters, clear the text box.

| **Note** |
| --- |
| Even after the preceding settings go into effect, when a person clicks a link in Event Viewer, the notification still appears, stating that Event Viewer will send information across the Internet and asking for confirmation. Regardless of the notification, if you carry out the preceding procedure and redirect events to a Web server in your organization, the information goes to that server, not across the Internet. |

# File Association Web Service and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of the file association Web service
- How the file association Web service communicates with sites on the Internet
- How to control the file association Web service to limit the flow of information to and from the Internet

**Benefits and Purposes of the File Association Web Service**

The file association Web service in Microsoft Windows Server 2003 extends the scope of information stored locally by the operating system about file name extensions, file types, and the applications or components to use when opening a particular file type. Both the locally stored information and the file association Web service are intended to provide you with the ability to open (double-click) a file without having to specify which application or component to open it with. The operating system associates the file name extension (for example, .txt or .jpg) with a file type, and it opens each file type with the application or component specified for that file type. For example, file name extensions .htm and .html are both "HTML Document" file types.

The operating system first checks for the file association information locally. If no local information is available about the file name extension and its associated file type, the operating system offers you the option of looking for more information on a Microsoft Web site. For details about the URL for this Web site, see "How the File Association Web Service Communicates with Sites on the Internet," later in this section.

**Overview: Using the File Association Web Service in a Managed Environment**

To limit the flow of information from the file association Web service to the Internet, you have several options. You can use firewall settings, you can disable the file association Web service using Group Policy, you can configure automatic server-based software installation through Group Policy, and you can train those who work on servers so that they understand how to specify an association between a file type and the application or component that is used to open that file type. You can also use scripts to limit the file types that can be stored, viewed, or used on computers in your organization, which will limit the likelihood that anyone will need to obtain information about those file types.

**How the File Association Web Service Communicates with Sites on the Internet**

The file association Web service communicates with sites on the Internet as follows:

- **Specific information sent or received**: If the operating system does not find local information about a file name extension, it offers you the option of sending a query to look for more information on a Microsoft Web site. The site is language-specific. The file name extension that you double-click is appended to the query. The query takes the following form:

  **http://shell.windows.com/fileassoc/***nnnn***/xml/redir.asp?Ext=***AAA*

  where *nnnn* is a hexadecimal value used in Windows Server 2003 to map to a language identifier (that is, to an RFC1766 identifier), and *AAA* is the file name extension for which information is needed. An example of a hexadecimal value and its corresponding language identifier is 0409 for en-us, English (United States).

  For more information about these hexadecimal values, see information about the multiple language (MLang) registry settings on the MSDN Web site at:

  http://go.microsoft.com/fwlink/?linkid=29165

  To search for information about MLang registry settings or the Microsoft Internet Explorer Multiple Language application programming interface (MLang API), use the Search tool on the MSDN Web site at:

  http://msdn.microsoft.com/

- **Default setting and ability to disable**: The service is enabled by default. It can be disabled by using Group Policy, as described in "Disabling the File Association Web Service," later in this section.

There are ways of reducing the likelihood that a person will trigger the file association Web service. One basic way is to configure automatic, server-based software installation based on Group Policy settings. For more information, see article 816102, "HOW TO: Use Group Policy to Remotely Install Software in Windows Server 2003," in the Microsoft Knowledge Base at:

http://go.microsoft.com/fwlink/?linkid=29166

- **Trigger and user notification**: When you try to open a file (for example, by double-clicking the file), and there is no local information about the correct application or component to use when opening the file, the operating system offers the option either to "Use the Web service to find the appropriate program" or to "Select the program from a list."

- **Logging**: No events are logged by the file association Web service.

- **Encryption, storage, and privacy**: The file name extension sent in a query to the Internet is not encrypted. Nothing in the query identifies the person who triggered the query. If the local computer's browser is configured to store information about recently visited Internet sites, the browser will store the query containing the file name extension. Otherwise, the query containing the file name extension is not stored anywhere.

- **Transmission protocol and port**: The transmission protocol is HTTP and the port is 80.

**Controlling the File Association Web Service to Limit the Flow of Information to and from the Internet**

If you want to limit the flow of information from the file association Web service to the Internet, you can use one or more of the following methods:

- Use your firewall to block access to any Web site that contains the following string:

  http://shell.windows.com/fileassoc/

- Disable the file association Web service by using Group Policy, as described in "Disabling the File Association Web Service," later in this section.

- Configure automatic, server-based software installation. To do this, configure one or more servers with the Software Installation extension of Group Policy in Windows Server 2003. When you do this, if someone tries to open a file for which the corresponding application is not installed locally, a copy of the application (stored on a server) is installed automatically. In this situation, the file association Web service will not be triggered. For more information, see article 816102, "HOW TO: Use Group Policy to Remotely Install Software in Windows Server 2003," in the Microsoft Knowledge Base at:

  http://go.microsoft.com/fwlink/?linkid=29166

- Train those who work on servers to work with file associations as follows:

  - Instruct them that an association exists (stored by the local operating system) between a file name extension, a file type, and the application or component that is used to open that file type.

  - Provide those who work on servers with information about the file name extensions for the files they need to work with most often, the file type for each extension, and the application that should be used to open each file type. For example, file name extensions .htm and .html are both "HTML Document" file types.

  - Show those who work on servers how to use Control Panel, **Folder Options**, and the **File Type** tab in **Folder Options** to associate a file name extension with a file type, and a file type with an application. Explain to them that the operating system stores this information on the local computer.

  - Instruct those who work on servers to always click **Select the program from a list** if they see a message box offering the two options, **Use the Web service to find the appropriate program** or **Select the program from a list**.

- Use scripts to scan your organization's computers for file types that you do not want to be stored, viewed, or used. Take actions to ensure that these files do not remain on individual computers' hard disks. If unwanted file types do not exist on the hard disks, it decreases the need for anyone to obtain information about the file name extension used for that file type.

**Procedures that Limit Internet Communication Initiated by the File Association Web Service**

This section contains the following information:

- A procedure for disabling the file association Web service by using Group Policy.
- Procedures that can be used as a basis for training those who work on servers about file name extensions, file types, and the application or component that the operating system uses when opening a specific file type.

**Disabling the File Association Web Service**

The following procedure explains how to disable the file association Web service by using Group Policy.

**To Disable the File Association Web Service by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. If you want the policy setting to apply to all users of a computer and to come into effect when the computer starts or when Group Policy is refreshed, click **Computer Configuration**. If you want the policy setting to apply to users and to come into effect when users log on or when Group Policy is refreshed, click **User Configuration**.
3. Click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.
4. In the details pane, double-click **Turn off Internet File Association service**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management or in User Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

**Specifying Associations Between File Name Extensions, File Types, and Applications or Components**

You can use the following procedures as a basis for training those who work on servers about file name extensions, file types, and the application or component that the operating system uses when opening a specific file type.

**To Associate a File Name Extension with a File Type**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Folder Options**, and then click the **File Types** tab.
3. Click **New**.
4. Type a new or existing file name extension, and then click **Advanced**.
5. In **Associated File Type**, do one of the following:
    - Type or select New to create a file type to associate with the file name extension.

- Type or select a different file type to associate with the extension.

| **Note** |
| --- |
| When you type a file name extension in the **Create New Extension** dialog box, the Associated File Type list displays the file type that is associated with that extension. To select **New**, scroll to the top of the list. |

**To Associate a File Name Extension with an Application**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Folder Options**, and then click the **File Types** tab.
3. Under **Registered file types**, click a file type.
4. Click **Change**, and then choose the application you want to use to open this file.

**Related Links**

For more information about automatic server-based software installation based on Group Policy settings, see article 816102, "HOW TO: Use Group Policy to Remotely Install Software in Windows Server 2003," in the Microsoft Knowledge Base at:

http://go.microsoft.com/fwlink/?linkid=29166

# Help and Support Center: Features That Communicate with the Internet

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of the Headlines and Online Search features in Help and Support Center
- How the Headlines and Online Search features communicate with sites on the Internet
- How to control the Headlines and Online Search features to limit the flow of information to and from the Internet

**Benefits and Purposes of Headlines and Online Search**
Help and Support Center is a self-help portal that was first included in Microsoft Windows Millennium Edition. It is also included in all versions of Windows Server 2003, including Windows Server 2003 with Service Pack 1 (SP1). You can access Help and Support Center in a number of ways, including:

- Selecting **Help and Support** from the Start menu.
- Selecting **Help and Support Center** from the Help menus for Control Panel, Windows Explorer, My Network Places, My Computer, or My Documents.

**Headlines**
A useful feature of Help and Support Center is the Headlines area. This area is typically titled "Top Issues" and is usually located in the lower-right corner of the main window, unless the window has been customized by the OEM or modified for certain languages. The Headlines area might also contain a hyperlink to additional content that can be viewed in Help and Support Center. Headlines provides a dynamic source of content that you can visit to find help and support on current issues as well as those that were known at the time the operating system was released. For example, it may display links to topics about new security bulletins, software updates, or new Help content.

**Online Search**
Online Search, another useful feature of Help and Support Center, enables users to query online Web sites automatically when performing a search. By default, the Microsoft Knowledge Base is designated as one of the Web sites for online searches. OEMs often customize the Online Search feature by, for example, adding a check box to the search window to enable the search engine to query their OEM-specific Web sites for results. To produce the most informative results when querying the Microsoft Knowledge Base, certain information such as the version of the product installed is collected from the user's computer and uploaded to the servers hosting the Microsoft Knowledge Base.

**Overview: Using Headlines and Online Search in a Managed Environment**
By using Group Policy or using the Windows user interface, you can control the extent to which the Headlines and Online Search features access the Internet. More details on the methods and procedures for controlling these features are described in the following subsections.

**How Headlines and Online Search Communicate with Sites on the Internet**
**Headlines**
The Headlines ("Top Issues") area is updated only when there is Internet connectivity. You are not required or prompted to connect to the Internet. Help and Support Center uses information contained in the NewsSet.xml file (stored in the *systemroot*\PCHealth\Helpctr\Config folder) to determine:

- Whether or not to update the Headlines area
- How frequently to update the Headlines area
- Where on the Internet to obtain the Headlines updates

This subsection summarizes the communication process:

- **Specific information sent or received**: If there is Internet connectivity, when you start Help and Support Center, the Help and Support service (helpsvc) compares the current date to the date specified by the TIMESTAMP attribute in the NewsSet.xml file and calculates the total number of days that have elapsed since the last time Headlines was successfully updated.

  Then, if the number of elapsed days is greater than the number of days specified by the FREQUENCY attribute in NewsSet.xml, the Help and Support service connects to the Web site specified by the URL attribute and downloads an updated version of the file NewsVer.xml to the *systemroot*\PCHealth\Helpctr\Config\News folder. The administrator (or other person at the server) is not uniquely identified.

  | **Note** |
  | --- |
  | For Headlines supplied by Microsoft, the URL attribute in NewsSet.xml is: **http://go.microsoft.com/fwlink/?LinkID=11**. This redirects to a different site such as: http://windows.microsoft.com/windowsxp/newsver.xml |

- The downloaded NewsVer.xml file contains links to the news content files (news blocks) for Windows Server 2003 operating systems and the installed language. These news blocks contain the information used to update the Headlines area—that is, links to and descriptions of the latest information from Help and Support Center, Windows, or support-related articles posted on Microsoft Web sites.

  | **Note** |
  | --- |
  | If the OEM has customized the Headlines feature, then the OEM-supplied Headlines may have links to the OEM's Web site. |

- If there is no Internet connectivity, Help and Support Center displays an offline message in the Headlines area similar to the following:

  "When you are connected to the Internet, this area will display links to timely help and support information. If you want to connect to the Internet now, start the New Connection Wizard and see how to establish a Web connection through an Internet service provider."

- **Default and recommended settings**: The Headlines feature is enabled by default. Recommended settings are described in the next subsection, "Controlling Headlines and Online Search to Limit the Flow of Information to and from the Internet."

- **Triggers**: The Headlines feature is automatically triggered if there is Internet connectivity when you start Help and Support Center.

- **User notification**: You are not given the choice to select whether or not to update the Headlines area before an update is performed. An "Updating ..." status indicator is displayed in the Headlines area, however, to indicate when an update is being performed. Once Help and Support Center has completed checking for new headlines, the Headlines area is labeled "Updated: date," where date is the current date.

- **Logging**: No information related to Headlines is entered into the event log.

- **Encryption**: The data transferred to Microsoft is not encrypted.

- **Access**: The only data generated on servers at Microsoft from the process of updates to the Headlines area is a single number telling how many times a connection has been made, by any computer, to the link that supports Headlines updates. No computer is identified in the process of a Headlines update. The data can be viewed by the Microsoft group that provides support for the link through which Headlines is updated.

- **Transmission protocol and port**: The transmission protocol used is HTTP and the port is 80.

- **Ability to disable**: You can disable Headlines by using Group Policy. For more information, see "Procedure for Disabling Headlines and Online Search," later in this section.

**Online Search**

Online Search can only query online Web sites like the Microsoft Knowledge Base when there is Internet connectivity; you are neither required nor prompted to connect to the Internet. When you perform a search in Help and Support Center, if you have set the search options to search the Microsoft Knowledge Base or an OEM-designated Web site, the search engine automatically searches the specified site.

This subsection summarizes the communication process:

- **Specific information sent or received**: To produce relevant results when querying the Microsoft Knowledge Base, certain information is collected from the computer and uploaded to a server at Microsoft that hosts the Microsoft Knowledge Base. The administrator (or other person at the server) is not uniquely identified. Following is a list of the information collected:

    - The search text string that was entered
    - The language code of the operating system
    - The product Knowledge Base to be searched (for example, the Windows Server 2003 family or Outlook)
    - The version of the operating system installed (for example, Standard Edition, Enterprise Edition, Datacenter Edition, or Web Edition)
    - The number of results specified for the result set
    - Titles field status (indicates whether or not to search the article title only)
    - Type field status (indicates whether to search using "all" or "any" of the search string)

- **Default and recommended settings**: Online Search is enabled by default. Recommended settings are described in the next subsection, "Controlling Headlines and Online Search to Limit the Flow of Information to and from the Internet."

- **Triggers**: Online Search is automatically triggered if you use the default search options or if you have set the search options to encompass searches on the Internet. (Online Search is also dependent on having Internet connectivity when the search is performed.)

- **User notification**: You are not notified before Help and Support Center performs Online Search. A permanent headline is provided in the Headlines area that tells how to set Online Search options, including how to turn the feature off.

- **Logging**: No information related to Online Search is entered into the event log.

- **Encryption**: The data transferred to Microsoft is not encrypted.

- **Access**: The data uploaded to the server at Microsoft is aggregated and clustered. Information about the most common queries is later made available to the Windows Product Support Services and Windows User Assistance teams to help in developing new content or in revising existing content.

- **Privacy**: Microsoft does not retrieve personal information, such as user name or e-mail address, from the computer during an online search. A permanent headline is provided in the Headlines area that tells how to set Online Search options, including how to turn the feature off.

- **Transmission protocol and port**: The transmission protocol used is HTTP and the port is 80.

- **Ability to disable**: You can disable Online Search by using Group Policy or through the Help and Support Center user interface.

**Controlling Headlines and Online Search to Limit the Flow of Information to and from the Internet**

The following tables describe Group Policy settings and other configuration options for both Headlines and Online Search. For more information, see "Procedures for Disabling Headlines and Online Search," later in this section.

| **Headlines: Configuration Tool** | **Setting** | **Result** |
|---|---|---|
| Group Policy | In Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings, enable **Turn off Help and Support Center "Did you know?"** content. | Help and Support Center no longer retrieves text for the Headlines area and instead replaces it with white space. |

| **Online Search: Configuration Tool** | **Setting** | **Result** |
|---|---|---|
| Help and Support Center user interface (Set Search Options pane) | Clear any check boxes for querying the Microsoft Knowledge Base or OEM Web sites for results. | Disables online searches. The search results window neither displays an area for the online Web sites (such as the Microsoft Knowledge Base) nor returns any search results from online Web sites. |
| Group Policy | In Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings, enable **Turn off Help and Support Center Microsoft Knowledge Base search**. | Removes the Knowledge Base section from the Help and Support Center Set search options page. Searches for information from Help topics are performed locally only. |

| **Headlines and Online Search: Configuration Tool** | **Setting** | **Result** |
|---|---|---|
| Firewall | Block HTTP port 80. | Displays offline message text in Headlines area. The search results window displays an area for the online Web sites (such as the Microsoft Knowledge Base), but it does not return any search results from online Web sites. |

**How Controlling Headlines and Online Search Can Affect Users and Applications**

The Headlines area provides a good way to obtain up-to-date solutions to common problems, updated self-help content, and information about software and driver updates. If you decide to disable the Headlines feature, the Headlines ("Top Issues") area in the Help and Support Center user interface will be blank and links to new content or software update notifications will never be presented.

The Online Search feature enables you to obtain help from online Web sites. If you decide to disable the Online Search feature, you will only be able to query local Help content.

Disabling Headlines and Online Search will not affect any other applications.

**Procedures for Disabling Headlines and Online Search**

The following procedures describe how to:

- Disable the Headlines feature by using Group Policy
- Disable the Online Search feature on individual computers
- Disable the Online Search feature by using Group Policy

**To Disable the Headlines Feature by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click Computer Configuration, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.

3. In the details pane, double-click **Turn off Help and Support Center "Did you know?" content**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the Restrict Internet communication policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

**To Disable the Online Search Feature on Individual Computers**

1. Click **Start**, and then click **Help** and **Support**.

2. Below the Search box, click **Set search options**.

3. Clear the **Microsoft Knowledge Base** check box and any other check boxes below it. For example, the manufacturer of your computer may have added a check box to enable your search to query their Web site for results.

4. Close Help and Support Center.

**To Disable the Online Search Feature by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.

3. In the details pane, double-click **Turn off Help and Support Center Microsoft Knowledge Base search**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the Restrict Internet communication policy setting, which is located in **Computer Configuration/Administrative Templates/System/Internet Communication Management**. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

# HyperTerminal and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of HyperTerminal
- How HyperTerminal communicates with sites on the Internet
- How to control HyperTerminal to prevent the flow of information to and from the Internet

**Benefits and Purposes of HyperTerminal**

HyperTerminal is a program that you can use to connect to other computers, Telnet sites, bulletin board systems (BBSs), online services, and host computers. HyperTerminal connections are made using a modem, a null modem cable (used to emulate modem communication), or an Ethernet connection.

HyperTerminal is not installed by default when a product in the Windows Server 2003 family is installed manually. HyperTerminal is installed by default, however, if the Windows Server 2003 product is installed using an answer file during automated installation.

HyperTerminal has capabilities beyond making connections to other computers. It can, for example, transfer large files from a computer onto your portable computer using a serial port rather than requiring you to set up your portable computer on a network. It can help debug source code from a remote terminal. It can also communicate with many older, character-based computers.

HyperTerminal records the messages passed to and from the computer or service on the other end of your connection. It can therefore serve as a valuable troubleshooting tool when setting up and using your modem. To make sure that your modem is connected properly or to view your modem's settings, you can send commands through HyperTerminal and check the results. HyperTerminal also has scroll functionality that enables you to view received text that has scrolled off the screen.

| **Note** |
| --- |
| HyperTerminal is designed to be an easy-to-use tool yet it is not meant to replace other full-featured tools. You can use HyperTerminal as described in this subsection, but you should not attempt to use HyperTerminal for more complex communication. For more information about what HyperTerminal does and does not support, see the Help topics at http://go.microsoft.com/fwlink/?linkid=29890. |

**Overview: Using HyperTerminal in a Managed Environment**

HyperTerminal is not installed by default when a product in the Windows Server 2003 family is installed manually. HyperTerminal is installed by default, however, if the Windows Server 2003 product is installed using an answer file during automated installation. In a managed environment, you might choose to prevent Hyperterminal from being installed on servers running Windows Server 2003. If you choose to allow Hyperterminal to be installed on servers, when deciding how to configure it, consider the following security issues:

- **Viruses**: Incoming files might contain viruses or malicious programs that could compromise or destroy data on your computer. To reduce this risk, use virus-scanning software and ensure that incoming files are from a reliable and trusted source.
- **ID and password**: HyperTerminal cannot automatically provide your login ID and password when you make a connection. If you provide a password when using HyperTerminal for a Telnet session, be aware that this password will be sent to the remote computer using plaintext (as with all Telnet connections).
- **Automatic download**: The automatic download feature of the Zmodem protocol can pose a security risk by allowing remote users to send files to your computer without your explicit permission. To avoid this risk, you should select a protocol other than Zmodem in the **Receive File** dialog box or you should clear the **Allow remote host initiated file transfers** check box on the **Settings** tab of Connection Properties.

Complete information about concepts and procedures associated with using or configuring HyperTerminal is beyond the scope of this white paper. For more information, access the HyperTerminal Help documentation in Help and Support Center on any computer running Windows Server 2003.

**How HyperTerminal Communicates with Sites on the Internet**

The exchange of information that takes place during the HyperTerminal connection is as follows:

- **Specific information sent or received**: When using HyperTerminal for Telnet connectivity, the user ID and password are sent in plaintext format (as with all Telnet connections). If files are being transmitted, only the protocol, terminal emulation data, and file-specific binaries are sent. The computer running HyperTerminal is identified by its IP address when the connection type is TCP/IP. The computer is not uniquely identified when the connection type is not TCP/IP.

- **Default settings**: HyperTerminal is not installed by default when a product in the Windows Server 2003 family is installed manually. HyperTerminal is installed by default, however, if the Windows Server 2003 product is installed using an answer file during automated installation. To remove or uninstall HyperTerminal, see "Controlling HyperTerminal to Prevent the Flow of Information to and from the Internet," later in this section.

- **Triggers**: When HyperTerminal is set to automatically answer incoming connections, a file transfer can be initiated if the Zmodem transfer protocol is used. Otherwise, communication through HyperTerminal is only triggered when the user deliberately initiates it.

- **User notification**: After a user starts a HyperTerminal connection session, the status of the connection that is currently open within HyperTerminal is displayed in the HyperTerminal title bar. The status of the file and text transfer is displayed in the HyperTerminal window during the transfer process. HyperTerminal does not display connection or transfer status information when the automatic download feature of the Zmodem protocol is used. For more information about the HyperTerminal automatic download feature, see "Overview: Using HyperTerminal in a Managed Environment," earlier in this section.

- **Encryption**: Information sent or received by HyperTerminal is not encrypted.

- **Transmission protocol and port**: The protocols used are Kermit, Xmodem, Xmodem-1K, Ymodem, Ymodem-G, and Zmodem transmissions protocols on port 23.

- **Ability to disable**: You can prevent Hyperterminal from being installed, remove it, or prevent it from being run. For more information, see "Controlling HyperTerminal to Prevent the Flow of Information to and from the Internet," later in this section.

**Controlling HyperTerminal to Prevent the Flow of Information to and from the Internet**

You can ensure that HyperTerminal cannot be used on a server running Windows Server 2003 by using the following methods, described in the procedures in this section:

- For unattended installations, specify an entry in an answer file that will prevent HyperTerminal from being installed.

- After installation, use Add or Remove Programs in Control Panel to remove HyperTerminal or to confirm that it is not installed.

- Use Group Policy to ensure that HyperTerminal cannot be run.

**To Ensure that HyperTerminal is Not Installed During Unattended Installation**

1. Using the methods you prefer for unattended installation or remote installation, create an answer file. For more information about unattended and remote installation, see Appendix A: Resources for Learning About Automated Installation and Deployment.

2. In the [Components] section of the answer file, include the following entry:

   **hypertrm = Off**

**To Remove HyperTerminal from an Individual Computer Running Windows Server 2003**

1. Click **Start**, and then either point to **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. Click **Add/Remove Windows Components** (on the left).
4. Double-click **Accessories and Utilities**, and then double-click **Communications**.
5. Make sure the check box for the **HyperTerminal** component is cleared.
6. Follow the instructions to complete the Windows Components Wizard.

| **Note** |
| --- |
| You must have administrative credentials to complete this procedure. |

**To Use Group Policy to Prevent HyperTerminal from Being Run**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.
2. In Group Policy, click **User Configuration**, click **Administrative Templates**, and then click **System**.
3. In the details pane, double-click **Don't run specified Windows applications**.
4. Click **Enabled**, click **Show**, click **Add**, and then type the executable name:

   **Hypertrm.exe**

# Internet Explorer 6.0 and Resulting Internet Communication in Windows Server 2003 with Service Pack 1

Applies To: Windows Server 2003 with SP1

This white paper provides information about the communication that flows between components in Windows Server 2003 with SP1 and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users.

This section of the white paper provides information about:

- The benefits of Microsoft Internet Explorer 6 in Windows Server 2003.
- A description of Internet Explorer Enhanced Security Configuration, which is enabled by default when you install a product in the Windows Server 2003 family.
- Examples of the security-related features provided in Internet Explorer 6 (as compared to Internet Explorer 5).
- Procedures for working with security-related settings in Internet Explorer.
- Resources for learning about topics related to security in Internet Explorer 6. This includes resources that help you learn about:
    - The Internet Explorer Enhanced Security Configuration
    - Security and privacy settings in Internet Explorer 6.
    - Mitigating the risks inherent in Web-based applications and scripts.
    - Methods for deploying specific configurations of Internet Explorer 6 across your organization using Group Policy, the Internet Explorer Administration Kit (IEAK), or both.

| **Note** |
| --- |
| This section of the white paper describes Internet Explorer 6, but does not describe the related components Outlook Express 6 (the e-mail component in Windows Server 2003), the New Connection Wizard, or the error reporting tool in Internet Explorer. For information about these components, see the respective sections of this white paper (the error reporting tool in Internet Explorer is described in the Windows Error Reporting and Internet Communication section of this white paper). |

| **Note** |
| --- |
| The New Connection Wizard replaces the Network Connection Wizard and the Internet Connection Wizard in Windows 2000. |

It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization where users connect to Web sites, run software from the Internet, download items from the Internet, and perform similar actions. This section, however, provides overview information as well as suggestions for other sources of information about how to balance users' requirements for Internet access with your organization's requirements for protection of networked assets.

The following are central locations in which to find information about Internet Explorer 6:

- Help for Internet Explorer (with Internet Explorer open, click the Help menu and select an appropriate option)
- The Internet Explorer page on the Microsoft Web site at:

http://www.microsoft.com/windows/ie/

- The Resource Kit for Internet Explorer. To learn about this and other Resource Kits, see the Microsoft TechNet Web site at:

  http://go.microsoft.com/fwlink/?linkid=29894

**Benefits and Purposes of Internet Explorer 6**

Internet Explorer 6 in Windows Server 2003 with SP1 is designed to make it easy to browse and interact with sites on an intranet or on the Internet. It differs from most of the other components described in this white paper in that its main function is to communicate with sites on the Internet or an intranet (which contrasts with components that communicate with the Internet in the process of supporting some other activity).

Internet Explorer 6 is also designed to be highly configurable, with security and privacy settings that can help protect your organization's networked assets while at the same time providing access to useful information and tools. In addition, Internet Explorer Enhanced Security Configuration, which is enabled by default when you install a product in the Windows Server 2003 family, helps make your computer more secure by limiting its exposure to malicious Web sites.

With this enhanced level of security, however, you might find that some Web sites are not displayed correctly in Internet Explorer when you are browsing from a server. Also, you might be prompted to enter your credentials when accessing network resources, such as files in shared folders with Universal Naming Convention (UNC) names. You can easily change the enhanced security settings.

If you want to establish a specific configuration on servers (instead of using Internet Explorer Enhanced Security Configuration), Internet Explorer 6 offers more security-related options and settings than were available in Internet Explorer 5. The subsections that follow provide more information about Internet Explorer Enhanced Security Configuration and about the security-related options and settings in Internet Explorer 6.

**Internet Explorer Enhanced Security Configuration**

Internet Explorer Enhanced Security Configuration is enabled by default when you install Windows Server 2003. With this configuration, each zone uses a higher security setting than was used by default in Windows 2000. You can easily change the enhanced security settings.

The following table outlines some of the differences that Internet Explorer Enhanced Security Configuration makes in security settings on a server. (For a description of zones, see "Examples of Security-Related Features Provided in Internet Explorer 6," later in this section.)

**Security settings with and without Internet Explorer Enhanced Security Configuration**

| Zone | With Internet Explorer Enhanced Security Configuration | Without Internet Explorer Enhanced Security Configuration (the same security levels as Windows 2000) |
|---|---|---|
| Internet zone | High security settings | Medium security settings |
| Trusted sites zone | Medium security settings | Low security settings |
| Local intranet zone | Medium-low security settings (intranet sites are not automatically detected) | Medium-low security settings (intranet sites are automatically detected) |

Also, with Internet Explorer Enhanced Security Configuration, several sites are added automatically to specific zones:

- The Windows Update Web site is added to the Trusted sites zone. This allows you to continue to get important updates for your operating system. For more information about Windows Update, see the Windows Update, Automatic Updates, and Internet Communication section of this white paper.

- The Windows Error Reporting site is added to the Trusted sites zone. This allows you to report problems you encounter with your operating system and search for fixes. For more information about Windows Error Reporting, see the Windows Error Reporting and Internet Communication section of this white paper.

- Several local computer sites (for example, http://localhost, https://localhost, hcp://system) are added to the Local intranet zone. This allows applications and code to work locally so that you can complete common administrative tasks.

You can enable or disable the Internet Explorer Enhanced Security Configuration for administrators, all other user groups, or both. For more information, see "To Remove Internet Explorer Enhanced Security Configuration and Restore the Default Internet Explorer 6 Security Settings," later in this section.

For more information about Internet Explorer Enhanced Security Configuration, see the resources listed in "Learning About Internet Explorer Enhanced Security Configuration," later in this section.

**Examples of the Security-Related Features Provided in Internet Explorer 6**
This subsection describes enhancements in some of the security-related features in Internet Explorer 6, as compared to Internet Explorer 5. These features include:

- A **Privacy** tab that provides greater flexibility in specifying whether cookies will be blocked from specific sites or types of sites. An example of a type of site that could be blocked is one that does not have a compact policy—that is, a condensed computer-readable privacy statement. (The **Privacy** tab was not available in Internet Explorer 5.)

- Security settings that specify how Internet Explorer 6 handles such higher-risk items as ActiveX controls, downloads, and scripts. These settings can be customized as needed, or they can be set to these predefined levels: high, medium, medium-low, or low. You can specify different settings for a number of zones, the most basic being the four preconfigured zones:

  - Local intranet zone: Contains addresses inside the boundary defined by your proxy server or firewall.

  - Trusted sites: Includes sites you designate as "trusted."

  - Restricted sites: Includes sites you designate as "restricted."

  - Internet zone: Includes everything that is not in another zone and is not on the local computer.

  You can also specify different settings for the customized zones that you add programmatically using the URL security zones application programming interface (API). For more information, search for "URL security zones" on the MSDN Web site at:

  http://msdn.microsoft.com/

- Support for content-restricted IFrames (inline floating frames). This type of support enables developers to implement these frames in a way that makes it more difficult for malicious authors to start e-mail-based or content-based attacks.

- Improvements in Windows Server 2003 Service Pack 1 (SP1) that increase the overall security and reliability of Internet Explorer 6. These improvements include a configurable pop-up blocker, an interface from which you can manage add-ons (programs that extend the capabilities of the browser), and enhancements to other security features.

For more information about features available in Internet Explorer, see "Resources for Learning About Topics Related to Security in Internet Explorer 6," later in this section, as well as the Internet Explorer page on the Microsoft Web site at:

http://www.microsoft.com/windows/ie/

**Procedures for Working with Security-Related Settings in Internet Explorer**
This subsection describes how to carry out the following:

- View security settings for zones in Internet Explorer

- Locate Group Policy settings that affect Internet Explorer, and view related Help

- Determine whether Internet Explorer Enhanced Security Configuration is enabled on a specific server

- Remove Internet Explorer Enhanced Security Configuration and restore the default Internet Explorer 6.0 security settings

**To View Security Settings for Zones in Internet Explorer**

1. On the server on which you want to view settings, start Internet Explorer by your preferred method, for example, by clicking the Internet Explorer icon on the taskbar.

2. On the **Tools** menu, click **Internet Options**.

3. Click the **Security** tab.

4. Select the zone for which you want to view security settings:

   - Internet
   - Local intranet
   - Trusted sites
   - Restricted sites

**To Locate Group Policy Settings that Affect Internet Explorer**

1. See Appendix B: Resources for Learning About Group Policy for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Internet Explorer**.

   View the available settings.

3. Click **User Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Internet Explorer**.

   View the available settings.

**To Determine Whether Internet Explorer Enhanced Security Configuration is Enabled on a Specific Server**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Add or Remove Programs**.

3. Click **Add/Remove Windows Components** (on the left).

4. Scroll down to **Internet Explorer Enhanced Security Configuration**. If the check box is selected, it is enabled. If the check box is cleared, it is not enabled.

5. If you want to see whether Internet Explorer Enhanced Security Configuration is enabled for administrator groups, all other user groups, or both, select **Internet Explorer Enhanced Security Configuration**, and then click **Details**.

**To Remove Internet Explorer Enhanced Security Configuration and Restore the Default Internet Explorer 6 Security Settings**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Add or Remove Programs**.

3. Click **Add/Remove Windows Components** (on the left).

4. Click **Internet Explorer Enhanced Security Configuration**, and then do one of the following:

   - To remove Internet Explorer Enhanced Security Configuration for both administrators and all other users, clear the **Internet Explorer Enhanced Security Configuration** check box, and then click **Next**.

   - To remove Internet Explorer Enhanced Security Configuration for administrators only or for users who are not in an administrator group, click **Details**, clear either the **For administrator groups** check box or the **For all other user groups** check box, and then click **Next**.

5. Follow the instructions to complete the Windows Components Wizard.

**Procedures for Setting the Security Level to High for Specific Web Sites**

The procedures that follow provide information about how to set the security level for a particular Web site to **High**, which prevents actions such as the running of scripts and the downloading of files from the site. For related information, see "Examples of the Security-Related Features Provided in Internet Explorer 6," earlier in this section, and "Learning About Security and Privacy Settings in Internet Explorer 6," later in this section.

**To Configure a Specific Computer with a Security Level of High for Specific Sites**

1. On the computer on which you want to configure a security level of High for specific sites, in Internet Explorer, click **Tools**, click **Internet Options**, and then click the **Security** tab.

2. Select **Restricted sites**.

3. Under **Security level for this zone**, make sure the slider for the security level is set to **High**. If the security level for the zone is **Custom** and you prefer to set it to **High**, click **Default Level** and make sure the slider for the security level is set to **High**.

   You can view the individual settings that make up **High** security by clicking **Custom Level**. For example, you can click **Custom Level** and then scroll down to confirm that for **High** security, the settings for active scripting and for file download are both **Disable**. After viewing the settings, click **Cancel**.

4. With **Restricted sites** still selected, click **Sites**.

5. In **Add this Web site to the zone**, type the Web site address. You can use an asterisk for a wildcard. For example, for Web sites at Example.Example.com and www.Example.com, you could type:

   **http://*.Example.com**

6. Click the **Add** button.

**To Use Group Policy to Set the Security Level to High for Specific Sites That Users or Administrators in Your Organization Might Connect To**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. In Group Policy, click **User Configuration**, click **Windows Settings**, click **Internet Explorer Maintenance**, and then click **Security**.

3. In the details pane, double-click **Security Zones and Content Ratings**.

4. Under **Security Zones and Privacy**, click **Import the current security zones and privacy settings**, and then click **Modify Settings**.

5. Select **Restricted sites**.

6. Under **Security level for this zone**, make sure the slider for the security level is set to **High**. If the security level for the zone is **Custom** and you prefer to set it to **High**, click **Default Level** and make sure the slider for the security level is set to **High**.

   You can view the individual settings that make up **High** security by clicking **Custom Level**. For example, you can click **Custom Level** and then scroll down to confirm that for **High** security, the settings for file download and for active scripting are both **Disable**. After viewing the settings, click **Cancel**.

7. With **Restricted sites** still selected, click **Sites**.

8. In **Add this Web site to the zone**, type the Web site address. You can use an asterisk for a wildcard. For example, for Web sites at Example.Example.com and www.Example.com, you could type:

   **http://*.Example.com**

9. Click the **Add** button.

#### Resources for Learning About Topics Related to Security in Internet Explorer 6

This subsection lists resources that can help you learn about the following topics related to security in Internet Explorer 6:

- Internet Explorer Enhanced Security Configuration
- Security and privacy settings available in Internet Explorer 6
- Methods for mitigating the risks inherent in Web-based programs and scripts
- Ways to use Group Policy objects that control configuration settings for Internet Explorer 6
- The Internet Explorer Administration Kit

In addition, for information about unattended installation, see the resources listed in Appendix A: Resources for Learning About Automated Installation and Deployment.

| **Note** |
| --- |
| For information about Internet Explorer on clients running Windows XP Professional with Service Pack 2, that is, for information similar to what is provided in this white paper but focused on clients instead of servers, see "Using Windows XP Professional with Service Pack 2 in a Managed Environment: Controlling Communication with the Internet" on the Microsoft Web site at http://go.microsoft.com/fwlink/?LinkId=29133. |

#### Learning About Internet Explorer Enhanced Security Configuration

For more information about Internet Explorer Enhanced Security Configuration, see one of the following:

- The informational pages displayed in Internet Explorer after you install a product in the Windows Server 2003 family. To view these pages, start Internet Explorer after completing the installation.
- Help topics in Internet Explorer. To view these topics, with Internet Explorer Enhanced Security Configuration enabled, start Internet Explorer, click **Help**, and then click **Enhanced Security Configuration**.
- Help topics in Help and Support Center. To view these topics, click **Start**, click **Help and Support**, and search for "enhanced security configuration."

#### Learning About Security and Privacy Settings in Internet Explorer 6

Two important sources of detailed information about the security and privacy settings in the version of Internet Explorer 6 in Windows Server 2003 with SP1 are as follows:

- "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1," which contains information about the pop-

up blocker, the interface from which you can manage add-ons (programs that extend the capabilities of the browser), and enhancements to other security features. This document is available on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46278

- Microsoft Internet Explorer 6 Resource Kit

  To learn about this and other resource kits, see the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=29894

  The Microsoft Internet Explorer 6 Resource Kit consists of a number of parts that include these titles:

  - "Privacy and Security Features"
  - "Preparation for Deployment"
  - "Customization and Installation"
  - "Maintenance and Support," including information about keeping programs updated
  - Appendices, including an appendix titled "Setting System Policies and Restrictions"

**Learning About Mitigating the Risks Inherent in Web-based Applications and Scripts**
In a network-based and Internet-based environment, code can take a variety of forms including scripts within documents, scripts within e-mail messages, or applications or other code objects running within Web pages. This code can move across the Internet and is sometimes referred to as "mobile code." Configuration settings provide ways for you to control the way Internet Explorer 6 responds when someone tries to run mobile code. Two examples of the ways you can customize the Internet Explorer configuration deployed in your organization are as follows:

- You can control the code (in ActiveX controls or in scripts, for instance) that administrators or operators can run. You can do this by customizing Authenticode® settings, which can, for example, prevent administrators or operators from running any unsigned code or enable them to only run code signed by specific authors.

- If you want to permit the use of ActiveX controls, but you do not want administrators or operators to download code directly from the Internet, you can specify that when Internet Explorer 6 looks for a requested executable, it goes to your own internal Web site instead of the Internet. For more information, see the white paper titled "Managing Mobile Code with Microsoft Technologies" at the end of this list, and search for "CodeBase".

You can use the following sources to learn more about mitigating the risks inherent in Web-based applications and scripts:

- To understand more about how a particular Microsoft programming or scripting language works, see the MSDN Web site at:

  http://msdn.microsoft.com/

- To learn about approaches to mitigating the risks presented by mobile code, see "Managing Mobile Code with Microsoft Technologies," a white paper on the TechNet Web site at:

  http://go.microsoft.com/fwlink/?linkid=29170

**Learning About Group Policy Objects That Control Configuration Settings for Internet Explorer 6**
You can control configuration settings for Internet Explorer 6 by using Group Policy objects (GPOs) on servers running Windows Server 2003. (You can also control the configuration of Internet Explorer by using the Internet Explorer Administration Kit. For more information, see "Learning about the Internet Explorer Administration Kit," later in this section.) For sources of information about Group Policy, see Appendix B: Resources for Learning About Group Policy.

To learn about specific Group Policy settings that can be applied to computers running Windows Server 2003 with SP1, see the following two sources of information:

- "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46278

- The Group Policy Settings Reference on the Microsoft Download Center Web site at:

  http://go.microsoft.com/fwlink/?linkid=29911

**Learning About the Internet Explorer Administration Kit**

With the deployment technologies available in the Internet Explorer Administration Kit (IEAK), you can efficiently deploy Internet Explorer and control the configuration of Internet Explorer across your organization. (You can also control the configuration of Internet Explorer by using Group Policy. For more information, see "Learning about Group Policy objects that control configuration settings for Internet Explorer 6," earlier in this section.)

A few of the features and resources in the IEAK include:

- **Internet Explorer Customization Wizard**. Step-by-step screens guide you through the process of creating customized browser packages that can be installed on client desktops.

- **IEAK Profile Manager**. After you deploy Internet Explorer, you can use the IEAK Profile Manager to change browser settings and restrictions automatically.

- **IEAK Toolkit**. The IEAK Toolkit contains a variety of helpful tools, programs, and sample files.

- **IEAK Help**. IEAK Help includes many conceptual and procedural topics that you can view by using the **Index**, **Contents**, and **Search** tabs. You can also print topics from IEAK Help.

For more information about the IEAK, see the Windows Web site at:

http://go.microsoft.com/fwlink/?linkid=29479

# Internet Information Services and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Internet Information Services (IIS) in Microsoft Windows Server 2003
- For servers from which you want to offer content on an intranet or the Internet, descriptions of some of the security-related features offered in IIS 6.0, and suggestions for other sources of information about security and IIS 6.0

| **Note** |
| --- |
| For servers from which you do not want to offer content on an intranet or the Internet, you do not need to remove IIS, since by default it is not installed with most products in the Windows Server 2003 family. The exception is Windows Server 2003, Web Edition, on which IIS is installed by default. If you use a server as a Web server and then deploy it for some other purpose, remove IIS from that server. |

- Controlling Internet printing
- Subcomponents that are part of IIS, with instructions for finding out which subcomponents are installed on a given server
- Viewing Help for IIS
- Other sources of information about IIS

It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization running servers that communicate across the Internet. This section, however, provides overview information as well as suggestions for other sources of information about balancing your organization's requirements for communication across the Internet with your organization's requirements for protection of networked assets.

**Benefits and Purposes of IIS**

IIS 6.0 is one of the optional components in products in the Windows Server 2003 family. IIS is a component that provides an easy way to publish information on the Internet or an intranet. In a managed environment, IIS is usually installed on selected servers only. IIS includes innovative security features and a broad range of administrative features for managing Web sites. By using programmatic features like Active Server Pages (ASP and ASP.NET), you can more easily create and deploy scalable, flexible Web applications.

IIS is not installed by default with products in the Windows Server 2003 family other than Windows Server 2003, Web Edition. IIS and related components can be added by using either **Add or Remove Programs** in Control Panel or Manage Your Server. After IIS 6.0 is installed, it is configured by default in a "locked down" state. The locked down state means that IIS 6.0 accepts requests for static files only, until it is configured to serve dynamic content. It also means that all time-outs and settings are set to restrictive defaults. You can enable or disable IIS 6.0 functionality based on the needs of your organization by using IIS Manager. You can also enable IIS 6.0 functionality through programmatic and command-line interfaces.

For more information about IIS features, including features related to security, see the following Web sites:

- The product information page for IIS 6.0 at:

  http://go.microsoft.com/fwlink/?LinkId=46005

- The technical overview document for IIS 6.0 at:

  http://go.microsoft.com/fwlink/?linkid=22805

- The IIS page on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=31134

If you have a Web site on which you want to use Microsoft .NET Passport for authentication and you also want to use Passport Manager Administration, a component available for Windows Server 2003, see Appendix I: Passport Manager Administration.

**Examples of Security-Related Improvements in IIS 6.0**

IIS 6.0 includes a variety of settings and features related to security, some of which are listed in the following table. For additional information about security-related improvements in the version of IIS 6.0 in Windows Server 2003 with SP1, see the links in the previous section.

**Examples of security-related settings and features in IIS 6.0**

| Setting or feature | Description |
|---|---|
| Disabling through Group Policy | With Windows Server 2003, domain administrators can prevent users from installing IIS 6.0 on their computers. |
| Running as an account with limited privileges | IIS 6.0 worker processes run in a user context with limited privileges by default. This drastically reduces the attack surface of the Web server. |
| Secure ASP | All functions built into ASP pages always run as an account with limited privileges (anonymous user). |
| Recognized file extensions | IIS 6.0 serves requests only to files that have recognized file extensions and rejects requests to file extensions it doesn't recognize. |
| Command-line tools not accessible to Web users | Attackers often take advantage of command-line tools that are executable through the Web server. In IIS 6.0, the command-line tools cannot be executed by the default Web server identity. |
| Write protection for content | Once attackers get access to a server, they try to deface Web sites. By preventing anonymous Web users from overwriting Web content, these attacks can be mitigated. |
| Time-outs and limits | Product settings are set to aggressive and secure defaults. |
| Upload data limitations | Administrators can limit the size of data that can be uploaded to a server. |
| Buffer overflow protection | The Windows Administration Service in IIS will detect if a worker process had a buffer overflow and will exit that process. |
| File verification | The core server verifies that the requested content exists before it gives the request to a request handler (Internet Server Application Programming Interface [ISAPI] extension). |

For more information about creating Web sites with IIS 6.0 and maintaining appropriate levels of awareness and control over the communication to and from those sites, see the IIS Help. For information about viewing the Help, see "To View Help After Installing IIS," later in this section.

**Controlling Internet Printing**

Internet printing makes it possible for clients to use printers located anywhere in the world by sending print jobs using Hypertext Transfer Protocol (HTTP). Additionally, a computer running Windows Server 2003 can use IIS to create a Web page that provides information about printers and provides the transport for printing over the Internet.

For Internet printing, it is important to consider both the server and the client:

- **Server**: Internet printing is an optional component (not installed by default) of IIS 6.0. A server running Windows Server 2003 can be configured to act as a print server allowing Internet printing. In a managed environment, you might want to ensure that the Internet printing subcomponent of IIS is not installed. For information about how to do this, see "Procedures for Checking or Controlling the Installation of IIS Subcomponents," later in this section.

- **Client**: Clients (typically, running Windows XP, not Windows Server 2003) can install an Internet printer using a Web browser, the Add Printer Wizard, or the Run dialog box. To control whether clients can support Internet printing, see the section about Internet printing in the white paper titled "Using Windows XP Professional with Service Pack 2 in a Managed Environment: Controlling Communication with the Internet." You can view this white paper on the TechNet Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29133

**Answer File Entries and Registry Keys for IIS Subcomponents**

For reference purposes, the following table shows the syntax for answer file entries associated with IIS in the Windows Server 2003 family as well as the corresponding registry keys. Do not change the registry keys. They are shown for use in a script that could check whether a particular component is installed on a particular server. A registry key value of 0x00000000 means the component is not installed, and a value of 0x00000001 means the component is installed.

| **Note** |
| --- |
| For more details about answer file entries related to IIS components, follow the steps in "To View Help After Installing IIS," later in this section, and then search for the topic called "Installing IIS." In that topic, look for a table showing the answer file entries. |

Answer file entries and registry keys associated with IIS subcomponents for the Windows Server 2003 family

| **IIS subcomponent** | **Syntax for answer file entry (in the [Components] section)** | **Registry key (for use in a script that checks whether a component is installed): 0x00000000 means it is not installed; 0x00000001 means it is installed** |
| --- | --- | --- |
| IIS common files | iis_common = On \| Off | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\CurrentVersion\ Setup\OC Manager\Subcomponents\ iis_common |
| Active Server Pages (ASP) for IIS | iis_asp = On \| Off | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\CurrentVersion\ Setup\OC Manager\Subcomponents\ iis_asp |
| File Transfer Protocol (FTP) service | iis_ftp = On \| Off | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\CurrentVersion\ Setup\OC Manager\Subcomponents\ iis_ftp |
| IIS Manager (Microsoft Management Console [MMC] snap-in) | iis_inetmgr = On \| Off | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\CurrentVersion\ Setup\OC Manager\Subcomponents\ iis_inetmgr |
| Internet Data Connector | iis_internetdataconnector = On \| Off | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\CurrentVersion\ Setup\OC Manager\Subcomponents\ iis_internetdataconnector |
| Network News Transfer Protocol (NNTP) service | iis_nntp = On \| Off | HKEY_LOCAL_MACHINE\Software\ Microsoft\Windows\CurrentVersion\ Setup\OC Manager\Subcomponents\ iis_nntp |

| | | |
|---|---|---|
| Server-Side Includes | iis_serversideincludes = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\iis_serversideincludes |
| Simple Mail Transfer Protocol (SMTP) service | iis_smtp = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\iis_smtp |
| Web Distributed Authoring and Versioning (WebDAV) publishing | iis_webdav = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\iis_webdav |
| World Wide Web (WWW) service | iis_www = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\iis_www |
| Remote administration (HTML) | sakit_web = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\sakit_web |
| Internet Server Application Programming Interface (ISAPI) for Background Intelligent Transfer Service (BITS) server extensions | BitsServerExtensionsISAPI = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\bitsserverextensionsisapi |
| Background Intelligent Transfer Service (BITS) server extensions snap-in | BitsServerExtensionsManager = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\bitsserverextensionsmanager |
| FrontPage server extensions | fp_extensions = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\fp_extensions |
| Internet printing | inetprint = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\inetprint |

| | | |
|---|---|---|
| ActiveX control and sample pages for hosting Terminal Services client connections over the Web | TSWebClient = On \| Off | HKEY_LOCAL_MACHINE\Software\<br>Microsoft\Windows\CurrentVersion\<br>Setup\OC Manager\Subcomponents\<br>TSWebClient |

**Note**

For several of the subcomponents in the previous table, the software for the subcomponent is installed regardless of the answer-file entry, but the subcomponent cannot be used unless the answer-file entry is set to On (or the procedure is followed for installing the subcomponent through **Add or Remove Programs** in Control Panel). These subcomponents are Internet Data Connector, Server-Side Includes, and WebDAV publishing.

**Procedures for Checking or Controlling the Installation of IIS Subcomponents and the IIS Lockdown Tool**

The following procedures explain how to:

- View the registry keys listed in the table in the previous subsection
- View or change the IIS components currently installed on a computer running a product in the Windows Server 2003 family
- Specify answer file entries that control whether IIS subcomponents are included during unattended installation

**To View Registry Keys Related to IIS Subcomponents**

1. Open Registry Editor by clicking **Start**, clicking **Run**, and then typing **regedit**.

   **Caution**

   Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. You can also use the Last Known Good Configuration startup option if you encounter problems after manual changes have been applied.

2. Navigate to:

   HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Setup\OC Manager\Subcomponents\.

3. View the registry keys listed in the table in the previous subsection, and find the value associated with each key. A value of 0x00000000 means the component is not installed. A value of 0x00000001 means the component is installed.

4. Close **Registry Editor**.

**To View or Change the IIS Components Currently Installed on a Computer Running Windows Server 2003**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. Click **Add/Remove Windows Components** (on the left).
4. Select **Application Server** and then click **Details**.
5. Find **Internet Information Services (IIS)** in the list, and perform one of the following steps:

   - If IIS is installed and you want to remove it, clear the check box for IIS and complete the wizard.

- If IIS is not installed and you want to add the default set of IIS subcomponents, select the check box for IIS and complete the wizard.

- If you want to view or select from the list of IIS subcomponents, after selecting IIS, click **Details**.

| **Note** |
| --- |
| The Internet Printing component is in the list of subcomponents that appears when you click **Details**. |

6. Follow the instructions to complete the Windows Components Wizard.

**To Specify Answer File Entries That Control Whether IIS Subcomponents are Included During Unattended Installation**

1. Using the methods you prefer for unattended installation or remote installation, create an answer file.

2. In the [Components] section of the answer file, add the appropriate entries listed in the table in "Answer File Entries and Registry Keys for IIS Subcomponents," earlier in this section. Ensure that the entries specify **Off** for components you do not want to install and **On** for components you want to install.

   If no IIS subcomponents are listed in an answer file for unattended installation of a product in the Windows Server 2003 family other than Windows Server 2003, Web Edition, the IIS subcomponents are not installed by default.

| **Note** |
| --- |
| For more details about answer file entries related to IIS components, follow the steps in the next procedure, "To View Help After Installing IIS," and then search for the Help topic called "Installing IIS." In that topic, look for a table showing the answer file entries. |

**To View Help After Installing IIS**

1. After installing IIS (including the IIS Manager subcomponent, which is included in default installations of IIS), click **Start**.

2. Either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

3. Double-click **Administrative Tools**, and then click **Internet Information Services (IIS) Manager**.

4. Click the **Help** menu and then click **Help Topics**.

**To Obtain the IIS Lockdown Tool**

- The IIS Lockdown Tool, designed for use on computers on which IIS is installed, is available from the Microsoft TechNet Web site at:

  http://go.microsoft.com/fwlink/?linkid=29896

**Related Links**

For more information about IIS, see the following Web sites:

# Internet Protocol Version 6 (IPv6) and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- An introduction to the IPv6 protocol
- The benefits of the IPv6 protocol
- How the IPv6 protocol can be used across the Internet
- How to control the IPv6 protocol to limit the flow of information to and from the Internet
- How to monitor and troubleshoot the IPv6 protocol after configuration is complete

**An Introduction to the IPv6 Protocol**

The current version of the Internet Protocol (known as IP version 4 or IPv4) has not been substantially changed since 1981, when the Internet Engineering Task Force (IETF) published the definitive specification of IP (RFC 791). IPv4 has proven to be robust, easily implemented, and interoperable. It has stood the test of scaling an internetwork to a global utility the size of today's Internet, which is a tribute to the protocol's initial design.

The initial design, however, did not anticipate the exponential growth of the Internet and the exhaustion of the IPv4 address space, or the effort required to maintain routing information. Because of the way in which IPv4 network IDs are allocated, there are routinely over 70,000 routes in the routing tables of Internet backbone routers. Most current IPv4 implementations are configured either manually or through a stateful address configuration protocol such as the Dynamic Host Configuration Protocol (DHCP). With more computers and devices using IP, there is a need for a simpler and more automatic configuration of addresses and other configuration settings that do not rely on the administration of a DHCP infrastructure.

Another factor driving the development of IPv6 is the need for improved security. Private communication over a public medium like the Internet requires encryption services that protect the data sent from being viewed or modified in transit. There is a standard for providing security for IPv4 packets (known as Internet Protocol security or IPSec). In IPv4, however, this standard is optional and proprietary solutions are prevalent. In IPv6, IPSec support is required.

To address these concerns, the IETF has developed a suite of protocols and standards known as IP version 6 (IPv6). This new version incorporates the concepts of many proposed methods for updating the IPv4 protocol.

For the latest set of RFCs and Internet drafts describing IPv6 and IPv4 coexistence and migration technologies, see the Internet Engineering Task Force (IETF) Web site at:

http://go.microsoft.com/fwlink/?LinkId=29136

(Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.)

**Benefits and Purposes of the IPv6 Protocol**

An IPv6 address is four times as large as an IPv4 address. The global addresses used on the IPv6 portion of the Internet are designed to create an efficient, hierarchical, and summarized routing infrastructure that addresses the common occurrence of multiple levels of Internet service providers. On the IPv6 Internet, the backbone routers have an efficient and hierarchical addressing and routing infrastructure that uses smaller routing tables.

IPv6 supports both stateful address configuration (such as address configuration in the presence of a DHCP server) and stateless address configuration (address configuration in the absence of a DHCP server). The support for IPSec is an IPv6 protocol suite requirement. This requirement provides a standards-based solution for network security needs and promotes interoperability between different IPv6 implementations.

The new format of the IPv6 header is designed to minimize header validation and processing. In addition, a new field in the IPv6 header helps to define how traffic is handled and identified for quality of service delivery.

IPv6 can be extended for new features by adding extension headers after the IPv6 header. Unlike the IPv4 header, which can only support 40 bytes of options, the size of IPv6 extension headers is only constrained by the size of the IPv6 packet.

The new Neighbor Discovery protocol in IPv6 is a series of Internet Control Message Protocol for IPv6 (ICMPv6) messages that

manage the interaction of neighboring nodes. Neighbor Discovery replaces Address Resolution Protocol (ARP), ICMPv4 Router Discovery, and ICMPv4 Redirect messages with efficient multicast and unicast messages.

The following table compares the key features of the IPv4 and IPv6 protocols.

**Comparison of Features in IPv4 and IPv6**

| IPv4 | IPv6 |
|---|---|
| Source and destination addresses are 32 bits (4 bytes) in length. | Source and destination addresses are 128 bits (16 bytes) in length. |
| IPSec support is optional. | IPSec support is required. |
| No identification of packet flow for Quality of Service (QoS) handling by routers is present within the IPv4 header. | Packet flow identification for QoS handling by routers is included in the IPv6 header using the Flow Label field. |
| Fragmentation is done by both routers and the sending host. | Fragmentation is not done by routers, only by the sending host. |
| Header includes a checksum. | Header does not include a checksum. |
| Header includes options. | All optional data is moved to IPv6 extension headers. |
| Address Resolution Protocol (ARP) uses broadcast ARP Request frames to resolve an IPv4 address to a link layer address. | ARP Request frames are replaced with multicast Neighbor Solicitation messages. |
| Internet Group Management Protocol (IGMP) is used to manage local subnet group membership. | IGMP is replaced with Multicast Listener Discovery (MLD) messages. |
| ICMP Router Discovery is used to determine the IPv4 address of the best default gateway and is optional | ICMP Router Discovery is replaced with ICMPv6 Router Solicitation and Router Advertisement messages and is required. |
| Broadcast addresses are used to send traffic to all nodes on a subnet. | There are no IPv6 broadcast addresses. Instead, a link-local scope all-nodes multicast address is used. |
| Must be configured either manually or through DHCP. | Does not require manual configuration or DHCP. |
| Uses host address (A) resource records in the Domain Name System (DNS) to map host names to IPv4 addresses. | Uses host address (AAAA) resource records in the Domain Name System (DNS) to map host names to IPv6 addresses. |
| Uses pointer (PTR) resource records in the INADDR.ARPA DNS domain to map IPv4 addresses to host names. | Uses pointer (PTR) resource records in the IP6.ARPA DNS domain to map IPv6 addresses to host names. |

For more information about Internet Protocol version 6, see the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=29519

**Using the IPv6 Protocol Across the IPv4 Internet**

On networks that do not have native support for IPv6 traffic, the IPv6 traffic is transmitted on the network by encapsulating the IPv6 packets with an IPv4 header, a technique known as IPv6 tunneling. One IPv6 tunneling technology that provides IPv6 connectivity across the IPv4 Internet is 6to4.

For more information about 6to4, see "Connection of IPv6 Domains via IPv4 Clouds," in RFC 3056 on the IETF Web site at:

http://go.microsoft.com/fwlink/?LinkId=29898

(Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.)

If native IPv6 connectivity does not exist, a 6to4-capable computer makes a Domain Name System (DNS) query for 6to4 relay routers. By default, this DNS query is presently set to "6to4.ipv6.microsoft.com" and the response contains a well-known IPv4 anycast address. (An *anycast* address is one that identifies multiple nodes and interfaces.) As more 6to4 relay routers are added in the future, this address will be assigned to more computers that are owned by various Internet service providers (ISPs).

If the DNS query provides multiple addresses, the host selects an appropriate 6to4 relay router by sending an IPv6 packet to

each one and choosing the one that responds first.

| Note |
| --- |
| 6to4 tunneling is enabled when IPv6 services are not native to your network and there is an assigned public IPv4 Internet address. |

The use of IPv6 in Microsoft Windows Server 2003 is currently supported only when IPv4 is also installed.

**Controlling IPv6 Protocol Traffic**

You can stop the ingress or egress of IPv6 traffic on your network by configuring your network firewalls to block all IPv6 packets. For 6to4 traffic, you can configure your firewalls to block all IPv4 packets that include the IPv6 protocol designation of 41 in the Protocol field of the IPv4 packet header.

The default settings for a member of the Users group do not permit those users to install networking protocols. You should limit who is allowed to install the IPv6 protocol stack on network computers by carefully limiting the number of users that have administrative logon credentials.

You can use the Active Directory directory service and Group Policy to filter and control the ability to add new networking protocols or modify existing networking configurations. For more information about these configuration methods, see Appendix B: Resources for Learning About Group Policy. For information about installing and uninstalling IPv6, see the list of procedures in the next subsection.

**Procedures for Configuration of the IPv6 Protocol**

Installing and uninstalling the IPv6 protocol stack can be done by using the Network Connections folder or the command prompt.

The following procedures tell how to find information about security in relation to IPv6 and describe installing and uninstalling the IPv6 protocol stack by using the Network Connections folder.

**To Find Information About Security in Relation to IPv6**

1. View updated product documentation for Windows Server 2003 products on the Web at:

   http://go.microsoft.com/fwlink/?linkid=29881

2. In the table of contents, navigate as follows:

   Network Services\Managing Core Network Services\IP Version 6\IPv6 Concepts\IPv6 Overview

3. View topics below “IPv6 Overview,” especially “Security information for IPv6.”

**To Install IPv6 Using the Network Connections Folder**

1. Click **Start**.

2. Either click **Control Panel** and then double-click **Network Connections**, or point to **Settings**, click **Control Panel**, and then double-click **Network Connections**.

3. Right-click any local area connection, and then click **Properties**.

4. Click **Install**.

5. In the **Select Network Component Type** dialog box, click **Protocol**, and then click **Add**.

6. In the **Select Network Protocol** dialog box, click **Microsoft TCP/IP version 6**.

**To Uninstall IPv6 Using the Network Connections Folder**

1. Click **Start**.

2. Either click **Control Panel** and then double-click **Network Connections**, or point to **Settings**, click **Control Panel**, and then double-click **Network Connections**.

3. Right-click any local area connection, and then click **Properties**.

4. Click **Microsoft TCP/IP version 6** in the list of installed components, and then click **Uninstall**.

5. Restart the computer.

The following two procedures describe installing and uninstalling the IPv6 protocol stack from the command prompt.

**To Install IPv6 on a Computer from the Command Prompt**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **netsh interface ipv6 install**, and then press ENTER.

**To Uninstall IPv6 from a Computer from the Command Prompt**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **netsh interface ipv6 uninstall**, and then press ENTER.

3. Restart the computer.

| **Note** |
| --- |
| The IPv6 configuration procedures require that you have administrative credentials on the computer. |

**Monitoring and Troubleshooting the IPv6 Protocol**
The following procedures describe ways to view TCP/IP configurations.

**To Display the Complete List of TCP/IP Interface Configurations for a Computer from the Command Prompt**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **ipconfig /all**, and then press ENTER.

**To Display the TCP/IP Routing Table from the Command Prompt**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **route print**, and then press ENTER.

**Troubleshooting a Command-line Installation Error**
The installation of the IPv6 protocol stack requires that you have administrative credentials. If you attempt to install the IPv6 protocol from the command line without having the required account credentials, the result is an "Access is denied" error (0x800700005).

# NetMeeting and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of NetMeeting® conferencing software
- Using NetMeeting in a managed environment
- How NetMeeting communicates with sites on the Internet
- How to control NetMeeting to limit the flow of information to and from the Internet

**Benefits and Purposes of NetMeeting**

NetMeeting conferencing software is a feature of Windows Server 2003 with Service Pack 1 (SP1) that enables real-time communication and collaboration over the Internet or an intranet. From a computer running the Windows 95, Windows 98, Windows NT® 4.0, Windows 2000, or Windows XP operating system, users can communicate over a network with real-time voice and video technology. Users can work together on virtually any Windows application, exchange or mark up graphics on an electronic whiteboard, transfer files, or use the text-based chat program.

NetMeeting helps small and large organizations take full advantage of their corporate intranet for real-time communication and collaboration. On the Internet, connecting to other NetMeeting users is made easy with Internet Locator Service (ILS), enabling participants to call each other from a dynamic directory within NetMeeting or from a Web page. Features include remote desktop sharing, virtual conferencing using Microsoft Outlook, security features, and the ability to embed the NetMeeting user interface in an organization's intranet Web pages.

To learn more about the NetMeeting features, see "Microsoft NetMeeting 3 Features" on the Microsoft TechNet Web site at:

http://go.microsoft.com/fwlink/?LinkId=29175

**Overview: Using NetMeeting in a Managed Environment**

NetMeeting supports communication standards for audio, video, and data conferencing. NetMeeting users can communicate and collaborate with users of other standards-based, compatible products. They can connect by modem, Integrated Services Digital Network (ISDN), or local area network (LAN) using Transmission Control Protocol/Internet Protocol (TCP/IP). In addition, support for Group Policy in NetMeeting makes it easy for administrators to centrally control and manage the NetMeeting work environment.

You can use Active Directory directory service and Group Policy to configure NetMeeting to help meet your security requirements. You can also control the configuration of NetMeeting by using the NetMeeting Resource Kit. For more information about the NetMeeting Resource Kit, see "Alternate Methods for Controlling NetMeeting," later in this section.

NetMeeting components and features require that several ports be open from the firewall. For more information, see "NetMeeting and Firewalls," later in this section.

**How NetMeeting Communicates with Sites on the Internet**

NetMeeting provides an infrastructure for communication between network applications and services. In this infrastructure, NetMeeting is both an application and a platform for other applications or services. The components and services in NetMeeting provide real-time communication and collaboration over the Internet or an organization's intranet.

NetMeeting audio and video conferencing features are based on the H.323 standard infrastructure, which enables NetMeeting to interoperate with other H.323 standards-based products. (H.323 is a standard approved by the International Telecommunication Union [ITU] that defines how audiovisual conferencing data is transmitted across networks.) NetMeeting data conferencing features are based on the T.120 infrastructure, enabling NetMeeting to interoperate with other T.120 standards-based products. (The T.120 standard is a suite of communication and application protocols developed for real-time, multipoint data connections and conferencing.)

Detailed information about the H.323 and T.120 standards is beyond the scope of this white paper. Further information can be found on the following sites.

- For more information about the H.323 standard and NetMeeting, see Part 3, Chapter 11, "Understanding the H.323 Standard," in the *NetMeeting 3.0 Resource Kit* at:

http://go.microsoft.com/fwlink/?LinkId=36134

- For more information about the H.323 specification, see the Web sites of the International Telecommunication Union (ITU) and the International Multimedia Telecommunications Consortium (IMTC) at:

  http://go.microsoft.com/fwlink/?LinkId=29510

  http://www.imtc.org/

- To learn more about the T.120 standard and NetMeeting, see Part 3, Chapter 10, "Understanding the T.120 Standard," in the *NetMeeting 3.0 Resource Kit* at:

  http://go.microsoft.com/fwlink/?LinkId=36134

- For more information about the T.120 architecture, see the International Multimedia Teleconferencing Consortium (IMTC) Web site at:

  http://www.imtc.org/

(Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.)

**NetMeeting Port Assignments**
When you use NetMeeting to call other users over the Internet, several IP ports are required to establish the outbound connection. The following table describes the port numbers, their functions, and the resulting connection.

**Port Assignments for NetMeeting**

| Port | Function | Outbound Connection |
|---|---|---|
| 389 | Internet Locator Service (ILS) | TCP |
| 522 | User Location Service (ULS) | TCP |
| 1503 | T.120 | TCP |
| 1720 | H.323 call setup | TCP |
| 1731 | Audio call control | TCP |
| 1024 through 65535 (dynamic) | H.323 call control | TCP |
| 1024 through 65535 (dynamic) | H.323 streaming | Real-Time Transfer Protocol (RTP) over User Datagram Protocol (UDP) |

For more information about NetMeeting communication ports and firewall configuration topics, see Part 2, Chapter 4, "Firewall Configuration" in the *NetMeeting 3.0 Resource Kit* at:

http://go.microsoft.com/fwlink/?LinkId=36134

**Controlling NetMeeting to Limit the Flow of Information to and from the Internet**
You can configure NetMeeting by using Group Policy objects (GPOs) on servers running Windows Server 2003. (You can also control the configuration of NetMeeting by using the NetMeeting Resource Kit. For more information, see "Alternate Methods for Controlling NetMeeting," later in this section.)

This subsection includes information about the following topics:

- NetMeeting and Group Policy
- NetMeeting security
- NetMeeting and firewalls

- Establishing a NetMeeting connection with a firewall
- Firewall limitations for NetMeeting

**NetMeeting and Group Policy**

Group Policy can be used to define the default NetMeeting configuration settings that will be automatically applied to users and computers. These settings determine which NetMeeting features and capabilities are available to a particular computer or to a particular group of users. Through the use of Group Policy you can enable, disable, or set configuration options for NetMeeting features or capabilities.

For additional information about Group Policy, see Appendix B: Resources for Learning About Group Policy.

You can use Group Policy to manage the following NetMeeting configuration options for users in your organization:

- NetMeeting Group Policy setting for computers
- NetMeeting Group Policy settings for users

**Configuring NetMeeting Setting for Computers Through Group Policy**

In Group Policy, the NetMeeting policy setting for computers is located in Computer Configuration\Administrative Templates\Windows Components\NetMeeting:

- **Disable remote Desktop Sharing**

For more information about how to use Group Policy to manage the NetMeeting computer setting, see "To Disable the NetMeeting Remote Desktop Sharing Feature Through Group Policy," later in this section.

| **Note** |
| --- |
| Group Policy settings for computers are applied when the operating system starts and during the periodic refresh cycle. |

**Configuring NetMeeting Settings for Users Through Group Policy**

The Group Policy configuration options that apply to users include general NetMeeting settings, and settings for application sharing, audio and video, and the options page.

**Configuring General NetMeeting Settings for Users Through Group Policy**

In Group Policy, general NetMeeting policy settings for users are located in User Configuration\Administrative Templates\Windows Components\NetMeeting:

- **Enable Automatic Configuration**: Configures NetMeeting to download settings for users each time it starts.
- **Disable Directory services**: Disables the directory feature—users will not log on to a directory server when NetMeeting starts. Users will not be able to view or make calls using the NetMeeting directory.
- **Prevent adding Directory servers**: Prevents the user from adding directory servers to the list of available directory servers they can use for placing calls.
- **Prevent viewing Web directory**: Prevents the user from viewing directories as Web pages in a browser.
- **Set the intranet support Web page**: Sets the Web address that NetMeeting will display when users choose the Online Support command from the NetMeeting **Help** menu.
- **Set Call Security options**: Sets the level of security for outgoing and incoming NetMeeting calls.
- **Prevent changing Call placement method**: Prevents the user from changing the way calls are placed, either directly or by means of a gatekeeper server.
- **Prevent automatic acceptance of Calls**: Prevents the user from turning on automatic acceptance of incoming calls.

- **Allow persisting automatic acceptance of Calls**: Sets automatic acceptance of incoming calls to be persistent.
- **Prevent sending files**: Prevents users from sending files to others in a conference.
- **Prevent receiving files**: Prevents users from receiving files from others in a conference.
- **Limit the size of sent files**: Sets the maximum file size that can be sent to others in a conference.
- **Disable Chat**: Disables the chat feature of NetMeeting.
- **Disable NetMeeting 2.x Whiteboard**: Disables the NetMeeting 2.x Whiteboard feature. (The 2.x feature provides compatibility with earlier versions of NetMeeting only.)
- **Disable Whiteboard**: Disables the whiteboard feature of NetMeeting.

| **Note** |
| --- |
| Group Policy settings for users are applied when a user logs on to the computer and during the periodic refresh cycle. |

**Configuring NetMeeting Application Sharing Settings Through Group Policy**

Group Policy settings for the NetMeeting Application Sharing feature are located in User Configuration\Administrative Templates\Windows Components\NetMeeting\Application Sharing:

- **Disable application Sharing**: Disables the NetMeeting application sharing feature completely. Users will not be able to host or view shared applications.
- **Prevent Sharing**: Prevents users from sharing anything themselves. They will still be able to view shared applications or desktops from others.
- **Prevent Desktop Sharing**: Prevents users from sharing their Windows desktop. They will still be able to share individual applications.
- **Prevent Sharing Command Prompts**: Prevents the user from sharing command prompts. Enabling this prevents the user from inadvertently sharing applications, since command prompts can be used to start other applications.
- **Prevent Sharing Explorer windows**: Prevents the user from sharing Windows Explorer windows. Enabling this prevents the user from inadvertently sharing applications, since Windows Explorer windows can be used to start other applications.
- **Prevent Control**: Prevents users from allowing others in a conference to control what they have shared. Enabling this enforces a read-only mode whereby the other participants cannot change the data in the shared application.
- **Prevent Application Sharing in true color**: Prevents users from sharing applications in true color, which uses more bandwidth.

| **Note** |
| --- |
| Group Policy settings for users are applied when a user logs on to the computer and during the periodic refresh cycle. |

**Configuring NetMeeting Audio and Video Settings Through Group Policy**

Group Policy settings for NetMeeting audio and video are located in User Configuration\Administrative Templates\Windows Components\NetMeeting\Audio & Video:

- **Limit the bandwidth of Audio and Video**: Configures the maximum bandwidth, specified in kilobytes per second, to be used for audio and video.

- **Disable Audio:** Disables the audio feature of NetMeeting. Users will not be able to send or receive audio.

- **Disable full duplex Audio**: Disables the full duplex audio mode. Users will not be able to listen to incoming audio while speaking into the microphone. Older audio hardware may not perform well when full duplex audio is enabled.

- **Prevent changing DirectSound Audio setting**: Prevents the user from changing the DirectSound® audio setting. DirectSound has better audio quality, but earlier audio hardware may not support DirectSound.

- **Prevent sending Video**: Prevents the user from sending video. Setting this option does not prevent the user from receiving video.

- **Prevent receiving Video**: Prevents the user from receiving video. Setting this option does not prevent the user from sending video.

| **Note** |
| --- |
| Group Policy settings for users are applied when a user logs on to the computer and during the periodic refresh cycle. |

**Configuring NetMeeting Options Settings Through Group Policy**

Group Policy settings for NetMeeting options are located in User Configuration\Administrative Templates\Windows Components\NetMeeting\Options Page. These settings correspond to elements of the NetMeeting Options page. To view this page, in NetMeeting, click **Tools** and then click **Options**. These Group Policy settings are as follows:

- **Hide the General page**: Removes the **General** tab on the **NetMeeting Options** page.

- **Disable the Advanced Calling button**: Disables the **Advanced Calling** button from the **General** page.

- **Hide the Security page**: Removes the **Security** tab on the NetMeeting **Options** page.

- **Hide the Audio page**: Removes the **Audio** tab on the NetMeeting **Options** page.

- **Hide the Video page**: Removes the **Video** tab on the NetMeeting **Options** page.

| **Note** |
| --- |
| Group Policy settings for users are applied when a user logs on to the computer and during the periodic refresh cycle. |

To learn about specific Group Policy settings that can be applied to computers running Windows Server 2003 SP1, see the Group Policy Settings Reference on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=29911

**NetMeeting Security**

The NetMeeting security architecture for data conferencing takes advantage of the existing, standards-compliant security features of Windows Server 2003 SP1 and Microsoft Internet Explorer. The NetMeeting security architecture utilizes a 40-bit encryption technology and has the following security features.

- **Password protection**: This feature enables the user to create or participate in a meeting that requires a password to join. Password protection helps to ensure that only authorized users participate in a password-protected meeting. A password is also required to use the remote desktop sharing feature.

- **User authentication**: This feature provides a way to verify the identity of a caller or meeting participant using a certificate.

- **Data encryption**: This feature helps to protect data exchanged during a meeting so that it is not easily read by any unauthorized parties that may intercept the data. The 40-bit data encryption applies to the whiteboard and chat features, shared applications, and transferred files. Audio and video communications are not encrypted.

NetMeeting security features integrate with security in Windows Server 2003 SP1 and Internet Explorer in a variety of ways, including the following:

- NetMeeting uses the NetMeeting private certificate store to provide personal certificates for user authentication and data encryption.
- NetMeeting uses the Windows certificate store to maintain NetMeeting certificates.
- NetMeeting uses Security Support Provider Interface (SSPI) functions to generate and process security tokens.

These security features can be implemented by an administrator or a NetMeeting user. Using the NetMeeting Resource Kit Wizard or Group Policy in NetMeeting, the administrator can enforce security settings that apply to all users. If allowed by the administrator, NetMeeting users can also select their own security settings in the NetMeeting user interface (UI) and change security settings for individual calls.

You can use the following sources to learn more about NetMeeting configuration and security topics.

- For more information about the NetMeeting Resource Kit Wizard, see Part 2, Chapter 2, "Resource Kit Wizard" in the *NetMeeting 3.0 Resource Kit* at:

  http://go.microsoft.com/fwlink/?LinkId=36134

- For more information about the security features available in NetMeeting, see Part 2, Chapter 5, "NetMeeting Security" in the *NetMeeting 3.0 Resource Kit* at:

  http://go.microsoft.com/fwlink/?LinkId=36134

**NetMeeting and Firewalls**

You can configure firewall components in a variety of ways, depending on your organization's specific security policies and overall operations. While most firewalls are capable of allowing primary (initial) and secondary (subsequent) Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) connections, it is possible that they are configured to support only specific connections based on security considerations. For example, some firewalls support only primary TCP connections, which some professionals view as the most reliable.

For NetMeeting multipoint data conferencing—program sharing, whiteboard, chat, file transfer, and directory access—your firewall only needs to pass through primary TCP connections on assigned ports. NetMeeting audio and video features require secondary TCP and UDP connections on dynamically assigned ports.

| **Note** |
| --- |
| NetMeeting audio and video features require secondary TCP and UDP connections. Therefore, when you establish connections through firewalls that accept only primary TCP connections, you are not able to use the audio or video features of NetMeeting. |

Detailed firewall configuration procedures for NetMeeting are beyond the scope of this white paper. For more information about NetMeeting firewall connections, see Part 2, Chapter 4, "Firewall Configuration" in the *NetMeeting 3.0 Resource Kit*, particularly the section titled, "Establishing a NetMeeting Connection with a Firewall" at:

http://go.microsoft.com/fwlink/?LinkId=36134

Microsoft NetMeeting can be configured to work with an organization's existing firewall security. Because of limitations in most firewall technology, however, few products are available that enable you to securely transport inbound and outbound NetMeeting calls containing audio, video, and data across a firewall. You should consider carefully the relative security risks of enabling different parts of a NetMeeting call in your firewall product. You must especially consider the security risks involved when modifying your firewall configuration to enable any component of an inbound NetMeeting call.

Some organizations have security or policy concerns that require them to limit how fully they support NetMeeting in their firewall configuration. These concerns are based on network capacity planning or weaknesses in the firewall technology being used. For example, security concerns might prohibit an organization from accepting any inbound or outbound flow of UDP data through the firewall. Because these UDP connections are required for NetMeeting audio and video features, disabling this function excludes audio and video features in NetMeeting for calls through the firewall. The organization can still use

NetMeeting data conferencing features such as program sharing, file transfer, whiteboard, and chat for calls through the firewall by allowing only TCP connections on ports 522 and 1503.

For more information about NetMeeting firewall security, see the section titled "Security and Policy Concerns," in the chapter of the NetMeeting Resource Kit from the previous link (scroll through the chapter until you find the section).

**Establishing a NetMeeting Connection with a Firewall**
When you use NetMeeting to call other users over the Internet, several IP ports are required to establish the outbound connection.

If you use a firewall to connect to the Internet, it must be configured so that the following IP ports are not blocked:

- TCP ports 389, 522, 1503, 1720, and 1731
- TCP and UDP ports (1024 through 65535)

To establish outbound NetMeeting connections through a firewall, the firewall must be configured to do the following:

- Pass through primary TCP connections on ports 389, 522, 1503, 1720, and 1731.
- Pass through secondary TCP and UDP connections on dynamically assigned ports (1024 through 65535).

The H.323 call setup protocol dynamically negotiates a TCP port for use by the H.323 call control protocol. Also, both the audio call control protocol and the H.323 call setup protocol dynamically negotiate UDP ports for use by the H.323 streaming protocol, the Real-Time Transfer Protocol (RTP). In NetMeeting, two UDP ports are designated on each side of the firewall for audio and video streaming, for a total of four ports for inbound and outbound audio and video. These dynamically negotiated ports are selected arbitrarily from all ports that can be assigned dynamically.

NetMeeting directory services require either port 389 or port 522, depending on the type of server you are using. The Microsoft Internet Locator Service (ILS), which supports LDAP for NetMeeting, requires port 389. The Microsoft User Location Service (ULS), developed for NetMeeting 1.0, requires port 522.

**Firewall Limitations for NetMeeting**
Some firewalls cannot support an arbitrary number of virtual internal IP addresses, or cannot do so dynamically. With these firewalls, you can establish outbound NetMeeting connections from computers inside the firewall to computers outside the firewall, and you can use the audio and video features of NetMeeting. Users outside the organization cannot, however, establish inbound connections from outside the firewall to computers inside the firewall. Typically, this restriction is due to limitations in the network implementation of the firewall.

| **Note** |
| --- |
| Some firewalls are capable of accepting only certain protocols and cannot handle TCP connections. For example, if your firewall is a Web proxy server with no generic connection-handling mechanism, you will not be able to use NetMeeting through the firewall. |

You can use the following sources to learn more about NetMeeting configuration and firewall topics.

- For more information about NetMeeting firewall connections, see Part 2, Chapter 4, "Firewall Configuration" in the *NetMeeting 3.0 Resource Kit*, particularly the section titled "Establishing a NetMeeting Connection with a Firewall" at:

  http://go.microsoft.com/fwlink/?LinkId=36134

- For more information about using NetMeeting and your firewall, see article 158623, "How to Establish NetMeeting Connections through a Firewall" in the Microsoft Knowledge Base at:

  http://go.microsoft.com/fwlink/?LinkId=29206

**Alternate Methods for Controlling NetMeeting**
You can create customized installation options for specific users or groups within your organization by using the NetMeeting Resource Kit Wizard. Additionally, you can use the NetMeeting Resource Kit Wizard to control user and computer access rights by creating custom configurations of client settings and specific features that you have selected to restrict or allow. For

example, you can control audio and video access, set data throughput limits and network speeds, and choose to display online support. The Resource Kit Wizard can also help you set up various configurations of NetMeeting for different types of users and different levels of security. It can help you save network bandwidth by restricting specific features. You can also use the Resource Kit Wizard both to change registry settings for all NetMeeting users and to implement such changes globally.

| **Note** |
| --- |
| By selecting certain options in the Resource Kit Wizard, be aware that you may be changing the NetMeeting user interface. For example, if you click **Restrict the Use of Video**, the **Video** tab does not appear in the NetMeeting user's **Options** dialog box. |

Part 4 of the Resource Kit for NetMeeting has an appendix that provides detailed information about responding to NetMeeting problems, including problem descriptions, causes, and resolutions.

For more information about the *NetMeeting 3.0 Resource Kit*, see the Microsoft TechNet Web site at:

http://go.microsoft.com/fwlink/?LinkId=36134

**Procedures for Configuring NetMeeting**

NetMeeting is designed to enhance the enterprise environment and enable users to communicate internally and externally with other NetMeeting users. You can use Group Policy to develop a NetMeeting feature management policy to support the specific business rules or communication policies that exist within your organization. For example, your organization may not want users to be able to access or use the NetMeeting chat feature from their computers. By using Active Directory and Group Policy, you can disable the chat feature from any or all computers that are affected by the application of the Group Policy configuration settings.

For lists of Group Policy settings that you can use to manage NetMeeting configuration options, see "NetMeeting and Group Policy," earlier in this section.

**Procedures for Managing NetMeeting Features Through Group Policy**

This subsection provides procedures for the following configuration methods:

- Locating the Group Policy objects (GPOs) for NetMeeting configuration settings. These are the settings listed in "NetMeeting and Group Policy," earlier in this section.
- Disabling the NetMeeting remote desktop sharing feature. This prevents users from using this feature.
- Disabling the NetMeeting advanced calling feature.
- Disabling the NetMeeting chat feature.

**To Locate the Group Policy Settings for NetMeeting User Configuration**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.
2. Click **User Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **NetMeeting**.
3. View the **Group Policy** objects that are available. For more information about these objects, see "NetMeeting and Group Policy," earlier in this section.

**To Disable the NetMeeting Remote Desktop Sharing Feature Through Group Policy**

Use the following steps to configure the Group Policy setting to prevent users from using the NetMeeting remote desktop sharing feature.

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.
2. Click **Computer Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **NetMeeting**.
3. In the **details** pane, double-click **Disable remote Desktop Sharing**.

4. Click **Enabled**.

| **Note** |
| --- |
| Group Policy settings for computers are applied when the operating system is initialized and during the periodic refresh cycle. |

**To Disable the NetMeeting Advanced Calling Feature Through Group Policy**
Use the following steps to configure the Group Policy setting to disable the advanced calling feature on the NetMeeting options page.

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **User Configuration**, click **Administrative Templates**, click **Windows Components**, click **NetMeeting**, and then click **Options Page**.

3. In the details pane, double-click **Disable the Advanced Calling** button, and then click **Enabled**.

**To Disable the NetMeeting Chat Feature Through Group Policy**
Use the following steps to configure the Group Policy setting to prevent the use of the NetMeeting Chat feature.

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **User Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **NetMeeting**.

3. In the **details** pane, double-click **Disable Chat**, and then click **Enabled**.

| **Note** |
| --- |
| Group Policy settings for users are applied when a user logs on to the computer and during the periodic refresh cycle. |

# Online Device Help and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Online Device Help
- How Online Device Help communicates with sites on the Internet
- How to control Online Device Help to limit the flow of information to and from the Internet

**Benefits and Purposes of Online Device Help**
Online Device Help (also known as the "Get help for my hardware device" wizard) delivers targeted content on problems with hardware and peripheral devices installed on the system. This mitigates the need for calls to support professionals to resolve hardware issues. You interact with Online Device Help in products in the Microsoft Windows Server 2003 family when installing new hardware (through the Found New Hardware Wizard).

At the conclusion of the Found New Hardware Wizard, when the system uses a device driver that is not found on the operating system installation CD or is not available through Windows Update, Online Device Help collects anonymous data on the problem device (including a unique hardware identifier for that device) and sends that information over the Internet to a server at Microsoft. If a match for the device is found, content on that device is then downloaded to the system and is displayed in the Help and Support Center user interface. This content may include:

- Information from the independent hardware vendor (IHV) about upcoming and planned device support.
- Links to the product compatibility area in Help and Support Center to enable users to search or browse the Windows Server Catalog Web site for compatible devices. The Windows Server Catalog Web site is located at:

  http://go.microsoft.com/fwlink/?LinkId=4303

- A link to the Web site of the IHV for that device.

The data provided by Online Device Help enables Microsoft to identify the number and system locale of users experiencing hardware problems due to missing drivers and to identify the most common problem devices. Microsoft works with these hardware vendors to provide targeted troubleshooting content on the most common problem hardware devices.

This section of the white paper explains how to control Online Device Help in a managed environment.

**Overview: Using Online Device Help in a Managed Environment**
You have control over whether to upload the data required by Online Device Help. You can also block Online Device Help at the firewall or through the Services snap-in. The configuration options and procedures for controlling Online Device Help are described later in this section.

**How Online Device Help Communicates with Sites on the Internet**
If no information for a particular hardware device is found on either the installation CD for the operating system or through Windows Update, you are prompted to release anonymous information about the hardware profile through Online Device Help. This subsection summarizes the communication process:

- **Specific information sent or received**: The following information is collected from the computer running Windows Server 2003 and is uploaded to a server at Microsoft. The user or administrator is not uniquely identified.
  - The hardware ID, also known as the PnPID (code that indicates the device manufacturer, device name, and version)
  - The time and date that the data was sent
  - Language code of the operating system, and platform and build information

- **Default and recommended settings**: Online Device Help is enabled by default. Recommended settings are described in the next subsection, "Controlling Online Device Help to Limit the Flow of Information to and from the Internet."

- **Triggers**: Online Device Help is triggered if no information for a particular hardware device is found after you complete the Found New Hardware Wizard.

- **User notification**: You are prompted to send anonymous hardware profile data to a server at Microsoft. If you opt to send this information, the privacy statement is displayed. You can view the contents of the hardware.xml file being uploaded by clicking a link on the privacy statement page.

- **Logging**: Errors that result from problems installing hardware devices without drivers are logged to the event log.

- **Encryption**: The data transferred to Microsoft is not encrypted.

- **Access**: The raw data uploaded to the server is accessible to operations engineers at Microsoft.com and is used in the Windows Hardware Quality Labs (WHQL) to improve Windows-compatible hardware and drivers.

- **Privacy statement**: Online Device Help is covered by its own privacy statement. The privacy statement (located in a file on your computer at systemroot\pchealth\helpctr\system\dfs\privacy.htm) is displayed when you opt to send the anonymous hardware profile data to Microsoft.

- **Transmission protocol and port**: The transmission protocol used is HTTP and the port is 80.

- **Ability to disable**: You cannot disable Online Device Help directly. Disabling Internet access or HTTP port 80 will, however, block Online Device Help, as will disabling the Upload Manager service.

**Controlling Online Device Help to Limit the Flow of Information to and from the Internet**

You have control over whether to upload anonymous hardware profile information about your system. You cannot, however, disable Online Device Help directly. To block Online Device Help, you can restrict Internet access or configure the Services snap-in to disable the Upload Manager service (uploadmgr).

**How Controlling Online Device Help Can Affect Users and Applications**

If you decide to disable Online Device Help, users or administrators will not be prompted to upload anonymous hardware profile information and they will not receive up-to-date, targeted self-help content on hardware issues relating to missing or problem drivers.

| **Note** |
| --- |
| If you restrict Internet access to block Online Device Help, the feature will queue the data and periodically retry to upload the hardware profile information for some period of time. If an Internet connection becomes available during that period, Online Device Help will upload the queued data. If an Internet connection does not become available, no data will be uploaded. Users will not be impacted in either case. |

**Procedure for Controlling Online Device Help**

You cannot disable Online Device Help directly but can do so indirectly by disabling the Upload Manager service in Windows Server 2003.

**To Disable Online Device Help by Disabling the Upload Manager Service**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Administrative Tools**, and then double-click **Services**.

3. In the details pane, right-click **Upload Manager**, and then click **Properties**.

   The Upload Manager service is the underlying service used by Online Device Help.

4. Click the **Log On** tab, then click the hardware profile that you want to configure, and then click **Disable**.

# Outlook Express 6.0 and Resulting Internet Communication in Windows Server 2003 with Service Pack 1

Applies To: Windows Server 2003 with SP1

This white paper provides information about the communication that flows between components in Windows Server 2003 with SP1 and sites on the Internet, and it describes steps to take to limit, control, or prevent that communication in an organization with many users.

This section of the white paper provides:

- A description of Microsoft Outlook Express 6 in Windows Server 2003 with Service Pack 1 (SP1). This section also provides a comparison of Outlook and Outlook Express.
- Descriptions of new security-related features in Outlook Express 6 in Windows Server 2003 with SP1 (as compared to Outlook Express 5), with information about how these new features are configured at the desktop.
- Information about controlling Outlook Express 6 through Group Policy to limit the risk associated with e-mail attachments. The Group Policy setting that you use for this is **Block attachments that could contain a virus**.

| **Note** |
| --- |
| This section of the white paper describes Outlook Express 6 in Windows Server 2003 with SP1, but does not describe related components such as Internet Explorer 6, the New Connection Wizard, or the tool that can report errors that occur in Outlook Express. For information about these components, see the respective sections of this white paper (the error reporting tool is described in Windows Error Reporting and Internet Communication). |

It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization where users send and receive e-mail messages, open attachments in e-mail messages, and perform similar actions. This section, however, provides information about features and configuration methods in Outlook Express 6 that can reduce the inherent risks associated with sending and receiving e-mail messages.

For more information about Outlook Express, see the following resources:

- Help for Outlook Express (which can be accessed in Outlook Express by clicking the **Help** menu and then selecting an appropriate option).
- The section about Internet Explorer 6 in this white paper, which describes security zones in Internet Explorer 6. These security zones are also used in Outlook Express 6.
- The Internet Explorer page on the Microsoft Web site at:

  http://www.microsoft.com/windows/ie/

- The Resource Kit for Internet Explorer (specifically, the chapter describing what's new in Internet Explorer 6). To learn about this and other Resource Kits, see the Microsoft TechNet Web site at:

  http://go.microsoft.com/fwlink/?linkid=29894

**Benefits and Purposes of Outlook Express 6**

Outlook Express 6 is designed to make it easy to send or receive e-mail messages and to browse or participate in newsgroups. It differs from many of the other components described in this white paper in that its main function is to communicate through the Internet or an intranet (in contrast to components that communicate with the Internet in the process of supporting some other activity).

Outlook Express is part of Windows Server 2003 with SP1, in contrast to Microsoft Outlook, which is an application included in Microsoft Office. Outlook provides comprehensive e-mail capabilities, including information management and collaboration

capabilities, useful to a wide spectrum of users from home to small business to large enterprise. Outlook Express, part of Windows Server 2003 with SP1, offers standard Internet e-mail and news access, useful to many home and small-business users. Outlook Express supports Post Office Protocol 3 (POP3), Internet Message Access Protocol (IMAP), Simple Mail Transfer Protocol (SMTP), and Network News Transfer Protocol (NNTP).

Outlook Express 6 offers more security-related options and settings than were available in Outlook Express 5. The following subsections describe the new options and ways of configuring them.

**New Security-Related Features in Outlook Express 6**

The version of Outlook Express in Windows Server 2003 with SP1 includes additional security-related features as compared to earlier versions of Outlook Express including Outlook Express 5. The following list describes these features. The table that follows this list shows how each option is configured in Outlook Express.

- **Warning about harmful e-mail**. To prevent e-mail messages from being sent without your knowledge, Outlook Express warns you when other programs, such as viruses or harmful attachments, attempt to send messages from your computer. This warning appears only if Outlook Express is configured as the default simple MAPI client, and another program attempts to use simple MAPI to programmatically send e-mail messages without presenting a visible user interface on the computer.

- **Blocking of potentially harmful attachments**. If this option is enabled, Outlook Express 6 blocks the opening or saving of specific e-mail attachments that are considered "unsafe." To determine whether an attachment is unsafe, Outlook Express 6 uses an updated API in Windows Server 2003 with SP1, the Attachment Manager API. The Attachment Manager API provides functionality to give each attachment a risk rating based on the extension, content type, registered handlers, and other heuristics. By using Group Policy, you can customize some aspects of Attachment Manager, such as the lists of high, medium, and low risk files.

  In addition, the prompts that are used for mail attachments, file downloads, shell process execution, and program installation have been modified to be both more consistent and clearer than they were in Windows Server 2003 without SP1.

  Blocking of potentially harmful attachments can be enabled or disabled through Group Policy as well as at the local computer. For more information about using this setting, see the table that follows and "To Locate the Group Policy Setting for Blocking E-mail Attachments in Outlook Express 6," later in this section.

  For more information about Attachment Manager and other changes that make the version of Outlook Express in Windows Server 2003 with SP1 more resistant than previous versions, see "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46278

  To learn about Group Policy settings with which you can adjust Attachment Manager, in Group Policy, go to User Configuration\Administrative Templates\Windows Components\Attachment Manager. For a detailed explanation of a setting, select the setting and click the **Extended** tab, or open the setting and click the **Explain** tab.

- **Plain text format option for reading of e-mail**. Starting with Outlook Express 6.0 in Windows Server 2003 with SP1, Outlook Express can be configured to read all e-mail messages in plain text format. Some HTML e-mail messages may not appear correctly in plain text, but no active content in the e-mail message is run when this setting is enabled.

- **Blocking of downloads of external content (to help limit spam)**. If this option is enabled, Outlook Express 6 will not contact an external Web server when an e-mail contains a reference to an image that resides on that external Web server. Businesses that use spam sometimes incorporate such external references for the purpose of validating e-mail addresses that they use, after which they send repeated e-mails to the validated addresses. The image involved might be a single pixel image that is not visible to the e-mail recipient, who is unaware that his or her e-mail address has been validated. This option can be enabled or disabled at the local computer. For more information about using this setting, see the table that follows and "To Start Outlook Express 6 and View or Configure Security Settings," later in this section.

  This option is new in the version of Outlook Express in Windows Server 2003 with SP1. For more details about other changes that make this version of Outlook Express more resistant than previous versions, see "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46278

The following table shows how each option is configured in Outlook Express 6.

**Options for Configuring Outlook Express 6**

| Option to Configure in Outlook Express 6 | Menu to Click | Menu Item to Click | Tab to Click |
|---|---|---|---|
| Warning about harmful e-mail | **Tools** | **Options** | **Security** |
| Blocking of potentially harmful attachments (also configurable through Group Policy) | **Tools** | **Options** | **Security** |
| Blocking of the downloading of images and other external content in HTML e-mail (this helps limit spam) | **Tools** | **Options** | **Security** |
| Plain text format option for reading of all e-mail | **Tools** | **Options** | **Read** |

**Overview: Using Outlook Express 6 in a Managed Environment**

Although there are inherent risks associated with sending and receiving e-mail (and e-mail attachments), with Windows Server 2003 SP1, you can use several different features and configuration methods in Outlook Express 6 to reduce the risks:

- You can use the graphical user interface to configure the security-related features in Outlook Express 6. For more information, see "New Security-Related Features in Outlook Express 6," earlier in this section and "To Start Outlook Express 6 and View or Configure Security Settings," later in this section.

- You can use a Group Policy setting, **Block attachments that could contain a virus**, to limit the risk associated with e-mail attachments in Outlook Express 6. For more information, see "To Locate the Group Policy Setting for Blocking E-mail Attachments in Outlook Express 6," later in this section.

**Procedures for Working with Outlook Express 6**

This subsection provides procedures for the following:

- Opening the dialog box from which you can configure security settings for Outlook Express 6.

- Locating the Group Policy setting, **Block attachments that could contain a virus**.

  You can use this Group Policy setting in situations where you want Outlook Express 6 to be available but where you want to limit the risk associated with e-mail attachments. For more information about this policy setting, see "New Security-Related Features in Outlook Express 6," earlier in this section.

**To Start Outlook Express 6 and View or Configure Security Settings**

1. Click **Start**, point to **All Programs** or **Programs**, and then click **Outlook Express**.

2. On the **Tools** menu, click **Options**.

3. Click the **Security** tab and view or configure the settings, including the check boxes for the following options:

   - **Warn me when other applications try to send mail as me**.

   - **Do not allow attachments to be saved or opened that could potentially be a virus**.

   - **Block images and other external content in HTML e-mail**.

   You can also view or configure the security zones setting. Outlook Express 6 uses two of the same security zones that you configure in Internet Explorer 6. For more information about security zones, see Internet Explorer 6.0 and Resulting Internet Communication in Windows Server 2003 with Service Pack 1 in this white paper.

4. Click the **Read** tab, and view or configure the settings, including the check box for **Read all messages in plain text**.

**To Locate the Group Policy Setting for Blocking E-mail Attachments in Outlook Express 6**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **User Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Internet Explorer**.

   In the details pane, double-click **Configure Outlook Express**.

3. If you enable this policy, you can select or clear the check box for **Block attachments that could contain a virus**.

**Related Links**

- For more details about changes in the version of Outlook Express in Windows Server 2003 with SP1, see "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46278

- For more information about security zones in Internet Explorer 6 (zones also used in Outlook Express 6), see Internet Explorer 6.0 and Resulting Internet Communication in Windows Server 2003 with Service Pack 1 in this white paper.

# Plug and Play and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Plug and Play
- How Plug and Play communicates with sites on the Internet
- How to control Plug and Play to prevent the flow of information to and from the Internet

**Benefits and Purposes of Plug and Play**

Windows Plug and Play provides ease of support for installing devices on computers in your network. You can simply plug in a Plug and Play device and Windows does the rest by searching locally for the driver and prompting to find out whether to also search Windows Update, installing the driver, updating the system, and allocating resources. After you install a Plug and Play device, the driver is configured and loaded dynamically, typically without requiring user input.

Plug and Play in Microsoft Windows Server 2003 with Service Pack 1 (SP1) provides the following functionality:

- Detects a Plug and Play device and determines its hardware resource requirements and device identification number (Plug and Play ID).
- Locates an appropriate device driver for newly installed devices.
- Allocates hardware resources.
- Dynamically loads, initializes, and unloads drivers.
- Notifies other drivers and applications when a new device is available.
- In conjunction with power management, handles stop and start processes for devices during hibernation, standby, and startup and shutdown operations.
- Supports a wide range of device types.

In order to install devices using the hardware wizards, you must be logged on as an administrator or a member of the Administrators group. You can then use the hardware wizards, such as the Hardware Update Wizard, to search the Windows Update site for device drivers. All drivers obtained through Windows Update are signed by Windows Hardware Quality Labs (WHQL). The WHQL provides compatibility testing services to test hardware and drivers for Windows operating systems.

| **Note** |
| --- |
| Some buses, such as Peripheral Component Interconnect (PCI) and universal serial bus (USB), take full advantage of Plug and Play. Older buses, such as Industry Standard Architecture (ISA), do not take full advantage of Plug and Play, and require more user interaction to ensure that devices are correctly installed. |

The Windows Update site is located at:

http://windowsupdate.microsoft.com/

**Overview: Using Plug and Play in a Managed Environment**

The Plug and Play feature is built into Windows Server 2003 and is always available. When a person who is logged on as an administrator installs a Plug and Play device, Windows Server 2003 first searches locally for an appropriate device driver. If the computer is connected to the Internet, Windows Server 2003 with SP1 prompts the person to find out whether to also search Windows Update for the latest device driver.

As an IT administrator in a highly managed network environment, you may want to control whether Windows Server 2003

with SP1 will search the Windows Update Web site for the latest device driver, and if so, whether the person installing or updating the device will be prompted before the Internet search begins. You can control these things through Group Policy.

There are also policy settings you can use to disable any access to Windows Update. If you do prevent access to Windows Update, there is the option for manually downloading the updates from the Windows Update Catalog, whereby they can be distributed on your organization's network as needed.

Using Group Policy to disable access to Windows Update, and to configure driver search locations, is described in "Controlling Automatic Device Updating to Prevent the Flow of Information to and from the Internet," later in this section.

**How Plug and Play Communicates with Sites on the Internet**

When a person logged on as an administrator installs new hardware, or updates the driver for existing hardware, Windows Server 2003 with SP1 will by default display a prompt to find out whether to search Windows Update for the latest device driver. If the person installing or updating the device consents to the Internet search, the interaction takes place as follows:

- **Specific information sent or received**: The Code Download Manager (CDM) calls Windows Update to find and download device drivers. The CDM also calls Help and Support Center, which logs Plug and Play IDs for devices that Microsoft does not have drivers for. Neither of these communications is under the direct control of Plug and Play. The CDM handles all of the communication between the computer and Windows Update. None of the communication between the computer and the Internet uniquely identifies the user.

- **Default setting**: Plug and Play is always available, and by default will prompt the person installing a device to find out whether to search the Windows Update Web site for the latest device driver.

- **Trigger and user notification**: When an administrator adds hardware or updates a driver on a computer, and the computer is connected to the Internet, by default, Windows Server 2003 with SP1 prompts to find out whether to search Windows Update for driver updates. The search is conducted if the administrator consents.

- **Logging**: If you use a Plug and Play driver with a device that is not Plug and Play, any associated issues or problems are recorded in the event log.

- **Encryption**: Data transfer is based on interaction with Windows Update. The data is transferred using HTTPS.

- **Transmission protocol and ports**: The transmission protocols and ports are HTTP 80 and HTTPS 443.

- **Ability to disable**: Plug and Play cannot be disabled, because system instability would result. You can disable access to Windows Update using Group Policy.

**Controlling Automatic Device Updating to Prevent the Flow of Information to and from the Internet**

Windows will automatically update device drivers using Plug and Play, and it will even search for compatible drivers for devices that are not Plug and Play. You therefore may want to exercise various levels of control over the ability of someone who logs on as an administrator to install new hardware and to update hardware devices and drivers.

You can use Group Policy to:

- Control whether Windows Update is included when Plug and Play searches for a device driver.

  This procedure is presented in the next subsection.

- Suppress the prompt that by default is displayed before Plug and Play begins searching the Windows Update Web site for a device driver. This setting only has an effect if you also use a setting to specify that Plug and Play will search the Windows Update Web site for device drivers.

  This procedure is presented in the next subsection.

- Turn off all access to Windows Update.

  If you turn off all access to Windows Update, it also means Plug and Play cannot search Windows Update. For more information about controlling access to Windows Update and for alternative approaches to updating such as Software Update Services, see the Windows Update, Automatic Updates, and Internet Communication section in this white paper.

**Procedure for Controlling Where Plug and Play Searches for Drivers**

When you install new hardware, Windows Server 2003 can potentially search four different locations for drivers in the following order: the hard drive, the floppy drive, the CD drive, and Windows Update. The default approach for Windows Server 2003 with SP1 is to search the first three locations, and then prompt you to find out whether to also search Windows Update. However, you can configure the driver search locations to remove selected locations.

This subsection includes procedures for configuring the following Group Policy settings:

- A setting that controls where Plug and Play searches for device drivers.
- A setting that specifically controls whether Plug and Play searches Windows Update for drivers. This setting is one in a collection of settings that control how various components communicate with the Internet,
- A setting that suppresses the prompt that by default is displayed before Plug and Play begins searching the Windows Update Web site for a device driver. This setting only has an effect if you also use a setting to specify that Plug and Play will search the Windows Update Web site for device drivers.

For additional procedures to configure policy settings for Windows Update, see the section Windows Update, Automatic Updates, and Internet Communication in this white paper.

**To Specify Driver Search Locations for Plug and Play Devices**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.
2. Click **User Configuration**, click **Administrative Templates**, and then click **System**.
3. In the details pane, double-click **Configure driver search locations**, and then click **Enabled**.
4. Select or clear check boxes to prevent or allow searching of floppy disk drives, CD-ROM drives, or Windows Update.

**To Disable Windows Update as a Driver Search Location**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.
3. In the **details** pane, double-click **Turn off Windows Update device driver searching**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in **Computer Configuration/Administrative Templates/System/Internet Communication Management**. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

**To Suppress the Prompt That is Displayed Before Windows Update is Searched for a Device Driver**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. If you want the policy setting to apply to all users of a computer and to come into effect when the computer starts or when Group Policy is refreshed, click **Computer Configuration**. If you want the policy setting to apply to users and to come into effect when users log on or when Group Policy is refreshed, click **User Configuration**.

3. Click **Administrative Templates** and then click **System**.

4. In the details pane, double-click **Turn off Windows Update device driver search prompt**, and then click **Enabled**.

This setting only has an effect if you also use a setting to specify that Plug and Play will search the Windows Update Web site for device drivers.

http://windowsupdate.microsoft.com/

# Program Compatibility Wizard and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of the Program Compatibility Wizard.
- How the Program Compatibility Wizard communicates with sites on the Internet.
- How to control the Program Compatibility Wizard to prevent the flow of information to the Internet.
- How to obtain the Application Compatibility Toolkit. You can use the toolkit to improve the user experience with incompatible applications.

**Benefits and Purposes of the Program Compatibility Wizard**

There are some applications that work on earlier versions of Windows that might fail to function properly on Microsoft Windows Server 2003 with Service Pack 1 (SP1). This can happen for several reasons—an application may expect older formats of Windows data, may expect user information to be in specific locations or formats, or may not be designed for the tighter security implemented in Windows Server 2003 SP1. In addition, applications written exclusively for Windows 95, Windows 98, or Windows Millennium Edition may use direct hardware access, which can greatly reduce operating system stability. Because of its Windows NT heritage, Windows Server 2003 SP1 requires that hardware access be handled through the correct channels.

To enable a better user experience, Microsoft has integrated technologies for application compatibility into Windows Server 2003. These technologies are applied whenever an application is installed on the operating system, whether in the course of a system upgrade or during regular operations. Some of these technologies work automatically to apply compatibility fixes, while others can be selected by users or administrators. This section describes the Program Compatibility Wizard, which can be used to make setting adjustments for an incompatible application and run the application successfully.

This section also provides a description of the Application Compatibility Toolkit, which you can use to locate and address compatibility problems. For example, with one of the tools, you can create custom messages that notify users of the problems with an incompatible application and redirect users to your intranet site.

**Overview: Using the Program Compatibility Wizard in a Managed Environment**

IT administrators who want to get an application to work quickly, without addressing compatibility for the application throughout the organization, may choose to use the Program Compatibility Wizard. You can use the wizard in situations where you want to determine quickly whether the prepackaged compatibility fixes can resolve problems you encounter, particularly if you are working on a computer where the Application Compatibility Toolkit is not installed. For more information about the Application Compatibility Toolkit, see "Using the Application Compatibility Toolkit to Improve the User Experience with Incompatible Applications," later in this section.

In Windows Server 2003 you can access the Program Compatibility Wizard by default through **Programs\Accessories** or **All Programs\Accessories**. At the completion of the wizard you are presented with "Program Compatibility Data" that states, "Microsoft has created temporary files that contain information about the settings you selected and whether the problems were fixed. Sending this information to Microsoft will help us improve program compatibility." You can then choose to send this information to Microsoft or not. You can also choose to click a link to a Web site to view the data collection policy and you can choose to view the temporary files that will be sent. Allowing users or administrators to do this, however, may present a privacy problem for highly managed organizations.

| **Note** |
| --- |
| As an alternative to running the Program Compatibility Wizard, you can set the compatibility properties for an application manually through the **Compatibility** tab of a program's **Properties** sheet. To do this, right-click the program icon, click **Properties**, click **Compatibility**, and then change the compatibility settings for your application. |

You can use Group Policy to control where data collected by the Program Compatibility Wizard is sent. You can prevent data transfer to the Internet by using Group Policy settings related to error reporting and you can have data from the wizard sent to a server on your intranet instead of to Microsoft. For more information about these procedures, see the section of this white paper titled Windows Error Reporting and Internet Communication.

#### How the Program Compatibility Wizard Communicates with Sites on the Internet

Although you can control information sent by the Program Compatibility Wizard, it is designed to communicate over the Internet to expedite problem solving. This subsection lists details of the communication process:

- **Specific information sent or received**: The results of the Program Compatibility Wizard data, including settings and problems that were encountered with the application being installed, are sent to Microsoft. The user is not uniquely identified.

- **Default and recommended settings**: Use of the Program Compatibility Wizard is enabled by default. Recommended settings are discussed in the next subsection, "Controlling Program Compatibility Wizard Data to Prevent the Flow of Information to the Internet."

- **Trigger and notification**: In the last dialog box of the wizard, users are asked if they want to send information to Microsoft. Data is not sent automatically.

- **Logging**: There is no information related to the Program Compatibility Wizard entered into the event log.

- **Encryption**: HTTPS is used to perform the data transfer to Microsoft.

- **Access**: The Microsoft product group has access to the raw data only.

- **Privacy**: The privacy statement is the same as that associated with Windows Error Reporting (WER) data. A link to the privacy statement on the Web is provided in the wizard. This privacy statement is available at:

  http://go.microsoft.com/fwlink/?LinkId=825

- **Transmission protocol and port**: The transmission protocol used is HTTPS and the port is 443.

- **Ability to disable**: You cannot disable the Program Compatibility Wizard. Using Group Policy, you can prevent data from being sent to the Internet.

For more information about the type of information that is sent to Microsoft, how the data is used, encryption, and the privacy statement, see the section of this white paper titled Windows Error Reporting and Internet Communication.

#### Controlling Program Compatibility Wizard Data to Prevent the Flow of Information to the Internet

Using Group Policy, you can configure **Configure Error Reporting** policy setting to prevent data collected by the Program Compatibility Wizard from being sent to Microsoft. By using configuration options within error reporting you can have the data sent to a server on your intranet instead of to Microsoft. When you configure error reporting this way, you activate Corporate Error Reporting (CER).

The **Configure Error Reporting** policy setting is located in **Computer Configuration\Administrative Templates\System\Error Reporting**. For more information and procedures for configuring error reporting, see the section of this white paper titled Windows Error Reporting and Internet Communication.

If you use this approach for reporting errors, the user experience with the Program Compatibility Wizard does not change. The dialog box that presents the option of sending data to Microsoft is the same. If the user selects **Yes**, the data is sent to the designated server on your intranet.

#### Using the Application Compatibility Toolkit to Improve the User Experience with Incompatible Applications

When a user tries to run a low-level application—such as an antivirus or disk-access utility—that is known to be incompatible and compromise system integrity, Windows XP blocks the application and informs the user about it. To do this, Windows XP uses information in databases stored locally on the computer. Compatibility fixes are contained in a database file named SYSMAIN.SDB. The warning information used when an application cannot be run successfully is contained in a related database file, APPHELP.SDB.

Before Windows XP Service Pack 2 (SP2), the operating system would also contact a Microsoft Web site for the latest information about incompatible applications. As of SP2, Windows XP only uses the information stored locally on the computer.

You can customize the way Windows XP responds to programs that are known to compromise system integrity by using the Application Compatibility Toolkit. For example, you can use one of the tools in the toolkit, the Compatibility Administrator tool, to create custom messages that notify users of the problems with an incompatible application and redirect users to your

intranet site. To do this, you need to first download the Application Compatibility Toolkit, and then use tools such as the Compatibility Administrator tool.

**To Read About and Download the Application Compatibility Toolkit**

1. Read about the toolkit and find links for downloading it from the Windows Web site at:

   http://go.microsoft.com/fwlink/?LinkId=29880

2. Follow the installation instructions. Once you have installed the toolkit, you can view the Windows Application Compatibility 3.0 Reference and you can run the Compatibility Administrator tool to make the changes you need.

**To Create Custom Messages for Applications with Incompatibility Problems**

1. Make sure that the Application Compatibility Toolkit is installed by using the previous procedure.

2. Click **Start**, point to **Programs** or **All Programs**, point to **Microsoft Windows Application Compatibility Toolkit**, and then click **Compatibility Administrator Tool 3.0**.

3. In the console tree, click **Custom Databases**, and then click **New Database**.

4. On the toolbar, click **AppHelp**. The **Create a custom AppHelp message** dialog box appears.

5. Enter information as prompted in the dialog box.

6. Save the new database file.

| **Note** |
| --- |
| When you have completed your entries and saved the file, you can deploy your changes to multiple computers running Windows XP. See "Deploying Compatibility Fixes," in Compatibility Administrator Help. |

**Event Logging for Events Related to the Blocking of Incompatible Applications**

Events related to the blocking of incompatible applications are not logged by default. You can enable event logging in the Application log (**Control Panel\Administrative Tools\Event Viewer**) by using Group Policy.

**To Enable Event Logging for Events Related to the Blocking of Incompatible Applications**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Application Compatibility**.

3. In the details pane, double-click **Turn On Application Help Log Events**, and then click **Enabled**.

**Related Links**

- For more information about application compatibility resources, see “Windows Application Compatibility” at:

  http://go.microsoft.com/fwlink/?LinkId=29880

# Remote Assistance and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Remote Assistance
- How Remote Assistance communicates with sites on the Internet
- How to control Remote Assistance to prevent the flow of information to and from the Internet

**Benefits and Purposes of Remote Assistance**

With Microsoft Windows Server 2003, users and administrators in your organization can use Remote Assistance to get help from a member of your support staff. Users or administrators can also collaborate in other ways through screen sharing. Remote Assistance is a convenient way for support professionals to connect to a computer from another computer running a compatible operating system, such as Windows Server 2003 or Windows XP, and to show the users or administrators a solution to the problem.

Using Windows Messenger Service or an e-mail program, such as Microsoft Outlook or Outlook Express, you can provide support to a user by connecting to the user's computer. After you are connected, you can view the user's computer screen, communicate in real time about what you both see on the user's computer, send files, use voice communication, and use your mouse and keyboard to work on the user's computer.

**Overview: Using Remote Assistance in a Managed Environment**

On Windows Server 2003, with or without Service Pack 1 (SP1), Remote Assistance is disabled by default. By opening Control Panel\System and clicking the Remote tab, you can enable Remote Assistance (unless it is disabled through Group Policy). Then you can open Help and Support Center, click **Remote Assistance**, and then click **Invite someone to help you**. When you do this, you can have someone inside or outside your network connect to your server.

Although a firewall on your organization's network will likely prevent outsiders from connecting directly to a computer on your intranet, some firewall settings might permit users or administrators to connect remotely to someone within your intranet or outside your network through Remote Assistance. As an administrator in a highly managed environment, you might want to prevent the use of this feature. You can do this during your deployment of Windows Server 2003 with SP1, or post-deployment using Group Policy.

In a domain environment there is also the option of a support person or IT administrator offering unsolicited assistance. From Help and Support Center using **Tools\Help and Support Center Tools\Offer Remote Assistance**, an administrator in the domain may offer assistance to users in the same domain or trusted domains without being asked. However, users can decline the invitation. This capability can be strictly controlled with Group Policy. Controlling the use of unsolicited as well as solicited Remote Assistance is described further in the subsection "Controlling Remote Assistance to Prevent the Flow of Information to and from the Internet."

**How Remote Assistance Communicates with Sites on the Internet**

When a user (referred to as the "novice") initiates a request for assistance through either the e-mail option or the **Save invitation as a file** option in Remote Assistance, the operating system starts Help and Support Center. Help and Support Center then passes the information to Remote Assistance.

When the person who is being contacted (the "expert") accepts the invitation from the novice, Remote Assistance calls Help and Support Center application programming interfaces (APIs) to initiate the session. Help and Support Center relies on Terminal Services to negotiate the session. Help and Support Center passes the Remote Assistance invitation (the "ticket") file to Terminal Services. The Remote Assistance session is established using RDP (Remote Desktop Protocol), and uses port 3389 through Terminal Services on the novice computer.

There are safeguards built into the Remote Assistance feature. All sessions are encrypted and can be password-protected. The novice (user soliciting the assistance) sets the maximum time for the duration of the ticket. Also, firewalls on your organization's network can be configured to prevent communication associated with Remote Assistance, for example, Remote Assistance connections that are inbound to computers behind the firewall.

The following information presents additional details on how information transfer over the Internet takes place when a connection is made:

- **Specific information sent or received**: Information that is transmitted in a Remote Assistance ticket includes user name, IP address, and computer name. Information necessary to provide functionality for Remote Assistance (for example, screen sharing, file transfer, and voice) is sent in real time using point-to-point connections.

- **Default and recommended settings**: Anyone with access to Help and Support Center can access the Remote Assistance feature. Users can prevent someone from connecting to their computer by declining an invitation. You can also prevent someone from remotely controlling a server running Windows Server 2003 SP1 by using Control Panel settings or Group Policy.

- **Triggers**: A user or administrator establishes contact with the expert by sending an invitation through e-mail, instant messaging, or by saving an invitation as a file and transferring it manually, such as on a floppy disk, to the expert. Or, an expert offers unsolicited assistance to a user.

- **User notification**: Whether assistance is solicited or unsolicited, the novice is notified of the offer of assistance from the expert. The novice must accept the connection before Remote Assistance begins.

- **Logging**: Events such as a person initiating a connection or a user or administrator accepting or rejecting an invitation are recorded in the event logs. Windows Server 2003 Service Pack 1 (SP1) records more details than were recorded previously, including events such as taking and releasing control. sending and accepting files, and ticket creation and deletion. SP1 also records details such as whether assistance is solicited or unsolicited as well as more detailed user name and IP address information.

- **Encryption**: The RDP (Remote Desktop Protocol) encryption algorithm for the main Remote Assistance communication and the RTC (Real-Time Communication) encryption algorithm for voice are used. The RDP encryption algorithm is RC4 128-bit.

- **Access**: No information is stored at Microsoft.

- **Transmission protocol and port**: The port is 3389 and the transmission protocols are RDP and RTC. For Offer Remote Assistance, Distributed Component Object Model (DCOM) is also used.

- **Ability to disable**: This component can be disabled by using Group Policy or locally through Control Panel.

- **Firewall protection**: Any firewall that blocks port 3389 will not allow a Remote Assistance connection to users outside the firewall. This does not prevent users from within the network protected by the firewall from connecting to each other. If you close port 3389, you will block all Remote Desktop and Terminal Services events through it as well. If you want to allow these services but want to limit Remote Assistance requests, use Group Policy. If the port is opened only for outbound traffic, a user can request Remote Assistance by using Windows Messenger.

| **Note** |
| --- |
| Windows Server 2003 with SP1 includes enhancements to the firewall component, now called Windows Firewall. To use Remote Assistance with Windows Firewall enabled, in Windows Firewall, on the **Exceptions** tab, select **Remote Desktop**. Alternatively, you can configure Windows Firewall through Group Policy with a setting at Computer Configuration\Administrative Templates\Network\Network Connections\Windows Firewall, either in Domain Profile or in Standard Profile. The setting to configure is **Windows Firewall: Allow Remote Desktop exception**. |

For more information about the Remote Assistance connection process, see article 300692, "Description of the Remote Assistance Connection Process" in the Microsoft Knowledge Base at:

http://go.microsoft.com/fwlink/?LinkId=29212

**Controlling Remote Assistance to Prevent the Flow of Information to and from the Internet**
Administrators can control the use of Remote Assistance in the following ways:

- Group Policy to prevent Remote Assistance from being solicited from this computer

- Group Policy to prevent unsolicited Remote Assistance from being offered to this computer

- Local control of Remote Assistance through Control Panel

Group Policy settings are described in detail in this subsection. Procedures for disabling Remote Assistance are presented in the next subsection.

**Using Group Policy**

There are two Group Policy settings you can configure to control the use of Remote Assistance:

- **Solicited Remote Assistance**. Use this policy setting to determine whether Remote Assistance can be solicited from a given computer. In Solicited Remote Assistance the user of a computer explicitly requests help from another party.

- **Offer Remote Assistance**. Use this policy setting to determine whether a support person or IT administrator (expert) can offer remote assistance to a computer without a user explicitly requesting it first through e-mail, a file, or instant messaging.

These policy settings are located in Computer Configuration\Administrative Templates\System\Remote Assistance. Configuration options for these policy settings are described in the following table.

**Group Policy Settings for Controlling Remote Assistance**

| Policy Setting | Description |
|---|---|
| Solicited Remote Assistance (enabled) | When this policy setting is enabled, a user can create a Remote Assistance invitation that a person ("expert") can use at another computer to connect to the user's computer. If given permission, the expert can view the user's screen, mouse, and keyboard activity in real time.<br><br>Additional configuration options are available when you enable this policy setting. |
| Solicited Remote Assistance (disabled) | If the status is set to **Disabled**, users cannot request Remote Assistance and this computer cannot be controlled from another computer. |
| Solicited Remote Assistance (not configured) | If the status is set to **Not Configured**, the configuration of solicited Remote Assistance is determined by the Control Panel settings. |
| Offer Remote Assistance (enabled) | When this policy setting is enabled, a remote user or administrator can offer Remote Assistance to the computer. When you configure this policy setting, you have two choices: you can select either **Allow helpers to only view the computer** or **Allow helpers to remotely control the computer**. In addition to making this selection, when you configure this policy setting, you also specify the list of users or user groups that will be allowed to offer remote assistance. Administrators of this computer can offer remote assistance to it by default. They do not need to be added to the list. |
| Offer Remote Assistance (disabled or not configured) | If you disable or do not configure this policy setting, users or groups cannot offer unsolicited remote assistance to this computer. |

For additional configuration options, see the Remote Assistance policy settings in Group Policy. To find more information about editing Group Policy, see Appendix B: Resources for Learning About Group Policy.

**Procedures for Disabling Remote Assistance**

This section presents procedures administrators can use for disabling Remote Assistance through Group Policy or Control Panel.

**To Disable the Use of Remote Assistance Using Group Policy**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, and then click **Remote Assistance**.

3. In the details pane, double-click **Solicited Remote Assistance**, click **Disabled**, and then click **OK**.

4. In the details pane, double-click **Offer Remote Assistance**, click **Disabled**, and then click **OK**.

**To Disable the Use of Remote Assistance Through Control Panel**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **System**.

3. In **System Properties**, click the **Remote** tab.

4. Under **Remote Assistance**, clear the check box labeled **Turn on Remote Assistance and allow invitations to be sent from this computer**.

# Search Companion and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Search Companion
- How Search Companion communicates with sites on the Internet
- How to control Search Companion to prevent the flow of information to and from the Internet

**Benefits and Purposes of Search Companion**
The Microsoft Search Companion Web service enables you to search for files and folders on your computer, to search for files, people, and other computers on your internal network, and to search for information on the Internet. Search Companion uses Indexing Service to maintain an index of all the files on the computer, making searches faster.

When employing Search Companion, you can specify several search criteria. For example, you can search for files and folders by name, type, or size. You can find files based on when they were last modified, or search for files containing specific text. When searching for information on the Internet, Search Companion enables you to enter search queries in natural language (meaning informal, or conversational language). It then suggests the best way to conduct the search, and sends the query to Internet services that are most likely to yield positive results.

**Overview: Using Search Companion in a Managed Environment**
When you search the Internet using Search Companion, the following information is collected:

- The text of the Internet search query
- Grammatical information about the query
- The list of tasks (suggestions) that the Search Companion Web service recommends to refine the search
- Any tasks you selected from the recommendation list

Search Companion does not collect:

- Personal information, such as user name or e-mail address
- Demographic information

Microsoft does not use the information it collects to identify you individually or associate such information with other data sources that may contain personal data. Microsoft does not collect information when you search on the local system, LAN, or intranet.

The Search Companion Web service is designed to upgrade automatically as new features become available. It therefore uses the Internet connection periodically to check for and replace necessary files. You can use Group Policy to prevent the Search Companion Web service from upgrading automatically from the Internet.

If you want to disable the Search Companion Web service, you can do so by changing to Classic Search for the Internet. Microsoft Windows does not collect any query information when Classic Search is used. You can also disable Search Companion (change to Classic Search) by modifying the registry settings. The procedures for both of these methods are described later in this section of the white paper.

**How Search Companion Communicates with Sites on the Internet**
Search Companion in Microsoft Windows Server 2003 improves the search process by consolidating search tasks, optimizing searches for the most common scenarios, and offering suggestions for refining the search.

The form that collects search criteria will post information to an ASP page that displays the search results. The search pages use a combination of XML and Microsoft Visual Basic® development system, Scripting Edition (VBScript) and Microsoft

JScript® development software for accessing the search objects. Because the script is run on the server, you can view the search pages from any browser.

Search Companion uses XML files to define both the user interface and some functional parameters of its tasks (for example, what list of file extensions constitutes the "Music" category of files). The first time in each Search Companion session that an XML file is referenced, by default, Search Companion checks to see if a later version of that XML file is available from sa.windows.com. The "check" is really a file download request, conditioned on the modified date of the file. If there is a later version of the XML file, Search Companion downloads it and replaces the earlier version. The XML files are located in a language-specific subfolder of *systemroot*\Srchasst\, and if the current user does not have administrative credentials, the old XML file cannot be overwritten. The downloading of these XML files can be prevented through Group Policy.

This subsection describes various aspects of the data that is sent to and from the Internet through Search Companion, and how the exchange of information takes place:

- **Specific information sent or received**: When you search the Internet using Search Companion, the following information is collected regarding your use of the service: the text of your Internet search query, grammatical information about the query, the list of tasks that the Search Companion Web service recommends, and any tasks you select from the recommendation list.

- **Default and recommended settings**: Search Companion is enabled by default.

- **Triggers**: The user selects **Start\Search** and uses search options to search the Internet. The user can also start Internet Explorer and use a toolbar button, shortcut key, or menu to search the Internet.

- **User notification**: There is no provision in Search Companion for user review or notification of data sent.

- **Uniquely identify users**: The user is not uniquely identified. Session-based cookies are used to maintain state information, but these randomly assigned GUIDs do not persist across browser sessions.

- **Logging**: No information is collected when you search your local system, LAN, or intranet. The only "storage" is the Internet Information Services (IIS) log of the file request on the server at Microsoft that provides the Search Companion Web service. Search Companion does not record your choice of Internet search engines, and it does not collect or request any demographic information or personal information (such as user name or e-mail address).

- **Encryption**: There is no encryption of data.

- **Access**: No user information is collected. The IIS logs (described in the "Logging" item, earlier in this list) are cycled annually, that is, logs are retained for twelve months, and discarded in the thirteenth month following collection.

- **Privacy**: The privacy statement is located at the following Web site:

  http://sa.windows.com/privacy/

- **Transmission protocol and port**: The transmission protocol is HTTP and the port is 80.

- **Ability to disable**: The feature can be disabled by changing to Classic Search.

**Controlling Search Companion to Prevent the Flow of Information to and from the Internet**

You can disable the Search Companion Web service by changing preferences to Classic Search for the Internet. You can also disable Search Companion by changing the registry settings manually. In addition, you can prevent Search Companion from checking for and downloading updated versions of the XML files that it uses. Procedures for all of these approaches are provided in the following subsection.

**Procedures for Configuration of Search Companion**

Search Companion can be configured in several ways as described previously.

**To Change to Classic Search for the Internet through the User Interface**

1. Click **Start**, and then either click **Search**, or point to **Search** and click **On the Internet**.

2. Click **Change preferences**.

3. Click **Change Internet search behavior**.

4. Click **With classic Internet search** and click **OK**.

5. On the File menu, click **Close**.

The next Internet search you perform will use the preference you specified.

**To Change to Classic Search for the Internet Through the Registry Key**

1. Close Internet Explorer (all instances).

2. Open Registry Editor by clicking **Start**, clicking **Run**, and then typing **regedit**.

| **Caution** |
| --- |
| Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. You can also use the Last Known Good Configuration startup option if you encounter problems after manual changes have been applied. |

3. Navigate to **HKEY_CURRENT_USER\Software\Microsoft\Internet Explorer\Main**.

4. Look for an entry called **Use Search Asst**. If it exists, skip to step 7.

5. On the **Edit** menu, point to **New**, and then click **String value**.

6. Type **Use Search Asst** as the name for the new value (the type is REG_SZ), and then press **ENTER**.

7. Click **Use Search Asst**, and then on the **Edit** menu, click **Modify**.

8. For **Value data**, type:

   **no**

| **Note** |
| --- |
| Type the entry and value exactly as shown, including spaces and capitalization. |

**To Prevent Search Companion from Downloading Updated Versions of the XML Files That It Uses**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.

3. In the details pane, double-click **Turn off Search Companion content file updates**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the Restrict Internet communication policy setting, which is located in **Computer Configuration/Administrative Templates/System/Internet Communication Management**. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

# Terminal Server Licensing and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The purposes of Terminal Server Licensing
- How Terminal Server Licensing communicates with sites on the Internet
- How to control Terminal Server Licensing to limit the flow of information to and from the Internet

| Note |
| --- |
| In Microsoft Windows Server 2003, several components that use technology related to Terminal Server have different names than they had in Windows 2000. Terminal Server was previously known as Terminal Services in Application Server mode. Remote Desktop for Administration was previously known as Terminal Services in Remote Administration mode. |

**Purposes of Terminal Server Licensing**

Terminal Server Licensing is an administrative tool that helps manage your Terminal Server licenses. Terminal Server Licensing can be installed on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. If you install Terminal Server, you must also install Terminal Server Licensing (although not necessarily on the same computer). However, there is a grace period of 120 days during which you can use Terminal Server even though you have not set up license servers yet and have not installed client license key packs.

| Note |
| --- |
| Terminal Server and Terminal Server Licensing are not available in Windows Server 2003, Web Edition. Remote Desktop for Administration, however, is available in Windows Server 2003, Web Edition. |

When you set up Terminal Server on a server, users can access applications running on that server, which means they can run the applications you provide even if they are working from hardware that might not otherwise support the applications.

Microsoft has introduced new licensing options to address business customer needs and to complement the technical capabilities of Windows Server 2003. For details about these changes, see the Windows Server 2003 licensing overview at:

http://go.microsoft.com/fwlink/?LinkId=46007

**Overview: Using Terminal Server Licensing in a Managed Environment**

You can control the communication that occurs between the Terminal Server Licensing component and sites on the Internet by choosing the server or servers on which to install the Terminal Server Licensing component, and by choosing among three methods for activation. (You also choose among the same three activation methods for obtaining client license key packs, which are digital representations of a group of client access licenses.) The three methods for activation are as follows:

- **Automatic**. This method requires the server running Terminal Server Licensing to have an Internet connection.
- **Web Browser**. This method requires an Internet connection, but the connection can be made from any computer, not just the computer that is running Terminal Server Licensing.
- **Telephone**. This method is used to contact the nearest Customer Support Center and receive an ID number to activate the Terminal Server License Server by phone.

For more details on these methods, see the subsections that follow.

**How Terminal Server Licensing Communicates with Sites on the Internet**

A server running the Terminal Server Licensing component communicates with the Microsoft Clearinghouse (a database for managing licensing) on the Internet only when you activate Terminal Server Licensing or when you initiate subsequent transactions with Microsoft to obtain client license key packs. The following list describes the communication that occurs when

you activate or obtain client license key packs directly over the Internet or when you connect to the Microsoft Clearinghouse from a computer other than the one where Terminal Server Licensing is installed.

| **Note** |
| --- |
| The information in the following list applies only to activation or obtaining client license key packs over the Internet. It does not apply when you activate by phone.<br><br>Activation by phone is done as follows: When you activate by phone, you start the licensing wizard, choose a country or region from the list that is displayed, and call the number shown. |

The rest of this subsection describes various aspects of the data that is sent to and from the Internet from Terminal Server Licensing and how the exchange of information takes place.

- **Specific information sent or received**: The information sent to the Microsoft Clearinghouse includes company name, first and last name of the user, license server name, and license server ID. Client license key packs are returned to the Terminal Server License Server.

- **Default and recommended settings**: Terminal Server Licensing is not installed by default.

- **User notification and triggers**: The administrator triggers activating, obtaining client license packs, or deactivating Terminal Server Licensing by performing the steps described in the subsection "Procedures for Configuring Terminal Server Licensing." When the Terminal Server Licensing component starts, the administrator is notified that activating, obtaining client license packs, or deactivating will initiate communication with Microsoft.

- **Logging**: Terminal Server Licensing logs events in the system log. The events can be viewed through Event Viewer.

- **Encryption**: Terminal Server Licensing uses the HTTP protocol over SSL (Secure Sockets Layer) to communicate on the Internet and the Web.

- **Access**: The Microsoft Clearinghouse is the database Microsoft maintains to activate license servers and to issue client license key packs. Microsoft customer service representatives have access to the licensing information and are able to successfully re-create the information on your Terminal Server License Server if technical problems occur. The information you provide might also be used internally at Microsoft to perform aggregate quality testing of the Terminal Server Licensing program.

- **Privacy statement**: To see the privacy statement for Terminal Server Licensing, click Microsoft's Terminal Server Licensing privacy policy at the following Terminal Services Web site:

  http://go.microsoft.com/fwlink/?LinkId=46192

- **Transmission protocol and port**: HTTPS over port 443, and remote procedure call (RPC) over port 135.

- **Ability to disable**: Terminal Server Licensing is not installed by default. Once installed, however, it can be disabled by the procedures described later in this section.

**External Connector license**

In place of individual Terminal Server client access licenses (TS CALs), you have the option of purchasing the Terminal Server External Connector license. This license enables external users to access a company's terminal servers without the need to purchase individual TS CALS for them or their devices. Generally speaking, an external user is a person who is not an employee or similar personnel of a company or its affiliates, and who is not a customer of hosted services (for specific information, see the External Connector license).

It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization running servers that communicate with the Internet. For more information about security and the Internet, see the introduction to this white paper, or see the Microsoft TechNet Web site at:

http://go.microsoft.com/fwlink/?LinkId=29482

**Controlling Terminal Server Licensing to Limit the Flow of Information to and from the Internet**

You can control the communication that occurs between the Terminal Server Licensing component and sites on the Internet in the following ways:

- **Install the Terminal Server Licensing component on selected servers only**. This follows the basic principle of stopping unnecessary services and keeping computers (especially servers) free of unnecessary software. For information about choosing which computer or computers on which to install Terminal Server Licensing, see the *Microsoft Windows Server 2003 Deployment Kit* on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46078

  When searching in documentation about Terminal Server Licensing, use the phrases "domain license server" and "enterprise license server" to discover information about these two options.

- **Review the method you want to use for activating Terminal Server Licensing before starting the licensing wizard**. Automatic activation is the fastest method, but if you prefer, you can activate by the other methods mentioned previously (connecting to a Web site from a computer other than the one where Terminal Server Licensing is installed, or activating by phone).

  You are required to activate a license server before it can issue licenses to Terminal Server clients. You are required to activate a license server only once. When you activate the license server, Microsoft provides the server with a limited-use digital certificate that validates server ownership and identity. Microsoft uses the X.509 industry standard certificate for this purpose. Using this certificate, a license server can make subsequent transactions with Microsoft and receive client license key packs.

**Procedures for Configuring Terminal Server Licensing**

Terminal Server Licensing servers can be configured in several ways as described previously. This subsection provides procedures for:

- Installing and uninstalling Terminal Server Licensing
- Activating Terminal Server Licensing
- Deactivating Terminal Server Licensing
- Viewing Help for Terminal Server and Terminal Server Licensing

**To Install or Uninstall Terminal Server Licensing**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. Click **Add/Remove Windows Components** (on the left).
4. Select **Terminal Server Licensing**, click **Next**, and then do one of the following:
   - If Terminal Server Licensing is installed and you want to remove it, clear the check box for **Terminal Server Licensing** and complete the licensing wizard.
   - If Terminal Server Licensing is not installed and you want to add it, select the check box for **Terminal Server Licensing** and then click **Next**.
5. In Terminal Server Licensing setup, do one of the following:
   - If your network includes several domains, click **Your entire enterprise**, and then provide the database location. An enterprise license server can serve terminal servers on any Windows Server 2003 domain.

- If you want to maintain a separate license server for each domain, or if your network includes workgroups or Windows NT 4.0 domains, click **Your domain or workgroup**, and then provide the database location.

6. Follow the instructions to complete the Windows Components Wizard.

**To Activate a License Server**

As mentioned previously in this section, you must activate a Terminal Server License Server before it can issue licenses to Terminal Server clients. Use Terminal Server Licensing to activate a Terminal Server License Server through the Microsoft Clearinghouse.

You can find procedure checklists along with complete instructions for configuring and activating Terminal Server License Servers in Help and Support Center. For more detailed instructions, see the procedure below titled, "To view Help for Terminal Server and Terminal Server Licensing" and "To view Help topics specific to Terminal Server Licensing."

**Deactivating a license server**

If Terminal Server and Terminal Server Licensing are already installed and you want to deactivate the license server, use one of the following procedures. You might need to deactivate a license server when the certificate of the server has expired, when the server becomes corrupted, or when the server is being redeployed. Note that when a license server's registration has expired, you are prompted to reactive the license server (not deactivate it). When you deactivate a license server, you will not be able to license additional clients from this server until the license server is reactivated.

**To Deactivate a License Using the Automatic Method**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**.

3. In the console tree, right-click the license server you want to deactivate, point to **Advanced**, and then click **Deactivate Server**. The licensing wizard starts.

4. In **Information Needed**, confirm that your name, phone number (optional), and e-mail address (required if you are using the Internet method) are correct, and then click **Next**.

5. Your request to deactivate the license server is sent to Microsoft where it is processed.

| **Note** |
| --- |
| The information sent to the Microsoft Clearinghouse during deactivation is the same information sent during activation, which includes company name, first and last name of the user, license server name, and license server ID. |

6. Click **Finish**.

**To Deactivate a License Using the Telephone Method**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**.

3. In the console tree, right-click the Terminal Server License Server you want to deactivate, point to **Advanced**, and then click **Deactivate Server**. The Terminal Server License Server Wizard starts.

4. Select **Telephone** and then click **Next**.

5. Specify your location and then click **Next**.

6. Call the telephone number displayed in the wizard, and give the customer support representative the product ID that is displayed below the telephone number.

7. Type the 35-digit confirmation code provided by the customer support representative in the boxes in the wizard, and then click **Next**.

8. Click **Finish**.

| **Note** |
| --- |
| Deactivating a license server does not remove the component. As mentioned previously, follow the basic principle of stopping unnecessary services and keeping computers (especially servers) free from unnecessary software by removing the Terminal Server Licensing component if you no longer plan to use it as a license server. |

| **Note** |
| --- |
| You cannot deactivate a license server using either the fax or Internet connection methods. |

**To View Help for Terminal Server and Terminal Server Licensing**

1. Click **Start** and then click **Help and Support**.

2. Click **Software Deployment** and then expand **Terminal Services**.

**To View Help Topics Specific to Terminal Server Licensing**

1. Click **Start** and then click **Help and Support**.

2. Click **Software Deployment** and then expand **Terminal Services**.

3. Expand **Terminal Server** and then expand **Checklists: Setting up Terminal Server**.

   When you are finished viewing appropriate checklists, collapse the items you were viewing.

4. Expand **Terminal Server Licensing**.

5. To get information about the following procedures, expand **How To**:

   - Install Terminal Server Licensing
   - Activate Terminal Server Licensing server
   - Install client license key packs
   - Deactivate a Terminal Server Licensing server
   - Reactivate a Terminal Server Licensing server
   - Repeat the installation of a client license key pack
   - Connect to a Terminal Server Licensing server
   - Change Terminal Server Licensing server properties

**Related Links**

- For details about new licensing options for Windows Server 2003, as well as information about the licenses necessary

with Terminal Server, see the Windows Server 2003 licensing overview at:

http://go.microsoft.com/fwlink/?LinkId=46007

- For descriptions of other ways you can use Terminal Server, see the overviews on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=24427

- For information about controlling the issuance of Terminal Server licenses, on a server running Windows Server 2003, open Help and Support Center and search for the topic "To control the issuance of Terminal Server licenses."

# Windows Error Reporting and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Windows Error Reporting
- How Windows Error Reporting communicates with sites on the Internet
- How to control Windows Error Reporting to prevent the flow of information to and from the Internet

**Benefits and Purposes of Windows Error Reporting**

The Windows Error Reporting feature in Microsoft Windows Server 2003 provides a service that allows Microsoft to track and address errors relating to the operating system, Windows components, and applications. This service, called the Error Reporting service, gives administrators and users the opportunity to send data about errors to Microsoft and to receive information about them. Microsoft developers can use the Error Reporting service as a problem-solving tool to address customer problems in a timely manner and to improve the quality of Microsoft products.

When users or administrators send information to Microsoft, in some cases Microsoft may provide information in return, such as a way to work around a problem or a link to a Web site for updated drivers, patches, or Microsoft Knowledge Base articles.

**Overview: Using Windows Error Reporting in a Managed Environment**

In Windows Server 2003 with Service Pack 1 (SP1), error reporting is enabled by default and you can choose to report errors to Microsoft. When an error occurs, a dialog box is displayed allowing you to report the problem. If you choose to report the problem, technical information about the problem is collected and then sent to Microsoft over the Internet. No information is sent unless you confirm that the error report is to be sent to Microsoft. When you are logged on as an administrator, you can choose to report system and application errors. When you are not logged on as an administrator you can choose to report application errors.

On Windows Server 2003 with SP1, you can configure or disable error reporting through **Control Panel\System\Advanced**. You can configure error reporting to send specified information such as system errors (Stop errors) only, or errors for Windows components, such as Windows Explorer or Microsoft Internet Explorer. You can also send information for applications, such as Microsoft Word.

Since error reporting is a valuable service, we recommend that IT administrators not disable it, but that they control what information is reported and where it is sent. For an organization where privacy is a concern, we recommend that the IT department review and filter error reports before they are sent to Microsoft. Though it is not recommended, you can also completely disable error reporting by using Group Policy.

The best method to use to prevent the automatic flow of error reporting information to and from the Internet is to redirect error reports to a server on your intranet by using Group Policy and to set up Corporate Error Reporting (CER).If you have Software Assurance with your volume license, you can use the Corporate Error Reporting tool to manage error reports that have been redirected to a network server. You use the tool to review the redirected error reports and then filter the reports that are sent to Microsoft based on your policies and the data contained within the error report. The tool is also useful for determining the types of problems users are experiencing most often.

If you have not yet deployed Windows Server 2003 with SP1, you can use unattended installation files to configure error reporting in the same way as in Group Policy. If it is necessary in your organization to completely disable Windows Error Reporting, you can do so with the unattended installation file or with Group Policy. For more information about these methods, see "Controlling Error Reporting to Prevent the Flow of Information to and from the Internet," later in this section.

**How Windows Error Reporting Communicates with Sites on the Internet**

The data that Microsoft collects is used strictly for the purpose of tracking down and solving problems that users are experiencing. The information is stored on servers at Microsoft with limited access that are located in controlled facilities. This subsection describes various aspects of the data that is sent to and from the Internet during error reporting, and how the exchange of information takes place.

- **Specific information sent or received**: For Windows Server 2003 with SP1, Microsoft collects various types of information related to two types of errors, user mode or application errors, and kernel mode or operating system failures. Some information that uniquely identifies the user might unintentionally be collected as part of the crash report. This information, if present, is never used to identify a user. The specific data collected is described later in this

subsection. Also, Microsoft may send information about a problem, including links to Web sites.

- **Default and recommended settings**: Error reporting for application and system errors is enabled by default on servers running Windows Server 2003 with SP1. For more information about recommended settings, see "Controlling Error Reporting to Prevent the Flow of Information to and from the Internet," later in this section.

- **Triggers**: The opportunity to send an error report is triggered by application or system errors.

- **User notification**: A dialog box appears notifying users that an error has occurred and asks if they want to send an error report to Microsoft. Users can review the data that will be sent.

- **Logging**: Descriptions of system and application errors are recorded in the event log.

- **Encryption**: All data that could include personally identifiable information is encrypted (HTTPS) during transmission. The "crash signature," which includes such information as the application name and version, module name and version, and offset (location) is not encrypted.

- **Access**: Microsoft employees and contingent staff may access the error reports to maintain the Error Reporting service or improve Microsoft products, and may not use the reports for other purposes.

  If the error report indicates that one or more non-Microsoft products were involved in causing the problem, Microsoft may send the report to the respective companies. Qualified software or hardware developers (employed by Microsoft or one of its partners) will analyze the fault data and try to identify and correct the problem.

- **Privacy**: The privacy statement for Microsoft Error Reporting is located at the following Web site:

  http://go.microsoft.com/fwlink/?LinkId=825

  Details related to privacy of data are presented in "Types of Data Collected," later in this section.

- **Transmission protocol and port**: The transmission protocol is HTTP and the ports are HTTP 80 and HTTPS 443.

- **Ability to disable**: The feature can be disabled through Group Policy or by administrators on individual servers.

**Types of Errors Reported**

In Windows Server 2003 there are two types of errors that are reported, user mode and kernel mode.

**User Mode Reporting**

When a user mode error occurs, such as an application error, the Error Reporting service does the following:

- Displays an alert stating that Windows Server 2003 detected a problem.

  Users can choose to report the problem or not. If they do report it, they will see that the information is being sent to Microsoft.

- Sends a problem report to Microsoft.

  Users may then be queried for additional computer information (to complete the error report) and again may choose to send it or not.

- When more information is available, offers it to the user or administrator.

  Users or administrators might be offered the option of selecting **More Information**, which directs them to updated drivers, patches, or Microsoft Knowledge Base articles.

If the error report indicates that one or more non-Microsoft products were involved in causing the problem, Microsoft may send the report to the respective companies. Qualified software or hardware developers (employed by Microsoft or one of its

partners) will analyze the fault data and try to identify and correct the problem.

**Kernel Mode Reporting**
When a kernel-mode (system) error occurs, Windows Server 2003 displays a Stop message and writes diagnostic information to a memory dump file. When you restart the computer by using normal mode or Safe Mode (with networking) and log on to Windows Server 2003 as an administrator, the Error Reporting service gathers information about the problem and displays a dialog box that gives you the option of sending a report to Microsoft.

**Types of Data Collected**
The Error Reporting service collects information about the computer configuration, what the software was doing when the problem occurred, and other information directly related to the problem. The Error Reporting service does not intentionally collect anyone's name, address, e-mail address, computer name, or any other form of personally identifiable information. It is possible that such information may be captured in memory or in the data collected from open files, but Microsoft does not use it to identify users. The Error Reporting service collects Internet Protocol (IP) addresses, but the addresses are not used to identify users, and in many cases are the address of a Network Address Translation (NAT) computer or proxy server, not a specific client behind that NAT computer or proxy server. IP address information is used in aggregate by the operators who maintain the servers that receive error reports. The other use for IP address information is to locate error reports that come from computers inside Microsoft—errors on those computers can be more thoroughly investigated as needed.

In rare cases, such as problems that are especially difficult to solve, Microsoft may request additional data, including sections of memory (which may include memory shared by any or all applications running at the time the problem occurred), some registry settings, and one or more files from the user's computer. When additional data is requested, the user can review the data and choose to send the information or not.

In Windows Server 2003 with SP1 the specific types of data that are collected when application errors or kernel failures occur are as follows.

**Application Errors**
If an application error occurs for which Error Reporting is available and you choose to send the report, the information included is as follows:

- The Digital Product ID, which can be used to identify your license.
- Information regarding the condition of the computer and the application at the time when the error occurred. This includes data stored in memory and stacks, information about files in the application's directory, as well as the operating system version and the computer hardware in use. This information is packaged into a *minidump*—a small memory dump. The minidump contains the following:
- Exception information: This is information regarding the problem that occurred. It tells Microsoft what kind of instruction the application received that caused it to generate an error.
- System information: This is data about the kind of CPU (processor) you have and what operating system you are running.
- A list of all the modules that are currently loaded and their version information.
- A list of all the threads that are currently running. For each thread, the current context and the whole stack are collected.
- Global data.

The minidump data is shown as a hexadecimal representation that the user cannot read.

| **Note** |
| --- |
| For the exact specification of the minidump format, see the Microsoft Platform SDK, which is available on the MSDN Web site. |

**Windows Kernel Failures**
Windows kernel fault reports contain information about what your operating system was doing when the problem occurred. These event reports contain the minimum information that can help to identify why the operating system stopped unexpectedly. If you choose to send the report, it includes:

- The operating system name (for example, Microsoft Windows Server 2003).

- The operating system version (for example, 5.1.2600 0.0).
- The operating system language as represented by the locale identifier (LCID) (for example, 1033 for United States English). This is a standard international numeric abbreviation.
- The loaded and recently unloaded drivers. These identify the modules used by the kernel when the Stop error occurred, and the modules that were used recently.
- The list of drivers in the Drivers folder on your hard disk (systemroot\System32\Drivers).
- The file size, date created, version, manufacturer, and full product name for each driver.
- The number of available processors.
- The amount of random access memory (RAM).
- The time stamp that indicates when the Stop error occurred.
- The messages and parameters that describe the Stop error.
- The processor context for the process that stopped. This includes the processor, hardware state, performance counters, multiprocessor packet information, deferred procedure call information, and interrupts (requests from software or devices for processor attention).
- The process information and kernel context for the halted process. This includes the offset (location) of the directory table and the database that maintains the information about every physical page (block of memory) in the operating system.
- The process information and kernel context for the thread that stopped. This information identifies registers (data-storage blocks of memory in the processor) and interrupt request levels, and includes pointers to data structures for operating system data.
- The kernel-mode call stack for the interrupted thread. This is a data structure that consists of a series of memory locations and one or more pointers.

**Controlling Error Reporting to Prevent the Flow of Information to and from the Internet**

To prevent the automatic flow of information to and from the Internet when users and administrators report errors, you can configure error reporting in two ways: while deploying Windows Server 2003 using answer files with unattended or remote installation, or after deployment using Group Policy. There may be some aspects of error reporting that you want to configure using answer files, and others you may want to configure using Group Policy. Review the tables in this subsection to determine the configuration options that will work best for your organization.

**Using Unattended Installation**

You can configure error reporting by using standard methods for unattended or remote installation. You use the **[PCHealth]** section of an answer file to make entries for this feature. The following table describes those entries.

**Entries for Configuring Error Reporting in an Answer File (for Unattended Installation)**

| Entry | Description |
|---|---|
| ER_Display_UI | Specifies whether Setup notifies the user that an error has occurred and shows details about the error. When the entry is **ER_Display_UI = 0**, Setup does not notify the user that an error has occurred. |

| | |
|---|---|
| ER_Enable_Applications<br><br>ER_Include_EXE(n)<br><br>and<br><br>ER_Exclude_EXE(n) | **ER_Enable_Applications = All**<br><br>Reports errors for all applications except for those listed in ER_Exclude_EXE(*n*).<br><br>**ER_Enable_Applications = Listed**<br><br>Reports errors only for those applications listed in ER_Include_EXE(n). You can automatically include Microsoft applications by using ER_Include_MSApps.<br><br>**ER_Enable_Applications = None**<br><br>Reports no application errors.<br><br>Examples of entries that list included applications are:<br><br>**ER_Include_EXE1 = iexplore.exe**<br><br>**ER_Include_EXE2 = explorer.exe**<br><br>Examples of entries that list excluded applications are:<br><br>**ER_Exclude_EXE1 = calc.exe**<br><br>**ER_Exclude_EXE2 = notepad.exe** |
| ER_Enable_Kernel Errors | Specifies whether Windows reports errors in the Windows kernel. When the entry is **ER_Enable_Kernel Errors = 0**, Windows does not report errors in the Windows kernel. |
| ER_Enable_Reporting | Specifies whether Windows automatically reports errors. When the entry is **ER_Enable_Reporting = 0**, Windows does not report errors. |
| ER_Enable_Windows_ Components | Specifies whether to report errors in Windows components. When the entry is **ER_Enable_Windows_Components = 0**, Windows does not report errors in Windows components. To exclude individual Windows components, use ER_Exclude_EXE(*n*), as described earlier in this table. |
| ER_Force_Queue_Mode | Specifies whether to send all reports in queue mode. When the entry is **ER_Force_Queue_Mode = 0**, Windows does not send reports in queue mode. |
| ER_Include_MSApps | Specifies whether to track and report errors in Microsoft applications. When the entry is **ER_Include_MSApps = 0**, errors in Microsoft applications are not tracked and are not reported. |
| ER_Include_Shutdown_ Errs | Specifies whether to report shutdown errors. When the entry is **ER_Include_Shutdown_Errs = 0**, shutdown errors are not reported. |

For complete details about the entries for error reporting, see the resources listed in Appendix A: Resources for Learning About Automated Installation and Deployment. Be sure to review the information in the Deploy.chm file (whose location is provided in that appendix).

**Using Group Policy**

You can use Group Policy to disable Windows Error Reporting, or you can use it to redirect error reports to a server on your intranet, after which you can enable Corporate Error Reporting. By controlling error reporting through Group Policy, you override actions users may take.

This subsection includes a list of the settings in both the **Error Reporting** policy and the **Advanced Error Reporting** policy.

**Error Reporting Policy Settings**

The error reporting policy settings that you configure for Corporate Error Reporting are located at Computer Configuration\Administrative Templates\System\Error Reporting. The following list describes the policy settings.

- **Configure Error Reporting, enabled**: Errors are reported to Microsoft through the Internet or to a server on your intranet. Enabling **Configure Error Reporting** will override any error reporting settings made using Control Panel. Default values will be used for any error reporting settings that are not configured, even if settings were adjusted through Control Panel.

  In **Configure Error Reporting**, you can select the following:

  - Do not display links to any Microsoft provided "more information" web sites

    - Do not collect additional files
    - Do not collect additional machine data
    - Force queue mode for application errors

  In **Configure Error Reporting**, you can enter:

    - Corporate upload file path
    - Text with which to replace instances of the word "Microsoft"

- **Configure Error Reporting, disabled**: Users will not be given the option to report errors. If **Display Error Notification** is enabled, users will still get a message indicating that a problem occurred, but they will not have the option to report it.
- **Configure Error Reporting, not configured**: A person logged in as an administrator will be able to adjust the setting using Control Panel, which is set to "Enable error reporting" by default on Windows Server 2003 SP1.
- **Display Error Notification, enabled**: This setting controls whether a user is given the choice to report an error. When enabled, the user will be notified that an error has occurred and will be given access to details about the error.
- **Display Error Notification, disabled**: The user is not given the choice of whether to report the error. If Configure Error Reporting is enabled, the error will be automatically reported, but the user will not be notified that an error has occurred.
- **Display Error Notification, not configured**: A person logged in as an administrator will be able to adjust the setting through Control Panel, which is set to enable notification by default.

**Advanced Error Reporting Policy Settings**

When you enable error reporting, you can choose to specify the types of errors that are reported. In a highly managed environment, administrators might want to do this based on the kinds of information included in the error report (see "Types of data collected," in the previous subsection).

With **Advanced Error Reporting settings** you can configure the following policy settings:

- **Default application reporting settings**
- **List of applications to always report errors for**
- **List of applications to never report errors for**
- **Report operating system errors**
- **Report unplanned shutdown events**

These policy settings are located in Computer Configuration\Administrative Templates\System\Error Reporting. When you configure these policy settings, they will override any adjustments to error reporting that administrators might make through Control Panel.

To find more information about editing Group Policy, see Appendix B: Resources for Learning About Group Policy.

**How Controlling Error Reporting Can Affect Administrators**

What administrators will see on a server when an error occurs depends on how you have configured the **Error Reporting** policy settings. Depending on which policy settings you have enabled and which options you have configured, you can have administrators input varying amounts of information during error reporting, or none at all. You can choose not to have any user interface when a fault occurs, or, you can have a notification that an error has occurred, but not allow for the opportunity to send a report.

Another factor in how the user interface is affected is how you have configured the following policy settings: **List of applications to always report errors for** and **List of applications to never report errors for**. For more information about these policy settings, see "Procedures for Configuring Error Reporting" and "Related Links," later in this section.

The following table presents two examples of what the user will see when an error occurs if you have enabled the **Error Reporting** policy settings and if you have entered a path to a server. The first option presents the recommended policy settings.

**How Sending Error Reports to an Intranet Server Affects the User Interface**

| Configuration Options | User Interface |
|---|---|
| **Configure Error Reporting** enabled; **Corporate file path** entered; **Display Error Notification** enabled | • User is notified that an error occurred<br>• User might be asked for additional data<br>• Reports go to an intranet server |
| **Configure Error Reporting** enabled; **Corporate file path** entered; **Display Error Notification** not enabled | • No user interface<br>• Reports automatically go to an intranet server |

**Procedures for Configuring Error Reporting**

The following procedures explain how to:

- Use the **Configure Error Reporting** policy setting so error reports are sent to a server on your intranet instead of to Microsoft, so you can then use the Corporate Error Reporting tool to filter reports.
- Locate the Group Policy settings for configuring error reporting.
- Locate the Group Policy setting for disabling error reporting.
- Prevent error reporting by using an answer file for unattended installation.

**To Enable Corporate Error Reporting**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.
2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, and then click **Error Reporting**.
3. In the details pane, double-click **Display Error Notification**, and then click **Enabled**.
4. Click **Next Setting**, and then under **Configure Error Reporting**, click **Enabled**.
5. In the **Corporate upload file path** box, enter a UNC (Universal Naming Convention) path (*servername**sharename*).

| Note |
|---|
| Administrators can then filter the error reports using the CER tool described in the previous subsection, "Controlling Error Reporting to Prevent the Flow of Information to and from the Internet." |

Use the following two procedures to locate the Group Policy settings described in "Using Group Policy," earlier in this section.

**To Locate Group Policy Settings for Configuring Error Reporting**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, and then click **Error Reporting**.

3. View the Group Policy settings that are available. For more information about these settings, see "Error Reporting Policy Settings," earlier in this section.

4. Click **Advanced Error Reporting settings**.

5. View the advanced settings that are available. For more information about these settings, see the list in "Advanced Error Reporting Policy Settings," earlier in this section.

**To Disable Windows Error Reporting by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.

3. In the details pane, double-click **Turn off Windows Error Reporting**, and then click **Enabled**.

| **Important** |
| --- |
| You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

**To Prevent Error Reporting by Using an Answer File for Unattended Installation**

1. Using the methods you prefer for unattended installation or remote installation, create an answer file. For information about unattended installation, and for complete details about the entries for error reporting, see the resources listed in Appendix A: Resources for Learning About Automated Installation and Deployment. Be sure to review the information in the Deploy.chm file (whose location is provided in that appendix).

2. In the [PCHealth] section of the answer file, create entries according to the table in "Using Unattended Installation," earlier in this section. For example, to disable error reporting, the entry is:

```
[PCHealth]
ER_Enable_Reporting = 0
```

# Windows Media Player and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Windows Media Player
- How Windows Media Player communicates with sites on the Internet
- Procedures for configuration of Windows Media Player

**Resources Describing Windows Media Player Configuration Options**
This section of the white paper describes Microsoft Windows Media Player (also called the Player) in the context of use on a server. The Player is not commonly used in a server environment, unless it is being used to test a Windows Media server, so this section of the white paper does not provide extensive information about implementing a specific configuration for the Player. For example, this section does not provide information about allowing or preventing downloads of codecs or other software for the Player. (A codec, short for compressor/decompressor, is software that compresses or decompresses audio or video data.) This section of the white paper also does not describe Windows Media Services, which is described in a separate section of the white paper.

For information about implementing a specific desktop configuration for Windows Media Player 9 Series in your organization, see the white paper titled "Using Windows XP Professional with Service Pack 2 in a Managed Environment: Controlling Communication with the Internet." The white paper includes information about allowing or preventing downloads for the Windows Media Player 9 Series (for example, downloads of codecs or other software for the Player). This white paper can be found on the TechNet Web site at:

http://go.microsoft.com/fwlink/?LinkId=29133

Note that there are differences between Windows Media Player 9 Series in Windows XP SP2 and Windows Media Player 10 in Windows Server 2003 with SP1. However, the applicable Group Policy settings affect these two versions of the Player in the same way. Specifically, Group Policy settings in the following locations have the same effect on both Windows Media Player 9 Series in Windows XP SP2 and Windows Media Player 10 in Windows Server 2003 with SP1:

User Configuration\Administrative Templates\Windows Components\Windows Media Player

Computer Configuration\Administrative Templates\Windows Components\Windows Media Digital Rights Management

For a list of additional resources, see "Related Links," later in this section.

**Benefits and Purposes of Windows Media Player**
Windows Media Player 10 is the media player included with Microsoft Windows Server 2003 Service Pack 1 (SP1). The Player enables playing and organizing digital media files on computers and on the Internet. If you choose to use the Player on a server, you can listen to radio stations, search for and organize digital media files, and (with the right hardware) play CDs and DVDs, create custom CDs, and copy files to a portable device.

Windows Media Player 10 is described in this white paper because it can access media files on the Internet. In a highly managed network environment, you might want to control access to the Internet, including access gained through Windows Media Player. The rest of this section briefly describes how the Player communicates with the Internet, and how to control this communication.

**Overview: Using Windows Media Player in a Managed Environment**
Windows Media Player 10 in Windows Server 2003 SP1 is an integral component of the operating system and is installed by default. The Windows Media Player interface is accessed by navigating to Programs\Accessories\Entertainment or All Programs\Accessories\Entertainment from the Start menu. The Player is not commonly used in a server environment, unless it is being used to test a Windows Media server. If you do not want the Player accessible, you can use Group Policy to block access to the Player. The procedure for this configuration method is described later in this section.

**How Windows Media Player Communicates with Sites on the Internet**
The Windows Media Player has a number of features that connect to sites on the Internet. When a person at a server selects a feature such as the media **Guide** or **Skin Chooser\More Skins**, Windows Media Player connects to www.WindowsMedia.com through either a local area network (LAN) or a modem connection. When a person at a server selects a feature such as **Music**,

**Radio**, or **Movies & TV**, Windows Media Player connects to a related site, by default, a site at MSN.com such as radio.msn.com.

WindowsMedia.com is a Web site operated by Microsoft and is tightly integrated into Windows Media Player. Media Guide is a Web page provided by WindowsMedia.com. Other services provided by WindowsMedia.com include the Player updates and download support for codecs, skins, and visualizations. (A codec, short for compressor/decompressor, is software that compresses or decompresses audio or video data.)

To support the playback of secure content, Windows Media Player will also contact:

- Non-Microsoft digital rights management (DRM) license servers
- Microsoft DRM upgrade service

The other common Internet connections that Windows Media Player makes are to Windows Media servers run by content providers.

For details about how Windows Media Player 10 communicates with the Internet, including details about what information is sent, see "Related Links," later in this section, and see the privacy statement for Windows Media Player 10 on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46465

**Procedure for Controlling Windows Media Player**

Windows Media Player can be configured as described previously. This subsection provides a procedure for using Group Policy to prevent users or administrators from starting Windows Media Player.

| **Note** |
| --- |
| For information about implementing a specific configuration for Windows Media Player in your organization, see the sources listed in "Related Links," later in this section. |

**To use Group Policy to Prevent Users and Administrators from Starting Windows Media Player**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.
2. Click **User Configuration**, click **Administrative Templates**, and then click **System**.
3. In the details pane, double-click **Don't run specified Windows applications**.
4. Select **Enabled**, click **Show**, click **Add**, and then enter the application executable name, Wmplayer.exe.

**Related Links**

- For more information about deploying and managing Windows Media Player in an enterprise environment, see the following pages on the Windows Media Web site at:

  http://www.microsoft.com/Windows/WindowsMedia/

  http://go.microsoft.com/fwlink/?LinkId=46006

- For the privacy statement for Windows Media Player 10, see the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46465

- For information about implementing a specific desktop configuration for Windows Media Player 9 Series in your organization, see the white paper titled "Using Windows XP Professional with Service Pack 2 in a Managed Environment: Controlling Communication with the Internet." This white paper can be found on the TechNet Web site at:

http://go.microsoft.com/fwlink/?LinkId=29133

- For information about Windows Media Services, see the corresponding section of this white paper.

# Windows Media Services and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Windows Media® Services on servers running Microsoft Windows Server 2003 with Service Pack 1 (SP1).

  | Note |
  | --- |
  | Windows Media Services 9 Series is included in most editions of Windows Server 2003. However, Windows Media Services is not included in the Web Edition or in the Itanium-based versions of Windows Server 2003. |

  Windows Media Services delivers advanced streaming functionality such as multicasting, wireless network support, Internet authentication, server plug-ins, and Cache/Proxy APIs.

- For servers from which you want to offer content that will be streamed to an intranet or the Internet, the following types of information are provided:

  - Examples of features in Windows Media Services 9 Series that help you control communication to and from a Windows Media server. Windows Media Services 9 Series is the version of Windows Media Services included with Windows Server 2003 SP1.

  - References to more detailed information about Windows Media Services, including information about ports and security-related topics.

  - Information about installing the Windows Media Services and the Windows Media Services subcomponents, along with instructions for viewing the Help that is included with Windows Media Services.

- For servers from which you do not want to offer content on an intranet or the Internet, information about excluding or removing Windows Media Services.

It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization running servers that communicate across the Internet. This section, however, provides overview information as well as suggestions for other sources of information about balancing your organization's requirements for communication across the Internet with your organization's requirements for protection of networked assets.

| Note |
| --- |
| This section of the white paper describes Windows Media Services (the server component), but it does not describe Windows Media Player (the client component) or Internet Information Services (IIS), both of which are involved in carrying out communication of multimedia content across the Internet. For information about these components, see the respective sections of this white paper. |

**Benefits and Purposes of Windows Media Services**

Windows Media Services is an optional component in Windows Server 2003. With Windows Media Services, you can manage and deliver Windows Media content over an intranet or the Internet. The clients receiving the content can render it as it is being received, that is, without downloading the content first. Streaming greatly reduces the wait time and storage requirements on the client. It also permits presentations of unlimited length, as well as live broadcasts.

For more information about features in Windows Media Services, see the sources in "Related Documentation and Links," later in this section.

**Examples of Features that Help You Control Communication to and from a Windows Media Server**

This subsection provides brief descriptions of some features in Windows Media Services 9 Series that help you control communication to and from a Windows Media server. These features are integrated with two aspects of basic functionality built into the Windows Server 2003 operating system:

- Authentication
- Authorization

**Authentication**
Authentication is a fundamental aspect of security for a server running Windows Media Services. It confirms the identity of any unicast client trying to access resources on your Windows Media server. Windows Media Services includes authentication plug-ins that you can enable in order to validate user credentials for unicast clients. Authentication plug-ins work together with authorization plug-ins: after users are authenticated, authorization plug-ins control access to unicast content.

Windows Media Services authentication plug-ins fall into the following categories:

- **Anonymous authentication**. These are plug-ins that do not exchange challenge and response information between the server and a player, such as the WMS Anonymous User Authentication plug-in.
- **Network authentication**. These are plug-ins that validate unicast clients based on user logon credentials, such as the WMS Negotiate Authentication plug-in.

When you make decisions about how authentication might affect users, consider the following points:

- For multicast streaming with Windows Media Services 9 Series, clients do not establish a connection, and therefore authentication and authorization do not apply for multicasting. (Multicast streaming is only available if you have Windows Server 2003, Enterprise Edition, Windows Server 2003, Datacenter Edition, or the x64-based versions of these operating systems.)
- If a player is connected through HTTP, the player disconnects from the server each time the user stops, pauses, fast-forwards, or rewinds the content. If the user tries to continue receiving the content, the authentication and authorization process occurs again.

For more information about authentication and about the specific authentication plug-ins that you can enable for Windows Media Services, see the list in "Related Documentation and Links," later in this section.

**Authorization**
In order to control access to unicast content on your Windows Media server, unless you identify users only by IP address, you must enable one or more authentication plug-ins and also one or more authorization plug-ins. Authentication plug-ins verify the credentials of unicast clients attempting to connect to the server. Authorization plug-ins verify that the unicast client is allowed to connect to the server. Authorization occurs after authentication is successful.

You can enable authorization plug-ins to control the access to content by authenticated users. If you enable an authorization plug-in, with one exception, you must also enable an authentication plug-in for unicast clients to be able to access your publishing points. The exception is the WMS IP Address Authorization plug-in, which does not require an authentication plug-in to authenticate a unicast client.

Note that for multicast streaming with Windows Media Services 9 Series, clients do not establish a connection, and therefore authentication and authorization do not apply for multicasting. (Multicast streaming is only available if you have Windows Server 2003, Enterprise Edition, Windows Server 2003, Datacenter Edition, or the x64-based versions of these operating systems.)

During the authorization process, the server checks the user against the set of access permissions for the resource to which the user is trying to connect.

For more information about authorization, see the list in "Related Documentation and Links," later in this section.

**Firewall Information for Windows Media Services**
This subsection provides information about configuring firewalls (or proxy servers or both) for use with Windows Media Services. For more information about firewalls, see the sources in "Related Documentation and Links," later in this section, as well as the Windows Media Web site at:

http://go.microsoft.com/fwlink/?linkid=29862

You can configure each control protocol plug-in (Microsoft Media Server [MMS] protocol, Real Time Streaming Protocol [RTSP], and HTTP) to use a specific port to make firewall configuration easier. If opening ports on your firewall is not possible,

Windows Media Services can stream content by using the HTTP protocol over port 80.

| Note |
| --- |
| Using HTTP to stream content is disabled by default. |

Windows Media Services was formerly known as Microsoft NetShow Services; some firewalls have a preconfigured NetShow setting, which may work for Windows Media Services.

**Configuring Firewalls for Unicast Streaming**

To configure a firewall for unicast streaming, you must open the ports on the firewall that are required for the connection protocols enabled on your server. If you are streaming content by using either the Microsoft Media Server (MMS) protocol or the Real Time Streaming Protocol (RTSP), you need to support both the User Datagram Protocol (UDP) and Transmission Control Protocol (TCP).

To enable Windows Media Player and other clients to use the HTTP, RTSP, or MMS protocols to connect to a Windows Media server that is behind a firewall, open the ports described in the following table.

**Ports to Open When Clients are Connecting Using HTTP, RTSP, or MMS Protocols**

| Ports | Description |
| --- | --- |
| In: TCP on ports 80, 554, and 1755 | The Windows Media server uses the TCP In ports to accept an incoming HTTP connection (port 80), RTSP connection (port 554), or MMS connection (port 1755) from Windows Media Player and other clients. |
| In: UDP on ports 1755 and 5005 | The Windows Media server uses UDP In port 1755 to receive resend requests from clients streaming by using MMSU (MMS used with UDP), and UDP In port 5005 to receive resend requests from clients streaming by using RTSPU (RTSP used with UDP). |
| Out: UDP on ports 1024 through 5000. | The Windows Media server uses UDP Out ports 1024 through 5000 to send data to Windows Media Player and other clients. |

To enable a distribution server that is behind a firewall to use the HTTP or RTSP protocols to stream content that originates from a server outside the firewall, open the ports described in the following table.

**Ports to Open When a Distribution Server is Behind a Firewall and Uses HTTP or RTSP to Stream Content that Originates from a Server Outside the Firewall**

| Ports | Description |
| --- | --- |
| In: UDP on ports 1024 through 5000 | The Windows Media server uses UDP In ports 1024 through 5000 to receive data from another server. |
| Out: TCP on ports 80 and 554 | The Windows Media server uses the TCP Out ports to establish an HTTP connection (port 80) or RTSP connection (port 554) to another server or encoder. |
| Out: UDP on port 5005 | When RTSPU distribution is used, the Windows Media server uses UDP Out port 5005 to send resend requests to another server. |

| Note |
| --- |
| If it is not possible to open all the UDP Out ports on a firewall, UDP packets sent by a Windows Media server may be blocked by the firewall and may not be able to reach the clients on the other side of the firewall. If this is the case, clients may still be able to receive a stream by automatically rolling over to a TCP-based protocol, such as HTTP or RTSPT (RTSP used with TCP). However, the rollover will cause a delay for the client receiving the stream. |

| Note |
| --- |
| If you know you will not be able to support UDP streaming through a firewall, you can decrease the rollover delay by clearing the UDP check box in the Unicast Data Writer plug-in Properties dialog box. For more information, see the Help for Windows Media Services. A procedure for viewing Help is included in "Procedures for Installing, Removing, or Excluding Windows Media Services and Its Subcomponents," later in this section. |

For more information, see the sources in "Related Documentation and Links," later in this section.

**Configuring Firewalls for Multicast Streaming**

If you distribute content using multicast streaming, network traffic is directed through the standard Class D IP addresses (224.0.0.1 through 239.255.255.255). For multicast streaming, you must enable multicast-forwarding on your network. The Internet Group Management Protocol (IGMP), supported by Windows Media Services, ensures that multicast traffic passes through your network only when a player requests a multicast connection, so that enabling multicasting on your routers does not flood your network.

The following firewall configuration enables multicast packets to traverse your firewall:

**IP multicast address range**: 224.0.0.1 through 239.255.255.255

To enable IP multicasting, you must allow packets sent to the standard IP multicast address range to come through your firewall. This IP multicast address range must be enabled on both the player and server sides, as well as on every router in between. For more information about multicasting, see the section called "Delivering a multicast stream" in the white paper on the Windows Media Web site at:

http://go.microsoft.com/fwlink/?linkid=29862

**Enabling Access to an Encoder Outside a Firewall**

Encoders use HTTP to connect to a server running Windows Media Services. By default, Windows Media Encoder uses port 80 for HTTP connections; however, the encoder administrator can specify a different port. If a different port is used, you must specify the same port when you identify the encoder connection URL for the Windows Media server and when opening the port on your firewall.

The following example of a firewall configuration allows a computer running Windows Media Encoder outside a firewall to access a Windows Media server behind a firewall by using HTTP:

**In/Out**: Transmission Control Protocol (TCP) on port 80.

(The In port is the port through which the server accepts connections. The Out port is the port through which the server sends data to clients.)

**Answer File Entries and Registry Keys for Windows Media Services Subcomponents**

For reference purposes, the following table shows the syntax for answer file entries associated with Windows Media Services in Windows Server 2003. The table also shows the corresponding registry keys. Do not change the registry keys. They are shown for use in a script that could check whether a particular subcomponent is installed on a particular server. A registry key value of 0x00000000 means the subcomponent is not installed, and a value of 0x00000001 means the subcomponent is installed.

| **Note** |
|---|
| For more details about answer-file entries related to Windows Media Services subcomponents, including information about dependencies between the entries, see the references listed in Appendix A: Resources for Learning About Automated Installation and Deployment. Be sure to review the information in the Deploy.chm file (whose location is provided in that appendix). |

**Answer File Entries and Registry Keys for Windows Media Services Subcomponents for Windows Server 2003**

| **Windows Media Services subcomponent** | **Answer file entry (in the [Components] section)** | **Registry key (for use in a script that checks whether a subcomponent is installed): 0x00000000 means it is not installed; 0x00000001 mean it is installed** |
|---|---|---|
| Core Windows Media server components | wms = On \| Off | No key available (check for subcomponents by using other keys) |
| Windows Media Services Administrator for the Web | wms_admin_asp = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\<br>Windows\CurrentVersion\Setup\OC Manager\<br>Subcomponents\wms_admin_asp |
| Windows Media Services MMC snap-in | wms_admin_mmc = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\<br>Windows\CurrentVersion\Setup\OC Manager\<br>Subcomponents\wms_admin_mmc |

| | | |
|---|---|---|
| Multicast and Advertisement Logging Agent components | wms_isapi = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\<br>Windows\CurrentVersion\Setup\OC Manager\<br>Subcomponents\wms_isapi |
| Windows Media Services server components | wms_server = On \| Off | HKEY_LOCAL_MACHINE\Software\Microsoft\<br>Windows\CurrentVersion\Setup\OC Manager\<br>Subcomponents\wms_server |

**Procedures for Installing, Removing, or Excluding Windows Media Services and Its Subcomponents**
The following procedures explain how to:

- Add or remove Windows Media Services on a computer after setup is complete for Windows Server 2003.
- View the Help that is included with Windows Media Services.
- Prevent the installation of Windows Media Services during unattended installation by using an answer file.
- Specify answer file entries that control whether Windows Media Services subcomponents are included during unattended installation.

| **Note** |
|---|
| Windows Media Services 9 Series is included in most editions of Windows Server 2003. However, Windows Media Services is not included in the Web Edition or in the Itanium-based versions of Windows Server 2003. |

**To Add or Remove Windows Media Services on an Individual Computer after Setup is Complete**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. Click **Add/Remove Windows Components** (on the left).
4. Select **Windows Media Services**.
5. Perform one of the following steps:
   - If Windows Media Services is installed and you want to remove it, clear the check box for **Windows Media Services** and complete the wizard.
   - If Windows Media Services is not installed and you want to add it, select the check box for **Windows Media Services** and complete the wizard.
   - If you want to view the list of Windows Media Services subcomponents, after selecting **Windows Media Services**, click **Details**.

**To View the Help That Is Included with Windows Media Services**

1. Make sure that Windows Media Services is installed by using the previous procedure.
2. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
3. Double-click **Administrative Tools** and then click **Windows Media Services**.

4. Click the **Help** menu and then click **Help Topics**.

**To Specify Answer File Entries that Control Whether Windows Media Services Subcomponents are Included During Unattended Installation**

1. Using the methods you prefer for unattended installation or remote installation, create an answer file.

2. In the [Components] section of the answer file, add the appropriate entries listed in the table in "Answer File Entries and Registry Keys for Windows Media Services Subcomponents," earlier in this section. Ensure that the entries specify **Off** for components you do not want to install and **On** for components you want to install.

   If no Windows Media Services subcomponents are listed in an answer file for unattended installation of Windows Server 2003, these components are not installed by default.

| **Note** |
| --- |
| For more information about unattended installation, and for details about dependencies between answer-file entries related to Windows Media Services subcomponents, see the references listed in Appendix A: Resources for Learning About Automated Installation and Deployment. Be sure to review the information in the Deploy.chm file (whose location is provided in that appendix). |

**To Prevent the Installation of Windows Media Services During Unattended Installation by Using an Answer File**

1. Using the methods you prefer for unattended installation or remote installation, create an answer file. For more information about unattended and remote installation, see Appendix A: Resources for Learning About Automated Installation and Deployment.

2. In the [Components] section of the answer file, ensure that there are no entries for the subcomponents listed in the table in "Answer File Entries and Registry Keys for Windows Media Services Subcomponents," earlier in this section. If you want to list any of these subcomponents, ensure that the entries specify **Off**.

If no Windows Media Services subcomponents are listed in an answer file for unattended installation of Windows Server 2003, these subcomponents are not installed by default.

# Windows Time Service and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about the following:

- The benefits of Windows Time Service
- How Windows Time Service communicates with sites on the Internet
- How to control Windows Time Service to limit the flow of information to and from the Internet
- How to monitor and troubleshoot Windows Time Service after configuration is complete

**Benefits and Purposes of Windows Time Service**

Many components of Microsoft Windows Server 2003 rely on accurate and synchronized time to function correctly. For example, without clocks that are synchronized to the correct time on all computers, Windows Server 2003 authentication might falsely interpret logon requests as intrusion attempts and consequently deny access to users.

With time synchronization, you can correlate events on different computers in an enterprise. With synchronized clocks on all of your computers, you ensure that you can correctly analyze events that happen in sequence on multiple computers. Windows Time Service automatically synchronizes a local computer’s time with other computers on a network to improve security and performance in your organization.

**Overview: Using Windows Time Service in a Managed Environment**

Computers keep the time on their internal clocks, which allows them to perform any function that requires the date or time. For scheduling purposes, however, the clocks must be set to the correct date and time, and they must be synchronized with the other clocks in the network. Without some other method in place, these clocks must be set manually.

With time synchronization, computers set their clocks automatically to match another computer's clock. One computer maintains very accurate time, and then all other computers set their clocks to match that computer. In this way, you can set accurate time on all computers.

Windows Time Service is installed by default on all computers running Windows Server 2003 and Windows XP. Windows Time Service uses Coordinated Universal Time (UTC), which is independent of time zone. Time zone information is stored in the computer's registry and is added to the system time just before it is displayed to the user.

By default, Windows Time Service starts automatically on computers running Windows XP. In a domain, time synchronization takes place when Windows Time Service turns on during system startup and periodically while the system is running. In the default configuration, the Net Logon service looks for a domain controller that can authenticate and synchronize time with the client. When a domain controller is found, the client sends a request for time and waits for a reply from the domain controller. This communication is an exchange of Network Time Protocol (NTP) packets intended to calculate the time offset and round-trip delay between the two computers.

Note that computers running Windows Server 2003 use the Network Time Protocol (NTP), while computers running Windows 2000 use the Simple Network Time Protocol (SNTP).

**How Windows Time Service Communicates with Sites on the Internet**

In Windows Server 2003, Windows Time Service automatically synchronizes the local computer's time with other computers on the network. The time source for this synchronization varies, depending on whether the computer is joined to a domain in the Active Directory directory service or to a workgroup.

**When a Server Running Windows Server 2003 is Part of a Workgroup**

In this scenario, the default setting for the time synchronization frequency is set to "once per week," and this default setting uses the time.windows.com site as the trusted time synchronization source. This setting will remain until you manually set it otherwise. One or more computers might be identified as a locally reliable time source by configuring Windows Time Service on those computers to use a known accurate time source, either by using special hardware or a time source available on the Internet. All other workgroup computers can be configured manually to synchronize their time with these local time sources.

**When a Server Running Windows Server 2003 is a Member of a Domain**

In this scenario, Windows Time Service configures itself automatically, using the Windows Time Service that is available on the domain controllers.

Windows Time Service on a domain controller can be configured as either a reliable or an unreliable time source. Windows Time Service running on a client will attempt to synchronize its time source with servers that are indicated as reliable. Windows Time Service can configure a domain controller within its domain as a reliable time source, and it synchronizes itself periodically with this source. These settings can be modified or overwritten, depending on specific needs.

**Communication Between Windows Time Service and the Internet**

The following list describes various aspects of Windows Time Service data that is sent to and from the Internet and how the exchange of information takes place.

- **Specific information sent or received**: The service sends information in the form of a Network Time Protocol (NTP) packet. For more information about Windows Time Service and NTP packets, see the references listed in "Related Links," later in this section.

- **Default and recommended settings**: Computers that are members of an Active Directory domain synchronize time with domain controllers by default. Domain controllers synchronize time with their parent domain controller. By default, the root parent domain controller will not synchronize to a time source. The root parent domain controller can be set to either synchronize to a known and trusted Internet-based time source, or a hardware time device that provides an NTP or SNTP interface. Its time accuracy can also be maintained manually.

  We recommend that you configure the authoritative time server to synchronize to a hardware source, not an Internet time source. For more information, see article 884776, "Configuring the Windows Time service against a large time offset" in the Microsoft Knowledge Base at:

  http://go.microsoft.com/fwlink/?LinkId=46021

- **Triggers and user notification**: Windows Time Service is started when the computer starts. Additionally, the service will continue to synchronize time with the designated network time source and adjust the computer time of the local computer when necessary. Notification is not sent to the user.

- **Logging**: Information related to the service is stored in the Windows System event log. The time and network address of the time synchronization source is contained in the Windows event log entries. Additionally, warning or error condition information related to the service is stored in the Windows System event log.

- **Encryption**: Encryption is not used in the network time synchronization for domain peers. (Authentication, however, is used.)

- **Information storage**: The service does not store information, as all information that results from the time synchronization process is lost when the time synchronization service request is completed.

- **Port**: NTP and SNTP use User Datagram Protocol (UDP) port 123 on time servers. If this port is not open to the Internet, you cannot synchronize your server to Internet SNTP or NTP servers.

- **Protocol**: The service on Windows Server 2003 implements NTP to communicate with other computers on the network.

- **Ability to disable**: Disabling the service might have indirect effects on applications or other services. Applications and services that depend on time synchronization, such as Kerberos V5 authentication protocol, may fail, or they may yield undesirable results if there is a significant time discrepancy among computers. Because most computers' hardware-based clocks are imprecise, the difference between computer clocks on the network usually increases over time.

**Controlling Windows Time Service to Limit the Flow of Information to and from the Internet**

Group Policy can be used to control Windows Time Service for computers that are running Windows Server 2003 to limit the flow of information to and from the Internet.

The synchronization type and NTP time server information can be managed and controlled through Group Policy. The Windows Time Service Group Policy object (GPO) contains configuration settings that specify the synchronization type. When the synchronization type is set to NT5DS, Windows Time Service synchronizes its time resource with the network domain controller. Alternatively, setting the type attribute to NTP configures Windows Time Service to synchronize with a specified NTP time server. The NTP server is specified by either its Domain Name System (DNS) name or its IP address when you select NTP as the synchronization type.

For more information about configuring Windows Time Service during deployment of products in the Windows Server 2003 family, see *Designing and Deploying Directory and Security Services* and *Designing a Managed Environment* in the *Microsoft Windows Server 2003 Deployment Kit* at:

http://go.microsoft.com/fwlink/?linkid=44319

Clients on a managed network can be configured to synchronize computer clock settings to an NTP server on the network to minimize traffic out to the Internet and to ensure that the clients synchronize to a single reliable time source. If you choose to do so, you can disable time synchronization for both non-domain and domain computers running Windows Server 2003 by using Group Policy. The procedures for configuring Windows Time Service are given at the end of this section of the white paper.

**How Windows Time Service Can Affect Users and Applications**

Windows components and services depend on time synchronization. For example, the Kerberos V5 authentication protocol on a Windows Server 2003 family domain has a default time synchronization threshold of five minutes. Computers that are more than five minutes out of synchronization on the domain will fail to authenticate using the Kerberos protocol. This time value is also configurable, allowing for greater or lesser thresholds. Failure to authenticate using the Kerberos protocol can prevent logons and access to Web sites, file shares, printers, and other resources or services within a domain.

When the local clock offset has been determined, the following adjustments are made to the time:

- If the local clock time of the client differs from the time on the server by more than the threshold amount, Windows Time Service will change the local clock time immediately. The threshold is five minutes if the computer is part of a domain. For more information about Windows Time Service settings in a domain, see "Related Links" later in this section.

  The threshold is one second if the computer is part of a workgroup. However, if a computer is part of a workgroup and the time differs from the time source by more than 15 hours, the time is not synchronized, as described later in this list.

- If the local clock time of the client differs from the server by less than the threshold amount, the service will gradually synchronize the client with the correct time.

- In a workgroup, if the local clock time of the client differs from the time on a time source by more than 15 hours, a workstation running Windows Time Service and using default settings will not synchronize with the time source. Such occurrences are rare, and are often caused by configuration setting errors. For example, if a user sets the date on the computer incorrectly, the time does not synchronize. Under these circumstances, most often the time is off by a day or more. Be sure to check the computer's calendar and ensure that the correct date has been set.

**Configuration Settings for Windows Time Service**

You can set the global configuration settings for Windows Time Service by using Group Policy. The settings that might be relevant to communication between Windows Time Service and the Internet are described in this subsection.

In Computer Configuration\Administrative Templates\System\Windows Time Service\Global Configuration Settings, there is only one setting that might, in certain scenarios, affect the way that Windows Time Service communicates when the computer is in a domain. This setting is **AnnounceFlags**, which controls whether this computer is marked as a reliable time server. A computer is not marked as reliable unless it is also marked as a time server. The settings are as follows:

- 0 Not a time server

- 1 Always a time server

- 2 Automatic time server, meaning the role is decided by Windows Time Service

- 4 Always a reliable time server

- Automatic reliable time server, meaning the role is decided by Windows Time Service

The default is 10, meaning that Windows Time Service decides the role.

In the Group Policy settings located in Computer Configuration\Administrative Templates\System\Windows Time Service\Time Providers, there are a number of settings that might affect the way that Windows Time Service communicates across the Internet. The following table describes some of these policy settings.

| Note |
| --- |
| The table lists the settings that most directly affect the way Windows Time Service communicates with time sources, but the table does not list all settings. For example, it does not list the setting that specifies the location of the Windows Time Service DLL or the setting that controls the logging of events for Windows Time Service. |

**Selected Group Policy Settings for Configuring the Windows Time Service NTP Client for Computers Running Windows Server 2003**

| Policy Setting | Effect of Setting | Default Setting |
| --- | --- | --- |
| NtpServer | Establishes a space-delimited list of peers from which a computer obtains time stamps, consisting of one or more DNS names or IP addresses per line. Computers connected to a domain must synchronize with a more reliable time source, such as the official U.S. time clock. This setting is used only when Type is set to NTP or AllSync.<br><br>0x01 SpecialInterval<br><br>0x02 UseAsFallbackOnly<br><br>0x04 SymmetricActive<br><br>0x08 NTP request in Client mode | time.windows.com, 0x1 |
| Type | Indicates which peers to accept synchronization from:<br><br>**NoSync**. The time service does not synchronize with other sources.<br><br>**NTP**. The time service synchronizes from the servers specified in the NtpServer registry entry.<br><br>**NT5DS**. The time service synchronizes from the domain hierarchy.<br><br>**AllSync**. The time service uses all the available synchronization mechanisms. | Default options<br><br>**NTP**. Use on computers that are not joined to a domain.<br><br>**NT5DS**. Use on computers that are joined to a domain. |
| CrossSiteSyncFlags | Determines whether the service chooses synchronization partners outside the domain of the computer.<br><br>None 0<br><br>PdcOnly 1<br><br>All 2<br><br>This value is ignored if the NT5DS value is not set. | 2 |
| ResolvePeerBackoffMinutes | Specifies the initial interval to wait, in minutes, before attempting to locate a peer to synchronize with. If the Windows Time Service cannot successfully synchronize with a time source, it will keep retrying, using the settings specified in ResolvePeerBackOffMinutes and ResolvePeerBackoffMaxTimes. | 15 |
| ResolvePeerBackoffMaxTimes | Specifies the maximum number of times to double the wait interval when repeated attempts fail to locate a peer to synchronize with. A value of zero means that the wait interval is always the initial interval in ResolvePeerBackoffMinutes. | 7 |
| SpecialPollInterval | Specifies the special poll interval in seconds for peers that have been configured manually. When a special poll is enabled, Windows Time Service will use this poll interval instead of a dynamic one that is determined by synchronization algorithms built into Windows Time Service. | 604800 (workgroup)<br><br>3600 (domain) |

For other sources of information about Group Policy, see Appendix B: Resources for Learning About Group Policy.

For information about configuring the authoritative time server in a domain, see article 884776, "Configuring the Windows Time service against a large time offset" in the Microsoft Knowledge Base at:

http://go.microsoft.com/fwlink/?LinkId=46021

**Procedures for Configuring Windows Time Service**

The following procedures explain how to set some of the Windows Time Service configuration settings available in Group Policy. For details about other Group Policy settings for Windows Time Service, see the table earlier in this section.

**To Set Group Policy for Windows Time Service Global Configuration Settings**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, and then click **Windows Time Service**.

3. In the details pane, double-click **Global Configuration Settings**, and then click **Enabled**. Configure settings as appropriate for your environment.

**To Configure the Group Policy Setting to Prevent Your Computer from Servicing Time Synchronization Requests from Other Computers on the Network**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Windows Time Service**, and then click **Time Providers**.

3. In the details pane, double-click **Enable Windows NTP Server**, and then select **Disabled**.

**Starting and Stopping Windows Time Service**

By default, Windows Time Service starts automatically at system startup. You can, however, start or stop the service manually by accessing services in Administrative Tools or by using the **net** command.

**To Manually Start Windows Time Service Using the Graphical Interface**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Administrative Tools**, and then double-click **Services**.

3. Select **Windows Time** from the list of services.

4. On the **Action** menu, click **Start** to begin the service.

**To Manually Stop Windows Time Service Using the Graphical Interface**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Administrative Tools**, and then double-click **Services**.

3. Select **Windows Time** from the list of services.

4. On the **Action** menu, click **Stop** to discontinue the service.

**To Manually Start Windows Time Service Using the Net Command**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **net start w32time**, and then press ENTER.

**To Manually Stop Windows Time Service Using the Net Command**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **net stop w32time**, and then press ENTER.

**Synchronizing Computers with Time Sources**

Use the following procedures to synchronize the internal time server with an external time source, and to synchronize the client time with a time server.

**To Synchronize an Internal Time Server with an External Time Source**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type the following, where *PeerList* is a comma-separated list of Domain Name System (DNS) names or Internet protocol (IP) addresses of the desired time sources:

   **w32tm /config /syncfromflags:manual /manualpeerlist:***PeerList*

   and then press ENTER.

3. Type **w32tm /config /update** and then press ENTER.

| **Note** |
| --- |
| The most common use of this procedure is to synchronize the internal network's authoritative time source with precise external time source. This procedure can be run on any computer running Windows 2000, Windows XP, or Windows Server 2003. |

| **Note** |
| --- |
| If the computer cannot reach the servers, the procedure fails and an entry is written to the Windows System event log. |

**To Synchronize the Client Time with a Time Server**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **w32tm /resync**, and then press ENTER.

| **Note** |
| --- |
| The W32tm command-line tool is used for diagnosing problems that can occur with Windows Time Service. |

**Monitoring and Troubleshooting Windows Time Service**

In many cases, problems with Windows Time Service can be attributed to network configuration. If the network is not configured correctly, computers might not be able to communicate to send time samples back and forth. Viewing the contents of NTP packets can help you to identify exactly where a packet is blocked on a network. An error associated with Windows Time Service might occur when a computer is unable to synchronize with an authoritative source. You can use the W32tm command-line tool to assist you in troubleshooting this and other types of errors associated with Windows Time Service.

The W32tm command-line tool is the preferred command-line tool for configuring, monitoring, and troubleshooting Windows Time Service. For more information, search for "W32tm" in Help and Support Center.

**Procedure to Follow When a Computer Is Unable to Synchronize**

By default, a computer running Windows Time Service will not synchronize with a time source if the computer's time is more than 15 hours off. For information about scenarios in which this can occur, see "How Windows Time Service Can Affect Users and Applications," earlier in this section.

**To Resynchronize the Client Time with a Time Server**

1. To open a Command Prompt window, click **Start**, click **Run**, type **cmd**, and then click **OK**.

2. At the command prompt, type **w32tm /resync /rediscover** and then press ENTER.

| **Note** |
| --- |
| When you run the preceding command, it redetects the network configuration and rediscovers network resources, causing resynchronization. You can then view the event log for more information about why the time service does not synchronize. |

http://go.microsoft.com/fwlink/?LinkId=44319

For information about configuring the authoritative time server in a domain, see article 884776, "Configuring the Windows Time service against a large time offset" in the Microsoft Knowledge Base at:

http://go.microsoft.com/fwlink/?LinkId=46021

# Windows Update, Automatic Updates, and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about the following:

- The benefits of Windows Update and Automatic Updates
- How Windows Update and Automatic Updates communicate with sites on the Internet
- How to control Windows Update and Automatic Updates to limit the flow of information to and from the Internet

| **Important** |
| --- |
| This section describes methods for controlling the way the Automatic Updates component interacts with the Windows Update Web site. To control the way Automatic Updates interacts with Windows Update, also control the type of accounts that people log on with. If an account does not allow software to be installed (for example, if the account is a user account), only one option for Automatic Updates will function while that person is logged on. That option is the automatic download and installation of updates, which means that updates are installed on the computer at a regularly scheduled time, regardless of what type of account the person who uses the computer has, or whether that person is logged on at the time. |

**Benefits and Purposes of Windows Update and Automatic Updates**

**Windows Update**

Windows Update is an online catalog that can be used to support computers running Microsoft Windows operating systems, including Windows Server 2003 with Service Pack 1 (SP1). The catalog contains items such as drivers, critical updates, Help files, and Internet products. Windows Update scans the computer and provides a tailored selection of updates that apply only to the software and hardware on that specific computer. Windows Update then enables you choose updates for your computer's operating system and hardware. New content is added to the Windows Update Web site regularly, so you can always get the most recent and secure updates and solutions.

Windows Update contains two key components:

- **Web site control**: The Windows Update Web site includes an ActiveX Web control program that downloads and installs updates. The Windows Update team receives feedback from their customers on how to improve their Web site, and responds by periodically updating the Web control. The newest version of the Web control program is downloaded automatically when you visit the Windows Update site or when any of the other Windows features calls on the Windows Update control. Just like downloading an ActiveX control, you may receive a security dialog box that a Web control is attempting to be installed. You may not receive the dialog box if you have selected to always trust Microsoft as a content provider (using security settings in Microsoft Internet Explorer). If you do not click Yes on the security dialog box, the control will not be updated and you will not be able to access the Windows Update site.

- **Updates**: As needed, you can access the Windows Update Web site and select component updates to download and install. You control the downloading and installation of the updates. The Windows Update Web site is located at:

  http://windowsupdate.microsoft.com/

**Automatic Updates**

Automatic Updates is not enabled by default. The person who installs the operating system is prompted to enable this option following setup. When Automatic Updates is configured so that updates automatically download and install, the person who uses the computer does not need to visit special Web pages or remember to periodically check for new updates. Automatic Updates can be configured to use one of the following options:

- **Automatic download and installation of updates**: Windows Server 2003 downloads and installs updates automatically on a schedule specified by an administrator of the computer. Updates are installed regardless of what type of account the person who uses the computer has, or whether that person is logged on at the time.

- **Automatic download only**: Windows Server 2003 automatically starts the download whenever it finds updates available for the computer. The updates are downloaded in the background, enabling you to continue working uninterrupted. After the download is complete, if you are logged on as an administrator, an icon in the notification area will prompt you that the updates are ready to be installed.

- **Notification only**: Windows Server 2003 sends a notification after which an administrator of the computer can respond by downloading and installing any updates.

- **Turn off Automatic Updates**: It is left to you to go to the Windows Update Web site and download updates from time to time.

An administrator can decline a specific update that has been downloaded. The administrator can download those declined files again by opening the Performance and Maintenance category in Control Panel, clicking the **System** tool, clicking the **Automatic Updates** tab, and then clicking **Offer updates again that I've previously hidden**. If any of the previously declined updates can still be applied to the computer, those updates will appear the next time that Windows Server 2003 notifies the administrator of available updates.

For more information about using Control Panel to configure Automatic Updates, see "Procedures for Controlling Windows Update and Automatic Updates," later in this section.

**Alternatives to Windows Update and Automatic Updates**
For managed environments, there are several alternatives to Windows Update:

- Windows Update Catalog Web site

- Microsoft Software Update Services (SUS)

- Distribution software, such as Microsoft Systems Management Server, that can be used to distribute software updates

  For more information, see the documentation for your distribution software, and see Appendix A: Resources for Learning About Automated Installation and Deployment, especially the "Related Documentation and Links" subsection in that appendix.

**Windows Update Catalog Web Site**
By using the Windows Update Catalog site, you can use your own software distribution tools to deploy updates to Windows in a managed environment without requiring users to connect to the Windows Update Web site. The Windows Update Catalog site provides a comprehensive catalog of updates that can be distributed over a managed network. It provides a single location for Windows Update content and drivers that display the Designed for Windows logo. Administrators can search the site using keywords or predefined search criteria to select the relevant downloads and then download the updates to a location on their internal network.

An enhancement in products in the Windows Server 2003 family enables you to select updates that you plan to deploy later, which means that you can control how and when the updates are deployed. For additional information, see information about Windows Update on the Microsoft Web site at:

http://windowsupdate.microsoft.com/

**Microsoft Software Update Services (SUS)**
Microsoft Software Update Services (SUS) is a version of Windows Update designed for installation inside the boundary defined by an organization's firewall. This feature is very useful for organizations that

- Do not want their systems or users connecting to an external Web site

- Want to first test these updates before deploying them throughout their organizations

Microsoft Software Update Services enables administrators to quickly and reliably deploy critical updates to servers running Windows Server 2003 and Windows 2000 Server as well as desktop computers running Windows XP Professional and Windows 2000 Professional.

For more information about Software Update Services and updated versions of Software Update Services, see the Microsoft

Web site at:

http://go.microsoft.com/fwlink/?LinkId=29906

**Overview: Using Windows Update and Automatic Updates in a Managed Environment**
As an administrator, you can use Group Policy to block the use of Windows Update or to specify an internal server for Automatic Updates to use when searching for updates. You can also disable Automatic Updates using Control Panel or using the Group Policy Administrative template, Wuau.adm. Details on the methods and procedures for controlling these features are described in the following subsections.

**How Windows Update and Automatic Updates Communicate with Sites on the Internet**
This subsection summarizes the communication process.

- **Specific information sent or received**: Drivers and replacement files (critical updates, Help files, and Internet products) may be downloaded to the computer. The computer is uniquely identified and is logged in the download and installation success report, but the person using the computer is not uniquely identified.

- **Data storage and access**: Windows Update tracks the total number of unique computers that visit the Windows Update Web site. The success or failure of downloading and installing updates is also recorded but no personal information, such as user name or e-mail address, is recorded as part of this. The information that is recorded is stored on servers at Microsoft with limited access that are located in controlled facilities.

  For more information, see "Privacy," later in this list.

| **Note** |
| --- |
| If you want to block the use of the Windows Update Web site, you can apply Group Policy settings to specify an internal server for updates and for storing upload statistics. For more information, see "Procedures for Controlling Windows Update and Automatic Updates." |

- **Default and recommended settings**: By default, Windows Server 2003 allows access to the Windows Update Web site. Recommended settings are described in the next subsection, "Controlling Windows Update and Automatic Updates to Limit the Flow of Information to and from the Internet."

- **Triggers**: You control whether to run Windows Update. If Automatic Updates is enabled following setup, it is triggered about once per day when there is an Internet connection.

- **User notification**:

  - **Windows Update Web site**: You control whether to go to the Windows Update Web site to download files to your computers.

  - **Automatic Updates**: The way that Automatic Updates notifies you depends on how Automatic Updates is configured. For more information, see "Automatic Updates," earlier in this section.

| **Note** |
| --- |
| For information about configuring Automatic Updates, see "To Configure or Disable Automatic Updates Using Control Panel on a Computer Running Windows Server 2003 with SP1," later in this section. |

- **Logging**: Automatic Updates logs events to the event log.

- **Encryption**: Initial data is transferred using HTTPS, and updates are transferred using HTTP. The data packages downloaded to the system by Microsoft are digitally signed.

- **Privacy**: To view the privacy statement for Windows Update, see the Windows Update Web site, and click **Windows Update Privacy Statement**. The Windows Update Web site is located at:

http://windowsupdate.microsoft.com/

Automatic Updates is covered by the same privacy statement that covers Windows Update.

- **Transmission protocols and ports**: The transmission protocols and ports used are HTTP 80 and HTTPS 443.

- **Ability to disable**: You can use Group Policy to prevent the operating system from being updated through Windows Update, to prevent access to Windows Update commands, or both. You can use Group Policy to specify an internal server to use for Automatic Updates. You can disable Automatic Updates using Control Panel tools or Group Policy. Procedures for these methods are given at the end of this section.

**Controlling Windows Update and Automatic Updates to Limit the Flow of Information to and from the Internet**
The recommended methods for controlling Windows Update and Automatic Updates or both are as follows.

| **Important** |
| --- |
| When using these methods, also control the type of accounts that people log on with. If an account does not allow software to be installed (for example, if the account is a user account), only one option for Automatic Updates will function while that person is logged on. That option is the automatic download and installation of updates, which means that updates are installed on the computer at a regularly scheduled time, regardless of what type of account the person who uses the computer has, or whether that person is logged on at the time. |

- You can use Group Policy settings to disable both Windows Update and Automatic Updates.

    - To disable Windows Update and Automatic Updates by preventing the operating system from being updated through Windows Update, configure **Turn off access to all Windows Update features** in Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings.

    - To disable Windows Update and Automatic Updates by preventing access to Windows Update commands, configure **Remove links and access to Windows Update** in User Configuration\Administrative Templates\Start Menu and Taskbar.

- You can use Group Policy to configure Automatic Updates so that instead of searching the Windows Update Web site, Automatic Updates searches your internal server for updates.

  To do this, configure **Specify intranet Microsoft update service location** in Computer Configuration\Administrative Templates\Windows Components\Windows Update. The server you specify in this setting must be one on which you are running Software Update Services or an updated version of Software Update Services.

- You can use Group Policy settings in the Administrative template Wuau.adm to selectively disable Automatic Updates.

  To do this, disable **Configure Automatic Updates** in Computer Configuration\Administrative Templates\Windows Components\Windows Update.

You can also configure Automatic Updates on individual computers by using Control Panel. For a description of the options available through Control Panel, see "Automatic Updates," earlier in this section.

**How Disabling Windows Update and Automatic Updates Can Affect Users or Administrators and Applications**
The following list shows the effects of two Group Policy settings, both of which prevent the use of Windows Update and Automatic Updates.

- Turn off access to all Windows Update features: This Group Policy setting is located in Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings.

When you enable this setting, the operating system cannot be updated through Windows Update, and Automatic Updates is disabled. Users or administrators can still perform actions such as clicking the **Windows Update** option on the **Start** menu, and the Windows Update Web site will appear in the browser. However, it will not be possible to update the operating system through Windows Update, regardless of the type of account being used to log on.

- Remove links and access to Windows Update This Group Policy setting is located in User Configuration\Administrative Templates\Start Menu and Taskbar. When you enable this setting, you will not be able to access the Windows Update Web site from any of the following locations:

  - The **Windows Update** option on the **Start** menu

  - The **Tools** menu in Microsoft Internet Explorer

  - The **Windows Update** button in **Add New Programs** (**Add New Programs** is in Control Panel under **Add or Remove Programs**)

  Enabling this setting also disables Automatic Updates notifications—that is, the user for which this policy setting is enabled will neither be notified about nor receive critical updates from Windows Update.

Removing access to Windows Update also prevents Device Manager from automatically installing driver updates from the Windows Update Web site. For more information about controlling Device Manager, see the section of this white paper titled Device Manager, Hardware Wizards, and Internet Communication.

Blocking Windows Update and Automatic Updates will not block applications from running.

The Windows Update site is located at:

http://windowsupdate.microsoft.com/

**Procedures for Controlling Windows Update and Automatic Updates**
This subsection provides procedures for the following:

- Configuring or disabling Automatic Updates by using Group Policy.

- Preventing the operating system from being updated through Windows Update by using Group Policy. With this policy, commands for accessing Windows Update are visible and the Windows Update site can be viewed through the browser, although Windows Update cannot be used.

- Turning off access to Windows Update commands and to Automatic Updates by using Group Policy.

- Specifying an internal server for Windows Update by using Group Policy.

- Configuring or disabling Automatic Updates using Control Panel on a computer running Windows Server 2003 SP1.

**To Configure or Disable Automatic Updates Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated (specifically, Wuau.adm), and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Windows Update**.

3. In the details pane, double-click **Configure Automatic Updates**.

4. Select **Not Configured**, **Enabled**, or **Disabled**. If you choose **Enabled**, choose from the available settings, which are equivalent to the Control Panel settings described in "Automatic Updates," earlier in this section.

| Note |
| --- |
| Disabling this setting disables Automatic Updates but does not block access to Windows Update. |

**To Prevent the Operating System from Being Updated Through Windows Update by Using Group Policy**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **System**, click **Internet Communication Management**, and then click **Internet Communication settings**.

3. In the details pane, double-click **Turn off access to all Windows Update features**.

| Important |
| --- |
| This policy also disables Automatic Updates.<br><br>You can also restrict Internet access for this and a number of other components by applying the **Restrict Internet communication** policy setting, which is located in Computer Configuration/Administrative Templates/System/Internet Communication Management. For more information about this Group Policy and the policies that it controls, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key. |

**To Turn Off Access to Windows Update Commands by Using Group Policy**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **User Configuration**, click **Administrative Templates**, and then click **Start Menu and Taskbar**.

3. In the details pane, double-click **Remove links and access to Windows Update**.

| Important |
| --- |
| This policy also disables Automatic Updates. |

**To Specify an Internal Server for Windows Update Using Group Policy**

1. As needed, see Appendix B: Resources for Learning About Group Policy, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **Windows Components**, and then click **Windows Update**.

3. In the details pane, double-click **Specify intranet Microsoft update service location** and then click **Enabled**.

4. Specify the name of the internal server to function as the update server, and specify the name of the server to store upload statistics.

| Important |
| --- |
| You must specify an upgrade server and a server to store upload statistics, but they can be the same server. The server you specify as the upgrade server must be one on which you are running Software Update Services or an updated version of Software Update Services. |

**To Configure or Disable Automatic Updates Using Control Panel on a Computer Running Windows Server 2003 with SP1**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Automatic Updates**.

3. Choose from the available options, which are described in "Automatic Updates," earlier in this section.

# Appendix A: Resources for Learning About Automated Installation and Deployment

Applies To: Windows Server 2003 with SP1

This appendix provides the following:

- An overview of automated installation and deployment
- Procedures and resources for obtaining more information about automated installation and deployment

**Overview: Automated Installation and Deployment**

In the enterprise environment, it is often not cost-effective to install Microsoft Windows Server 2003 or Microsoft Windows XP Professional using the standard interactive setup on each computer. To greatly lower the total cost of ownership (TCO) and ensure configuration uniformity, you can perform an automated installation of Windows Server 2003 and Windows XP on multiple computers. By using an automated installation method, you can ensure that certain components and applications are not available on your organization's computers, or that certain components and applications are preconfigured in such a way that helps prevent unwanted communication over the Internet.

**Methods for Automating the Setup Process**

There are several options for automating the setup process. Any or all of the following tools can help ensure that all of your servers and clients are configured to appropriately limit communication over the Internet:

- Unattended setup using Setup (Winnt32.exe)

  Unattended setup enables you to simplify the process of setting up the operating system on multiple computers. To run an unattended setup, you can create and use an answer file, which is a customized script that answers Setup questions automatically. Then you can run Setup (Winnt32.exe) from the command line with the appropriate options for invoking unattended setup.

  Using Winnt32.exe, you can upgrade your previous version of the operating system using all user settings from the previous installation, or you can perform a fresh installation using the answer file that provides Setup with your custom specifications. The latter method is most likely the best option to limit component communication over the Internet, provided you use an appropriate answer file. Details about specific answer file entries are included in the respective component sections of this white paper.

- Remote Installation Services (RIS)

  With RIS, you can install the operating system by itself or a complete computer configuration, including desktop settings and applications. RIS installations can be either CD-based (through the use of Risetup.exe) or image-based (through the use of Riprep.exe). You can also specify which RIS server will provide installations to a given client computer, or you can allow any RIS server to provide the installation.

- Image-based installation using the System Preparation (Sysprep) tool.

  Image-based installation is also a good choice if you need to install an identical configuration on multiple computers. You typically use the Sysprep tool in conjunction with a non-Microsoft disk imaging tool or Microsoft Windows Server 2003 Automated Deployment Services (ADS) to perform imagebased installations.

  On a master computer, you install the operating system and any applications that you want installed on all of the target computers. Then you run Sysprep and a disk imaging utility. Sysprep prepares the hard disk on the master computer so that the disk imaging utility can transfer an image of the hard disk to the other computers. This method decreases deployment time dramatically compared to standard or unattended installations. You can customize the images so that only the files required for a specific configuration appear on the image, such as additional Plug and Play drivers that might be needed on various systems. The image can also be copied to a CD and distributed to remote sites that have slow links.

- System management software, such as Microsoft Systems Management Server (SMS)

  This type of software assists with the many tasks that are involved when you apply automated procedures to multiple servers and client computers throughout your organization. These tasks include the following:

  - Selecting computers that are equipped for the operating system and that you are ready to support
  - Distributing the operating system source files to all sites, including remote sites and sites without technical support staff
  - Monitoring the distribution to all sites
  - Providing the appropriate user rights to do the upgrade
  - Automatically initiating the installation of the software package with the possibility of having the user control the timing
  - Resolving problems related to the distributions or installations
  - Reporting on the rate and success of deployment

Using system management software helps to further ensure that all computers within your organization have received the standardized operating system configuration that helps prevent unwanted communication over the Internet.

**Using Scripts for Configuring Computers**
In addition to the automated installation methods described here, another common method of controlling the configuration of computers in a domain is to use scripts. For more information about scripts, see "Related Documentation and Links," at the end of this section.

**Procedures for Accessing Additional Information About Automated Setup Tools**
Windows Server 2003 includes extensive documentation describing unattended installation, RIS, and image-based installation with Sysprep. You can view this documentation from any computer that has Internet access (regardless of the operating system running on that computer). You can also view Help for Windows Server 2003 from any computer running Windows Server 2003. The following procedure gives the details.

**To Access Help for a Computer Running Windows Server 2003**

1. Open Help and Support by doing one of the following:

   - On any computer running a product in the Windows Server 2003 family, click **Start**, and then click **Help and Support**.
   - View product documentation on the Web at:

     http://go.microsoft.com/fwlink/?LinkId=29881

     On this site, click the link for the appropriate product.

2. Locate the specific topics as follows:

   - For unattended installation: Navigate to Getting Started\Installing and upgrading the operating system\Concepts\Planning for unattended Setup
   - For RIS: Navigate to Software Deployment\Remote Installation Services
   - For Winnt32.exe: Navigate to Administration and scripting tools\Command-line reference\Command-line reference A-Z\Winnt32

| Note |
| --- |
| Detailed information about unattended installation, RIS, and image-based installation with Sysprep is also available in the sources listed in "Related Documentation and Links." |

**Related Documentation and Links**

You can also find additional information about all of the topics described earlier in this appendix in a variety of other locations:

- On the CD for Windows Server 2003, you can find additional information about unattended installations in the *Microsoft Windows Corporate Deployment Tools User's Guide*, found in \Support\Tools\Deploy.cab. To view the guide and the associated reference information, make sure Deploy.chm and Ref.chm are in the same folder, and open Deploy.chm. For the most up-to-date information, be sure to view the version of the guide that is included in Windows Server 2003 with SP1, rather than an older version from the original release of Windows Server 2003.

- For additional information about unattended installation, RIS, and image-based installation with Sysprep, see the following sources.

    - *The Microsoft Windows Server 2003 Deployment Kit*, especially the book titled *Automating and Customizing Installations*. The *Microsoft Windows Server 2003 Deployment Kit* is available on the Web at:

      http://go.microsoft.com/fwlink/?LinkId=29887

    - "Installation and Setup Technologies" in the Core Operating System Collection of the *Windows Server 2003 Technical Reference* on the Microsoft Web site at:

      http://go.microsoft.com/fwlink/?LinkId=46281

- For general information about Group Policy, see Appendix B: Resources for Learning About Group Policy.

- To learn about specific Group Policy settings that can be applied to computers running Windows Server 2003 with SP1, see the Group Policy Settings Reference on the Microsoft Download Center Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29911

- For more information about scripting, see the Script Center on the TechNet Web site at:

  http://go.microsoft.com/fwlink/?LinkId=24771

- The Help documentation for Windows Server 2003, included in the product and on the Web, contains information about Windows Script Host. You can find the documentation on the Web at:

  http://go.microsoft.com/fwlink/?LinkId=29221

# Appendix B: Resources for Learning About Group Policy

Applies To: Windows Server 2003 with SP1

This appendix provides the following:

- A list of resources for learning about Group Policy and about the Group Policy settings that can be used with Windows Server 2003 with SP1.
- A procedure for updating Administrative templates (.adm files) to the set of templates included in Windows Server 2003 with SP1.

**Resources for Learning about Group Policy**

To learn about using Group Policy and the Group Policy Management Console (GPMC), see the following resources.

- Windows Server 2003 Group Policy page on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46022

- The Group Policy Technology Center Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29866

- *Designing a Managed Environment* in the *Microsoft Windows Server 2003 Deployment Kit* at:

  http://go.microsoft.com/fwlink/?linkid=44319

- The Group Policy Collection of the *Windows Server 2003 Technical Reference* at:

  http://go.microsoft.com/fwlink/?LinkId=29907

- Article 816662, "Recommendations for Managing Group Policy Administrative Template (.adm) Files" in the Microsoft Knowledge Base at:

  http://go.microsoft.com/fwlink/?LinkId=29128

To learn about Group Policy settings that can be used with Windows Server 2003 with SP1, see the following resources.

- The Group Policy Settings Reference on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29911

- "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46278

**Installing Group Policy Management Console (GPMC)**

Group Policy Management Console (GPMC) unifies the management of all aspects of Group Policy. Using GPMC, you can manage Group Policy objects (GPOs), Windows Management Instrumentation (WMI) filters, and permissions on your network.

GPMC is available for download from the Microsoft Web site. For instructions for downloading and installing GPMC, see the Microsoft Windows Server 2003 Web site at:

http://go.microsoft.com/fwlink/?linkid=29909

To run GPMC, click **Start**, point to **Administrative Tools**, and then click **Group Policy Management**.

**Updating Administrative Templates**

You can use Group Policy to control registry keys using the settings supplied with Administrative templates. An updated set of Administrative templates is included with each new release of Windows and includes policy settings for earlier versions of Windows and earlier service packs as well as new policy settings. Use the following procedure to update the Administrative templates in your domain with the templates provided with Windows Server 2003 with SP1.

**To Update Administrative Templates to the Version Provided in Windows Server 2003 with SP1**

1. In the domain where you want to configure Group Policy, on a computer running Windows Server 2003 with SP1, ensure that you have installed GPMC. On that computer, log on as a member of the Domain Admins group, or with an account from which you can manage GPOs in the domain.

   For information about installing GPMC, see "Installing Group Policy Management Console (GPMC)," earlier in this section.

2. Click **Administrative Templates** under either **User Configuration** or **Computer Configuration** (it does not matter which one). Be sure that you click it so that it is selected (highlighted). When you select **Administrative Templates**, the Administrative templates are updated throughout the domain.

   For more information about managing .adm files, see article 816662, "Recommendations for Managing Group Policy Administrative Template (.adm) Files" in the Microsoft Knowledge Base at:

   http://go.microsoft.com/fwlink/?LinkId=29128

| **Caution** |
| --- |
| You should treat the .adm files that are provided with the operating system as read-only. These files will be updated from time to time in service packs and in future releases. To use an existing .adm file as a template for a custom .adm file, first copy the original .adm file into a new filename and then edit the new file. |

# Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key

Applies To: Windows Server 2003 with SP1

**The Internet Communication Management Key in Group Policy**

Windows Server 2003 Service Pack 1 (SP1) contains Group Policy settings that were not available in the original release of Windows Server 2003. Some of these settings can be found in Group Policy under a new key called **Internet Communication Management**. This new key is located within GPMC in Computer Configuration\Administrative Templates\System and in User Configuration\Administrative Templates\System. This appendix describes the settings under the **Internet Communication Management** key, and the way in which one setting, **Restrict Internet communication**, controls multiple other settings.

The settings under the **Internet Communication Management** key are designed to help you control the way components in Windows Server 2003 with SP1 communicate with the Internet. Other settings can also help with controlling the way components communicate with the Internet.

Individual settings under **Internet Communication Management** for specific components are described in the appropriate sections of this white paper and in the Explain text in the settings, as well as being described in this appendix. For example, the setting called **Turn off Event Viewer "Events.asp" links**, located under **Internet Communication Management**, is described in the section about Event Viewer, in the Explain text in the setting itself, and in this appendix. Many other Group Policy settings (beyond the ones described in this appendix) are also described in appropriate sections of this white paper.

**Controlling Multiple Settings Through the Restrict Internet Communication Setting**

There are multiple ways to configure the new Group Policy settings under **Internet Communication Management** in Windows Server 2003 with SP1. You can configure settings individually, which means you could configure, for example, **Turn off Event Viewer "Events.asp" links** differently from **Turn off Windows Error Reporting**. Alternatively, you can enable or disable the entire collection of settings at one time by configuring a setting that controls them all. This setting is called **Restrict Internet communication**.

If you want to enable or disable **Restrict Internet communication** and then create exceptions to this master setting by configuring individual settings in the **Internet Communication Management** key, you must use two GPOs. To do this, ensure that you understand how processing and precedence works for multiple GPOs (for example, see the Help for GPMC). Choose or create a GPO that has lower precedence than another GPO. In the GPO with lower precedence, enable or disable **Restrict Internet communication**. Then, in the GPO that has precedence over it, apply the individual settings that are exceptions to the master setting. If you do not use two GPOs when setting both **Restrict Internet communication** and individual settings that are exceptions to the master setting, the settings might not work as expected.

To check the effect of multiple Group Policy settings, you can use **Group Policy Results** in GPMC. For more information, see the Help in GPMC.

**Settings That Affect Computer Configuration**

This subsection of the appendix describes settings under **Internet Communication Management** in the Administrative template for computer configuration (which contrasts with the template for user configuration, described later in this appendix). For all these settings, the following is true:

- The settings apply to all users of a computer running Windows Server 2003 with SP1 and come into effect when the computer starts or when Group Policy is refreshed.
- Within GPMC, these settings are located in Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings.
- All of the settings can be enabled or disabled in one step by enabling or disabling the master setting that controls them, **Restrict Internet communication**. This setting is located in Computer Configuration\Administrative Templates\System\Internet Communication Management. When you change this setting, the change affects all of the settings in the following list, even if you previously configured individual settings in different ways.

**Note**

This appendix does not describe all Group Policy settings that are available in Windows Server 2003 with SP1. It describes only the settings available under **Internet Communication Management**. For sources of information about new settings available in Windows Server 2003 with SP1, see Appendix B: Resources for Learning About Group Policy.

**Individual Settings That Affect Computer Configuration**

The following list describes the computer configuration settings under **Internet Communication Management** that are outlined in the previous subsection.

**Note**

More details about each setting are available in the Explain text for the setting. To view the text, select the setting in Group Policy and click the **Extended** tab, or open the setting and click the **Explain** tab.

- **Turn off the "Publish to Web" task for files and folders**: Specifies whether the tasks for publishing items to the Web are available from File and Folder Tasks in Windows folders. These tasks are **Publish this file to the Web**, **Publish this folder to the Web**, and **Publish the selected items to the Web**.

  This setting is also described in Appendix J: Online Ordering Wizards, Add Network Place Wizard, and New Connection Wizard in this white paper.

- **Turn off Internet download for Web publishing and online ordering wizards**: Specifies whether Windows should download a list of providers for the Web Publishing Wizard, the Add Network Place Wizard, and the Online Print Wizard. By default, Windows displays providers downloaded from a Windows Web site in addition to providers specified in the registry. If you enable this setting, Windows will not download providers and only the service providers that are stored in the local registry will be displayed. When Windows Server 2003 with SP1 has been installed but the Web publishing and online ordering wizards have not yet been used, no service providers are stored in the local registry. If this Group Policy setting is applied at that time, the wizards will not display links to service providers.

  For more information about the registry keys in which providers can be specified, see "Registering a Service" at the MSDN Web site at:

  http://go.microsoft.com/fwlink/?LinkId=29134

  This setting is also described in Appendix J: Online Ordering Wizards, Add Network Place Wizard, and New Connection Wizard in this white paper.

- **Turn off the "Order Prints" picture task**: Specifies whether the "Order Prints Online" task is available from Picture Tasks in Windows folders.

  This setting is also described in Appendix J: Online Ordering Wizards, Add Network Place Wizard, and New Connection Wizard in this white paper.

- **Turn off the Windows Messenger Customer Experience Improvement Program**: Affects Windows XP with SP2, not Windows Server 2003. This setting specifies whether Windows Messenger collects anonymous information about how Windows Messenger software and service is used. With the Customer Experience Improvement program, users can allow Microsoft to collect anonymous information about how the product is used. This information is used to improve the product in future releases.

- **Turn off Help and Support Center "Did you know?" content**: Specifies whether to show the Headines area of Help and Support Center. By default, the Headlines area in Windows XP is labeled **Did you know?** and in Windows Server 2003 is labeled **Top Issues**. By default, this content is dynamically updated when users are connected to the Internet and open Help and Support Center.

  This setting is also described in the section of this white paper titled Help and Support Center: Features That Communicate with the Internet.

- **Turn off Help and Support Center Microsoft Knowledge Base search**: Specifies whether users can perform a

Microsoft Knowledge Base search from Help and Support Center. The Knowledge Base is an online source of technical support information and self-help tools for Microsoft products. By default, if a user performs a search through Help and Support Center, the Knowledge Base is included in the search. It can be excluded if a user opens the Search Options page in Help and Support Center and clears the Microsoft Knowledge Base check box.

This setting is also described in the section of this white paper titled Help and Support Center: Features That Communicate with the Internet.

- **Turn off Windows Error Reporting**: Specifies whether error reports from a system or application that has stopped responding are sent to Microsoft. Error reports are used to improve the quality of the product. This setting overrides any user setting made from the Control Panel for error reporting.

  This setting and other ways of controlling error reporting through Group Policy are described in Windows Error Reporting and Internet Communication in this white paper.

- **Turn off Internet File Association service**: Specifies whether to use the Web-based File Association service, or whether to use only locally stored information about file name extensions, file types, and the applications or components to use when opening a particular file type. The file association Web service is used only when a user tries to open a file and there is no locally stored information about the file name extension.

  This setting is also described in File Association Web Service and Internet Communication in this white paper.

- **Turn off Internet Connection Wizard if URL connection is referring to Microsoft.com**: Affects Windows XP with SP2, not Windows Server 2003. This setting specifies whether the Internet Connection Wizard can connect to Microsoft to download a list of Internet Service Providers (ISPs). If you enable this setting, and a user running the New Connection Wizard clicks **Choose from a list of Internet Service Providers (ISPs)**, finishes the wizard, and clicks **Refer me to more Internet Service Providers**, a message appears, saying that the user cannot complete the Internet Connection Wizard. This prevents users from retrieving the list of ISPs, which resides on Microsoft servers.

- **Turn off Event Viewer "Events.asp" links**: Specifies whether Internet links shown within events in Event Viewer are activated. When such a link is activated and the user clicks it, information that identifies the event is sent to a Microsoft Web site so that explanatory text, if available, can be sent back to the user.

  This setting and the information sent and received when an Event Viewer link is clicked are described in Event Viewer and Internet Communication in this white paper.

- **Turn off Automatic Root Certificates Update**: Specifies whether to automatically update root certificates using the list of trusted certification authorities that Microsoft maintains on the Windows Update Web site. If you enable this setting, when a user is presented with a certificate issued by an untrusted root authority, the user's computer will not contact the Windows Update web site.

  This setting and the way that root certificate updates work are described in Certificate Support and Internet Communication in this white paper.

- **Turn off Registration if URL connection is referring to Microsoft.com**: Specifies whether the Windows Registration Wizard connects to Microsoft.com for online registration.

  This setting and the differences between registration and activation are described in the section of this white paper titled Activation, Registration, and Resulting Internet Communication in Windows Server 2003 with Service Pack 1.

- **Turn off Search Companion content file updates**: Specifies whether Search Companion should automatically download content updates during local and Internet searches.

  This setting and the way that Search Companion works for local and Internet searches are described in Search Companion and Internet Communication in this white paper.

- **Turn off printing over HTTP**: Specifies whether to allow printing over HTTP from this computer. Note that this setting does not control whether the computer can act as an Internet print server.

Internet printing is described briefly in the subsection titled "Internet Printing" in Internet Information Services and Internet Communication in this white paper.

- **Turn off downloading of print drivers over HTTP**: Specifies whether to allow this computer to download print drivers over HTTP when needed.

  Internet printing is described briefly in the subsection titled "Internet Printing" in Internet Information Services and Internet Communication in this white paper.

- **Turn off Windows Update device driver searching**: Specifies whether Windows searches Windows Update for device drivers when no local drivers for a device are present.

  This setting is described in Plug and Play and Internet Communication in this white paper. Related details about the searching of Windows Update for device drivers are described in Device Manager, Hardware Wizards, and Internet Communication in this white paper.

- **Turn off access to all Windows Update features**: Specifies whether Windows Update can be used to update the operating system on this computer.

  This setting is described in Windows Update, Automatic Updates, and Internet Communication in this white paper.

- **Turn off Windows Movie Maker automatic codec downloads**: Affects Windows XP with SP2, not Windows Server 2003. This setting specifies whether Windows Movie Maker automatically downloads missing codecs for audio and video files. A codec—compressor/decompressor—is software that compresses or decompresses audio or video data.

- **Turn off Windows Movie Maker online Web links**: Affects Windows XP with SP2, not Windows Server 2003. This setting specifies whether links to Web sites are available in Windows Movie Maker.

- **Turn off Windows Movie Maker saving to online video hosting provider**: Affects Windows XP with SP2, not Windows Server 2003. This setting specifies whether users can send a final movie to a video hosting provider on the Web.

#### Settings That Affect User Configuration

This subsection of the appendix describes settings under **Internet Communication Management** in the Administrative template for user configuration (which contrasts with the template for computer configuration). For all these settings, the following is true:

- The settings apply to the individual user and come into effect when the user logs on or when Group Policy is refreshed.

- Within GPMC, these settings are located in User Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings.

- All of the settings can be enabled or disabled in one step by enabling or disabling the master setting that controls them, **Restrict Internet communication**. This setting is located in User Configuration\Administrative Templates\System\Internet Communication Management. When you change this setting, the change affects all of the settings in the following list, even if you previously configured individual settings in different ways.

| **Note** |
| --- |
| This appendix does not describe all Group Policy settings available in Windows Server 2003 with SP1. It describes only the settings available under **Internet Communication Management**. For sources of information about new settings available in Windows Server 2003 with SP1, see Appendix B: Resources for Learning About Group Policy. |

#### Individual Settings That Affect User Configuration

The user configuration settings under **Internet Communication Management** are as follows. For a description of a particular setting, find the setting under "Individual Settings That Affect Computer Configuration," earlier in this section.

Alternatively, you can select the setting in Group Policy and click the **Extended** tab, or open the setting and click the **Explain** tab.

- Turn off the "Publish to Web" task for files and folders
- Turn off Internet download for Web publishing and online ordering wizards
- Turn off the "Order Prints" picture task
- Turn off the Windows Messenger Customer Experience Improvement Program
- Turn off Internet File Association service
- Turn off printing over HTTP
- Turn off downloading of print drivers over HTTP
- Turn off Windows Movie Maker automatic codec downloads
- Turn off Windows Movie Maker online Web links
- Turn off Windows Movie Maker saving to online video hosting provider

# Appendix D: Differences in Windows Server 2003 Before and After Service Pack 1

Applies To: Windows Server 2003 with SP1

In Windows Server 2003 Service Pack 1 (SP1), Microsoft introduces a set of security technologies that help to improve the ability of computers running Windows Server 2003 to withstand malicious attacks from viruses and worms. The technologies include additional network protection, memory protection, and improved computer maintenance. Also included are technologies for safer e-mail handling and enhanced browsing security. In addition, SP1 includes enhanced Administrative templates for Group Policy settings. Together, these security technologies will help to make it more difficult to attack Windows Server 2003 with SP1, even if the latest updates are not applied. These security technologies together are particularly useful in mitigation against worms and viruses.

This white paper provides information about some of the improvements in Windows Server 2003 SP1 as compared to the original release of Windows Server 2003. In particular, Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key provides information about some of the Group Policy settings available only in SP1 and later. These settings are designed to provide specific ways to control the way components in Windows Server 2003 with SP1 communicate with the Internet.

For additional information about the differences between the original release of Windows Server 2003 and Windows Server 2003 with SP1, see the following resources:

- The release notes for Windows Server 2003 SP1 on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=44311

- "Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1" on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46278

- Other information about Windows Server 2003 SP1 on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=36940

  http://go.microsoft.com/fwlink/?LinkId=46225

# Appendix E: Windows Firewall and Security Configuration Wizard

Applies To: Windows Server 2003 with SP1

Windows Firewall is a host firewall technology that replaces Internet Connection Firewall in Windows Server 2003 with Service Pack 1 (SP1) and Windows XP with Service Pack 2 (SP2). Windows Firewall is off by default on Windows Server 2003 with SP1, but is easily turned on.

Security Configuration Wizard (SCW) is an attack surface reduction tool for Windows Server 2003 with SP1. When you run it, you can create, edit, apply, or roll back a security policy (stored as an XML file). Any security policy that you create takes effect only when you apply it to a server.

**Overview: Windows Firewall and Security Configuration Wizard**
Windows Firewall provides stateful inspection of incoming Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) traffic and is designed to help protect you from network attacks that pass through your perimeter network or originate inside your organization, such as Trojan horse attacks, port scanning attacks, and worms. By running Windows Firewall on each of your clients and servers, you can extend your defense-in-depth strategy to the innermost layer of your security architecture.

SCW determines the minimum functionality required for a server's role or roles, and disables functionality that is not required. For example, it can disable unneeded services and block unused ports. SCW guides you through the process of creating, editing, applying, or rolling back a security policy based on the selected roles of the server. The security policies that are created with SCW are XML files that, when applied, configure services, network security, specific registry values, audit policy, and if applicable, Internet Information Services (IIS).

**Group Policy Settings that Affect Windows Firewall**
Windows Server 2003 with SP1 includes Group Policy settings through which you can configure Windows Firewall. (Windows XP with SP2 also includes these settings.)

**To Locate the Group Policy Settings for Windows Firewall**

1. See Appendix B: Resources for Learning About Group Policy, for information about using Group Policy. Ensure that your Administrative templates have been updated, and then edit an appropriate GPO.

2. Click **Computer Configuration**, click **Administrative Templates**, click **Network**, click **Network Connections**, and then click **Windows Firewall**.

3. Click either **Domain Profile** or **Standard Profile**.

4. View the **Group Policy** objects that are available.

For more details about any of the Group Policy settings, use a Group Policy interface to navigate to the setting and then click the **Extended** tab, or open the setting and then click the **Explain** tab.

There is a setting through which you can disable Windows Firewall. This setting is located in Computer Configuration\Administrative Templates\Network\Network Connections\Windows Firewall\Domain Profile and is called **Windows Firewall: Protect all network connections**. If you disable this policy setting, Windows Firewall does not run and cannot be started.

| **Note** |
| --- |
| In Computer Configuration\Administrative Templates\Network\Network Connections, the setting called **Prohibit use of Internet Connection Firewall on your DNS domain network** still exists. This setting has no effect if **Windows Firewall: Protect all network connections** is enabled or disabled. However, if **Windows Firewall: Protect all network connections** is set to **Not Configured**, your servers are in a DNS domain, and you enable **Prohibit use of Internet Connection Firewall on your DNS domain network**, it will prevent Windows Firewall from running (Internet Connection Firewall is the former name for Windows Firewall). |

**Resources for Learning About Windows Firewall and Security Configuration Wizard**

The following resources provide detailed information about using Windows Firewall and Security Configuration Wizard:

- For how-to and conceptual topics about Windows Firewall, along with information about how Windows Firewall differs from Internet Connection Firewall (the earlier version of Windows Firewall), see the Help for Windows Firewall on the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=33577

- By using an answer file for unattended or remote installation and including entries in the [WindowsFirewall] section, you can control Windows Firewall settings at deployment time. For more information, see the references listed in Appendix A: Resources for Learning About Automated Installation and Deployment. Be sure to review the information in the Deploy.chm file (whose location is provided in that appendix).

- For the Windows Firewall Operations Guide, see the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=43262

- For a collection of overviews and guides for using SCW, see "Security Configuration Wizard for Windows Server 2003" at the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?linkid=45503

- For instructions for using Security Configuration Wizard, see the Microsoft Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46018

  http://go.microsoft.com/fwlink/?LinkId=46017

# Appendix F: Internet Connection Sharing and Network Bridge

Applies To: Windows Server 2003 with SP1

Internet Connection Sharing and Network Bridge are features designed for home and small office networks, and can be used with Windows Firewall (formerly called Internet Connection Firewall or ICF). These features are included in some of the Microsoft Windows Server 2003 family operating systems. Information about these features is presented here so you as an IT administrator can be aware of these potential capabilities within your organization's network.

The following list describes the editions and versions of Windows Server 2003 that do and do not include Internet Connection Sharing, Windows Firewall (formerly called Internet Connection Firewall), and Network Bridge:

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

For more information about Windows Firewall, see Appendix E: Windows Firewall and Security Configuration Wizard.

This appendix includes the following:

- An overview of Internet Connection Sharing and Network Bridge.

- How Internet Connection Sharing and Network Bridge can be used in a managed environment.

- How to control or prevent the use of Internet Connection Sharing and Network Bridge.

**Overview: Internet Connection Sharing and Network Bridge**

Internet Connection Sharing and Network Bridge provide the following functionality:

- Internet Connection Sharing (ICS)

  ICS provides Internet access for a home or small office network by using one common connection as the Internet gateway. In an ICS network, a single computer is chosen to be the ICS host. The ICS host has at least two network adapters: one connected to the Internet, one or more connected to the private network. All Internet-destined traffic flows through the ICS host. ICS uses DHCP to assign private IP addresses on the network, and Network Address Translation (NAT) to allow multiple computers on the private network to connect to the public network through the ICS host.

  In a home or small office environment, there can be security benefits in using ICS. Only the ICS host is visible from the Internet. The private network is "hidden." Also, NAT blocks any network traffic that did not originate from the private network or is a response to traffic originating from the private network.

  In addition, ICS provides name resolution to the home network through a DNS proxy.

  | **Note** |
  | --- |
  | You should not use Internet Connection Sharing in an existing network with Windows Server 2003 domain controllers, Domain Name System (DNS) servers, gateways, Dynamic Host Configuration Protocol (DHCP) servers, or systems configured for static IP addresses. |

- Network Bridge

  Network Bridge removes the need for routing and bridging hardware in a home or small office network that consists of multiple LAN segments. Network Bridge forwards traffic among the multiple LAN segments, making them appear to be a

single IP subnet.

| ⚠Caution |
| --- |
| If neither Windows Firewall nor ICS is enabled on your network, do not set up Network Bridge between the public Internet connection and the private network connection. Setting up Network Bridge between the public Internet connection and the private network connection creates an unprotected link between your network and the Internet, leaving your network vulnerable to external attacks. When either Windows Firewall or ICS is enabled, this risk is mitigated. |

**Using Internet Connection Sharing and Network Bridge in a Managed Environment**

On Windows Server 2003 with SP1, Internet Connection Sharing and Network Bridge are not enabled by default (and Windows Firewall is also not enabled by default). Also, Internet Connection Sharing (ICS) is available only on computers that have two or more network connections. An administrator or user with administrative credentials can enable ICS by clicking the **Advanced** tab on network connections (**Control Panel\Network Connections**). Also, when running the New Connection Wizard, administrators can choose to enable ICS. ICS lets administrators configure a computer as an Internet gateway for a small network, and it provides network services such as name resolution through Domain Name System (DNS). It also provides addressing through Dynamic Host Configuration Protocol (DHCP) to the local private network.

The **Network Bridge** menu command **Bridge Connections** is available only when two or more network adapters are present. By default, Network Bridge is disabled, but administrators can use **Bridge Connections** to enable Network Bridge.

In a domain environment, you should not allow these features to be enabled or configured. See the following subsection for information about how to disable them.

It is important to be aware of all the methods users and administrators have for connecting to your networked assets, and to review whether your security measures provide in-depth defense (as contrasted with a single layer of defense, more easily breached).

**Controlling the Use of Internet Connection Sharing and Network Bridge**

You can block administrators and users from accessing ICS and Network Bridge by using answer files during initial installation and by using Group Policy post-deployment.

**Using Answer Files for Unattended or Remote Installation**

Using standard methods for preparing an unattended or remote installation, you can make entries in the [Homenet] section of the answer file. If you make entries in the [Homenet] section, also investigate making entries in the [WindowsFirewall] section. Thes sections include entries for installing home and small office networking settings for network adapters, Internet Connection Sharing, Windows Firewall, and Network Bridge. For example, to prevent users and administrators from enabling Internet Connection Sharing by using an answer file, the entry is as follows:

```
[Homenet]
EnableICS = No
```

For additional configuration options for [Homenet] and [WindowsFirewall] entries for the answer file, and for more information about unattended installation, see the references listed in Appendix A: Resources for Learning About Automated Installation and Deployment. Be sure to review the information in the Deploy.chm file (whose location is provided in that appendix).

**Using Group Policy to Disable Internet Connection Sharing and Network Bridge**

Group Policy settings for disabling Internet Connection Sharing and Network in your domain environment are as follows. For information about Group Policy settings for Windows Firewall, see Appendix E: Windows Firewall and Security Configuration Wizard.

| Note |
| --- |
| For more details about any of the Group Policy settings, use a Group Policy interface to navigate to the setting and then click the **Extended** tab, or open the setting and then click the **Explain** tab. For other sources of information about Group Policy, see Appendix B: Resources for Learning About Group Policy. |

- **Prohibit use of Internet Connection Sharing on your DNS domain network**, located in Computer Configuration\Administrative Templates\Network\Network Connections.

If you enable this policy setting, ICS cannot be enabled or configured by administrators, and the ICS service cannot run on the computer. In the **Advanced** tab in the Properties dialog box for a local area network (LAN) or remote access connection, under **Internet Connection Sharing**, it says "Internet Connection Sharing has been disabled by the Network Administrator."

Also, if you enable this policy setting, the Internet Connection Sharing page is removed from the New Connection Wizard.

- **Prohibit installation and configuration of Network Bridge on your DNS domain network**, located in Computer Configuration\Administrative Templates\Network\Network Connections.

  When you enable this policy setting, administrators cannot create a Network Bridge. Enabling this policy setting does not remove an existing Network Bridge from a computer.

| **Important** |
| --- |
| The preceding policy settings (both with have "DNS" in the name of the setting) are dependent on the network context that the computer is in. They apply only when a computer is connected to the same DNS domain network it was connected to when the policy setting was refreshed on that computer. If a computer is connected to a DNS domain network other than the one it was connected to when the policy setting was refreshed, the policy setting does not apply. |

For more information about home and small office networking features, see Help for Windows Server 2003 with SP1 on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46009

# Appendix G: Message Queuing and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The purposes of Message Queuing
- How Message Queuing handles messages
- Finding additional sources of information about Message Queuing

**Purposes of Message Queuing 3.0**

Message Queuing (MSMQ) is one of the optional components in Microsoft Windows Server 2003. Information about Message Queuing is presented here so you as an IT administrator can be aware of the potential capabilities for use within your organization's network, if you determine that you will be installing Message Queuing.

Message Queuing 3.0, the version in products in the Microsoft Windows Server 2003 family, is a message queuing service that enables applications on different systems to communicate with each other. Message Queuing implements asynchronous communication by enabling applications to send messages to and receive messages from other applications that may be running on the same computer or on different computers connected by a network. With Message Queuing, these applications can communicate across the Internet and other heterogeneous networks, and with computers that might be temporarily offline.

**Overview: Using Message Queuing in a Managed Environment**

Applications can use Message Queuing to send messages and to continue running regardless of whether the receiving application is running or reachable over the network. To create a message, an application specifies the message fields or properties and supplies the field values. The application then issues an MSMQ application programming interface (API) call to send the message. The MSMQ queue manager (the designated server) transmits the message to the destination message queue. If the destination location is not connected to the network when the message is sent, the message queuing system stores the message at an interim location. The system forwards the message automatically when a connection is established.

To receive a message, an application issues an API call that reads the message from the queue. When an application receives a request message, it processes the request by reading the contents of the message and acting accordingly. If required, the receiving application can send a response message back to the original requester. While in transit between senders and receivers, MSMQ keeps messages in holding areas called queues. MSMQ queues protect messages from being lost in transit and provide a place to retrieve messages when the receivers are ready to receive them.

Message Queuing 3.0 provides support for sending messages over the Internet. This support includes referencing queues by URLs, sending and receiving XML-based messages that are formatted using Simple Object Access Protocol (SOAP), and providing security for HTTP messaging. MSMQ also provides support for Web farms and firewalls. For more information about sending messages over the Internet, refer to "Related Links," later in this section.

It is beyond the scope of this white paper to describe all aspects of maintaining appropriate levels of security in an organization running applications that communicate across the Internet. This section, however, provides overview information as well as suggestions for other sources of information about balancing your organization's requirements for running Internet applications with your organization's requirements for protection of networked assets.

**Controlling Message Queuing to Prevent the Flow of Information to and from the Internet**

**Installing and Uninstalling Message Queuing**

Message Queuing is not installed by default. However, if your organization has determined that MSMQ is an essential component of the business process, it can be installed as described in this subsection. Although MSMQ is highly configurable, it is beyond the scope of this white paper to describe all the configuration options available to you. If you will be using MSMQ, you can refer to the "Related Links" subsection following these procedures for more detailed information about deploying Message Queuing.

**To Install or Uninstall Message Queuing**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.
2. Double-click **Add or Remove Programs**.

3. Click **Add/Remove Windows Components** (on the left).

4. In Windows Components, select **Application Server**, and then click **Details**.

5. Click **Message Queuing** and do one of the following:

    - If Message Queuing is installed and you want to remove it, clear the check box for **Message Queuing** and complete the Message Queuing wizard.

    - If Message Queuing is not installed and you want to add it, select the check box for **Message Queuing**.

6. If you are installing Message Queuing, select **Details**, select one or more of the options listed, and complete the Windows Components wizard.

**Accessing the Operating System Help Documentation for Message Queuing**

The operating system has Help documentation describing the use of Message Queuing. You can view this documentation from any computer that has Internet access (regardless of the operating system running on that computer), or from any server running a product in the Windows Server 2003 family.

**To Access the Help Documentation for Message Queuing**

Open Help for Windows Server 2003 by doing one of the following:

- Click **Start**, and then click **Help and Support**. Click **Application and Development Support**, and then click **Using Message Queuing**.

- View Help on the Web at:

  http://go.microsoft.com/fwlink/?LinkId=29881

**Related Links**

For more information about Message Queuing, see the following references:

- The Message Queuing Web site at:

  http://go.microsoft.com/fwlink/?LinkId=46016

- The Message Queuing and Queued Components (MSMQ) SDK documentation, as described in the following list:

    - "Using Message Queuing"

      http://go.microsoft.com/fwlink/?LinkId=46015

    - "Internet Messaging"

      http://go.microsoft.com/fwlink/?LinkId=46014

    - "HTTP Messages"

      http://go.microsoft.com/fwlink/?LinkId=46013

    - "New Features for Windows XP and the Windows Server 2003 family"

      http://go.microsoft.com/fwlink/?LinkId=46012

# Appendix H: Connection Manager and Internet Communication

Applies To: Windows Server 2003 with SP1

This section provides information about:

- The benefits of Connection Manager 1.3
- How Connection Manager communicates with sites on the Internet
- Controlling Connection Manager to limit the flow of information to and from the Internet

**Benefits and Purposes of Connection Manager 1.3**

Connection Manager 1.3 is a client dialer and connection software program included with products in Microsoft Windows Server 2003. It provides support for local and remote connections to your network service using a network of access points, such as those available worldwide through Internet service providers (ISPs). Connection Manager 1.3 includes features that both simplify and enhance the implementation of connection support for you and your users.

Connection Manager is implemented using the Connection Manager Administration Kit (CMAK). CMAK is designed for network administrators, information officers, and other team members who are responsible for the design, development, testing, distribution, and support of connection software for users who connect to your Internet or network service.

You can customize Connection Manager so that the set of files you distribute to your users (called a service profile) can be easily installed and run. Using Connection Point Services you install Phone Book Service, which enables the distribution of phone books for a Connection Manager service profile.

In addition to the support for basic dial-up connections, you can also use the CMAK wizard to incorporate support for virtual private network (VPN) connections using tunneling protocols to tunnel through a public network (such as when dialing into an ISP to access an organization's server). Connection Manager can create a VPN connection through a preexisting dial-up session, local area network (LAN), or digital subscriber line (DSL).

For more information about Connection Manager, see the instructions in "Accessing Help Documentation for Connection Manager," later in this appendix.

**How Connection Manager Communicates with Sites on the Internet**

Administrators control whether to enable the phonebook download feature and which server the client computer sends the request to. The client computer initiates the connection to the phone book server in order to update its data. The phone book server sends one of the following elements to the Connection Manager client while there is a connection:

- Phone book update file: The server sends a phone book update file when the version of the phone book of the connecting client is earlier than the version of the phone book server.
- Replacement phone book: This is sent when there is a difference of more than five versions between the client and the server phone book file versions.
- Standard HTTP error message

The following list describes various aspects of the Connection Manager information that is sent to and from the Internet and how the exchange of information takes place:

- **Specific information sent or received**: The information sent by Connection Manager in the phone book server query string contains the following elements:
    - **osarch**: Specifies the type of processor that the requesting computer is using.
    - **ostype**: Specifies the version of the Windows operating system of the computer making the request.
    - **cmver**: Specifies the version of Connection Manager of the computer making the request.

    - **lcid**: Specifies the locale identifier (LCID) describing the system default locale information of the computer making the request.
    - **pbver**: Specifies the current version of the phone book being used by the computer making the request.
    - **pb**: Specifies the name of the phone book being used by the computer making the request.

- **Default settings**: By default, Connection Point Services and the Connection Manager Administration Kit are not installed with Windows Server 2003. (You can add these components by using Add or Remove Programs in Control Panel.)
- **Triggers**: Connection Manager is triggered when users start it to connect to the Internet or their organization's network.
- **Logging**: Information is logged in the Connection Manager log file but not in the operating system event log. The logging feature for Connection Manager is used for troubleshooting and can be disabled.
- **Encryption**: The information contained in the query string is sent as plaintext and is not encrypted.
- **Storage**: The information that is sent is used by the phone book server to process the request being made, although the information is not stored.
- **Transmission protocol and port**: The transmission protocol used is HTTP and the port is 80.
- **Ability to disable**: On the server, you can prevent Connection Point Services and the Connection Manager Administration Kit from being installed, which prevents Connection Manager from being used. For clients, you can disable Connection Manager by not providing the user with a Connection Manager service profile. Also for clients, the Connection Manager phone book download and synchronization feature can be disabled using a Connection Manager service profile.

For more information about the Connection Manager Administration Kit (CMAK), see "Before you start: Understanding Connection Manager and the Administration Kit," on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46011

You can also view the same information in Help, as described in "Accessing Help Documentation for Connection Manager," later in this appendix.

**Controlling Connection Manager to Limit the Flow of Information to and from the Internet**
Connection Manager client software is installed by default. Administrators determine when to create and distribute a Connection Manager service profile, without which Connection Manager cannot run.

You can limit the use of Connection Manager by creating and distributing a service profile only to users and administrators who need to use the Connection Manager client to initiate local or remote network access point connections. You can use the Connection Manager Administration Kit (CMAK) wizard to create a customized service profile to configure Connection Manager not to update the client phone book information.

For a list of items to consider when designing a service profile for Connection Manager, see "Security information for the Connection Manager Administration Kit" on the Microsoft Web site at:

http://go.microsoft.com/fwlink/?LinkId=46010

**Procedures for Installing the Connection Manager Administration Kit and for Viewing Help**
This subsection lists procedures for the following tasks:

- Installing the Connection Manager Administration Kit on your server
- Accessing Help documentation for Connection Manager

**Installing Connection Manager Administration Kit on Your Server**
The Connection Manager Administration Kit (CMAK) and Connection Point Services (used to install Phone Book Service) are not installed by default on Windows Server 2003. Use the following procedure to add these components.

**To Add the Connection Manager Administration Kit and Connection Point Services After Server Installation**

1. Click **Start**, and then either click **Control Panel**, or point to **Settings** and then click **Control Panel**.

2. Double-click **Add or Remove Programs**.

3. Click **Add/Remove Windows Components** (on the left).

4. In the Windows Components Wizard, scroll down and double-click **Management and Monitoring Tools**.

5. Select **Connection Manager Administration Kit** and **Connection Point Services** and any other subcomponents you want to install.

6. Follow the instructions to complete the Windows Components Wizard.

**Accessing Help Documentation for Connection Manager**

Windows Server 2003 has Help documentation describing the Connection Manager Administration Kit. You can view this documentation from any computer that has Internet access (regardless of the operating system running on that computer), or from any server running Windows Server 2003. The following procedure provides the details.

**To Access Help Documentation for a Server Running Windows Server 2003**

1. Open Help for Windows Server 2003 by doing one of the following:

   - On any computer running Windows Server 2003, click **Start**, and then click **Help and Support**.

   - View Help on the Web at:

     http://go.microsoft.com/fwlink/?LinkId=29881

     As appropriate, navigate from this Web site to the documentation for the server product you are using.

2. To view information about Connection Manager Administration Kit, navigate to Network Services\Managing Remote Connections\Connection Manager Administration Kit.

# Appendix I: Passport Manager Administration

Applies To: Windows Server 2003 with SP1

The following appendix provides information about:

- The benefits and purposes of Passport Manager Administration
- Using Passport Manager Administration in a managed environment
- Resources for learning about Passport Manager Administration

**Benefits and Purposes of Passport Manager Administration**
Passport Manager Administration is a utility designed for use on Web sites on which you want to use Microsoft .NET Passport for authentication. In Microsoft Windows Server 2003 family operating systems, Passport Manager Administration provides a graphical-interface alternative to editing the registry to change Passport Manager object settings. The most common use of the Passport Manager Administration utility is to change the default object settings that Passport Manager methods use if certain optional parameters are omitted when the methods are called.

Although some parameters of Microsoft .NET Passport methods are listed as optional, these methods still generate URLs or results that reflect inherent default values when called. These default parameter values can be used to provide consistent values for your Web site, such as the required time window within which all users must be authenticated.

Primary default object settings that affect Passport Manager implementation include: Time Window, Force Login, and Language ID.

**Using Passport Manager Administration in a Managed Environment**
By configuring options in Passport Manager Administration to work with software on your Web site, you can control how Web browsers are authenticated to your Web site. With Passport Manager Administration, you can configure the settings for cookies, such as choosing to disable the use of cookies. You can also choose to have cookies deleted once users sign out of your Web site. (Cookies are a form of data passed both ways between Web browsers and servers. Cookies sent to a user's browser have some implications for privacy.)

To ensure that cookies are deleted when users sign out of a Web site, make sure the following conditions are met:

- The Site ID value in Passport Manager Administration should be the value given to you when you received your Passport encryption key.
- The path and file name of the page to which cookies are written (specified in Passport Manager Administration) should match the ExpireCookieURL provided when you registered your site. Also, if cookies are written to a page in a subdomain of your own domain, you should precede the domain path with a dot (".").
- The path to the page where cookies are written should be the root directory of the Web site. This ensures that cookies written to all possible paths are deleted. If this is not done, not all the cookies may be deleted.
- If your site uses multiple servers with Passport Manager installed on them, you should verify that all of the servers are writing the cookies to the same domain and path.

**Related Links**
You can find additional information about Passport Manager Administration at these sites:

- For more information about .NET Passport and how to download it, see the SDK documentation on the MSDN Web site at:

  http://go.microsoft.com/fwlink/?linkid=7739

- The Help file for Passport Manager Administration utility provides detailed information about configuring settings for this utility. You can find this Help file at:

http://go.microsoft.com/fwlink/?linkid=7738

# Appendix J: Online Ordering Wizards, Add Network Place Wizard, and New Connection Wizard

Applies To: Windows Server 2003 with SP1

This appendix provides information about the following:

- Online ordering wizards and tasks
- Add Network Place wizard
- New Connection wizard

While these features are not primarily designed for use on servers, information about them is presented here so IT administrators can be aware of these potential capabilities within the organization's network.

**Online Ordering Wizards and Tasks**
In Microsoft Windows Server 2003, you can click tasks in Windows Explorer to run several different wizards to order picture prints online, sign up for a service that offers online storage space, or publish files that can be viewed in a browser. These wizards present you with one or more service providers from which to request the online service. The task or wizard obtains the names and URLs of these service providers from two sources: a list stored locally (in the registry) and a list stored on a Microsoft Web site. By default, Windows displays providers from a list on the Microsoft Web site in addition to providers listed in the registry.

As an administrator, you can use several Group Policy settings in Windows Server 2003 with SP1 to control the way the wizards and tasks work.

**Wizards and Tasks That Can Be Used for Online Ordering**
In Microsoft Windows Server 2003, you can use the following tasks in Windows Explorer and the following wizards for online ordering.

- **Online Print Ordering Wizard and related tasks**: In Windows Explorer, when common tasks are shown and you select either a picture or a folder that is configured as a picture folder, you can choose picture tasks including **Order prints online**. This starts the Online Print Ordering Wizard.

  A folder can be configured as a picture folder by right-clicking the folder, clicking **Properties**, clicking the **Customize** tab and, under **Use this folder type as a template**, selecting **Pictures or Photo Album**.

- **Add Network Place Wizard and related tasks**: This wizard and the related tasks are described in "Add Network Place Wizard and Web Publishing Wizard," later in this appendix. You can use the wizard to sign up for a service that offers online storage space.

- **Web Publishing Wizard and related tasks**: This wizard and the related tasks are described in "Add Network Place Wizard and Web Publishing Wizard," later in this appendix. You can use the wizard to publish files over the Internet or a local network so that those files can be viewed in a Web browser.

**Controlling the Way Online Ordering Wizards and Tasks Communicate with the Internet**
You can control the way online wizards and tasks communicate with the Internet by using Group Policy settings available in Windows Server 2003 with SP1. Because the following Group Policy settings are part of Windows Server 2003 with SP1 but were not part of the original release of Windows Server 2003, in order to use them, you must ensure that your Administrative templates have been updated before you can use these settings. For more information, see Appendix B: Resources for Learning About Group Policy.

- To prevent the preceding wizards and tasks from accessing the Microsoft Web site for the list of providers to offer to users, configure the following Group Policy setting in Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings: **Turn off Internet download for Web publishing and online ordering wizards**.

By default, the Web publishing and online ordering wizards display providers downloaded from a Windows Web site in addition to providers specified in the registry. If you enable this setting, Windows will not download providers and only the service providers that are stored in the local registry will be displayed. When Windows Server 2003 with SP1 has been installed but the Web publishing and online ordering wizards have not yet been used, no service providers are stored in the local registry. If this Group Policy setting is applied at that time, the wizards will not display links to service providers.

For more information about the registry keys in which providers can be specified, see "Registering a Service" on the MSDN Web site at:

http://go.microsoft.com/fwlink/?LinkId=29134

- To disable the Web Publishing Wizard and related File and Folder Tasks, see "Add Network Place Wizard and Web Publishing Wizard," later in this section.

- To disable the Online Print Ordering Wizard, configure the following Group Policy setting in Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings: **Turn off the "Order Prints" picture task**.

| **Note** |
| --- |
| If you want the policy settings to apply to all users of a computer and come into effect when the computer starts or when Group Policy is refreshed, use the settings listed in the preceding paragraphs. If you want the policy settings to apply to users and come into effect when users log on or when Group Policy is refreshed, configure the same settings in User Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings. |

For information about other settings that control the way wizards and other components communicate with the Internet, see Appendix C: Group Policy Settings Listed Under the Internet Communication Management Key.

**Add Network Place Wizard and Web Publishing Wizard**

In the Microsoft Windows Server 2003 operating systems, you can use the Add Network Place Wizard to create shortcuts to shared folders and resources on the network or on Web or File Transfer Protocol (FTP) servers. You can use the Web Publishing Wizard to publish files over the Internet or a local network so that those files can be viewed in a Web browser. If you do not have folders on a Web server already or do not have an account with a Web service provider, the Add Network Place Wizard or the Web Publishing Wizard can help you set these up.

This appendix includes the following:

- An overview of the Add Network Place Wizard and the Web Publishing Wizard

- How to control the use of the Add Network Place Wizard and the Web Publishing Wizard

**Overview: Add Network Place Wizard and Web Publishing Wizard**

The Add Network Place Wizard and the Web Publishing Wizard are enabled by default. You can use these wizards as follows:

- **Add Network Place Wizard**: You can access this wizard through **My Network Places\Add Network Place** or in Windows Explorer through **Tools\Map Network Drive** (through the link labeled "Sign up for online storage or connect to a network server").

  The wizard can be used to sign up for a service that offers online storage space, or to create a shortcut to a Web site, an FTP site, or other local network connection. To add a shortcut in My Network Places to a folder on a Web server, the Web server must support network places. Supporting network places requires the Web Extender Client (WEC) protocol and Microsoft FrontPage® Server Extensions, or the Web Distributed Authoring and Versioning (WebDAV) protocol and Internet Information Services (IIS). You must also have read and write access to the Web server.

- **Web Publishing Wizard**: In Windows Explorer, when common tasks are shown, you can access this wizard through several different tasks. These tasks are **Publish this file to the Web**, **Publish this folder to the Web**, and **Publish the selected items to the Web**.

You can use the Web Publishing Wizard to publish files over the Internet or a local network so that those files can be viewed in a Web browser.

You can remove access to the Add Network Place Wizard and the Web Publishing Wizard using Group Policy.

For more information about the WEC and WebDAV protocols, see "About Web Folder Behaviors" on the MSDN Web site at:

http://go.microsoft.com/fwlink/?LinkId=29223

**Controlling the Use of the Add Network Place Wizard and the Web Publishing Wizard**
To control the Add Network Place Wizard and the Web Publishing Wizard, use Group Policy.

**Controlling Whether the Wizards Download Information from a Microsoft Web site**
To control whether the Add Network Place Wizard and the Web Publishing Wizard display a list of service providers downloaded from a Windows Web site, use the Group Policy setting **Turn off Internet download for Web publishing and online ordering wizards**. This setting is described in "Online Ordering Wizards and Tasks," earlier in this appendix.

**Controlling the Use of the Add Network Place Wizard**
To block users and administrators from accessing the Add Network Place Wizard from the **Map Network Drive** command, configure the following Group Policy setting in User Configuration\Administrative Templates\Windows Components\Windows Explorer: **Remove "Map Network Drive" and "Disconnect Network Drive"**. This policy setting does the following:

- If you enable this policy setting, the system removes the **Map Network Drive** and **Disconnect Network Drive** commands from the toolbar and **Tools** menus in Windows Explorer and My Network Places. The system also removes these commands from menus that appear when you right-click the Windows Explorer or My Network Places icons.

- This policy setting does not prevent you from connecting to another computer by typing the name of a shared folder in the **Run** dialog box.

- This policy setting does not remove the **Add Network Place** task from My Network Places.

**Controlling the Use of the Web Publishing Wizard**
To control access to the Web Publishing Wizard and related tasks, configure a Group Policy setting. The File and Folder Tasks affected by this setting are **Publish this file to the Web**, **Publish this folder to the Web**, and **Publish the selected items to the Web**. The setting is located in Computer Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings, and is called **Turn off the "Publish to Web" task for files and folders**.

If you want the policy setting to apply to all users of a computer and come into effect when the computer starts or when Group Policy is refreshed, use the setting listed in the preceding paragraph. If you want the policy setting to apply to a particular set of users and come into effect when users log on or when Group Policy is refreshed, use the same setting in User Configuration\Administrative Templates\System\Internet Communication Management\Internet Communication settings.

**New Connection Wizard**
In Microsoft Windows Server 2003 operating systems, you use the New Connection Wizard to create Internet and other types of network connections for home and small office networks. While this feature is designed for home and small office use, information about this feature is presented here so IT administrators can be aware of these potential capabilities within the organization's network.

This appendix includes the following:

- An overview of the New Connection Wizard

- How to control the use of the New Connection Wizard

**Overview: New Connection Wizard**
The New Connection Wizard in Windows Server 2003 operating systems replaces the Windows 2000 Network Connection Wizard and Internet Connection Wizard. Administrators for a home or small office network can use the New Connection Wizard to create any type of network connection including Internet, incoming, dial-up, virtual private network (VPN), and direct connection.

You can start the New Connection Wizard in a variety of ways:

- By starting any program that requires an Internet connection when no Internet connection has yet been configured. An example of such a program is Internet Explorer.

- By opening Network Connections and clicking **Create a new connection**. Network Connections can be opened in a variety of ways, including through **Control Panel\Network Connections**.

- By opening Internet Options and, on the **Connections** tab, clicking the **Setup** button. Internet Options can be opened in a variety of ways, including through **Control Panel\Internet Options**.

- By clicking **Start**, clicking **Programs** or **All Programs**, clicking **Accessories**, clicking **Communications**, and then clicking **New Connection Wizard**.

**Controlling the Use of the New Connection Wizard**

You can control how administrators and users can use the New Connection Wizard by configuring Group Policy.

| **Note** |
| --- |
| Some of the Group Policy settings described in this section do not affect administrators. The descriptions provide details. |

- Group Policy setting: **Disable Internet Connection Wizard**

  This Group Policy setting is in User Configuration\Administrative Templates\Windows Components\Internet Explorer. It affects administrators as well as users.

  If you enable this policy, the **Setup** button on the **Connections** tab in the **Internet Options** dialog box appears dimmed.

  | **Note** |
  | --- |
  | Note that this policy overlaps with the **Disable the Connections page** policy (located in \User Configuration\Administrative Templates\Windows Components\Internet Explorer\Internet Control Panel), which removes the **Connections** tab from the interface. |

- Group Policy setting: **Prohibit Access to the New Connection Wizard**

  This Group Policy setting is in User Configuration\Administrative Templates\Network\Network Connections. It affects users but not administrators.

  This policy setting determines whether users can use the New Connection Wizard, which creates new Internet or intranet connections.

- Group Policy setting: **Enable Windows 2000 Network Connections settings for Administrators**

  This Group Policy setting is also in User Configuration\Administrative Templates\Network\Network Connections.

  | **Note** |
  | --- |
  | This policy setting is intended to be used in a situation in which the Group Policy object (GPO) contains computers running both Windows 2000 and Windows Server 2003, and identical Network Connections policy setting behavior is required between those computers. |

With this policy setting enabled, policy settings that exist in both Windows 2000 and Windows Server 2003 behave the same for administrators.

The set of Network Connections policy settings that exists in Windows 2000 also exists in Windows Server 2003. In Windows 2000, all of these policy settings have the ability to prohibit the use of certain features by administrators. By default, Network Connections policy settings in Windows Server 2003 do not prohibit the use of features from administrators.

For information about using Group Policy, see Appendix B: Resources for Learning About Group Policy.

# Related Links for Controlling Communication with the Internet

Applies To: Windows Server 2003 with SP1

This section contains a list of the Web sites that are found in other sections of this white paper, with some additional Web sites that provide general information about Microsoft products.

**Links to Product Information, Support Information, TechNet, Microsoft Developer Network, and Information in Resource Kits**

# User Data and Settings Management

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Published: March 1, 2002

By Craig Marl

This white paper explains the IntelliMirror user data and settings management features in Microsoft Windows Server 2003. These key components of change and configuration management can help administrators reduce total cost of ownership (TCO).

**In This White Paper**

User Profiles Overview in User Data and Settings Management

User Profile Structure

Enhancements to User Profiles in Windows Server 2003 and Windows XP

How to Configure a Roaming User Profile

Security Considerations when Configuring Roaming User Profiles

Best Practices for User Profiles

Folder Redirection Overview

How to Configure Folder Redirection

Security Considerations when Configuring Folder Redirection

Best Practices for Folder Redirection in User Data and Settings Management

Related Technologies: Offline Files and Synchronization Manager

Common Scenarios for IntelliMirror User Data and Settings Features

Appendix: Group Policy Settings for Roaming User Profiles

Related Links for User Data and Settings Management

User data includes the documents, images, spreadsheets, presentations and e-mail messages on a user's computer. User settings include application configurations, preferences, window sizes, toolbar settings and so forth on a users computer.

With Microsoft IntelliMirror management technologies, administrators can manage user data and settings in ways that reduce the total cost of ownership (TCO) for the computing systems.

By using IntelliMirror on both the server and client, administrators can protect and manage user data and settings. Non-recoverable data from local workstations can be copied to servers, where it can be easily backed up and centrally managed. Personalized data, applications, and settings can follow each user to different computers throughout the network. Administrators can easily replace faulty computers and restore all user data and settings on a new computer.

When fully deployed, IntelliMirror uses the Active Directory service and Group Policy for policy-based management of user desktops. A Windows 2000, Windows XP Professional or Windows Server 2003 computer can be automatically configured to meet specific requirements of a users business roles, group memberships, and location. Group Policy and the Active Directory are not necessary for every IntelliMirror feature. Some of the features can be set on the local level or through local polices. An organization can tailor use of IntelliMirror to its needs.

This paper discusses two of the key components that provide user data and settings management in IntelliMirrorUser Profiles and Folder Redirection. It also provides an architectural overview of these features, and presents sample scenarios showing how IntelliMirror is used throughout a computers lifecycle.

# User Profiles Overview in User Data and Settings Management

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A user profile describes the desktop computing configuration for a specific user, including the users environment and preference settings.

A profile is created the first time that a user logs on to a computer running Windows Server 2003, Windows XP, Windows 2000, or Windows NT Workstation. A user profile is a group of settings and files that defines the environment that the system loads when a user logs on. It includes all the user-specific configuration settings, such as program items, screen colors, network connections, printer connections, mouse settings, and window size and position. Profiles are not user policies and the user has a profile even if you don't use Group Policy.

A user's data can be stored on the local hard disk drive, or IntelliMirror can be set so that the data roams with the user wherever he or she logs on. User data can include shortcuts to executable files, personal files, and user settings, such as a custom dictionary.

Depending on how you manage your network, you or a user can define the desktop settings.

The following user profiles are available in Windows Server 2003, Windows XP Professional, and Windows 2000 Professional:

- **Local User Profile.** Created the first time that a user logs on to a computer, the local user profile is stored on a computer's local hard disk. Any changes made to the local user profile are specific to the computer on which the changes are made.

- **Roaming User Profile.** A copy of the local profile is copied to, and stored on a server share. This profile is downloaded every time that a user logs on to any computer on the network, and any changes made to a roaming user profile are synchronized with the server copy upon logoff.

- **Mandatory User Profile.** A type of profile that administrators can use to specify particular settings for users. Only system administrators can make changes to mandatory user profiles. Changes made by the user to desktop settings are lost when the user logs off.

- **Temporary User Profile.** A temporary profile is issued any time that an error condition prevents the users profile from being loaded. Temporary profiles are deleted at the end of each session - changes made by the user to their desktop settings and files are lost when the user logs off.

| **Note** |
| --- |
| If you need to provide managed desktop configurations for groups of users or computers, consider using Group Policy instead of mandatory profiles. |

**Advantages of User Profiles**

A primary goal of user profiles is to separate each users settings and data from that of other users and the local computer. Separating each users state provides several advantages:

- It allows for stateless computers. An organization can configure computers to store all the key user settings and data away from the local computer. This allows for much easier computer replacement and backup. When a computer needs replacing, it can simply be swapped outall of the users state information is safely maintained separately on the network and is independent of a particular computer. When the user logs onto the new computer for the first time, the server copy of the users state is copied to the new computer.

- It allows a users system and desktop customizations to travel with the user from computer to computer, without requiring the user to reconfigure any settings. When a user logs on to any computer on the network that supports the roaming profile, the users desktop appears just as that user left it before logging off. With roaming user support, users can share computers, but each user has his or her personal desktop (both roaming and mandatory profiles support this functionality).

# User Profile Structure

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A user profile consists of:

- A registry hive. The registry is a database used to store computer- and user-specific settings. Portions of the registry can be saved as files, called hives. These hives can then be reloaded for use as necessary. User profiles take advantage of the hive feature to provide roaming profile functionality. The user profile registry hive is the NTuser.dat in file form, and is mapped to the HKEY_CURRENT_USER portion of the registry when the user logs on. The NTuser.dat hive maintains the users environment preferences when the user is logged on. It stores those settings that maintain network connections, Control Panel configurations unique to the user (such as the desktop color and mouse), and application-specific settings. The majority of the settings stored in the registry are opaque to user profiles settings are owned and maintained by individual applications and operating system components.

- A set of profile folders stored in the file system. User profile files are stored in the filesystem in the Documents and Settings directory, in a per user folder. The user profile folder is a container for applications and other operating system components to populate with subfolders and per-user data, such as shortcut links, desktop icons, startup applications, documents, configuration files and so forth. Windows Explorer uses the user profile folders extensively for special folders such as the users desktop, start menu and my documents folder.

Together, these two components record user-configurable settings that can migrate from computer to computer.

The default location of user profiles was changed from the Windows NT 4.0 operating system to allow administrators to secure the operating system folders without adversely affecting user data. On a clean installed computer running Windows Server 2003, Windows XP or Windows 2000, profiles are stored in the %Systemdrive%\Documents and Settings folder. In contrast, on computers running Windows NT 4.0, profiles are stored inside the system directory, at %Systemroot%\profiles folder (typically WINNT\profiles).

| **Note** |
| --- |
| If you upgrade a computer from Windows NT 4.0, the profile location remains %Systemroot%\profiles. |

Table 1 below shows the location of user profiles for each of the possible installation scenarios:

**Table 1 User Profile Locations**

| Operating system | Location of user profile |
| --- | --- |
| Windows Server 2003 clean installation (no previous operating system) | %SYSTEMDRIVE%\Documents and Settings; for example, C:\Documents and Settings |
| Windows Server 2003 upgrade of Windows 2000 | SYSTEMDRIVE%\Documents and Settings; for example, C:\Documents and Settings |
| Windows Server 2003 upgrade of Windows NT 4.0 | %SYSTEMROOT%\Profiles; for example, C:\WinNT\Profiles |

**Configuration Preferences Stored in the Registry Hive**

The NTuser.dat file contains the following configuration settings:

- **Windows Explorer settings.** All user-definable settings for Windows Explorer, as well as persistent network connections.

- **Taskbar settings.**

- **Printer settings.** All network printer connections.

- **Control Panel.** All user-defined settings made in the Control Panel.

- **Accessories.** All user-specific application settings affecting the Windows environment, including: Calculator, Clock, Notepad, Paint, and HyperTerminal, among others.

- **Application Settings.** Many applications store some per user settings in the users registry hive (HKEY_CURRENT_USER). An example of these types of settings would be Microsoft Word 2000s toolbar settings.

**Configuration Preferences Stored in Profile Directories**

Figure 1 below shows the structure of the user profile.

**Figure 1: User Profile.**

Each users profile contains the following folders:

- **Application data***. Application-specific data, such as a custom dictionary for a word processing program. Application vendors decide what data to store in this directory.

- **Cookies**. Internet Explorer cookies.

- **Desktop**. Desktop items, including files and shortcuts.

- **Favorites**. Internet Explorer favorites

- **Local Settings***. Application settings and data that **do not roam** with the profile. Usually either machine specific, or too large to roam effectively.

    - **Application data**. Computer specific application data.

    - **History**. Internet Explorer history.

    - **Temp**. Temporary files.

    - **Temporary Internet Files**. Internet Explorer offline cache.

- **My Documents**. The new default location for any documents that the user creates. Applications should be written to save files here by default.

    - **My Pictures**. Default location for users pictures.

    - **My Music**. Default location for users music.

- **NetHood***. Shortcuts to My Network Places items.

- **PrintHood***. Shortcuts to printer folder items.
- **Recent**. Shortcuts to the most recently used documents.
- **SendTo**. Shortcuts to document storage locations and applications.
- **Start Menu**. Shortcuts to program items.
- **Templates***. Shortcuts to template items.

* These directories are hidden by default. To see these directories, change the View Options.

The Folder Redirection feature of IntelliMirror allows an administrator to redirect the location of certain folders in the user profile to a network location. When these redirected folders are accessed either by the operating system or by applications, the operating system automatically redirects to the location on a network share specified by the administrator. From a user perspective, this is similar to the roaming scenario because users have the same settings regardless of which computers they use. However unlike roaming, these settings actually remain on the network share. Folder redirection can be used with all types of user profiles: local, roaming, or mandatory.

Using Folder Redirection with local profiles can provide some of the benefits of roaming profiles (such as having a users data available at any computer or maintaining data on the server) without the need to implement roaming profiles. Remember though, using Folder Redirection with a local profile would only result in the users documents and files being available from all computers. To have settings and configurations move with the user, you would need to use roaming profiles.

Combining Folder Redirection with roaming profiles gives the benefit of roaming profiles, while minimizing network traffic caused by synchronization of the profile.

Folder redirection is accomplished using Group Policy. The use of Folder Redirection with roaming profiles is discussed later in this article.

Table 2 below lists the folders that roam with the profile by default and indicates whether they can be redirected using Group Policy.

**Table 2 Folders that Roam with the Profile**

| Folder Name | Description | Roams with profile by default | Redirect with Group Policy |
|---|---|---|---|
| Application Data | Per-user roaming application data. | Yes | Yes |
| Cookies | Users Internet Explorer cookies. | Yes | No |
| Desktop | Desktop items, including files and shortcuts. | Yes | Yes |
| Favorites | Users Internet Explorer favorites. | Yes | No |
| Local Settings | Temporary files and per-user non-roaming application data. | No | No |
| My Documents | Users documents. | Yes | Yes |
| NetHood | Shortcuts to My Network Places items. | Yes | No |
| PrintHood | Shortcuts to printer folder items. | Yes | No |
| Recent | Shortcuts to recently used documents | Yes | No |
| Send To | Shortcuts to document storage locations and applications. | Yes | No |

| | | | |
|---|---|---|---|
| Start Menu | Users personal start menu. | Yes | Yes |
| Templates | Per-user customized templates. | Yes | No |

**Non-Roaming Folders**
The default behavior of roaming user profiles in Windows NT 4.0 is to include all the folders in the user profile directory. Thus when a user first logs on, all folders within the profile folder are copied from the server to the client at logon and copied back at logoff,

Windows 2000 introduced a per-user local settings folder into the user profile that is not copied during log on or logoff. This folder is intended for the storage of operating system components and other applications can store non-roaming per-user data. A typical example of the usage of this folder is for Microsoft Internet Explorer to store a users Favorites in the roaming portion of the user profile but store the Temporary Internet Files in the local (non-roaming) portion of the user profile. This will allow a user to retain access to their favorite URLs, but will save copying of temporary cache files at logon and logoff.

On computers running Windows Server 2003, Windows XP or Windows 2000, the History, Local Settings, Temp and Temporary Internet Files folders do not roam by default. Other Non-Roaming Folders are configured using the Group Policy Object Editor. The path for this setting in the Group Policy name space is:

User Configuration\Administrative Templates\System\User Profiles\Exclude directories in roaming profile

Once enabled this allows multiple folder names to be defined, all relative to the root of the users profile. Once included in the policy these folders will not be copied to the local machine at logon, nor copied back to the server at logoff. This setting is likely to result in decreased time taken for a user to logon, by restricting the amount of data within a user profile that really does roam with the user.

**How Do Users Get Their Profile?**
The way in which users get their profiles depends on the type of profile they're configured to use. This section describes this process.

**Local Profile - New User**

1. The user logs on.

2. The operating system checks the list of user profiles located in HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\ProfileList to determine if a local profile exists for the user.

3. Because this is a new user, no local profile is found. If the computer is part of a domain, the operating system checks if a domain wide default profile exists in a folder named **Default User** on the domain controllers **NETLOGON** share.

    - If a domain wide profile exists, it is copied to a subfolder on the local computer with the user name under %SYSTEMDRIVE%\Documents and Settings\. For example, a new user with the user name JDoe would have a profile created in %SYSTEMDRIVE%\Documents and Settings\JDoe.

    - If a default domain profile does not exist, then the local default profile is copied from the %Systemdrive%\Documents and Settings\Default User folder to a subfolder on the local computer with a user name under %Systemdrive%\Documents and Settings\.

4. If the computer is not part of a domain, the local default profile is copied from the %Systemdrive%\Documents and Settings\Default User folder to a subfolder on the local computer with a user name under %Systemdrive%\Documents and Settings\.

5. The users registry hive (NTUSER.DAT) is mapped to the HKEY_CURRENT_USER portion of the registry.

6. The users %userprofile% environment variable is updated with the value of the local profile folder

7. When the user logs off, a profile is saved to the local hard disk of the computer.

**Local Profile - Existing User**

1. The user logs on.

2. Windows checks the list of user profiles located in HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\ProfileList to get the path to the users profile.

3. The users registry hive (NTUSER.DAT) is mapped to the HKEY_CURRENT_USER portion of the registry.

4. The users %userprofile% environment variable is updated with the value of the local profile folder.

5. When the user logs off, the profile is saved to the local hard disk of the computer.

**Roaming Profile - New User**

1. The user logs on.

2. The path to the users roaming profile is retrieved from the user object on the Domain Controller.

3. Windows checks to see if a profile exists in the roaming path, if no profile exists a folder is created.

4. Windows checks the list of user profiles located in HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\ProfileList to determine if a cached copy of the profile exists. If a local copy of the profile is not found, and the computer is part of a domain, Windows checks to determine if a domain wide default profile exists in the Default User folder on the domain controllers NETLOGON share.

    - If a domain wide profile exists, it is copied to a subfolder on the local computer with their user name under %Systemdrive%\Documents and Settings\.

    - If a default domain profile does not exist, then the local default profile is copied from the %Systemdrive%\Documents and Settings\Default User folder to a subfolder on the local computer with their user name under %Systemdrive%\Documents and Settings\.

5. The users registry hive (NTUSER.DAT) is mapped to the HKEY_CURRENT_USER portion of the registry.

6. The users %userprofile% environment variable is updated with the value of the local profile folder

7. The user can then run applications and edit documents as normal. When the user logs off, their local profile is copied to the path configured by the administrator. If a profile already exists on the server, the local profile is merged with the server copy (see merge algorithm later in this paper for more details).

**Roaming Profile - Existing User**

1. The user logs on.

2. The path to the users roaming profile is retrieved from the user object on the Domain Controller.

3. Windows checks to see if a profile exists in the roaming path, if no profile exists a folder is created.

4. Windows checks the list of user profiles located in HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\ProfileList to get the path to the users cached profile if it exists.

5. The contents of the local cached profile are compared with the copy of the profile on the server, and the two profiles are merged. (See the new merge algorithm later in this paper for more details).

6. The users registry hive (NTUSER.DAT) is mapped to the HKEY_CURRENT_USER portion of the registry.

7. The users %userprofile% environment variable is updated with the value of the local profile folder

8. The user can then run applications and edit documents as normal. When the user logs off, the local profile is copied to the path configured by the administrator. If a profile already exists on the server, the local profile is merged with the server copy.

# Enhancements to User Profiles in Windows Server 2003 and Windows XP

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

User data management and user settings management features provide several enhancements that increase the usability, resilience, and performance of user profiles:

- New Group Policy settings
- Support for Windows XP fast network logon
- New System Service profiles
- More robust roaming

**New Group Policy Settings**

User profiles policies have moved to their own node in the Group Policy Object Editor: Administrative Templates\ System\User Profiles. In addition there are three new policies under computer policies:

- **Prevent Roaming Profile Changes from Propagating to the server.** This policy determines if the changes a user makes to their roaming profile are merged with the server copy of their profile. If this policy is set at login, the user will receive their Roaming Profile, but any changes a user makes to their profile will not be merged to their roaming profile at logoff.
- **Add the Administrator security group to the roaming user profile share.** In Windows 2000, the default file permissions for newly generated roaming profiles are full control, or read and write access for the user, and no file access for the administrators group. This policy allows an administrator to choose the same behavior as Windows NT 4.0, and have the administrators group given full control of the user's profile directories.
- **Only allow local user profiles.** This setting determines if roaming user profiles are available on a particular computer. By default, when roaming profile users log on to a computer, their roaming profile is copied down to the local computer. Using this setting, an administrator can prevent users configured to use roaming profiles from receiving their roaming profile on a specific computer.

**Support for fast network logon**

**Fast network logon overview**

Windows XP includes new features that provide faster start up of a computer by not waiting for the network during boot and logon.

By default, Windows XP (but not Windows Server 2003) does not wait for the network to be fully initialized at startup and logon. Any existing users logging on are logged on using cached credentials, which results in shorter logon times. Because the computer doesn't wait for the network to be fully started, Group Policy is applied in the background once the network becomes available. This has a number of effects on the logon process:

- **Changes to some Group Policy extensions can take up to three logons to become effective.** Because background refresh becomes the default behavior, some policy extensions such as Software Installation and Folder Redirection may require as many as three logons to apply changes. This is because to be able to operate safely, these extensions require that no users be logged on, so they must be processed in the foreground before users are actively using the computer. In the case of Advanced folder redirection, because policy is evaluated based on security group membership three logons will be required: the first logon to update the cached user object (and security group membership), the second logon for policy to detect the change in security group membership and require a foreground policy application, and the third logon to actually apply folder redirection policy in the foreground.
- **Changes to some user object properties may take two logons to become effective.** Because users are logged on

using cached credentials, changes that are made to the user object, such as adding a roaming profile path, home directory, or user object logon script, may take up to two logons to be detected. The user object is updated in the background after the user has logged on, so any changes to its properties will not take effect until the next logon at least. Certain key fields in the user object are also checked at logoff, so if the user is logged on at the time of the change, the change may be detected at logoff.

**Changes in roaming user profiles to support fast network logon**
When a user logs onto a computer they have not logged onto for some time, the timestamps of the local user registry hives are compared to the server registry hive and the newest wins. Typically this is the server copy of the registry, as the timestamps are checked before the hive is loaded.

However, when Windows XP is operating in fast network logon mode, the user is always logged on with a cached profile. The effect of this is that when the system detects that the user is now a roaming user, the local registry hive has already been loaded and therefore the hive timestamp is always changed. This introduces the possibility that if a user logs onto multiple computers, an older profile can overwrite a newer server profile because the users roaming status is one step behind (due to the cached logon). To avoid this situation, the roaming profile algorithm treats the transition from local to roaming on a given computer as a special case:

At logon, checks are made to see which of the following conditions are true:

- Is this is the first roaming logon for a user that previously had a local profile?
- Is there a server copy of the users profile?

If all of these conditions are met, then the algorithm is subtly changed, the new algorithm does the following:

1. The contents of the local profile are merged with the server copy of the profile as normal, with the exception of the user registry hive (ntuser.dat).
2. The server copy of the user registry is always copied from the server profile to the local profile, regardless of the time stamps on the hives.

In all other cases, the algorithm remains unchanged. Its only the first time that a user becomes roaming on a specific computer that this check is made. Once the user has become a roaming user, the computer always waits for the network (so that the profile can be downloaded) and the behavior is exactly the same as Windows 2000.

With this change, it is recommended that if an administrator removes the profile path from a users user object, that they either rename or delete the corresponding profile folder. If the profile folder is not removed, and the administrator re-adds the same profile path, the user will receive the older server copy of their registry.

**New System Service profiles**
Windows XP and Windows Server 2003 introduce three new user profiles for the System:

- LocalService
- NetworkService
- System

**LocalService and NetworkService profiles**
The LocalService and NetworkService profiles are automatically created for two new built in user accounts that are used by the Service Control Manager to host services that do not need to run as the local system account. While these two new profiles are normal user profiles, because they are required by the system to run, they are treated slightly differently:

- LocalService and NetworkService profiles are not shown in the profiles list on the system properties dialog.
- Both LocalService and NetworkService profiles are located in %systemroot%\Documents and Settings by default, but are marked as super hidden so that they are not ordinarily visible.

**System Profile**
In Windows 2000, when an application or service used the LoadUserProfile API to load a user profile for a process running as the local system, Windows created a profile named %computername%$ , where %computername% is the name of the local computer. This could cause problems for some applications and services, because depending on whether the system profile was loaded, HKEY_CURRENT_USER could in fact resolve to different registries either HKEY_USERS \S-1-5-18 or HKEY_USERS\.DEFAULT depending on whether another component has loaded the SYSTEM profile.

To avoid this, Windows Server 2003 and Windows XP create a new profile for the system, located in %systemroot%\System32\Config\SystemProfile. This profile is always loaded, and is a link to HKEY_USERS\.DEFAULT. This ensures that system components always have a consistent profile and registry.

**More robust roaming**
In Windows 2000, an issue exists whereby poorly written applications and services that keep registry keys open during logoff prevent Windows from unloading the user's registry hive. When this occurs, changes that a user has made to their profile are not saved to the server. This has three symptoms:

- The user experience is impacted, as users may wonder why changes have not been saved when they log onto another computer.
- Since "locked" profiles never get unloaded, they end up using a lot of memory on a terminal server that has many users logging in.
- If a profile is marked for deletion at logoff (to cleanup the machine or for temporary profiles), profiles do not get deleted.

The three symptoms are solved as follows:

- In Windows 2000 when a user logs off, if the profile is "locked", Windows polls the profile for 60-seconds before giving up. Windows Server 2003 and Windows XP now save the users registry hive at the end of the 60-second delay, and roam the profile correctly.
- When the application or service closes the registry key "unlocking" the profile, Windows Server 2003 or Windows XP will unload the users registry, thus freeing the memory consumed by the profile.
- If a profile is marked for deletion at logoff, when the reference count drops to zero, it will be unloaded and deleted. In the event that the application never releases the registry key, Windows Server 2003 or Windows XP will delete all profiles marked for deletion at the next machine boot.

Note that if a roaming user logs onto back onto a machine that failed to unload her profile previously, and the profile has still not unloaded, the user will receive the currently loaded profile. If the user has logged onto another computer in the meantime, and made changes to their profile, the changes will not be available on the machine with the locked profile.

**Improved Merge Algorithm**
This section describes how Windows Server 2003 or Windows XP reconciles local and server copies of a users profile. To improve the experience of users, roaming profiles have a new algorithm to synchronize copies of a profile. This prevents problems from occurring when a user logs into two different computers simultaneously. The Windows NT 4.0 algorithm worked well in the most common cases where users logged on to only a single computer. However, when a user logged onto multiple computers at the same time, the user sometimes experienced unexpected behavior caused by the assumption that each computer had the master copy of the profile.

For Windows Server 2003, Windows XP, and Windows 2000, the algorithm was changed to support the merging of user profiles at the file level and to provide support for last writer wins.

To illustrate the behavior of the new algorithm, several examples are presented that compare the behavior of Windows NT 4.0 to the current model.

**Overview of the Windows NT 4.0 Algorithm**
In Windows NT 4.0, the algorithm is an Xcopy with full synchronization support, meaning it has the ability to mirror a profile from one location to another, and any extra files or directories in the destination location are removed. The algorithm is based on the concept that there is only one master profile at any one time. When the user is logged on, the master profile is on the local computer. When the user is not logged on, the master profile is on the server.

1. The user logs on to computer A, the primary computer.
2. The roaming profile is Xcopied from the server location to the local profile location.
3. The user creates documents, changes colors, and so on. All of these changes are stored in the local profile location.
4. As the user logs off the computer, the profile is Xcopied from the local profile location back to the server location.

This is an exact mirroring process. If there are any extra files in the server location, they are deleted to ensure that the server location is a duplicate of the local profile. As mentioned previously, this works well in the majority of cases, where a user logs on to only a single computer; but a user who logs on to multiple computers at the same time might experience unexpected behavior.

**Examples of Windows NT 4.0 Merge Algorithm Issues**
When using Windows NT 4.0, a problem arises if the user logs on at two or more computers. Building on the preceding example:

1. The user logs on to computer A.
2. The user logs on to computer B.
3. The user creates a document on computer A and stores it in the user profile.
4. The user logs off of computer A.
5. The user logs off of computer B.

The document that the user created in step 3 is deleted because, from the perspective of computer B, the master profile is stored locally. The extra files on the server must be deleted so that the local profile is currently the master server profile.

The Windows XP algorithm preserves the document because it is able to compare the time the document was created with the time the profile was loaded. If the document was created or modified after the profile load time, the file must be preserved because it came from a different source.

A similar problem can occur when files are modified. For example, suppose that the user has a document called Document.doc in his or her My Documents folder in the server copy of the profile:

1. The user logs on to computer A.
2. The user logs on to computer B.
3. The user modifies the document on computer A.
4. The user logs off computer A.
5. The user logs off computer B.

The changes made to the document on computer A are lost because when the user logged off computer B, the computer overwrote the new version of the document with the old one; the computer is programmed to recognize that it had the master version of the profile.

The current algorithm preserves the changes to the document because it compares the time the document was modified with the time the profile was loaded. This results in a much better experience for the user.

**Overview of Windows Server 2003 Merge Algorithm**
Windows Server 2003 and Windows XP merge user profiles at the file level. The merged profile contains the superset of files that are in the local computer and server copies of the users profile. In the case where the same file is in both the local and server copy of the profile, the file that was modified most recently is used. This means that new files are not deleted, and updated versions of existing files are not overwritten.

When a document or file is updated, the new algorithm compares the timestamp of the destination file with the timestamp of the source file. If the destination file is newer, it is not overwritten.

When a user logs on to a computer, the current time is saved; when the user logs off, this timestamp is used to determine which files are new in the server profile and which files have been deleted in the local profile. For example, if the server profile has a document in the **My Documents** folder called Review.doc and this file does not exist in the local profile, either it is a new file from a different computer, or it was originally in the local profile and the user deleted it. Knowing the time when this new profile was loaded, it is possible to compare it against the timestamp of Review.doc. If Review.doc was created or written to after the profile load time, the file must be preserved because it came from a different source. If the Review.doc timestamp is older than the profile load time, Review.doc must be deleted because it would have been copied to the local computer at load time.

In addition, some files might need to be removed from the local cache so that items that were deleted between sessions remain deleted. For example:

1. The user logs on to computer A.
2. The user creates or modifies a document on computer A.
3. The user logs on to computer B.
4. The user logs off computer B; computer B has a copy of the document.
5. The user deletes the document and logs off computer A.

To ensure that the files are deleted, the cached version of the profile is synchronized with the profile on the server when a user logs on. All files in the local cache that are not present in the server and that were not modified since the last logoff time are removed. By using these changes, Windows XP can merge user profiles.

There are several files that will **always** be copied because the timestamp on those files is changed as part of the profile unloading process. The ntuser.dat and ntuser.ini files will always be copied to the server.

**Quotas on Profile Size**

Often, over time a roaming user profile may potentially grow to a large size, as the user stores more data on their desktop, installs more applications and increases the complexity of their roaming environment. While much of this enhances the user experience, it may result in greater logon and logoff times for the user, as the data is copied down from or back up to the server.

While excluding some of the profile folders from roaming can reduce profile size, there may be situations in which it is more useful to actively restrict the overall quota size, to prevent it growing to an excessive size. The Proquota.exe program is a tool that you can set to monitor the size of a user's profile. If an individuals user profile exceeds the predetermined file limit, the user cannot log off from the computer until the user reduces the size of files.

Profile quota size is managed using the Group Policy snap-in. You can use the **Limit Profile Size** policy, available in the **User Configuration\Administrative Templates\System\User Profiles** node of the Group Policy snap-in to set the maximum size of the roaming user profile and to determine the systems response when the limit is reached. Click the Explain tab of this policy setting for more details.

**Deleting cached roaming profiles**

If you are concerned with disk size on a multi-user computer for example, a public computer where thousands of users can log on, you can also use the Group Policy setting that removes cached versions of the profile on logoff. The policy is called **Delete cached copies of roaming profiles**, and it is accessed under the **Computer Configuration\Administrative Templates\System\User Profiles** node of the Group Policy snap-in.

**Changes to the way Guest profiles are handled**

Windows 2000 and Windows NT 4.0 always delete the user profile of users belonging to the local Guests security group when users log off. Windows XP and Windows Server 2003, continue to delete the profile of guest users, only when the computer is joined to a domain. When the computer is part of a workgroup, the user profile of users belonging to the local Guests group is not deleted at logoff.

The exception is when the user is a member of the local Guests group AND a member of local Administrators, in this case the profile is NOT deleted when in a domain.

**Group Policy Settings for Roaming User Profiles**

See the Appendix for a list of policy settings related to roaming user profiles. For details about these policy settings, click the policys **Explain** tab.

# How to Configure a Roaming User Profile

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can configure a roaming profile by using the following procedure.

To configure a roaming profile for users:

1. Create a folder on the server where user profiles will be stored. This will be the top-level folder that contains all the individual user profiles.

2. Configure the folder as a shared folder, and give all users **Full Control** permissions.

3. Open the **Active Directory Users and Computers** snap-in and navigate to the individuals **User** object.

4. Right-click the **user's name** and click **Properties** on the shortcut menu.

5. Click the **Profile** tab.

6. For the **Profile Path**, type the path to the network share where the user profile is to be stored. For example, for a user whose network name is JDoe, the following path, \\NetworkShare\Profiles\%username%, would create a directory called JDoe in the Profiles share on the server used to store user profiles.

You can also populate the profile path by using an Active Directory Scripting Interface (ADSI) script. ADSI provides a single set of interfaces for managing network resources. Administrators can combine ADSI with Visual Basic Scripting Edition (VbScript) or Jscript scripts to manage resources in the directory service such as users, services, and so on.

To learn about ADSI and ADSI scripts, see the Microsoft Platform SDK.

**User Profiles Troubleshooting**

The first troubleshooting step should be to examine the Application event log on the client computer, and determine the error.

If this is a roaming profile, be sure to check for the correct permissions (see Security Considerations when Configuring Roaming User Profiles for the required permissions) - one of the most common causes of roaming user profile errors is incorrect permissions on the profile share.

In addition to logging events in the Application Event log, User Profiles can provide a detailed log to aid troubleshooting. To create a detailed log file for user profiles:

1. Start regedit and locate the following path:
   HKEY_LOCAL_MACHINE\Software\Microsoft\WindowsNT\CurrentVersion\Winlogon

2. Create a new value called UserEnvDebugLevel as a REG_DWORD, and set the value to 30002 in hexadecimal format.

The log file can be found at: %windir%\debug\usermode\userenv.log

# Security Considerations when Configuring Roaming User Profiles

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**When creating the roaming profile share, limit access to the share to only users that need access.**

Because a users roaming profile contains personal information, such as documents and EFS certificates care should be taken to protect it as well as possible. In general:

- Restrict the share to only users that need access. Create a security group for users that have profiles on a particular share, and limit access to only those users.
- When creating the share, hide the share by putting a $ after the share name. This will hide the share from casual browsers; the share will not be visible in My Network Places.
- Unless you need special permissions on the profile folder, don't pre-create profile folders for the user, allow the system to create them.
- Only give users the minimum amount of permissions needed. The permissions needed are shown in the tables below:

**Table 3 NTFS Permissions for Roaming Profile Parent Folder**

| User Account | Minimum permissions required |
|---|---|
| Creator/Owner | Full Control, Subfolders And Files Only |
| Administrator | None |
| Security group of users needing to put data on share. | List Folder/Read Data, Create Folders/Append Data - This Folder Only |
| Everyone | No Permissions |
| Local System | Full Control, This Folder, Subfolders And Files |

**Table 4 Share level (SMB) Permissions for Roaming Profile Share**

| User Account | Default Permissions | Minimum permissions required |
|---|---|---|
| Everyone | Full Control | No Permissions |
| Security group of users needing to put data on share. | N/A | Full Control, |

**Table 5 NTFS Permissions for Each Users Roaming Profile Folder**

| User Account | Default Permissions | Minimum permissions required |
|---|---|---|
| %Username% | Full Control, Owner Of Folder | Full Control, Owner Of Folder |
| Local System | Full Control | Full Control |
| Administrators | No Permissions* | No Permissions |

| | | |
|---|---|---|
| Everyone | No Permissions | No Permissions |

**Unless the Add the Administrator security group to the roaming user profile share policy is set, in which case the Administrators group has Full Control. (requires Windows 2000 Service pack 2 or later)*

**Use at least Windows 2000 servers to host profile shares.**

Because a users roaming profile contains personal information which is copied to and from the client computer, and the server hosting the roaming profile, it is important to ensure that data is protected as it travels over the network.

The biggest potential threats to the privacy and integrity of a users data come from intercepting the data as it passes over the network, tampering with the data as it passes over the network, and spoofing the server hosting the users data.

Several features of Windows 2000 and Windows Server 2003 can help to secure a users data:

- **Kerberos** - Kerberos is standard on all versions of Windows 2000 and Windows Server 2003s, and ensures the highest level of security to network resources. While NTLM authenticates the client only, Kerberos authenticates the server and the client. When NTLM is used, the client doesn't know whether the server is valid this is particularly important if the client is exchanging personal files with the server, as is the case with Roaming Profiles. Kerberos provides better security than NTLM and is not available on Windows NT version 4.0 or earlier operating systems.

- **IPSec**- The IP Security Protocol (IPSec) provides network-level authentication, data integrity, and encryption ensuring that roamed data is:

    - Safe from data modification while enroute.

    - Safe from interception, viewing, or copying.

    - Safe from being accessed by unauthenticated parties.

- **SMB Signing**- The Server Message Block (SMB) authentication protocol supports message authentication, which prevents active message and "man-in-the-middle" attacks. SMB signing provides this authentication by placing a digital signature into each SMB, which is then verified by both the client and the server. In order to use SMB signing, you must either enable it or require it on both the SMB client and the SMB server. Note: SMB signing imposes a performance penalty; although it doesn't consume any more network bandwidth, it does use more CPU cycles on the client and server side.

**Always use the NTFS Filesystem for volumes holding users data.**

For the most secure configuration, configure servers hosting roaming profiles to use the NTFS File System. Unlike FAT, NTFS supports Discretionary access control lists (DACLs) and system access control lists (SACLs), which control who can perform operations on a file and what events will trigger logging of actions performed on a file.

# Best Practices for User Profiles

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To get the best experience possible from roaming user profiles, it is important to read all the documentation and plan your implementation thoroughly. This section presents best practices for using roaming user profiles.

**Turn off the fast logon enhancement**

With the fast logon enhancement in Windows XP when users change from a local to a roaming profile, it will take two logons on each machine for profile changes to be registered. This is because the user always logs on with cached credentials; therefore it takes one logon for the network to notice that the user has become roaming and the second logon to apply these settings.

To ensure the best possible experience, enable the setting **Always wait for the network at computer startup and logon**, located at Computer Configuration\Administrative Templates\System\Logon.

**Redirect the location of the My Documents Folder outside of the users Roaming Profile.**

To decrease initial logon time to a new computer, it is recommended that you redirect the location of the My Documents folder outside of the users roaming profile. The best way to do this is with Folder Redirection. If you don't have Active Directory enabled, you can do this with a logon script or instruct the user to do so manually.

**Let the system create profile folders for each user.**

To ensure that Roaming user profiles work optimally, create only the root profile share on the server, and let the system create the folders for each user. If you must create folders for the users, ensure that you have the correct permissions set. For details on the required permissions see **Security Considerations when Configuring Roaming User Profiles**.

**Don't use Offline Folders on Roaming Profile Shares.**

Make sure that you turn off Offline Folders for shares where roaming user profiles are stored. If you do not turn off Offline Folders for a users profile, you may experience synchronization problems as both Offline Folders and Roaming Profiles try to synchronize the files in a users profile.

| **Note** |
| --- |
| This does not affect using Offline Folders with redirected folders such as My Documents. |

**Do not use Encrypted File System (EFS) on files in a Roaming User Profile.**

The Encrypted File System is not compatible with files within Roaming User Profiles. If you encrypt profile folders or files using EFS the users profile will not roam.

| **Note** |
| --- |
| This does not affect encrypting files on remote shares. |

**Do not Set Disk Quotas too low for users with Roaming Profiles.**

If a users disk quotas are set too low, roaming profile synchronization may fail. Make sure enough disk space is allocated to allow the system to create a temporary duplicate copy of a users profile. Because the temporary profile is created in the users context as part of the synchronization process, it debits his or her quota.

**Use Group Policy loopback policy processing sparingly if you use roaming profiles.**

Group Policy loopback processing enables a different set of user type Group Policies to be applied based on the computer being logged onto. This policy is useful when you need to have user type policies applied to users of specific computers. There are two methods for doing this. One allows for the policies applied to the user to be processed, but to also apply user policies based on the computer that the user has logged onto. The second method does not apply the users settings based on where the user object is, but only processes the policies based on the computers list of GPOs.

Use caution when using loopback policy processing and roaming profilesespecially when users may roam between Windows 2000 or Windows XP-based computers and Windows NT 4.0-based computers. You may see some tattooing applications can store policy settings in HKCU\Software\Policies regardless of operating system version. Windows NT 4 also stored some explorer policy settings in HKCU\Software\Microsoft\windows\currentversion\explorer\policies. Windows 2000

and Windows XP clears these keys each time before re-applying current policy, but because Windows NT 4 does not clear them, you will get settings left if you roam from a Windows 2000-based machine.

**Roaming between the same operating system versions**

Because the contents of the users registry are opaque to roaming user profiles, you should minimize as much as possible significant differences between operating system installations on computers the users will roam between. When using roaming profiles, try to ensure that:

- The same application versions are installed.
- Applications are installed to the same path and drive.
- The operating system is installed on the same %systemdrive% and in the same %windir%.
- The operating system language and system locale are the same.

**Roaming between different operating system versions**

Although roaming between Windows 2000 and Windows XP should be a smooth process, there are some precautions you can take to minimize possible issues:

- If you can avoid roaming between versions of the operating system, then do so. There's nothing inherent in roaming that will cause problems, but the data that applications put in the profile may have unintended side effects on other versions of the operating system.
- Make sure that you have the same application versions installed.
- Make sure that applications are installed to the same path and drive.
- Make sure that the different versions of the operating system are installed on the same %systemdrive% and in the same %windir%.
- If Users roam between Windows NT 4.0-based clients and Windows XP- Windows 2000-based clients, consider setting the Profile Path during install on Windows XP or Windows 2000. Differences in the default profile path (%windir%\Profiles vs. %systemdrive%\Documents and Settings) may cause problems for users roaming between Windows NT 4.0-based clients and Windows XP- or Windows 2000-based clients. To minimize the chance of problems, make sure the path to the profile is the same on both clients.

# Folder Redirection Overview

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Folder redirection is a feature of IntelliMirror that allows users and administrators to redirect the path of a folder to a new location. The new location can be a folder on the local computer or a directory on a network share. Users have the ability to work with documents on a server as if the documents were based on the local drive. For example, you can redirect the My Documents folder, which is usually stored on the computer's local hard disk, to a network location. The documents in the folder are available to the user from any computer on the network. The My Documents folder is the location on the Windows Server 2003, Windows XP or Windows 2000 desktop where the user can save documents and graphic files.

Previously, administrators who wanted to redirect folders to the network had to use logon scripts to change registry values. In Windows Server 2003 and Windows XP, the same task can be accomplished by using Group Policy.

**Advantages of Using Folder Redirection**

Folder redirection provides a number of advantages. Some of the following benefits relate to redirecting any folder, but redirecting My Documents can be particularly advantageous.

- Even if a user logs on to various computers on the network, the users documents are always available.
- The system administrator can use Group Policy to set disk quotas, limiting the amount of space taken up by users' special folders.
- Data specific to a user can be redirected to a different hard disk on the user's local computer from the hard disk holding the operating system files. This protects the user's data if the operating system needs to be reinstalled.
- Data stored on a shared network server can be backed up as part of routine system administration. This is safer and it requires no action on the part of the user.

You can also combine Folder Redirection and roaming user profiles to decrease logon and logoff times for roaming and mobile users. Besides the improved availability and backup benefits of having the data on the network, users also have performance gains with low-speed network connections and subsequent logon sessions. Because only some of their documents are copied, performance is improved when the users profiles are copied from the server. Not all of the data in the user profile is transferred to the desktop each time the user logs on only the data that user requires.

When you combine the use of Folder Redirection and roaming user profiles, you can provide fast computer replacement. If a user's computer needs to be replaced, the data that a user requires can quickly be re-established on a replacement computer. By using Folder Redirection to redirect the My Documents and Application Data folders, in conjunction with roaming user profiles and Group Policy-based deployment of applications, an organization can move the key user state to a network location. This means the users documents, settings, and applications follow them, regardless of which Windows XP computer the user logs on to.

For increased availability, Offline File technology gives users access to My Documents even when they are not connected to the network. For more information, see the Complementary Technologies section later in this article. This is particularly useful for those who use laptop computers.

**Folders that Can Be Redirected**

My Documents, Application Data, Desktop, and Start Menu are the top level folders that can be redirected. These were identified as the key folders that an organization would need to redirect to preserve important user data and settings. There are several advantages to redirecting each of these folders. The usefulness of each will vary according to your organizations needs.

- **My Documents.** The place in the shell for users to save their documents and pictures. Because common dialog boxes in Windows Server 2003 and Windows XP point to the My Documents folder by default, there is a greater tendency for users to save files there. Data stored on a shared network server can be backed up as part of routine system administration, and is safer because it requires no action from the user.
- **Application Data.** Often applications place large data, such as dictionaries, in the Application Data portion of the user's profile, which roams with the user. To improve performance, Application Data was added to the list of folders that can be redirected. This means that users can still have access to Application Data (such as the custom dictionary), but without the

need to download the (possibly large) files at every logon.

- **Desktop.** Some organizations want to configure computers to look the same. By redirecting the desktop for a group of users, you can ensure that all users share the same desktop, with the same desktop items.

- **Start Menu.** For compatibility with Windows NT 4.0, Windows Server 2003 and Windows XP allow you to use Folder Redirection to redirect the **Start** menu folder. **Start** menu redirection is treated differently from other redirected folders in that the contents of the users **Start** menu are not copied to the redirected location. It is assumed that a redirected **Start** menu has been pre-created by an administrator and that all users **Start** menus will be the same. As a best practice for computers running Windows Server 2003 or Windows XP, do not use Folder Redirection to redirect the **Start** menu folder, use Group Policy to control what appears on the **Start** menu.

**Folder Redirection Improvements for Windows XP and Windows Server 2003**

This section provides information about the differences between Windows 2000 and Windows Server 2003.

**User Interface changes**

The Folder Redirection user interface has been simplified for Windows Server 2003. The main goals of these changes were to simplify the use of Folder Redirection by removing the requirement that administrators be familiar with environment variables such as %USERNAME%.

In addition to the simplified UI, several new redirection options have been added:

- **Create a folder for each user under the root path**

  Rather than having to enter a UNC path such as \\server\share\%username%\MyDocuments, the administrator can simply type in the path to the share such as \\server\share, and Folder Redirection will automatically append the user name and the folder name when the policy is applied. This removes the need for administrators to be familiar with environment variables, and minimizes the chances of errors and spelling mistakes.

- **Redirect to home directory (My Documents Only)**

  Windows Server 2003 and Windows XP allow you to redirect a users My Documents folder to their home directory. This option is intended only for organizations that have a legacy deployment of home directories and wish to transition users to the My Documents metaphor while maintaining compatibility with their existing home directory environment. **You should only select this option if you have already deployed home directories in your organization.**

  Folder redirection treats redirection to the home directory as a special case and certain checks are skipped:

  - Redirection to the home folder is only supported on Windows XP and Windows Server 2003 computers. **Redirection to the home directory policy will fail to apply on Windows 2000 computers.**

  - Security is not checked it is assumed that the administrator has set directory security correctly, no ACL check is made and no reACLing is done. The **Grant the user exclusive rights to My Documents** checkbox on the settings page of the property sheet is disabled.

  - No ownership checks are made - normally folder redirection will fail if a user is not the owner of the folder they are being redirected to. Because redirection to the home directory is intended for use in a legacy environment, this ownership check is skipped.

  - Users must have the home folder property correctly set on their user object - The folder redirection client side extension retrieves the actual path for the user's home directory from the user object at logon time. Users affected by Folder Redirection Policy must have this path correctly set or folder redirection will not apply.

- **Redirect to a specific path**

  This option is intended to allow an administrator to redirect folders to an alternate local drive/partition, or to enter unusual configurations not anticipated by the new user interface. Functionally it works in exactly the same way as the Windows 2000 folder redirection user interface.

- **Redirect to the local user profile**

  This option is intended to allow an administrator to redirect the selected folder to the default location in the local user profile, for example: %userprofile%\<Folder Name>. This setting can be used to remove redirection for a particular folder, without removing the GPO. Note: Setting the redirection option to Not Configured (or No Administrative policy specified in the Windows 2000 UI) **does not** redirect the folder to the local profile, this option means that Folder Redirection is not configured *if a folder was previously redirected it will continue to be redirected to the previous location*. If an administrator wished to return the folder to the local user profile they can use this redirection setting.

**My Pictures no longer shown in the Folder Redirection Node**
To simplify the user interface and to help support the best practice that the My Pictures folder should always follow the My Documents folder, the My Pictures folder is not shown in the Folder Redirection node for new GPOs. If you have previously redirected the My Pictures folder separately, the My Pictures node will still appear.

**Redirected Folders automatically made available offline**
By default in Windows XP and Windows Server 2003, any redirected shell folders such as My Documents, Desktop, Start Menu, and Application Data are automatically made available offline. This is in contrast to Windows 2000, which required administrators to configure the Administratively assigned offline files policy setting to ensure all files in the redirected folders were always available offline. This setting was difficult to use with advanced folder redirection, and involved extra administrative overhead.

The default behavior can be overridden by enabling the Do not automatically make redirected folders available offline policy. This setting can be found in the Group Policy Object Editor in the User Configuration\Administrative Templates\Network\Offline Files section.

Note that on Windows Server 2003 Offline files are disabled by default.

# How to Configure Folder Redirection

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Administrators manage Folder Redirection settings by using the Group Policy snap-in.

**To configure Folder Redirection:**

1. To start the Group Policy snap-in from the Active Directory Users and Computers snap-in, click Start, point to Programs, click Administrative Tools, and then click Active Directory Users and Computers.

2. In the MMC console tree, right-click the domain or the OU for which to access Group Policy, click Properties, and click Group Policy.

3. To create a new Group Policy object (GPO), right-click the domain or OU you want to associate with the GPO, select Properties from the context menu, and then in the domain or OU containers Properties page, click the Group Policy tab.

4. Click New, and type the name to use for the GPO. For example, type Redirect MyDocuments GPO.

5. Click Edit to open the Group Policy snap-in and edit the new GPO.

6. In the Group Policy console, expand the User Configuration, Windows Settings, and Folder Redirection nodes. Icons for the personal folders that can be redirected will be displayed.

7. To redirect any of these folders, right-click the folder name, click Properties, and then select one of the following options from the Setting drop-down box:

   - Basic - Redirect everyone's folder to the same location. All folders affected by this Group Policy object will be stored on the same network share.

   - Advanced Specify locations for various user groups. Folders are redirected to different network shares based on security group membership. For example, folders belonging to users in the Accounting group can be redirected to the Finance server, while folders belonging to users in the Sales group are redirected to the Marketing server.

8. On the My Documents Properties page, in the **Target folder location** drop down box select **Create a folder for each user under the root path**. In the Root Path text box, type the name of the shared network folder to use, or click **Browse** to locate it. Note: Unlike Windows 2000, you do not need to type in the %username% variable. The folder redirection code will automatically create a My Documents folder for each user, inside a folder based on their user name. For example, type **\\FolderServer\MyDocumentsFolders** rather than **\\FolderServer\MyDocumentsFolders\%username%** as you would on Windows 2000.

9. In the folders **Properties** dialog box, select the **Settings** tab, configure the options you want to use, and then click **Finish** to complete the Folder Redirection. The available options for settings are:

   - **Grant the user exclusive rights to My Documents.** If selected, this sets the NTFS security descriptor for the %username% folder to Full Control for the user and local system only; this means that administrators and other users do not have access rights to the folder. This option is enabled by default. Note: Changing this option after the policy has been applied to some users will only effect new users receiving the policy.

   - **Move the contents of My Documents to the new location.** Moves any document the user has in the local My Documents folder to the server share. This option is enabled by default.

   - **Leave the folder in the new location when policy is removed.** Specifies that files remain in the new location when the Group Policy object no longer applies. This option is enabled by default.

   - **Redirect the folder back to the local user profile location when policy is removed.** If enabled, specifies that the folder be copied back to the local profile location if the Group Policy object no longer applies.

The My Documents Properties page provides two additional options for the My Pictures folder:

**Make My Pictures a subfolder of My Documents.** If selected, when the My Documents folder is redirected, My Pictures remains a subfolder of My Documents. By default, My Pictures automatically follows the My Documents folder.

**Do not specify administrative policy for My Pictures.** If selected, Group Policy does not control the location of My Pictures; this is determined by the user profile.

An important point to note is that you should not pre-create the directory defined by user name. Folder Redirection will handle setting the appropriate ACLs on the folder. If you choose to pre-create folders for each user, be sure to set the permissions correctly (see the permissions tables in the Best Practices section later in this paper).

For more information about using the Group Policy snap-in and the Folder Redirection extension, refer to the Windows Server 2003 online Help and the Step-by-Step Guide to User Data and User Settings at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/directory/activedirectory/stepbystep/usrdata.mspx.

**Changing settings after Folder Redirection policy has been applied.**
It is possible to change the Folder Redirection options on the Settings tab after the policy has been applied, you should note that changing the value of the **Grant the user exclusive rights to <folder name>** setting will only apply to new users effected by the policy. Any existing users that received the policy will use the original **Grant the user exclusive rights to <folder name>** setting.

**Folder Redirection and environment variables**
The folder redirection client side extension is only able to process two environment variables: %username% and %userprofile%. Other environment variables such as %logonserver%, %homedrive% and %homepath% will not work with folder redirection.

**Folder Redirection and mapped drives**
Because folder redirection is processed early in the logon process, drives mapped via logon scripts (including the homedrive for folders other than My Documents), the folder redirection client side extension is not able to redirect to these locations. At the time that redirection takes place, the drives do not exist hence redirection fails.

**Folder Redirection Troubleshooting.**
Folder redirection processing contains 5 steps:

1. Determine which folders to redirect based on changes to policy at logon time.
2. Determine desired redirected location and verify access.
3. If folder does not exist: create folders, set ACLs.
4. If folder exists, check ACLs and ownership.
5. If desired, move contents.

Folder redirection failures only affect the folder redirection extension on a per folder basis. If you're pre-creating folders rather than letting the folder redirection extension automatically create the folder, typical errors include:

- Redirecting to a folder that is incorrectly ACLd.
- User is not the owner of the folder.
- Destination does not exist.

**Enabling logging**
In addition to logging events in the Application Event log, Folder Redirection can provide a detailed log to aid troubleshooting. To create a detailed log file for folder redirection, use the following registry key:

- HKLM\Software\Microsoft\Windows NT\CurrentVersion\Diagnostics
- Set: FdeployDebugLevel = Reg_DWORD 0x0f

| Note |
| --- |
| The log file can be found at: %windir%\debug\usermode\fdeploy.log |

**Using Logon Scripts to Redirect Folders**

Although using Group Policy to redirect users folders is the recommended method, there are alternate ways to achieve similar results. You can use logon scripts to set the values of the User Shell Folders key in the registry, which will give you basic functionality similar to Folder Redirection.

Alternatively, you could use Windows NT 4.0 system policies to set the appropriate values. However if you choose to do this, you loose the advantages of using Group Policy to set folder paths, such as automatic moving of files when the path changes, and the registry settings will persist.

# Security Considerations when Configuring Folder Redirection

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**When creating the redirection share, limit access to the share to only users that need access.**

Because redirected folders contain personal information, such as documents and EFS certificates care should be taken to protect them as well as possible. In general:

- Restrict the share to only users that need access. Create a security group for users that have redirected folders on a particular share, and limit access to only those users.
- When creating the share, hide the share by putting a $ after the share name. This will hide the share from casual browsers; the share will not be visible in My Network Places.
- Only give users the minimum amount of permissions needed. The permissions needed are shown in the tables below:

**Table 12 NTFS Permissions for Folder Redirection Root Folder**

| User Account | Minimum permissions required |
|---|---|
| Creator/Owner | Full Control, Subfolders And Files Only |
| Administrator | None |
| Security group of users needing to put data on share. | List Folder/Read Data, Create Folders/Append Data - This Folder Only |
| Everyone | No Permissions |
| Local System | Full Control, This Folder, Subfolders And Files |

**Table 13 Share level (SMB) Permissions for Folder Redirection Share**

| User Account | Default Permissions | Minimum permissions required |
|---|---|---|
| Everyone | Full Control | No Permissions |
| Security group of users needing to put data on share. | N/A | Full Control, |

**Table 14 NTFS Permissions for Each Users Redirected Folder**

| User Account | Default Permissions | Minimum permissions required |
|---|---|---|
| %Username% | Full Control, Owner Of Folder | Full Control, Owner Of Folder |
| Local System | Full Control | Full Control |
| Administrators | No Permissions | No Permissions |
| Everyone | No Permissions | No Permissions |

**Use at least Windows 2000 servers to host redirected file shares.**

Because a users redirected files contain personal information which is copied to and from the client computer, and the server hosting the redirected folders, it is important to ensure that data is protected as it travels over the network.

The biggest potential threats to the privacy and integrity of a users data come from intercepting the data as it passes over the network, tampering with the data as it passes over the network, and spoofing the server hosting the users data.

Several features of Windows 2000 and Windows Server 2003 can help to secure a users data:

- **Kerberos** - Kerberos is standard on all versions of Windows 2000 and Windows Server 2003, and ensures the highest level of security to network resources. While NTLM authenticates the client only, Kerberos authenticates the server and the client. When NTLM is used, the client doesn't know whether the server is valid this is particularly important if the client is exchanging personal files with the server, as is the case with Roaming Profiles. Kerberos provides better security than NTLM and is not available on Windows NT version 4.0 or earlier operating systems.

- **IPSec**- The IP Security Protocol (IPSec) provides network-level authentication, data integrity, and encryption ensuring that roamed data is:

    - Safe from data modification while enroute.

    - Safe from interception, viewing, or copying.

    - Safe from being accessed by unauthenticated parties.

- **SMB Signing**- The Server Message Block (SMB) authentication protocol supports message authentication, which prevents active message and "man-in-the-middle" attacks. SMB signing provides this authentication by placing a digital signature into each SMB, which is then verified by both the client and the server. In order to use SMB signing, you must either enable it or require it on both the SMB client and the SMB server. Note: SMB signing imposes a performance penalty; although it doesn't consume any more network bandwidth, it does use more CPU cycles on the client and server side.

**Always use the NTFS Filesystem for volumes holding users data.**

For the most secure configuration, configure servers hosting redirected files to use the NTFS File System. Unlike FAT, NTFS supports Discretionary access control lists (DACLs) and system access control lists (SACLs), which control who can perform operations on a file and what events will trigger logging of actions performed on a file.

**Do not rely on EFS to encrypt users files when transmitted over the network**

When using the Encrypting File System (EFS) to encrypt files on a remote server, encrypted data is not encrypted when in transit over the network, but only when stored on disk.

The exceptions to this are when your system includes Internet Protocol security (IPSec) or Web Distributed Authoring and Versioning (WebDAV). IPSec encrypts data while it is transported over a TCP/IP network. If the file is encrypted before being copied or moved to a WebDAV folder on a server, it will remain encrypted during the transmission and while it is stored on the server.

**Encrypt the Offline Files cache**

While the Offline Files cache is protected on NTFS partitions by ACLs by default, encrypting the cache enhances security on a local computer. By default, the cache on the local computer is not encrypted, so any encrypted files cached from the network will not be encrypted on the local computer. This may pose a security risk in some environments.

When encryption is enabled, all files in the Offline Files cache are encrypted. This includes existing files as well as files added later. The cached copy on the local computer is affected, but the associated network copy is not.

The cache can be encrypted in one of two ways:

1. Via Group Policy, by enabling the **Encrypt the Offline Files Cache** setting, located at Computer Configuration\Administrative Templates\Network\Offline Files, in the Group Policy editor.

2. Manually, by selecting Tools and then Folder Options in the command menu of Windows Explorer. Select the Offline Files tab, and check the **Encrypt offline files to secure data** checkbox.

**Note**

Encryption of the Offline File cache is only available on Windows XP and above, it is not possible to encrypt the cache on Windows 2000 computers.

For more information about encrypting the Offline files cache, see How to Encrypt Offline Files at: http://www.microsoft.com/technet/prodtechnol/winxppro/maintain/encryptoffline.mspx

**Let the system create folders for each user.**

To ensure that Folder Redirection works optimally, create only the root share on the server, and let the system create the folders for each user. Folder Redirection will create a folder for the user with appropriate security.

If you must create folders for the users, ensure that you have the correct permissions set, also note that if pre-creating folders you must clear the "grant the user exclusive rights to XXX checkbox on the settings tab of the Folder Redirection page. If you don't clear this checkbox, then Folder Redirection will first check a pre-existing folder to ensure the user is the owner. If the folder is pre-created by the administrator, this check will fail and redirection will be aborted. Folder Redirection will then log an event in the Application event log:

Error: Folder Redirection

Event ID: 101

Event Message:

Failed to perform redirection of folder XXXX. The new directories for the redirected folder could not be created. The folder is configured to be redirected to \\server\share, the final expanded path was \\server\share\XXX .

The following error occurred:

This security ID may not be assigned as the owner of this object.

It is strongly recommended that you do not pre-create folders, and allow Folder Redirection to create the folder for the user.

**Ensure correct permissions are set if redirecting to a users home directory.**

Windows Server 2003 and Windows XP allow you to redirect a users My Documents folder to their home directory. When redirecting to the home directory, the default security checks are not made - ownership and the existing directory security are not checked and any existing permissions are not changed - it is assumed that the permissions on the users home directory are set appropriately.

If you are redirecting to a users home directory, be sure that the permissions on the users home directory are set appropriately for your organization.

# Best Practices for Folder Redirection in User Data and Settings Management

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

To get the best results from using Folder Redirection, it is important that you read the Group Policy documentation and plan your implementation thoroughly, particularly with respect to Group Policy.

To learn more about how Group Policy and Folder Redirection were developed in Windows 2000, see the Windows 2000 Management Services page at http://www.microsoft.com/windows2000/technologies/management/default.asp.

**Do not use redirect to home directory option unless you have already deployed home directories in your organization.**

Windows Server 2003 allows you to redirect a users My Documents folder to the users home directory. This option is intended only for organizations that have a legacy deployment of home directories and wish to transition users to the My Documents metaphor while maintaining compatibility with their existing home directory environment. You should only select this option if you have already deployed home directories in your organization.

**Let the system create folders for each user.**

To ensure that Folder Redirection works optimally, create only the root share on the server, and let the system create the folders for each user. If you must create folders for the users, ensure that you have the correct permissions set. See Security Considerations when Configuring Folder Redirection for the permissions required.

**Considerations for Group Policy Removal**

It is important to consider the behavior of your Folder Redirection policy settings when Group Policy is removed.

You specify policy removal options in the selected folders Properties page, shown in Figure 2 below. This is accessed under the User Configuration\Windows Settings\Folder Redirection node of the Group Policy snap-in by right-clicking a folder, and clicking Properties. See Configuring Folder Redirection.

Table 10 below summarizes what happens to Redirected Folders and their contents when the Group Policy object no longer applies.

**Table 10 Summary of Redirected Folders**

| Folder Properties page settings | When policy is removed: | |
|---|---|---|

| State of the Move the contents of special folder to the new location option | Setting selected for the Policy Removal option | |
|---|---|---|
| Enabled | **Redirect the folder back to the user profile location when policy is removed** | The special folder returns to its user profile location.<br>The folder contents are copied back to the user profile location.<br>The contents are not deleted from the redirected location.<br>The user can continue to access the contents, but only on the local computer. |
| Disabled | **Redirect the folder back to the user profile location when policy is removed** | The special folder returns to its user profile location.<br>**Note**<br>In this case, the folder contents are not copied or moved to the user profile location. As a result, the user can no longer see the contents. |
| Either Enabled or Disabled | **Leave the folder in the new location when policy is removed** | The special folder remains at its redirected location.<br>The contents remain at the redirected location.<br>The user continues to have access to the contents at the redirected folder. |

**Important**

Changing the redirection option to Not Configured **does not** redirect the folder to the local profile, this option means that Folder Redirection is not configured *if a folder was previously redirected it will continue to be redirected to the previous location*. If an administrator wished to return the folder to the local user profile they should use the **Redirect to the local user profile** setting.

**Use Offline Folder settings on a server share where the users data is stored.**

This is especially useful for users with laptops. In particular, redirected folders of any type should be coupled with Offline Files.

Table 11 below details the recommended configuration to use for Offline Files.

**Table 11 Recommended Configuration for Offline Files**

| Redirected Folder | Recommended Offline Folder Settings |
|---|---|
| My Documents | Auto-caching for documents or manual caching for documents (if you want users to have to manually make files and folders available offline). |
| My Pictures | Auto-caching for documents or manual caching for documents (if you want users to have to manually make files and folders available offline). |
| Application Data | Auto-caching for programs. |
| Desktop | Auto-caching for programs if the desktop is read only. |

**Always enable the Synchronize all offline files before logging off Group Policy setting.**

Enabling this setting ensures that offline files are fully synchronized and that all the files in the users redirected folder are available when they are working offline. If this setting is not enabled, the system only performs a quick synchronization, and as

a result only recently used files will be cached.

**Have My Pictures follow My Documents.**

It is recommended that you configure the My Pictures folder to follow the My Documents folder, unless you have a compelling reason not to.

**In general, accept the Default Settings for Folder Redirection.**

If you are storing roaming profiles on the same server as Offline Files is enabled, Redirected Folders ensure that Offline Files are set to synchronize at logon and logoff.

When a share is unavailable, Offline Files considers the whole server to be unavailable until the offline cache is manually synchronized. Roaming profiles will not be synchronized with the server while Offline Folders considers the server to be unavailable. If you are using Offline Files in conjunction with Folder Redirection and roaming user profiles, for the best performance you should ensure that you leave the default setting of synchronizing Offline Files at logoff enabled.

**Do not open multiple instances of Outlook 2000 when redirecting the Application Data folder.**

If a user has redirected Application Data and has multiple instances of the Outlook 2000 messaging and collaboration client running on different machines, and one of those instances is Outlook 2000, the user will experience poor performance opening e-mails. Outlook 2000 continually holds the file outcmd.dat open. This file stores information about toolbar customizations (such as position) made in Outlook. When another instance of Outlook attempts to access this file, it cannot do so since it is locked by the running instance of Outlook 2000. The second copy of Outlook keeps trying to access outcmd.dat many times, which causes a long delay when opening messages, replying to messages, and so on.

| **Note** |
| --- |
| Outlook version 2002 (included in Office XP) doesn't hold outcmd.dat openthis is only a problem when running Outlook 2000 on one of the machines. |

# Related Technologies: Offline Files and Synchronization Manager

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section highlights technologies that complement the Folder Redirection feature.

**Offline Files**

Offline Files is a feature introduced in Windows 2000 that complements Folder Redirection. Offline Files let users disconnect from the network and work as if they were still connected. When the computer is offline, the files and folders appear in the same directory as they did online as if they still resided in the same location on the network. This allows the user to edit files when they are disconnected. The next time they connect to the network, the offline changes are synchronized with the network share.

By using Offline Files, users can continue to work with a copy of network files even when they are not connected to a network. If your organization has mobile users with portable computers, Offline Files gives them access to their files when they are not connected to the network, and ensures that they are always working with the current version of network files. By using a cached version of the files, users can open and update files even when they are not connected to the network. Offline Files stores the data in the computer's cache to make network files available offline. The cache is a portion of disk space that a computer accesses when it is not connected to the network. The view of shared network items that you have made available offline remains as it is when connected, even if users lose a connection to the network or they remove a portable computer from the docking station. Users can continue to work with the Offline Files as they normally do when online. Users have the same access permissions to those files and folders as when they are connected to the network. When users dock a portable computer and the network connection is restored, any changes they made while working offline are updated to the network.

If two users on the network make changes to the same file, they can save their version of the file to the network, or keep the other user's version, or save both.

Shared files or folders on a Windows Server 2003 or Windows XP-based network can be available offline. You can also make files available for offline use from any computer that is sharing files using server message blockbased file and printer sharing, including Windows 2000, Windows 95, Windows 98, and Windows NT 4.0.

| **Note** |
| --- |
| The Offline Files feature is not available on Novell NetWare networks. |

When configuring a shared folder, you have the option of choosing whether all the files in the folder are automatically available offline, or whether a user must explicitly mark a file to be available offline.

Offline Files is a completely stand-alone technology, which means that you don't need to pair it with Folder Redirection and set up and configure network shares, but it works well if you do pair the two technologies. For example, if a shortcut to a file is available offline, that file is made available offline, but if a shortcut to a folder is available offline, the contents of that folder are not available offline. If you pair the two technologies, Offline Files and Folder Redirection, both the shortcut and the folder are available offline.

By using the manual caching for documents, users manually specify any files that they want available when they are working offline. Automatic caching for documents is recommended for folders that contain user documents. Opened files are automatically downloaded and made available when users work offline. Older copies of the files are automatically deleted to make room for newer and more recently accessed files. The automatic caching of programs is used for folders with read-only data or run-from-the-network applications. To ensure proper file sharing, the server version of the file is always opened.

**Synchronization Manager**

When using Offline Files and folders, users can synchronize all network resources by using the Synchronization Manager. The Synchronization Manager can be set to automatically synchronize some or all resources. For example, users can set certain files and folders to be synchronized every time they log on or off the network. The Synchronization Manager quickly scans the system for any changes, and if it detects changes, the resources are automatically updated. Only resources that have changed are updated vastly speeding up the synchronization process.

# Common Scenarios for IntelliMirror User Data and Settings Features

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This section presents sample scenarios that illustrate some of the practical uses of the user data and settings management features in IntelliMirror.

The scenarios present a snapshot of a users computer in various uses and stages throughout a typical lifecycle. Each of the scenarios fits into an entire picture or can be seen as a separate event and shows how IntelliMirror benefits the entire organization by reducing the time and effort associated with maintaining the computing environment.

The following scenarios are explained:

- The New Hire
- The Laptop User
- Computer Replacement
- A Shared Computer Environment

**The New Hire**

One of the most critical and time consuming IT tasks is setting up the new hire with a computer. In an organization that is using IntelliMirror, the new hire logs on to a new computer and finds documents and shortcuts already on the desktop. There are shortcuts to common files, URLs, and folders that are useful to all employees (for example, the employee handbook, a shortcut to the departmental shared documents store, and a shortcut to the users departmental guidelines and procedures). Desktop options, application configurations, Internet settings, and so on, are all configured to the corporate standard, ensuring that if the user needs to call the help desk, the support staff knows the configuration the user started with.

In this example, the user gets a pre-configured user profile that was set up for all new users, and was configured before the new hire logged on to the network. The administrator configured a computer to look and behave according to the corporate standard, and then using the User Profile[1] utility built into the System Control Panel application, copied the user profile to a Default User folder on the domain controllers Netlogon share. When the new hire logged onto the network for the first time, Windows copied this default profile to the local computer and used this profile as the basis for the new hires profile. In addition to configuring the default profile the user received, the administrator also used Group Policy to redirect the users My Documents folder to a network location, so that the users documents are safely stored on a network server and can be backed up regularly.

**The Laptop User**

A laptop user working at the office creates several documents and saves them to his or her My Documents folder. After saving documents, the user logs off, unplugs the laptop computer from the network and takes it home. While at home and off the network, the user continues to edit the documents saved earlier in My Documents.

The user returns to the office and logs on to the network. Since the user has done some offline work, a dialog box appears advising the user that data in My Documents has changed and is being synchronized with the network copy.

In this scenario, the users My documents folder has been redirected to a network server, the documents are transparently saved to the network location and also saved in the local computers cache (because the network folder is setup to be available offline), so that they are available when the computer is disconnected from the network.

The whole process can be transparent to the user; the experience is no different than saving documents to the local hard disk.

As soon as the user reconnects to the network, IntelliMirror attempts to reconnect to the network location of the redirected folders. When IntelliMirror reconnects, it determines if there are differences in the data between the local copy of the folder and the network copy. In this scenario, the user has made modifications to a document on the local computer. IntelliMirror identifies this change and prompts the user to update the version stored on the network.

**Computer Replacement**

The computer that the user is working on suddenly stops working because of a complete hardware failure. The user calls the support line, and about 20 minutes later a new computer, loaded only with the Windows XP Professional operating system arrives for the user. Without waiting for technical assistance, the user plugs in the new computer, connects it to the network, and boots it. The computer allows the user to log on to the corporate network, and the user finds that the desktop has the same appearance as the original computer that it replaced. It has the same color scheme, the users preferred background picture is on the screensaver, and all the application icons, shortcuts, and favorites are present. More importantly, all the users data files have been restored.

In a disaster recovery scenario, IntelliMirror assists in getting the users computer replaced and running quickly and with the minimum of support. In this example, because the user was configured to use roaming user profiles, a copy of the users working environment was safely stored on a network server. When the new computer arrived, the user was able to log on and the server copy of the users profile was downloaded to the new computer. An administrator could also have used Folder Redirection to redirect the users key folders such as My Documents and Application Data, to ensure that the users documents were safely stored on the server.

**A Shared Computer Environment**

In this scenario, a user works in a department where the computer he or she uses may change from day to day a call center or IT support environment, for example. The user is working on an important document late one night when the shift ends. The user saves the document and logs off the computer. When the user returns to work the next day, he or she logs onto the first available computer a different computer from the one used the previous night. The user logs onto the network, and sees that the desktop has the same look and feel as the original computer. The user opens the My Documents folder on the desktop and finds the document exactly where he or she saved it and continues the work started the previous night.

In this example, the user was configured to use roaming user profiles, so that a copy of the users working environment was stored on a network server. When the user logged onto the computer, the users existing preferences, shortcuts and documents were copied to the local computer, so that the user could continue working as if using the original computer. A variation on this scenario is using roaming profiles in conjunction with Folder Redirection. Users can have the same work environment and access to the same documents on any computer. Changes made on one computer are synchronized with the other computer the next time the user logs on.

[1] To access the User Profile utility, click Start, point to Settings, select Control Panel, select System, and then select the User Profiles tab in the System Properties dialog box.

# Appendix: Group Policy Settings for Roaming User Profiles

Updated: March 1, 2002

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy Settings for Roaming User Profiles**

| Policy | Location in Group Policy Snap-in | Description |
|---|---|---|
| **Limit profile size** | User Configuration\Administrative Templates\System\User Profiles | Sets the maximum size of a roaming user profile and determines the system's response when a roaming user profile reaches the limit. |
| **Connect home directory to root of the share** | User Configuration\Administrative Templates\System\User Profiles | Restores the definitions of the %HOMESHARE% and %HOMEPATH% environment variables to those used in Windows NT 4.0 and earlier. |
| **Exclude directories in roaming profile** | User Configuration\Administrative Templates\System\User Profiles | Lets you add to the list of folders excluded from the user's roaming profile. |
| **Delete cached copies of roaming profiles** | Computer Configuration\Administrative Templates\System\ User Profiles | Determines whether the system saves a copy of a user's roaming profile on the local computer's hard disk drive when the user logs off. This policy and the related policies in this folder define a strategy for managing user profiles that reside on remote servers. Specifically, they indicate to the system how to respond when a remote profile is slow to load. |
| **Slow network connection timeout for user profiles** | Computer Configuration\Administrative Templates\System\ User Profiles | Defines a slow connection for roaming user profiles. If the server on which the user's roaming user profile resides takes longer to respond than the thresholds set by this policy permit, the system considers the connection to the profile to be slow. This policy and related policies in this folder together define the system's response when roaming user profiles are slow to load. |
| **Add the Administrator security group to the roaming user profile share**<br>*New for Windows XP and Windows Server 2003* | Computer Configuration\Administrative Templates\System\ User Profiles | This policy allows an administrator to choose the same behavior as Windows NT 4.0, and have the administrators group given full control of the user's profile directories. |
| **Prevent Roaming Profile Changes From Propagating to the server**<br>*New for Windows XP and Windows Server 2003* | Computer Configuration\Administrative Templates\System\ User Profiles | This policy determines if the changes a user makes to their roaming profile are merged with the server copy of their profile. If this policy is set, at login the user will receive their Roaming Profile, but any changes a user makes to their profile will not be merged to their roaming profile at logoff. |

| | | |
|---|---|---|
| **Only allow local profiles**<br>*New for Windows XP and Windows Server 2003* | Computer Configuration\Administrative Templates\System\ User Profiles | This setting determines if roaming user profiles are available on a particular computer. By default, when roaming profile users log on to a computer, their roaming profile is copied down to the local computer. Using this setting, an administrator can prevent users configured to use roaming profiles from receiving their roaming profile on a specific computer. |
| **Prompt user when slow link is detected** | Computer Configuration\Administrative Templates\System\ User Profiles | Notifies users when their roaming profiles are slow to load, letting a user decide whether to use a local copy or to wait for the roaming user profile.<br>If you disable this policy or do not configure it, when a roaming user profile is slow to load, the system does not notify the user. It loads the local copy of the profile. If you have enabled the Wait for remote user profile policy, the system loads the remote copy without prompting the user. |
| **Maximum retries to unload and update user profile** | Computer Configuration\Administrative Templates\System\ User Profiles | Windows 2000 Only. Determines how many times the system tries to unload and update the registry portion of a user profile. When the number of trials specified by this policy is exhausted, the system stops trying. As a result, the user profile might not be current, and local and roaming user profiles might not match. |
| **Do not detect slow network connections** | Computer Configuration\Administrative Templates\System\ User Profiles | Disables the slow link detection feature.<br>Slow link detection measures the speed of the connection between a user's computer and the remote server that stores the roaming user profile. When the system detects a slow link, the related policies in this folder tell the system how to respond. |
| **Wait for remote user profile** | Computer Configuration\Administrative Templates\System\ User Profiles | Directs the system to wait for the remote copy of the roaming user profile to load, even when loading is slow. The system waits for the remote copy when the user is notified about a slow connection, but does not respond in the time allowed. |
| **Timeout for dialog boxes** | Computer Configuration\Administrative Templates\System\ User Profiles | Determines how long the system waits for a user response before it uses a default value. The default value is used when the user does not respond to messages explaining that any of the following events has occurred:<br>• The system detects a slow connection between users' computers and the server that stores the users' roaming user profiles.<br>• The system cannot access users' server-based profiles when users log on or off.<br>• Users' local profiles are newer than their server-based profiles. |

# SSL/TLS in Windows Server 2003

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

Chris Crall, Mike Danseglio, and David Mowers

Microsoft Corporation

Published: July 2003

The Microsoft® Windows Server™ 2003 operating system supports Schannel, an implementation of three protocols (TLS 1.0, SSL 3.0 & SSL 2.0) that provide network security for applications and services. This paper focuses on the Secure Sockets Layer (SSL 3.0) protocol and Transport Layer Security (TLS 1.0) protocol. These protocols offer certificate-based authentication and secure data transfers using symmetric encryption keys.

**In This White Paper**

Introduction (SSL/TLS in Windows Server 2003)

Overview of SSL/TLS Encryption

SSL/TLS in Detail

SSL/TLS Scenarios

SSL and Firewalls

Performance Considerations

# Introduction (SSL/TLS in Windows Server 2003)

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

How can you secure data being sent between applications across an untrusted network? The Security Support Provider Interface (SSPI) in the Microsoft® Windows Server™ 2003 operating system provides one answer to this very common security question. SSPI is an application interface that provides the security services for Windows Server 2003. SSPI supports Schannel, an interface that implements three industry standard protocols:

- Transport Layer Security (TLS) version 1.0
- Secure Sockets Layer (SSL) version 3.0
- Secure Sockets Layer (SSL) version 2.0

SSL/TLS is most widely recognized as the protocol that provides secure HTTP (HTTPS) for internet transactions between Web browsers and Web servers. It can also be used for other application level protocols such as FTP, LDAP, and SMTP. The SSL/TLS protocol enables server authentication, client authentication, data encryption and data integrity over networks such as the World Wide Web.

SSPI is documented in the Microsoft Platform Software Development Kit (SDK), which also includes sample applications.

**History and Standards for SSL and TLS**

SSL was developed by Netscape Communications Corporation in 1994 to secure transactions over the World Wide Web. Soon after, the Internet Engineering Task Force (IETF) began work to develop a standard protocol to provide the same functionality. SSL 3.0 was used as the basis for that work, which is known as the Transport Layer Security protocol (TLS). The implementation of the SSL/TLS protocol in Windows Server 2003 closely follows the specification defined in RFC 2246, "The TLS Protocol Version 1.0."

**Differences Between SSL and TLS**

Although there are some slight differences between SSL 3.0 and TLS 1.0, this paper will refer to the protocol as SSL/TLS. One important difference is that TLS 1.0 applies a Keyed-Hashing for Message Authentication Code (HMAC) algorithm, whereas SSL 3.0 applies the Message Authentication Code (MAC) algorithm. The HMAC produces an integrity check value as the MAC does, but with a hash function construction that makes the hash much harder to break. For more information about the HMAC, see "The Handshake Protocol" later in this paper.

| **Note** |
| --- |
| Although their differences are minor, TLS 1.0 and SSL 3.0 do not interoperate. If the same protocol is not supported by both parties, the parties must negotiate a common protocol to communicate successfully. |

**Benefits of SSL/TLS**

SSL/TLS provides numerous benefits to clients and servers, including:

**Strong authentication, message privacy, and integrity.** The primary feature of SSL/TLS is the ability to secure transmitted data using encryption. SSL/TLS also offers server authentication and, optionally, client authentication to prove the identities of parties engaged in secure communication. It also provides data integrity through an integrity check value. In addition to protecting against data disclosure through encryption, the SSL/TLS security protocol can be used to protect against masquerade attacks, man-in-the-middle or bucket brigade attacks, rollback attacks, and replay attacks.

**Interoperability.** SSL/TLS works with most Web browsers, including Microsoft Internet Explorer and Netscape Navigator, and on most operating systems and Web servers including the Microsoft® Windows operating system, UNIX, Novell, Apache (version 1.3 and later), Netscape Enterprise Server, and Sun Solaris. In addition, it is often integrated in news readers, LDAP servers, and a variety of other applications.

**Algorithm flexibility.** SSL/TLS provides options for the authentication mechanisms, encryption algorithms, and hashing algorithms that will be used during the secure session.

**Ease of deployment.** SSL/TLS is used transparently by many applications on Windows Server 2003. Using SSL for secure

browsing when using Internet Explorer and Internet Information Services (IIS) is as easy as selecting a check box.

**Ease of use.** Because SSL/TLS is implemented beneath the application layer, most of its operations are completely invisible to the client. This allows the client to have little or no knowledge of secure communications and still be protected from attackers.

#### Drawbacks of SSL/TLS

There are a few drawbacks to using SSL/TLS, including:

**Increased processor load.** This is the most significant drawback to implementing SSL/TLS. Cryptography, specifically public key operations, are CPU intensive. As a result, there is a performance penalty when using SSL. Unfortunately, there is no single answer to the frequently asked question: how much of performance penalty? The penalty varies widely depending on how often connections are established and how long they last. The greatest overhead occurs while connections are being set up.

**Administrative overhead.** An SSL/TLS environment is complex and requires maintenance; the system administrator needs to configure the system and manage certificates.

# Overview of SSL/TLS Encryption

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

SSL/TLS is primarily used to encrypt confidential data sent over an insecure network such as the Internet. In the HTTPS protocol, the types of data encrypted include the URL, the HTTP header, cookies, and data submitted through forms. A Web page secured with SSL/TLS has a URL that begins with "https://".

The SSL/TLS security protocol is layered between the application protocol layer and TCP/IP layer, where it can secure and then send application data to the transport layer. Because it works between the application layer and the TCP/IP layer, SSL/TLS can support multiple application layer protocols.

The SSL/TLS protocol can be divided into two layers. The first layer is the Handshake Protocol Layer, which consists of three sub-protocols: the Handshake Protocol, the Change Cipher Spec Protocol, and the Alert protocol. The second layer is the Record Protocol Layer. Figure 1 illustrates the various layers and their components.

**Figure 1. SSL/TLS Protocol Layers**

**The Handshake Layer**

The Handshake Layer consists of three sub-protocols:

- **Handshake.** This sub-protocol is used to negotiate session information between the client and the server. The session information consists of a session ID, peer certificates, the cipher spec to be used, the compression algorithm to be used, and a shared secret that is used to generate keys.

- **Change Cipher Spec.** The Change Cipher Spec sub-protocol is used to change the *keying material* used for encryption between the client and server. Keying material is raw data that is used to create keys for cryptographic use. The Change Cipher Spec sub-protocol consists of a single message to tell other party in the SSL/TLS session, who is also known is the peer, that the sender wants to change to a new set of keys. The key is computed from the information exchanged by the Handshake sub-protocol.

- **Alert.** Alert messages are used to indicate a change in status or an error condition to the peer. There are a wide variety of alerts to notify the peer of both normal and error conditions. A full list can be found in RFC 2246, "The TLS Protocol Version 1.0.". Alerts are commonly sent when the connection is closed, an invalid message is received, a message cannot be decrypted, or the user cancels the operation.

**Handshake Sub-Protocol Functions**

The Handshake sub-protocol provides a number of very important security functions. It performs a set of exchanges that starts authentication and negotiates the encryption, hash, and compression algorithms.

**Authentication**

For authentication purposes, the Handshake Protocol uses an X.509 certificate to provide strong evidence to a second party that helps prove the identity of the party that holds the certificate and the corresponding private key. A certificate is a digital form of identification that is usually issued by a certification authority (CA) and contains identification information, a validity period, a public key, a serial number, and the digital signature of the issuer.

A CA is a mutually trusted third party that confirms the identity of a certificate requester (usually a user or computer), and then issues the requester a certificate. The certificate binds the requester's identity to a public key. CAs also renew and revoke certificates as necessary. For example, if a client is presented with a server's certificate, the client computer might try to match the server's CA against the client's list of trusted CAs. If the issuing CA is trusted, the client will verify that the certificate is authentic and has not been tampered with. Finally, the client will accept the certificate as proof of identity of the server.

For more information about certificates and how they are used, see http://go.microsoft.com/fwlink/?LinkId=18015.

| **Note** |
| --- |
| Windows Server 2003 includes software that allows it to function as a certification authority. For more information, see Help and Support Center in Windows Server 2003. |

**Encryption**

There are two main types of encryption: symmetric key (also known as shared secret key) and asymmetric key (also known as public key or public-private key). SSL/TLS uses both symmetric key and asymmetric key encryption.

- **Symmetric Key**. In symmetric key encryption, the same key is used to encrypt and decrypt the message. If two parties want to exchange encrypted messages securely, they must both possess a copy of the same symmetric key. Symmetric key cryptography is often used for encrypting large amounts of data because it is computationally faster than asymmetric cryptography. Typical algorithms include DES (Data Encryption Standard), 3-DES (Triple DES), RC2, RC4, and AES (Advanced Encryption Standard).

- **Asymmetric Key**. Asymmetric or public key encryption uses a pair of keys that have been derived together through a complex mathematical process. One of the keys is made public, typically by asking a CA to publish the public key in a certificate for the certificate-holder (also called the subject). The private key is kept secret by the subject and never revealed to anyone. The keys work together, with one being used to perform the inverse operation of the other: If the public key is used to encrypt data, only the private key of the pair can decrypt it; if the private key is used to encrypt, the public key must be used to decrypt. This relationship allows a public key encryption scheme to do two important things. First, anyone can obtain the public key for a subject and use it to encrypt data that only the user with the private key can decrypt. Second, if a subject encrypts data using its private key, anyone can decrypt the data by using the corresponding public key. This is the foundation for digital signatures. The most common algorithm is RSA (Rivest, Shamir & Adleman).

SSL/TLS uses public key encryption to authenticate the server to the client, and optionally the client to the server. Public key cryptography is also used to establish a *session key*. The session key is used in symmetric algorithms to encrypt the bulk of the data. This combines the benefit of asymmetric encryption for authentication with the faster, less processor-intensive symmetric key encryption for the bulk data.

**Hash Algorithms**

During the Handshake process the hash algorithm is also agreed upon. A hash is a one-way mapping of values to a smaller set of representative values, so that the size of the resulting hash is smaller than the original message and the hash is unique to the original data. A hash is similar to a fingerprint: a fingerprint is unique to the individual and is much smaller than the original person. Hashing is used to establish data integrity during transport. Two common hash algorithms are Message Digest 5 (MD5) and Standard Hash Algorithm 1 (SHA-1). MD5 produces a 128 bit hash value and SHA-1 produces a 160 bit value.

The hash algorithm includes a value used to check the integrity of the transmitted data. This value is established using either a MAC or an HMAC. The MAC uses a mapping function to represent the message data as a fixed-length, preferably smaller, value and then hashes the message. The MAC ensures that the data has not been modified during transmission. The difference between a MAC and a digital signature is that a digital signature is also an authentication method. SSL uses a MAC.

The HMAC is similar to the MAC but uses a hash algorithm in combination with a shared secret key. The shared secret key is appended to the data to be hashed. This makes the hash more secure because both parties must have the same shared secret key to prove the data is authentic. TLS uses an HMAC. For more information about HMAC see RFC 1024, "Keyed-Hashing for Message Authentication."

For more information about public key cryptography, see "Designing a Public Key Infrastructure" in *Designing and Deploying Directory and Security Services of the Microsoft® Windows® Server 2003 Deployment Kit*, (or see "Designing a Public Key Infrastructure" on the Web at http://go.microsoft.com/fwlink/?LinkID=4735).

**The Record Layer**

The protocol at the record layer receives and encrypts data from the application layer and delivers it to the Transport Layer. The Record Protocol takes the data, fragments it to a size appropriate to the cryptographic algorithm, optionally compresses it (or,

for data received, decompresses it), applies a MAC or HMAC (HMAC is supported only by TLS) and then encrypts (or decrypts) the data using the information negotiated during the Handshake Protocol.

# SSL/TLS in Detail

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

This section provides a detailed explanation of the SSL/TLS protocol, specifically the handshake protocol, its associated messages and alerts, and the record protocol.

**The Handshake Protocol**

The handshake protocol is a series of sequenced messages that negotiate the security parameters of a data transfer session. Figure 2 illustrates the message sequence in the handshake protocol.

**Figure 2. Handshake Protocol Messages**

**Initial Client Message to Server**

**Client Hello.** The client initiates a session by sending a Client Hello message to the server. The Client Hello message contains:

- **Version Number.** The client sends the version number corresponding to the highest version it supports. Version 2 is used for SSL 2.0, version 3 for SSL 3.0, and version 3.1 for TLS. Although the IETF RFC for TLS is TLS version 1.0, the protocol uses 3.1 in the version field to indicate that it is a higher level (newer and with more functionality) than SSL 3.0.

- **Randomly Generated Data.** ClientRandom[32], the random value, is a 4-byte number that consists of the client's date and time plus a 28-byte randomly generated number that will ultimately be used with the server random value to generate a master secret from which the encryption keys will be derived.

- **Session Identification (if any).** The sessionID is included to enable the client to resume a previous session. Resuming a previous session can be useful, because creating a new session requires processor-intensive public key operations that can be avoided by resuming an existing session with its established session keys. Previous session information, identified by the sessionID, is stored in the respective client and server session caches.

- **Cipher Suite.** The A list of cipher suites available on the client. An example of a cipher suite is TLS_RSA_WITH_DES_CBC_SHA, where TLS is the protocol version, RSA is the algorithm that will be used for the key exchange, DES_CBC is the encryption algorithm (using a 56-bit key in CBC mode), and SHA is the hash function.

- **Compression Algorithm.** The requested compression algorithm (none currently supported).

The following is an example of a Client Hello message:

```
ClientVersion 3,1
ClientRandom[32]
SessionID: None (new session)
Suggested Cipher Suites:
   TLS_RSA_WITH_3DES_EDE_CBC_SHA
   TLS_RSA_WITH_DES_CBC_SHA
Suggested Compression Algorithm: NONE
```

#### Server Response to Client

**Server Hello.** The server responds with a Server Hello message. The Server Hello message includes:

- **Version Number.** The server sends the highest version number supported by both sides. This is the lower of: the highest version number the server supports and the version sent in the Client Hello message.

- **Randomly Generated Data.** ServerRandom[32], the Random Value, is a 4-byte number of the server's date and time plus a 28-byte randomly generated number that will be ultimately used with the client random value to generate a master secret from which the encryption keys will be derived

- **Session Identification (if any).** This can be one of three choices.

    - New session ID – The client did not indicate a session to resume so a new ID is generated. A new session ID is also generated when the client indicates a session to resume but the server can't or won't resume that session. This latter case also results in a new session ID.

    - Resumed Session ID– The id is the same as indicated in the client hello. The client indicated a session ID to resume and the server is willing to resume that session.

    - Null – this is a new session, but the server is not willing to resume it at a later time so no ID is returned.

- **Cipher Suite.** The server will choose the strongest cipher that both the client and server support. If there are no cipher suites that both parties support, the session is ended with a "handshake failure" alert.

- **Compression Algorithm.** Specifies the compression algorithm to use (none currently supported).

The following is an example of a Server Hello Message:

```
Version 3,1
ServerRandom[32]
SessionID: bd608869f0c629767ea7e3ebf7a63bdcffb0ef58b1b941e6b0c044acb6820a77
Use Cipher Suite:
TLS_RSA_WITH_3DES_EDE_CBC_SHA
Compression Algorithm: NONE
```

**Server Certificate.** The server sends its certificate to the client. The server certificate contains the server's public key. The client will use this key to authenticate the server and to encrypt the premaster secret.

The client also checks the name of the server in the certificate to verify that it matches the name the client used to connect. If the user typed www.contoso.com as the URL in the browser, the certificate should contain a subject name of www.contoso.com or *.contoso.com. Internet Explorer will warn the user if these names do not match.

**Server Key Exchange.** This is an optional step in which the server creates and sends a temporary key to the client. This key can be used by the client to encrypt the Client Key Exchange message later in the process. The step is only required when the public key algorithm does not provide the key material necessary to encrypt the Client Key Exchange message, such as when the server's certificate does not contain a public key.

**Client Certificate Request.** This is an optional step in which the server requests authentication of the client. This step might be used for Web sites (such as a banking Web site) where the server must confirm the identity of the client before providing sensitive information.

**Server Hello Done.** This message indicates that the server is finished and awaiting a response from the client.

#### Client Response to Server

**Client Certificate.** If the server sent a Client Certificate Request, the client sends its certificate to the server for client authentication. The client's certificate contains the client's public key.

**Client Key Exchange.** The client sends a Client Key Exchange message after computing the premaster secret using both random values. The premaster secret is encrypted by the public key from the server's certificate before being transmitted to the server. Both parties will compute the master secret locally and derive the session key from it.

If the server can decrypt this data and complete the protocol, the client is assured that the server has the correct private key. This step is crucial to prove the authenticity of the server. Only the server with the private key that matches the public key in

the certificate can decrypt this data and continue the protocol negotiation.

This message will also include the protocol version. The server will verify that it matches the original value sent in the client hello message. This measure guards against rollback attacks. Rollback attacks work by manipulating the message in order to cause the server and the client to use a less secure, earlier version of the protocol.

**Certificate Verify.** This message is sent only if the client previously sent a Client Certificate message. The client is authenticated by using its private key to sign a hash of all the messages up to this point. The recipient verifies the signature using the public key of the signer, thus ensuring it was signed with the client's private key.

**Change Cipher Spec.** This message notifies the server that all messages that follow the Client Finished message will be encrypted using the keys and algorithms just negotiated.

**Client Finished.** This message is a hash of the entire conversation to provide further authentication of the client. This message is the first message that the record layer encrypts and hashes.

#### Server Final Response to Client

**Change Cipher Spec Message.** This message notifies the client that the server will begin encrypting messages with the keys just negotiated.

**Server Finished Message.** This message is a hash of the entire exchange to this point using the session key and the MAC secret. If the client is able to successfully decrypt this message and validate the contained hashes, it is assured that the SSL/TLS handshake was successful, and the keys computed on the client machine match those computed on the server.

#### The Alert Sub-Protocol

The alert sub-protocol is a component of the Handshake protocol that includes event-driven alert messages that can be sent from either party. Following an alert message the session is either ended or the recipient is given the choice of whether or not to end the session. The alerts are defined in the TLS specification in RFC 2246. Table 1 lists the alert messages and their descriptions.

**Table 1. Event-Driven Alert Messages from the Alert Sub-Protocol**

| Alert Message | Fatal? | Description |
|---|---|---|
| unexpected_message | Yes | Inappropriate message |
| bad_record_mac | Yes | Incorrect MAC |
| decryption_failed | Yes | Unable to decrypt TLSCiphertext correctly |
| record_overflow | Yes | Record is more than 2^14+1024 bytes |
| handshake_failure | Yes | Unacceptable security parameters |
| bad_certificate | Yes | There is a problem with the Certificate |
| unsupported_certificate | No | Certificate is unsupported |
| certificate_revoked | No | Certificate has been revoked |
| certificate_expired | No | Certificate has expired |
| certificate_unknown | No | Certificate is unknown |
| illegal_parameter | Yes | Security parameters violated |
| unknown_ca | Yes | CA unknown |
| access_denied | Yes | Sender does not want to negotiate |
| decode_error | Yes | Unable to decode message |
| decrypt_error | Yes | Handshake cryptographic operation failed |
| export_restriction | Yes | Not in compliance with export regulations |

| | | |
|---|---|---|
| protocol_version | Yes | Protocol version not supported by both parties |
| insufficient_security | Yes | Security requirements no met |
| internal_error | Yes | Error not related to protocol |
| user_canceled | Yes | Not related to protocol failure |
| no_renegotiation | No | Negotiation request rejected. |

**The Record Protocol**

The record protocol receives the data from the application layer and:

- Fragments the data into blocks or reassembles fragmented data into its original structure.
- Numbers the sequence of data blocks in the message to protect against attacks that attempt to reorder data.
- Compresses or decompresses the data using the compression algorithm negotiated in the handshake protocol.
- Encrypts or decrypts the data using the encryption keys and cryptographic algorithm negotiated during the handshake protocol.
- Applies an HMAC (or a MAC for SSL 3.0) to outgoing data. Computes the HMAC and verifies that it is identical to the value transmitted in order to check data integrity when a message is received.

Once the record protocol has completed its operations on the data, it sends the data to the TCP/IP transport layer for transmission. If the data is incoming, it is sent to the appropriate process for reception.

# SSL/TLS Scenarios

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

Many people think of SSL and TLS as protocols used with Web browsers for securely browsing the Internet. However, these are also general purpose protocols that can be used whenever authentication and data protection are necessary. The following examples depict a few uses of SSL/TLS today. This is not an exhaustive list. In fact the ability to access these protocols through the SSPI interface means that anyone take advantage of them for just about any application. Many applications are being modified to take advantage of the features of SSL/TLS.

**Secure transaction with an e-commerce Web site.** This is a typical use of SSL between a browser and a Web server. An example is an e-commerce shopping site where clients need to furnish their credit card numbers. The protocol would first confirm that the Web site's certificate was valid and then send the client's credit card information as cipher text. For this type of transaction, where the server's certificate is from a trusted source, only server-side authentication occurs. SSL/TLS would need to be enabled for the Web page, such as an order form, where the data transactions occur.

**Authenticated client access to a secure Web site.** Both the client and server need certificates from a mutually trusted CA. With Schannel, client certificates can be mapped on a one-to-one or many-to-one basis to their Windows Server 2003 user or computer accounts and can be managed by Active Directory Users and Computers. This is invisible to the users, who can be authenticated to a Web site without needing to supply a password.

If you want to give several users access to confidential material, you can create a group, map the users' certificates to the group, and give the group permissions to the material.

In one-to-one mapping, the server has a copy of the client's certificate; whenever the client logs in, the server verifies that they are identical. This one-to-one mapping is typically used for private material, such as a banking site where only one individual has the right to view a personal account.

**Remote Access.** Schannel is used to provide authentication and data protection when users remotely log in to Windows-based systems or networks. Telecommuting is a common use for this technology. Users can more securely access their e-mail or enterprise applications from home or while traveling, reducing the risk of exposure of the information to anyone on the Internet.

**SQL Access.** Microsoft® SQL Server™ provides the ability for administrators to require authentication of the client when connecting to the server running SQL Server. In addition, either the client or server can be configured to require encryption of the data transferred between them. Very sensitive information, such as financial or medical databases, can be protected to prevent unauthorized access and disclosure of information on the network.

**E-mail.** Exchange servers can use Schannel to protect data as it moves from server to server on the Intranet or Internet. Full end-to-end security might require the use of Secure/Multipurpose Internet Mail Extensions (S/MIME); however, the protection of data in a server-to-server exchange allows companies to use the Internet to securely transfer e-mail among divisions within the same company, subsidiaries and partners. This can be done regardless of whether S/MIME is used.

# SSL and Firewalls

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

You must make some additional decisions if you need to conduct SSL/TLS transactions through a firewall. A firewall is a program that can exist in many different forms, but essentially functions as a barrier between your local area network (LAN) and the outside world. The SSL/TLS protocol interprets a computer on which a firewall is running as presenting a man-in-the-middle attack, which prevents the transaction from happening.

You can use one of two approaches to facilitate SSL/TLS transactions through a firewall:

- **Open the firewall to allow all traffic through a designated port.** The typical port for HTTP over SSL is 443. This port can be opened to allow traffic through to the destination Web server. Unfortunately, this means that the firewall can make security decisions based only on the apparent origin of the packet and its destination. The firewall cannot examine the encrypted data in the requests.

- **Configure the firewall or boundary system as a proxy server.** In this case, the boundary system is the destination for the SSL traffic from the client. The client will authenticate to the boundary system, which will then forward, or *proxy*, the requests to the internal system. The connection from the boundary system to the internal system might or might not be protected by using SSL. This presents an authentication problem because the proxy needs to transmit the authenticated identity of the original user to the internal system. It is not possible to use the certificate mapping features of Windows Server 2003 at the application server, because the authentication process that relies on the user's certificate takes place at the proxy.

# Performance Considerations

Updated: July 31, 2003

Applies To: Windows Server 2003 with SP1

Using the SSL protocol for encryption protects data traveling over the Internet, but it also imposes a performance penalty. SSL can slow down an application or Web site considerably. The most obvious performance degradation when using SSL/TLS results from the time required to establish a session and then encrypt and decrypt the data, all of which heavily use processor cycles.

There are ways to minimize this impact. This section discusses the performance issues related to the cryptography involved and ways to accelerate the performance of the public key operations in SSL/TLS by using hardware solutions. It also covers considerations for scaling Web sites that use SSL/TLS, and performance tuning options for Schannel in Windows Server 2003.

**Asymmetric Encryption**

The process of SSL/TLS key exchange can exact a performance penalty. Nearly all commercially available Web servers and clients implement and support RSA as the asymmetric key exchange algorithm. Although there are other key exchange algorithms supported by SSL/TLS, RSA is the most widely used algorithm.

**Offload Hardware Advantages**

The high computational cost of the RSA public-key encryption algorithm makes it attractive to use encryption offload hardware to accelerate processing. Using offload hardware offers two advantages over performing the RSA encryption in software:

- **Optimizes processing.** The general-purpose processors normally used in computers do most things very well. However, special processors optimized for RSA are able to perform specific mathematical operations much more efficiently.

- **Decreases system-wide load.** Offloading the large number of clock cycles required for RSA decryption to a specialized processor frees the computer's general purpose processor to do other things, such as serving Web pages to other clients, while the decryption completes.

**Offload Devices**

There are three types of offload devices: RSA offload; Hardware Security Modules (HSMs), and Internet Hardware Devices. The first two, RSA offload and HSM devices, are typically cards (such as PCI cards) that plug into the bus on the computer. They interact with the Windows Server 2003 operating system through the Crypto API (CAPI). Internet Hardware Devices are network devices.

- **RSA-offload only devices.** This type of device is designed to provide offloading of RSA operations from the host CPU. These devices are typically cards that are installed with a minimum of effort and little to no configuration. They perform the RSA operation only, and offer no additional features, such as improved key security.

- **Hardware Security Modules (HSM).** These devices are primarily targeted to deployments where security of the private key is a priority. By default, private keys are stored in software. With HSMs, not only are the RSA operations offloaded, but private keys never leave the HSM. These devices are normally tamper-proof and meet varying levels of security certification.

- **Internet Hardware Devices.** This loosely-defined class of devices is generally targeted at solving various problems in deploying e-commerce and internet solutions. These devices all offload SSL operations from the Web Servers by terminating the SSL connections at the device and then proxy the request as standard HTTP. Many of these devices have additional features such as content caching and load-balancing.

**Symmetric Encryption**

Symmetric encryption is so efficient that offloading it to specialized hardware is unnecessary, and might even be counterproductive. For most symmetric algorithms, fewer clock cycles are required to process the data to be encrypted or decrypted on the main processor than to move it from main memory, through the I/O bus, onto the offload hardware, back through the bus and back into memory. Add in the necessary trip through the bus to the network adapter, and it becomes clear why this is commonly referred to as the triple-trip problem. Because all these trips would themselves require resources, and because most symmetric algorithms are optimized for computer processing, it is far more efficient to simply perform the operation on the processor.

**Considerations for Scaling When Using SSL**

Scaling out a Web site means adding servers and then sending client requests to these additional computers, thereby increasing the performance of the site. This is often done by using technologies such as software load balancing, hardware load balancing, and DNS round robin. The traditional methods for scaling out a Web site can still be utilized with SSL/TLS, but you must also deal with a specific requirement imposed by SSL/TLS.

Once an SSL/TLS session is established between a specific client and a specific server, only that server can encrypt and decrypt the requests and responses for that client. Consequently, during an SSL/TLS session a client cannot send an SSL response to a server different from the one with which the client has already negotiated. This would result in an error, and a new SSL/TLS session would have to be negotiated between the client and the new server.

Therefore, when scaling out an SSL/TLS site you must use a method that allows a client to maintain its session with the same SSL/TLS server. This requirement can be met when using Network Load Balancing in Windows Server 2003 by configuring affinity as Single or Class C. The Single option specifies that Network Load Balancing direct multiple requests from the same client IP address to the same cluster host. Class C affinity specifies that Network Load Balancing direct multiple requests from the same TCP/IP Class C address range to the same cluster host.

Most load balancing solutions provide similar functionality. For more information about Network Load Balancing, see The Network Load Balancing Technical Overview link on the Web Resources page at http://go.microsoft.com/fwlink/?LinkID=291.

For example, you might have an SSL/TLS site that runs on a multiprocessor server and can process only 100 transactions per second (Tx/Sec), but you require a processing rate of 300 Tx/sec. To meet this requirement, you could create a Network Load Balancing cluster using two additional servers of the same configuration, and configure the cluster for Single affinity or Class C affinity. In theory you would have increased the performance of your site to 300 Tx/sec. In fact, you would also need to take into account some slight differences in the configuration and possible overhead from using Network Load Balancing. However, it is clearly possible to scale out an SSL/TLS site so long as you observe the requirements imposed by SSL/TLS.

Another technique for increasing performance of an SSL/TLS site is *scaling up*. Scaling up refers to adding larger servers, adding additional processors, or adding special SSL/TLS accelerators to your environment. Scaling up will allow more transactions to be performed by the increase hardware capacity. There are no special considerations for SSL/TLS when scaling up a server.

**Performance Tuning Parameters for SSL/TLS**

The administrator of a Windows Server 2003–based system can tune several Schannel parameters to control session reconnects. These parameters can be used to increase performance or save memory in some application scenarios.

**The Schannel Cache**

SSL/TLS supports a reconnect operation that can be used to enable a client and server to resume a previously negotiated session. This is desirable in many cases because the SSL/TLS reconnect does not require the time needed for a full RSA handshake. But there are cases in which reconnects can be troublesome, such as during performance testing or when the connection pattern of the site is that the same client never reconnects to the same Web server.

Reconnects are enabled by the Schannel cache, which keeps a list of previous SSL/TLS sessions that are established with the current credential handle. The sessions are referenced by the SSL/TLS session ID. Schannel currently maintains up to ten thousand cached sessions for a maximum of ten hours.

Schannel cache values are stored in the following registry subkey:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurityProviders\SCHANNEL

You can add or modify these values by using the registry editor Regedit.exe. Table 2 describes the entries and their values.

| ⚠Caution |
|---|
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Resource Kit Registry Reference for Windows Server 2003 at http://go.microsoft.com/fwlink/?LinkID=4543. |

**Table 2. Schannel Registry Settings**

| Entry | Datatype | Description |
|---|---|---|
| MaximumCacheSize | REG_DWORD | The maximum number of SSL/TLS sessions to maintain in the cache. The default value is 10,000 |

| | | |
|---|---|---|
| ClientCacheTime | REG_DWORD | The time, in milliseconds, to expire each client side cache element. The default is 10 hours. |
| ServerCacheTime | REG_DWORD | The time, in milliseconds, to expire each server side cache element. The default is 10 hours. |

Setting either MaximumCacheSize or ServerCacheTime to zero disables the server-side session cache and prevents reconnects. Increasing MaximumCacheSize or ServerCacheTime above the default values causes LSASS.EXE to consume additional memory. Each session cache element typically requires 2-4k bytes of memory.

# Choosing the Right Printer Drivers

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

**In This White Paper**

Introduction (Choosing the Right Printer Drivers)

User-mode vs. Kernel-mode Drivers

Unidrv and PostScript-based Drivers

Designed for Windows Drivers

Alternate Options

Summary (Choosing the Right Printer Drivers)

Related Links (Choosing the Right Printer Drivers)

# Introduction (Choosing the Right Printer Drivers)

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

The Microsoft Windows printing architecture consists of a print spooler and a set of printer drivers. By calling device-independent Win32 printing and Graphics Device Interface (GDI) functions, applications can create print jobs and send them to any of a variety of devices, including laser printers, vector plotters, raster printers, and fax machines. Printer drivers include a user interface (UI) component that allows users to control a printer's selectable options.

An application's calls to Win32 GDI functions are passed to the GDI graphics engine, which either spools the drawing instructions as an enhanced metafile (EMF) or, in conjunction with a printer driver, renders a printable image that can be sent to the spooler. Spooler components interpret EMF files, and they can insert page layout information and job control instructions into the data stream. The spooler then sends the data stream to the serial, parallel, USB, or network port driver associated with the target printer's I/O port. The device interprets the job, formatted in Printer Description Language (PDL) for the device, and outputs the printed document.

The printer drivers that you select to run on your Windows 2003 print server can have a great impact on its performance, reliability, and scalability.

Printer performance and reliability can be improved by selecting robust, well-tested drivers. These drivers are less likely to crash and therefore require less maintenance by the print administrator.

Scalability is affected by the quantity of unique drivers on a specific server. By reusing the same driver for multiple printers, you lower the chances that drivers will interact in a negative way and reduce the amount of spooler process and registry space used.

The following types of drivers, explained in detail later in this document, are recommended for achieving the optimal performance, reliability, and scalability goals:

- User-mode drivers
- Unidrv-based drivers
- PostScript drivers
- Drivers with the Designed for Windows logo

The following driver types should be avoided unless there are no other options:

- Kernel-mode or Microsoft Windows NT 4.0 drivers
- Monolithic drivers (that is, neither a Unidrv nor PostScript-based driver)
- Drivers without the Designed for Windows logo (unsigned drivers)

# User-mode vs. Kernel-mode Drivers

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

Drivers can be written in either user mode (also called version 3 drivers) or kernel mode (also called version 2 drivers). In Windows NT 4.0, drivers were moved into kernel mode to improve performance. However, when a kernel-mode driver fails, it can crash an entire system, whereas the failure of a user-mode driver causes only the current process to crash. Because of this difference, and because performance enhancements were made in Windows 2000 and Windows Server 2003, native drivers on Windows 2000 and later run in user mode. Windows Server 2003 can still run kernel-mode drivers, although this is not recommended for the stability reasons mentioned previously. It is also possible to install kernel-mode drivers using the Additional Drivers option on Windows 2003 print servers to support Windows NT 4.0 clients.

All drivers on the Windows Server 2003 CD are user mode, except those in the printers\nt4\i386 directory, which are kernel mode to support Windows NT 4.0 clients.

To check whether a driver that you have installed is user mode or kernel mode, do the following:

1. Click **Start**, and then choose **Printers Folder**.
2. Click **File**, and then click **Server Properties**.
3. Click the **Drivers** tab.
4. Look at the **Version** column for a specific driver. If the version indicates Windows NT 4.0 you have a kernel-mode driver. If the version is Windows 2000, Windows XP and Windows Server 2003, you have a user-mode driver.

| **Note** |
| --- |
| The Server Properties dialog box contains information and settings about the entire print server. |

# Unidrv and PostScript-based Drivers

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

Unidrv and Postscript are the standard, well-tested core rendering engines included in Windows Server 2003. In addition, there is a core plotter driver in Windows Server 2003 which a few drivers use. All drivers included on the Windows Server 2003 CD are based on the PostScript, plotter or Unidrv-based drivers, the majority of which were written in conjunction with Independent Hardware Vendors (IHVs) and are also available on the IHVs independent Web sites. These full-featured drivers are supported by both Microsoft and the IHVs.

Because approximately 3,800 drivers based on Unidrv or PostScript are included on the Windows Server 2003 CD and have been thoroughly tested by Microsoft, the IHVs, and multiple customers, these core engines have been proven to be reliable and stable. Drivers based on these engines are less likely to have problems than those based on monolithic engines.

To determine whether a driver you have installed is using the Unidrv or Postscript rendering engines, do the following:

1. Click **Start**, and then choose **Printers Folder**.
2. Click **File**, and then click **Server Properties**.
3. Click the **Drivers** tab.
4. Select a driver, and then click **Properties**.
5. Look at the **Driver File** list box of in the Driver Properties dialog box. If UNIDRV.DLL or PSCRIPT5.DLL appears, the driver is using one of these rendering engines.

| **Note** |
| --- |
| The Postscript rendering engine was co-written by Microsoft and Adobe Systems. You can find the same PostScript engine on the Adobe Web site (http://www.adobe.com) as is on the Windows Server 2003 CD. PostScript 5.1 was included in Windows 2000. PostScript 5.2 is included in Windows 2000 SP3 and Windows Server 2003. |

# Designed for Windows Drivers

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

The "Designed for Windows" logo identifies hardware and software products that have been designed and tested to meet Microsoft standards for compatibility with the Windows Server 2003 operating system. Products displaying the logo have passed rigorous testing that assures they are easy to use, stable, and take advantage of the new features of Windows Server 2003. Hardware is tested to specifications set by the Windows Hardware Quality Labs (WHQL).

Businesses that use products meeting the Designed for Windows logo criteria stand to gain the following benefits:

- **Lower support costs:** Drivers with the logo follow standard Windows look-and-feel guidelines. A consistent UI helps users get up to speed without phoning the help desk.
- **Help manage "DLL Hell":** Drivers with the logo do not overwrite other drivers or uninstall key components.
- **Proper use of operating system:** Products with the logo make proper use of the Windows registry and other key operating system files.
- **Compliance with the Americans with Disabilities Act and other equal rights legislation:** Products with the logo meet usability standards for a wide range of people.

A list of all drivers that currently have the Designed for Windows logo is available at http://www.microsoft.com/whdc/hcl/default.mspx.

| **Note** |
| --- |
| Most but not all drivers with the Designed for Windows logo are user-mode drivers. All drivers recently granted the Designed for Windows Server 2003 logo are user-mode drivers. However, some kernel-mode drivers with proven reliability were grandfathered in during the initial stages of the logo process during the release of Windows 2000. |

# Alternate Options

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

If you are unable to find user-mode drivers with the Designed for Windows logo that are based on the Unidriver or PostScript engines, try using a compatible driver for your printer that supports a majority of the important features. For more information, see the Print Server Upgrade, Migration, and Interoperability white paper at http://www.microsoft.com/windows2000/technologies/fileandprint/print/default.asp.

# Summary (Choosing the Right Printer Drivers)

Updated: March 1, 2003

Applies To: Windows Server 2003 with SP1

As described in the preceding sections, the drivers chosen to run on your print server can affect the stability, reliability, and performance of the server. For best performance, look for user-mode drivers with the Designed for Windows logo that are Unidrv or Postscript based drivers.

# GPMC Scripting: Automate GPO management tasks

Updated: August 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

By Darren Mar-Elia

Learn how to automate many common GPO management tasks with scripting interfaces included in the Group Policy Management Console (GPMC). This article is from the August 2003 issue of Windows & .NET Magazine.

**In This White Paper**

Getting Started with GPMC Scripting

Retrieving Permissions for a GPO

Obtaining RsoP Reports

GPMC Opens New Possibilities

In April, Microsoft released the Group Policy Management Console (GPMC), which provides a Microsoft Management Console (MMC)—based UI for easy management of Windows Server 2003 and Windows 2000 Group Policy. The GPMC represents a big step forward in Group Policy object (GPO) management capabilities as compared with Windows 2000's native tools. With the native tools, scripting GPO management is difficult. However, GPMC includes a set of scripting interfaces for automating many common GPO management tasks. Using these scripting interfaces, you can manage the Group Policy environment, including generating reports of GPO settings, creating and copying GPOs, and finding unlinked GPOs. Microsoft provides several GPMC scripts that cover many common scripting tasks. You can also create your own scripts to perform custom GPO management tasks.

Although you can manage Windows 2000 domain-based Group Policies, GPMC runs only on Windows 2003 and Windows XP Professional computers. (For more information about GPMC's requirements and features, see "Windows Server 2003's Group Policy Management Console," July 2003, http://www.windowsitpro.com, InstantDoc ID 39190.) You can download the GPMC from the Microsoft Download Center (http://www.microsoft.com/downloads/details.aspx?FamilyId=0A6D4C24-8CBD-4B35-9272-DD3CBFC81887&displaylang=en). When you install the GPMC, the system creates a folder called Scripts, which contains all the prewritten GPMC scripts. On a Windows 2003 or XP client, this folder is in the %programfiles%\gpmc directory. The main administrative scripts have a .wsf extension, which is one of the file formats associated with Windows Script Host (WSH). Scripts with the .wsf extension are XML-formatted files that can call other scripts written in VBScript or JScript, which means that one script can take advantage of both the VBScript and JScript scripting engines. For the scripts in this article, I use VBScript without relying on .wsf files.

The GPMC interfaces are implemented in gpmgmt.dll, which resides in the %programfiles%\gpmc directory. Microsoft geared these interfaces toward automating the GPMC functions as well as managing GPOs. Thus, you can use the interfaces not only to script GPMC operations such as creating mapping tables for GPO migrations but also to query and modify GPOs. However, the GPMC interfaces don't let you read or configure policy settings within a GPO. For example, you can't create a script that enables the *Remove Run from Start Menu* Administrative Template policy within a GPO. This limitation is unfortunate; nonetheless, the GPMC interfaces still provide a level of automation that surpasses what has been available to date. Let's take a look at how to get started with GPMC scripting and how you can use the GPMC objects to perform various administrative tasks, such as retrieving permissions for a GPO and obtaining Resultant Set of Policies (RSoP) reports.

# Getting Started with GPMC Scripting

Updated: August 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Learning to write GPMC scripts is fairly straightforward. All GPMC scripts that you write will follow the same basic steps. As with most new objects that you use in the WSH environment, you first need to create instances of, or instantiate, the objects you want to use. In all GPMC scripts, the first object you need to instantiate is the GPM object. This object is the root object in the GPMC object model. You need the GPM object to access other GPMC interfaces, which then provide access to further capabilities. For example, you need the GPM object to access the IGPMDomain interface, which lets you create a reference to an Active Directory (AD) domain. After you have the reference to the AD domain, you can call IGPMDomain's GetGPO method to access the IGPMGPO interface and create a reference to a particular GPO that you want to manage. From here, the IGPMGPO interface contains methods and properties for managing that GPO. You can learn more about the GPMC object model in the Help file called gpmc.chm, which is in the Scripts folder. You can also learn about the object model in the Microsoft Developer Network's (MSDN's) Group Policy Management Console Reference at http://msdn.microsoft.com/library/en-us/gpmc/gpmc/group_policy_management_console_reference.asp.

Another interface that you're likely to run across is IGPMConstants, which is a special interface in GPMC scripting. This interface provides a set of properties that represent GPO-related constants that you'll often need in your GPMC scripts. For example, suppose you need to set the permissions to control who can edit a GPO. You could use a complex set of file-system and AD ACLs to represent the Edit permission, but that approach would take a lot of code work. So, Microsoft provided the IGPMConstants interface to do the work for you. You can simply call the IGPMConstants interface's PermGPOEdit property to represent the appropriate permission. To access the IGPMConstants interface, you use the GPM object's GetConstants method. After using the GetConstants method to obtain a reference to the GPMConstants object, you can then use any of the GPMConstants properties within your scripts.

Listing 1 shows the code that you use to create the GPM and GPMConstants objects. Let's look at two sample scripts—GetGPOPerms.vbs and RSoPLogging.vbs—to see how you build on this code. Admittedly, these scripts aren't the most basic. I didn't want to duplicate the GPMC scripts that Microsoft provides.

**Listing 1 Code That Creates the GPM and GPMConstants Objects**

# Retrieving Permissions for a GPO

Updated: August 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The script in Listing 2, GetGPOPerms.vbs, demonstrates how to use several GPMC objects to list the permissions for a GPO in a test domain. GetGPOPerms.vbs begins by instantiating the GPM and GPMConstants objects. Next, the script accesses IGPMDomain, a useful interface that lets you retrieve information about a domain and manage GPOs within it. To access IGPMDomain, you use the GPM object's GetDomain method, which returns a GPMDomain object. As callout A in Listing 2 shows, the GetDomain method takes three arguments. The first argument is the name of the domain that stores the GPOs you want to manage. The domain name must be the domain's DNS name (e.g., mycompany.net). As callout A shows, you can hard-code this argument's value in the script. Another approach is to have the scripts' users provide the domain name at the command line when they launch the script.

The second argument lets you specify which domain controller (DC) you want to use to connect to the domain. A null string ("") signifies that you don't have a DC preference, which means that the GetDomain method will use the PDC emulator. For the third argument, you specify the option you want to use to find a DC with which to connect. You have three options: GPM_USE_ANYDC, (use any available DC), GPM_USE_PDC (use the PDC emulator DC), or GPM_DONOTUSE_W2KDC (use a DC running Windows 2003). As callout A shows, GetGPOPerms.vbs uses the GPMConstants object's UseAnyDC property to specify the GPM_USE_ANYDC option.

After you connect to the domain, the real fun starts. As the code at callout B in Listing 2 shows, you use the GPMDomain object's GetGPO method to retrieve the GPMGPO object that represents the GPO for which you want to list the permissions. To use GetGPOPerms.vbs, you need to replace the domain name mycompany.net with the DNS name of your AD domain. Notice that the GetGPO method's argument is the GPO's globally unique identifier (GUID) and not the GPO's friendly name. In this script, I included the GUID for the Default Domain Policy that's present in every AD domain. This GUID is the same for all AD domains.

If the scripts' users will be providing the necessary GPO information at the command line, having them input the hard-to-type GUID might not be an option. An alternative is to have the users provide the GPOs' friendly names; you can then obtain the corresponding GUID by using the GetGPObyName function, which Microsoft provides in the lib_commongpmcfunctions.js file in the Scripts folder. GetGPObyName uses the IGPMSearchCriteria interface to search all the GPOs in a domain and, on matching the friendly name entered, returns a GUID that the script can pass to GetGPO. However, GetGPObyName is a JScript function. If you'd rather use VBScript, you can write a VBScript version of GetGPObyName or use the GetGPOs, GPOName, and GPOGuid methods in the IADsTools COM object, which is part of the Windows 2000 Support Tools. For more information about these methods, see the article "Scripting with IADsTools," April 2003, http://www.windowsitpro.com, InstantDoc ID 38286.

Next, the script uses the GPMGPO object's GetSecurityInfo method to retrieve the permissions for the GPO. The GetSecurityInfo method returns a reference to a GPMSecurityInfo collection object, which the script assigns to the GPOSec variable. The GPMSecurityInfo object contains the set of permissions assigned to the GPO. The script then iterates through the collection and uses the GPMSecurityInfo object's Count property to count and return the number of permission entries in the collection.

To retrieve each permission entry, the script uses the GPMSecurityInfo object's Item property, which returns a reference to a GPMPermission object. After the script assigns this reference to the Ace variable, the script uses the GPMPermission object's Trustee property to access the GPMTrustee object. By calling the GPMTrustee object's TrusteeName property, the script determines the name of the user or group assigned to the current permission, then assigns the name to the PrincipalName variable.

The code at callout C in Listing 2 uses a Select Case statement to determine the security right assigned to that user or group. A GPO can have five different security rights, as defined in the IGPMConstants interface. The Select Case statement contains these five rights.

The first line in the Select Case statement tells the VBScript runtime engine to compare the Ace.Permission value (i.e., the GPMPermission object's Permission property value) to each case. When the Permission property value matches one of the five security rights, the script assigns a user-friendly description of that permission to the Perm variable. Finally, the script uses WSH's WScript.Echo command to output the user's or group's name and permission to the console screen.

# Obtaining RsoP Reports

Updated: August 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A useful feature of the GPMC is its ability to perform Group Policy logging and Group Policy planning. Using the GPMC interfaces, you can programmatically obtain the results from Group Policy—logging and Group Policy—planning sessions. For example, to obtain the results from a Group Policy—logging session, you need to use RSoP Windows Management Instrumentation (WMI) providers.

RSoPLogging.vbs, which Listing 3 shows, demonstrates how you can use the RSoP interfaces to execute a logging query and create a logging report in HTML format. The first few lines in the script create the GPM and GPMConstants objects. Next, the script uses the GPM object's GetRSOP method to create an instance of the GPMRSOP object. This method takes three parameters, the first of which specifies the RSoP mode. As the code at callout A in Listing 3 shows, one way you can provide this mode is to use the GPMConstants object's RSOPModeLogging property. If you were performing an RSoP planning session, you would use the RSOPModePlanning property instead. The second parameter specifies the path to the WMI namespace in which previous RSoP data reside. In this case, the parameter is a null string because no previous data exists. The last parameter is always 0.

After creating an instance of the GPMRSOP object, the script sets two properties—GPMRSOP object's LoggingComputer and LoggingUser properties—for the RSoP logging query. The LoggingComputer property specifies the name of the target machine (in this case, myworkstation), whereas the LoggingUser property specifies the name of the target user (in this case, Darren). Next, the script executes the logging query by calling the GPMRSOP object's CreateQueryResults method, which has no parameters.

Finally, the script calls the GPMRSOP object's GenerateReportToFile method, which takes two parameters. The first parameter specifies the type of report to generate (HTML or XML). The script uses the Constants object's ReportHTML property to specify an HTML report. If you prefer to receive an XML report, you can use the ReportXML property instead of the ReportHTML property. The second parameter specifies the pathname for the report.

The GenerateReportToFile method can return a reference to the GPMResult object. The GPMResult object has two properties—Result and Status—that you can use to determine when the report has finished running or failed to run successfully. However, in RSoPLogging.vbs, the generation of the report is the last task, so you don't need to know when the report is done. (You'll know the report is done when the script finishes executing.) Thus, the script doesn't store the reference to GPMResult.

**Listing 3 RSoPLogging.vbs**

```
BEGIN COMMENT
' Create the GPM and GPMConstants objects.
END COMMENT
Set GPMC = CreateObject("GPMgmt.GPM")
Set Constants = GPMC.GetConstants()
` BEGIN CALLOUT A
BEGIN COMMENT
' Create a reference to an RSoP object.
END COMMENT

# GPMC Opens New Possibilities

Updated: August 1, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The new GPMC interfaces are extremely flexible, powerful, and fairly well documented by Microsoft. They provide a lot more control over the Group Policy infrastructure than the Windows 2000 native tools. If you create custom scripts and use them in conjunction with the scripts that Microsoft provides, you can automate most GPO management tasks.

# Introduction (Advanced Certificate Enrollment and Management)

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Complex infrastructure environments and branch-office deployment environments often dictate unique and advanced management techniques to manage a PKI or certificate deployment to remote servers. Network and infrastructure services, such as domain controllers, Internet Authentication Servers (IAS), Internet Information Services (IIS), and other stand-alone applications, often require X.509 certificate enrollment or provisioning to provide or enable secure protocols, messaging, or application services. In many of these deployment scenarios, automatic system provisioning or even traditional certificate enrollment may not be possible due to one or more reasons, such as:

- Stand-alone servers with no relationship to an Active Directory® domain
- Firewalls blocking required communication ports
- Complete lack of connectivity without a virtual private network (VPN) or Internet Protocol Security (IPSec) certificate credential to authenticate to the master network

For example, a branch office domain controller may be connected to the central site only through a firewall, and only port 25 is open for Simple Mail Transfer Protocol (SMTP) replication. The domain controller cannot automatically or manually enroll a domain controller certificate over Remote Procedure Call/Distributed Component Object Model (RPC/DCOM) and, therefore, SMTP replication will fail. Because the certification authority is located in the central site and the firewall is blocking RPC traffic, the branch office domain controller cannot contact the certification authority to enroll its certificate. In this situation, a domain controller certificate must be requested, processed, and installed in an asynchronous or offline process. This white paper explains several remote deployment scenarios along with the step-by-step procedures to perform X.509 certificate enrollment to implement a secure infrastructure.

**Supported Scenarios**
Although it is preferable to describe and support all environments, it is not always possible due to technology limitations or documentation requirements. This white paper documents and focuses on domain controller certificate enrollment for Windows 2000 and Windows Server™ 2003 domain controllers from a Windows 2000 or Windows Server 2003 stand-alone certification authority (CA) as well as from a Windows Server 2003 enterprise CA. Because of technical constraints, manual certificate enrollment from a Windows 2000 enterprise CA is not covered in detail.

**Assumptions**
In this white paper, it is assumed that all domain controllers have been configured and function properly. It is also assumed that the CA has been implemented according to the recommended best practices by Microsoft® as documented in the white paper at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/ws3pkibp.mspx

**Process Overview**
To provide a high-level overview of an advanced enrollment scenario, the following diagrams illustrate step-by-step references of the various procedures and processes that are described in detail in later sections.

Domain Controller Offline Processing with a Windows 2000 Stand-alone CA
Domain Controller
Certification Authority
Start
Is the Domain Controller Windows 2000?
Yes
Copy certutil.exe and certreq.exe to a new folder on the Domain Controller.
No
Determine the Domain Controller's GUID and FQDN.
Prepare the ASN.1 string with certificate extensions.
Prepare the INF file.
Run certreq -new to generate keys and build the request.
Verify the certificate request with certutil -dump.
Copy the request to a removable storage.
Is this the first offline certificate request?
No
2
Yes
1
Accept and install the certificate on the Domain Controller.
3
Is this an offline Directory E-mail Replication certificate?
Yes
Publish the certificate in Active Directory.
Verify the published certificate.
No
Finish
Set the registry flag to allow the CA to accept subject alternate names and restart the CA service.
1
Make removable storage available to the CA.
2
Are extensions part of the request?
No
Confirm that the CA policy module sets the request status to pending.
Yes
Submit the certificate request to the CA.
Are extensions part of the request?
No
Set extensions with certutil -setextensions.
Verify certificate extensions in the pending certificate request.
Issue the certificate.
Yes
Retrieve the certificate and store it on a removable storage.
3

Domain Controller Offline Processing with a Windows 2003 Stand-alone CA
Domain Controller
Certification Authority
Start
Is the Domain Controller Windows 2000?
Yes
No
Copy certutil.exe and certreq.exe to a new folder on the Domain Controller.
Determine the Domain Controller's GUID and FQDN.
Prepare the INF file.
Run certreq -new to generate keys and build the certificate request.
Verify the certificate request with certutil -dump.
Copy the request to a removable storage.
Is this the first offline certificate request?
No
Yes
2
1
Accept and install the certificate on the Domain Controller.

Set the registry flag to allow the CA to accept subject alternate names and restart the CA service.
1
Make removable storage available to the CA.
2
Are extensions part of the request?
No
Yes
Confirm that the CA policy module sets request status to pending.
Submit the certificate request to the CA.
Are extensions part of the request?
No
Yes
Set extensions with certutil -setextensions.
Verify certificate extensions in the pending certificate request.
Issue the certificate.
Retrieve the certificate and store the certificate on a removable storage.
3

Domain Controller Offline Processing with a Windows Server 2003 Enterprise CA
Domain Controller
Certification Authority
Start
Is the Domain Controller Windows 2000?
Yes
Copy certutil.exe and certreq.exe to a new folder on the Domain Controller.
No
Determine the Domain Controller's GUID and FQDN.
Prepare the INF file.
Run certreq -new to generate keys and build the request.
Verify the request with certutil -dump.
Copy the request to a removable storage.
Is this the first offline certificate request?
No
2
Yes
1
Install the certificate on the Domain Controller.
3
Is this an offline Directory E-mail Replication certificate?
Yes
Publish the certificate in Active Directory.
Verify the published certificate.
No
Finish
Set the registry flag to allow the CA to accept subject alternate names and restart the CA service.
1
Duplicate default certificate templates, Offline Directory E-mail Replication, and Domain Controller Authentication.
Configure templates in which the certificate subject and subject alternate name are supplied in the request.
Is the CA on Windows Server 2003 SP1 or later?
no
Run fixdctemplate.vbs.
yes
Attach certificate templates to the CA.
Make removable storage available to the CA.
2
Are extensions part of the request?
No
Confirm that the template sets the request status to pending.
Yes
Submit the certificate request to the CA.
Are extensions part of the request?
No
Set extensions with certutil -setextensions.
Verify certificate extensions in the pending certificate request.
Yes
Issue the certificate.
Retrieve the certificate and store the certificate on a removable storage.

# Requesting Offline Domain Controller Certificates (Advanced Certificate Enrollment and Management)

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

In branch-office scenarios with limited connectivity or those requiring a VPN or IPSec connection to the primary data center will often require an asynchronous enrollment process to enroll or provision the domain controller with an X.509 certificate. Asynchronous or (offline) certificate requests for domain controllers must be created with command-line tools because the operating system does not natively support an offline enrollment Wizard such as the one found in IIS. Since any type of certificate request can be created with the command-line tools, you can also build other certificate request types with these tools once you understand the general procedures. The following sections provide the steps required to enroll a domain controller for a certificate through an offline process.

| **Note** |
| --- |
| Some differences and capabilities exist between a Windows 2000 system and a Windows Server 2003 family operating system. The differences and required procedures specific to an operating system family are noted accordingly. |

**Preparing a Windows 2000 Domain Controller**

For a Windows 2000 family operating system, the first step is to prepare the Windows 2000 domain controller. Since Windows 2000 has no natively installed tools to create certificate requests at a command line, a Windows Server 2003 tool must be used. The version of the certreq.exe and certutil.exe command-line tools available on Windows 2000 have only limited capabilities and do not satisfy the requirements for offline certificate request processing, which is required for this scenario. For example, the Windows 2000 version of certreq.exe does not support the –new option which is required to create new certificate requests. Certutil.exe has many more options to verify and process certificates.

The Windows Server 2003 Administration Tools Pack includes the latest version of certreq.exe and certutil.exe and is required as part of this process. To install the tools on a Windows 2000 computer, you must first install the Windows Server 2003 Administration Tools Pack on a Windows XP or Windows Server 2003 system because it cannot be installed directly on a Windows 2000 computer.

The Windows Server 2003 Administration Tools Pack can be downloaded from the Web site at http://www.microsoft.com/downloads/details.aspx?FamilyID=c16ae515-c8f4-47ef-a1e4-a8dcbacff8e3&DisplayLang=en

To install the tools on a Windows 2000 system, perform the following steps.

| **Important** |
| --- |
| Once you have copied the new files to the Windows 2000 domain controller, two versions of these files will reside on the Windows 2000 computer. Do not remove the natively installed files on the Windows 2000 system because other applications, like the Certificates MMC Snap-in, depend on these native versions. Also, do not register certcli.dll and certadm.dll on the Windows 2000 system through the regsvr32.exe command. |

1. Log on to a computer that runs Windows XP Service Pack 1 or Windows Server 2003.
2. Install the Windows Server 2003 Administration Tools Pack.
3. Copy the following files to a removable storage medium such as a diskette.
    - certreq.exe
    - certutil.exe
    - certcli.dll
    - certadm.dll

4. Log off the computer.

5. Make the removable storage medium available to the domain controller that requires an offline domain controller certificate.

6. Log on to the domain controller as a domain administrator and create a new directory to store the files, for example, *%HOMEDRIVE%\W2K3AdmPak*.

| **Note** |
| --- |
| Do not include this path in your system search path to avoid conflicts with the tool versions that already exist on your computer. |

7. From the removable storage medium, copy the four files to the newly created directory.

**Generating an Offline Certificate Request**

This section applies to both Windows 2000 and Windows Server 2003 domain controllers. The next step is to generate an offline certificate request for the domain controller. As mentioned previously, you must create an offline certificate request with a command-line tool called certreq.exe. This tool supports a rich set of command-line options, but only a few options are required in this procedure. For more information about the certreq.exe tool and its syntax, see Appendix 3: Certreq.exe Syntax.

Certreq.exe requires a text (instruction) file to generate an appropriate X.509 certificate request for a domain controller. You can create the file with your preferred (ASCII) text editor and save the file with an *.inf extension to any directory on your hard drive.

In general, a domain controller certificate that is to be used for SMTP replication must meet the following requirements.

- The certificate must contain the "Certificate Template Name" (referenced by the object identifier 1.3.6.1.4.1.311.20.2) extension.

- The certificate must contain a "Subject Alternative Name" extension that includes the Globally Unique Identifier (GUID) of the domain controller account and the fully qualified domain name (FQDN) of the domain controller Domain Name System (DNS) host name. The subject alternative name is uniquely identified with object identifier 2.5.29.17.

Typically, both extensions are automatically inserted in the certificate by an enterprise CA when the certificate is enrolled automatically or manually while connected to a CA. However, when you request the domain controller certificate offline, you must provide these extensions explicitly in the offline request.

There are several different approaches to adding extensions in certificate requests and, ultimately, issued X.509 certificates. For a Windows 2000 CA, you can either include the extension(s) in the INF instruction file, or you can add the extension(s) to a pending certificate request. If you add the extension(s) to a pending certificate request, it is not necessary to also use the INF instruction file to perform the same task.

For a Windows Server 2003 CA, you can either use the same procedures as a Windows 2000 CA, or you can specify certificate extensions using certreq.exe from a command-line when the certificate request is submitted.

| **Important** |
| --- |
| When you submit extensions from the certreq.exe command-line tool, you cannot set the critical flag for the submitted extensions. Therefore, if an extension is required to be marked critical, you must use an INF instruction file as the submission method. |

**Identifying the Domain Controller GUID**

Active Directory replication via SMTP requires the domain controller GUID as an attribute in the domain controller certificate. Thus, you must identify the domain controller GUID if you are going to issue certificates for SMTP replication from a Windows Server 2003 enterprise or stand-alone CA. Since the GUID of the domain controller is stored in Active Directory, there are several ways to read this attribute from the domain controller's computer object. You do not need to be logged on to a domain

controller or the CA to read the GUID from Active Directory; any computer that has read permissions to objects in the domain is sufficient to complete this task. The following is a partial list of tools that can be used to determine the domain controller GUID from Active Directory.

- Adsiedit.exe (available as part of the Windows® support tools)
- Ldp.exe (available as part of the Windows support tools)
- Dsquery.exe (available as part of the Windows support tools)
- Netdiag.exe (available as part of the Windows support tools)
- Replmon.exe (available as part of the Windows support tools)
- Windows Management Instrumentation (WMI)

For more information, see the Microsoft Knowledge Base article "Determining the Server GUID of a Domain Controller" at http://support.microsoft.com/default.aspx?scid=kb;en-us;224544

Since it may be complicated in some scenarios to easily identify a domain controller GUID, a script is provided in Appendix 2 to look up the GUID from Active Directory automatically when the certificate request is generated. This script simplifies the process for administrators. For more information, see Reqdccert.vbs – Generates Domain Controller Certificate Requests.

**Creating an Offline Certificate Request**

Every X.509 certificate that is issued by a CA requires a unique certificate request to initiate the issuance process. If required, you can create several certificate requests as a batch process before submitting them to a CA.

However, to avoid potential errors and confusion, ensure that you are using unique names for your request files. It is necessary to create the certificate request as a member of the local Administrators group because only this group has interactive logon permissions to a domain controller by default. The first step is to define the input information in an INF file.

To create the INF file that will supply input information for the request, perform the following steps.

1. Log on as a member of the local Administrators group on the domain controller that requires a certificate.
2. Make the reqdccert.vbs script, found in Appendix 2, available locally to the domain controller.
3. If you plan to submit the certificate request to a Windows 2000 or Windows Server 2003 stand-alone CA, run the script from a command-line prompt without any additional parameters. In this case, the *Domain Controller* certificate template is assumed and the domain controller's GUID and DNS name are included as a subject alternative name in the issued certificate.

   If you plan to submit the certificate request to a Windows Server 2003 enterprise CA, you must specify the specific name of the certificate template that is used for enrollment. The name depends on the certificate template name that was previously chosen in **Certificate Template Creation**. In addition, you must specify if the certificate is enrolled for either domain controller authentication or for e-mail replication. This is required because the authentication and e-mail replication templates differ in the subject alternative name construction.

   According to your requirement, run one of the following commands at the command-line prompt.

   To create a certificate request for a domain controller authentication certificate with a custom template:

   ```
   cscript reqdccert.vbs <Templatename> A
   ```

   To create a certificate request for a directory e-mail replication certificate with a custom template:

   ```
   cscript reqdccert.vbs <Templatename> E
   ```

   To create a certificate request with the default domain controller template:

```
cscript reqdccert.vbs
```

The script creates an INF file that is used as an input file to build the certificate request. It also creates some additional syntax that contains the appropriate command syntax to submit the request to the CA and verify the certificate.

For a detailed description of the tasks that are performed by the script, see Reqdccert.vbs – Generates Domain Controller Certificate Requests in Appendix 2.

4. Open a command-prompt window. On a Windows 2000 domain controller, type

```
%HOMEDRIVE%\W2K3AdmPak\CERTREQ -new <dcname>.inf <dcname>.req
```

On a Windows Server 2003 domain controller, type

```
CERTREQ -new <dcname>.inf <dcname>.req
```

Replace the <dcname> variable with the hostname of the domain controller. If you are unsure of the name, look up the name of the INF file saved in your current directory. Note that it may take a few seconds or minutes before the command prompt returns. Depending on the size and available cycles of the system CPU as well as the key length that was set in the INF file, it may take several minutes for the key material to be generated.

| **Important** |
| --- |
| The certreq.exe tool performs several tasks that are often not apparent. First, it generates the public and private key material, and then, it generates the actual certificate request. The key material generation process is the reason why certificate requests must not be generated for several domain controllers on a single computer. The key material must be unique per domain controller to ensure a secure solution. |

**Viewing the Certificate Request**

At this stage, you have successfully generated the public and private key material and created the certificate request. The certificate request is stored in a file and is kept in the *Certificate Enrollment Requests* store of the local computer. To find the enrollment request that was generated, perform the following steps.

1. While still logged on as a member of the local Administrators group, start the Microsoft Management console.

2. Add the Certificates MMC Snap-In.

3. Select Computer Account when the Add window asks for the certificate store that should be managed.

4. In the Certificates MMC Snap-In, navigate to **Certificate Enrollment Requests** in the left pane.

   The certificate request appears in the right pane. It is expected that there is no more than one certificate request pending in this container. Otherwise, this would imply that other certificate request attempts have been submitted but have not yet been approved or accepted.

5. When you double-click the certificate request, the message “You have a private key that corresponds to this certificate” is displayed in the General tab at the bottom. As mentioned previously, certreq.exe has generated the certificate request and the key material. You can safely ignore the warning at the top of the window that says the certificate might be altered. This is an expected warning since the certificate has not yet been issued.

**Verifying a Certificate Request**

It is recommended that the offline domain controller certificate request be validated before it is sent to a CA for processing. Verification will ensure that all request fields are set properly and that the certificate, when processed and issued, will provide the expected functionality. To examine the previously generated certificate request, perform the following step.

- While still logged on as a member of the local Administrators group to the domain controller, type certutil –dump <dcname>.req at a command-line prompt, and then press Enter.

Replace the <dcname> option with the name used in the previous section to generate the offline request. If you have properly created a request that has used the DomainController certificate template, the command will display an output similar to the following:

```
PKCS10 Certificate Request:
Version: 1
Subject:
    CN=W2K3-BO-DC.contoso2.com
Public Key Algorithm:

CertUtil: -dump command completed successfully.
```

It should be expected from the output of the certificate request that the majority of attributes from the generated INF file appear in the actual encoded certificate request.

The reqdccert.vbs script creates an INF instruction file that contains the extension information for DNS name and GUID of the domain controller in an encoded format. This enables the certificate requested to be constructed with certreq.exe –new, whereby the extension information will be automatically included in the certificate request from the INF file.

**Deleting a Certificate Request**

Sometimes it may be necessary to either delete an unneeded or unused certificate request or even delete erroneous certificate requests due to mistakes in the INF input file. If you are logged on as a normal user, you can remove certificate requests only from your own certificate store. However, if you are logged on as Administrator, you can also remove certificate requests from the computer's certificate store. To delete a certificate request, perform the following steps.

1. Open the Certificates MMC Snap-In for the computer account (as described previously).
2. Navigate to Certificate Enrollment Requests in the left pane.
3. Remove the pending certificate request in the right pane by pressing Delete on your keyboard.
4. Close the Certificates MMC Snap-In.
5. If the request has already been submitted to a CA, it may be necessary to also deny the pending request on the CA.

The key material that was generated for the certificate request will remain on the system in the local system (computer) profile unless explicitly deleted by an administrator. Orphaned key material may only be removed manually at the command-line prompt using certutil.exe. However, the administrator will need to know the key container.

| **Important** |
| --- |
| If you delete keys manually from your computer, you will invalidate all data that was encrypted with an encryption key. If you have not implemented a key recovery mechanism, it is recommended that you leave unused keys on the system instead of deleting them. |

Use the following command to display the list of available key containers for the machine context.

```
certutil –store my
```

Use the following command for the current user's context.

```
certutil –store –user my
```

The output will display the key container name for each certificate. Key container names typically are created with random GUID strings as the name.

If you have determined the *keycontainername* for a specific certificate, you can delete the key container with the following command.

```
certutil.exe -delkey <KeyContainerName>
```

The -delkey option is supported only with the Windows Server 2003 version of certutil. On Windows 2000, you must add a prefix to the commands. The prefix is the path you have copied the Windows Server 2003 version of certutil to. In this white

paper, the *%HOMEDRIVE%\W2K3AdmPak* path is used.

**Transferring the Request to a CA**

Once the request file has been generated and validated on the domain controller, it can be transferred to the CA for processing and issuance. Transfer the following files to the CA.

- <dcname>-req  This file contains the certificate request that was generated on the domain controller.

- <dcname>-req.bat  This batch file was created by reqdccert.vbs and contains the correct command-line parameters to submit the request to the CA.

At this point, you can log off of your domain controller.

# Processing Domain Controller Certificates

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Due to differences in the Certificate Services components in Windows 2000 and Windows Server 2003, the issuing process for domain controller certificates depends on the certificate template version and the specific certificate template. Since the processes and steps required are different, both types are outlined separately in the following sections.

**Certificate Templates**
The Windows 2000 and 2003 Server enterprise certification authority (CA) supports the concept of certificate templates. Certificate templates define how an enterprise CA should process a certificate request and generate a specific certificate type when issued. A difference exists between the *Domain Controller* certificate templates in a Windows 2000 and Windows Server 2003 Active Directory environment. It is necessary to understand the differences before you submit the certificate request to a CA. For a broader discussion on certificate templates, see the following references.

- Implementing and Administering Certificate Templates in Windows Server 2003 at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/ws03crtm.mspx

- Selecting Certificate Templates at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/library/depkit/C71D2CD3-82EF-4E3C-8746-1340D0EF4E9A.mspx

**Windows 2000 Certificate Templates**
A Windows 2000 CA provides only one certificate template for domain controller certificates: *Domain Controller*. It may be manually or automatically enrolled through Automatic Certificate Request Service (ACRS) settings in Group Policy. The certificate template name is hard-coded in the operating system and it must be used to enroll Windows 2000 domain controllers. In Windows 2000, you cannot modify certificate templates and thus, only the *Domain Controller* template may be used.

With a domain controller certificate that was issued by a Windows 2000 CA, a domain controller can use the certificate for any of the following purposes.

- Provide mutual authentication for Public Key Cryptography for Initial Authentication in Kerberos (PKINIT) or smart card logon.

- Encrypt Active Directory replication traffic if SMTP replication is enabled.

- Enable Lightweight Directory Access Protocol (LDAP) over Secure Sockets Layer (SSL) connections to Active Directory.

- Authenticate using SSL client authentication for an application that requires this functionality.

If Windows 2000 style auto-enrollment (ACRS in Group Policy) is enabled in a connected environment, a Windows 2000 domain controller will auto-enroll certificates based on the *Domain Controller* template.

**Windows Server 2003 Certificate Templates**
In contrast to a Windows 2000 enterprise CA, a Windows Server 2003 enterprise CA provides three templates for domain controller certificates. In Windows Server 2003, the *Domain Controller* certificate template is known as a V1 certificate template and exists to support auto-enrollment for Windows 2000 domain controllers. The two other certificate templates are *Directory E-mail Replication* and *Domain Controller Authentication*. Both certificate templates are V2 templates, which implies they can be modified, duplicated, and used for the new style certificate auto-enrollment.

Windows XP and Windows Server 2003 systems that are joined to an Active Directory domain support a more advanced auto-enrollment mechanism than previously available in Windows 2000. To support a Windows 2000 computer in a mixed environment with Windows XP and Windows Server 2003 systems, both methods are supported by a Windows Server 2003 CA. For more information about the new style auto-enrollment, see the white paper at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/plan/autoenro.mspx

The capabilities of the Windows 2000 V1 *Domain Controller* certificate template have been divided into two V2 certificate

templates to provide more specific functionality. Instead of having one multi-purpose domain controller certificate that can be used for almost everything, the *Domain Controller Authentication* certificate template is tailored for smart card logon support; the *Directory Email Replication* certificate is made for supporting SMTP e-mail replication. Thus, if you do not require Active Directory replication via SMTP, you do not have to deploy *Directory Email Replication* certificates.

| **Note** |
| --- |
| Both certificate templates are configured by default to supersede the former *Domain Controller* certificate template, which will be performed when both a Windows 2000 enterprise CA and domain controller are upgraded to Windows Server 2003. For more information about superseding templates, see the Implementing and Administering Certificate Templates in Windows Server 2003 white paper at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/ws03crtm.mspx |

To summarize the previous points, the following table provides an overview of the certificate templates that are used by default in Windows 2000 and Windows Server 2003.

| **Domain Controller Operating System** | **Windows 2000 Stand-alone CA** | **Windows 2000 Enterprise CA** | **Windows Server 2003 Stand-alone CA** | **Windows Server 2003 Enterprise CA** |
| --- | --- | --- | --- | --- |
| **Windows 2000** | Domain Controller | Domain Controller | Domain Controller | Domain Controller |
| **Windows Server 2003** | Domain Controller | Domain Controller | Domain Controller | • Domain Controller Authentication<br>• Directory Email Replication |

These same templates can also be used for domain controller offline certificate enrollment. In the case of a Windows Server 2003 enterprise CA, it will also be required to customize the *Domain Controller* certificate template. For more information about this process and requirements, see **Certificate Template Configuration**.

**Using Version 2 Templates with Windows 2000 Computers**

In a mixed environment where you may support or have multiple operating system versions installed, your choice of template version may be limited by the client operating system. Only Windows XP client systems are able to enroll for version 2 templates through the Certificates MMC Snap-In. Windows 2000 clients are not able to display or enroll for version 2 templates through the Certificates MMC Snap-In or automatic certificate request settings in Group Policy. Nevertheless, a Windows 2000 computer can be used to enroll for user certificates that are based on version 2 templates through the Windows Server 2003 Web enrollment pages. As an alternative, you could install certreq.exe on a Windows 2000 computer and request certificates based on version 2 templates manually using that method.

**Domain Controller Certificate Details**

Since many of the offline domain controller enrollment processes involve complex, manual procedures, the following section is provided to assist in understanding the most important characteristics of a domain controller certificate as a reference.

| **Certificate Purpose** | **Domain Controller** | **Domain Controller Authentication** | **Directory E-mail Replication** |
| --- | --- | --- | --- |
| Domain controller authentication–A domain controller can prove its identity to another party, such as a client computer, during smart card logon. | Yes | Yes | No |
| SSL–If a Web server is installed on the domain controller, the Web server can leverage the domain controller certificate to establish SSL connections with clients. This also supports LDAP over SSL connections to the domain controller. | Yes | Yes | No |
| Client authentication (SSL)–This would be used if the computer acts as an SSL client to another application on a separate server. | Yes | Yes | No |
| E-mail encryption–SMTP e-mail can be encrypted and signed with this certificate. | Yes | No | Yes |

A certificate that was issued by a CA based on the *Domain Controller* certificate template has the following characteristics.

- The subject contains the domain controllers FQDN prefix with the "CN=" relative distinguished name element.
- The certificate purposes (also known as extended key usage) are set to "Client Authentication (1.3.6.1.5.5.7.3.2)" and "Server Authentication (1.3.6.1.5.5.7.3.1)". The numbers in parentheses are the corresponding standard object identifier for each certificate purpose.
- The common name of the template is set to "DomainController".
- The Subject Alternative Name contains the domain controller's GUID in object identifier 1.3.6.1.4.1.311.25.1 and the FQDN of the domain controller.

A certificate that was issued based on the *Domain Controller Authentication* certificate template has the following characteristics.

- The subject of the certificate is empty.
- The certificate purposes (also known as extended key-usage) are set to "Client Authentication (1.3.6.1.5.5.7.3.2)", "Server Authentication (1.3.6.1.5.5.7.3.1)", and "Smart Card Logon (1.3.6.1.4.1.311.20.2.2)". The numbers in parentheses are the corresponding object identifier for each certificate purpose.
- The common name of the template is set to "Domain Controller Authentication" or the name of the template that was specified in the certificate request for this certificate type.
- The Subject Alternative Name extension contains the domain controller's fully qualified DNS name of the domain controller.

A certificate that was issued based on the *Directory Email Replication* certificate template has the following characteristics.

- The subject of the certificate is empty.
- The certificate purpose (also known as extended key-usage) is set to "Directory Service Email Replication (1.3.6.1.4.1.311.21.19)". The numbers in parentheses are the corresponding object identifier for each certificate purpose.
- The common name of the template is set to "DirectoryEmailReplication" or the name of the template that was specified in the certificate request for this certificate type.
- The Subject Alternative Name extension contains the domain controller's GUID in object identifier 1.3.6.1.4.1.311.25.1 and the FQDN of the domain controller.

**Windows Server 2003 Certificates and Publishing in Active Directory**

Certificates, which are enrolled from an enterprise CA with the *Domain Controller* or the *Directory Email Replication* certificate template, are published by default into the requester's object in Active Directory. When a certificate is auto-enrolled, the requestor is naturally a domain controller. These certificate templates publish certificates in Active Directory primarily to facilitate encrypted replication of Active Directory content with SMTP; both replication partners must have access to the public key (certificate) of their replication partner.

Only enterprise certification authorities publish certificates in Active Directory as an automatic process. If you enroll a *Domain Controller* certificate manually from a stand-alone CA, you must publish the certificate manually in Active Directory. Remember that stand-alone CAs do not offer the *Domain Controller Authentication* and *Directory Email Replication* certificate template format(s), so regardless of the CA version, you can only issue *Domain Controller* certificates from a stand-alone CA.

By default, certificates that have been built with the *Domain Controller Authentication* certificate template are not published in Active Directory because smart card logon requires the domain controller's certificate in Active Directory. Therefore, it is not recommended that *Domain Controller Authentication* certificates be published in Active Directory by manipulating the default *Domain Controller Authentication* certificate template.

**Windows 2000 Server CA Configuration**

By default, a Windows 2000 Server CA does not permit subject alternative names that are specified in a certificate request to

be accepted and inserted in the issued certificate. This applies for both stand-alone and enterprise CAs. This functionality is required to submit and process offline domain controller certificate requests. To permit this functionality, the CA configuration must be modified.

| **Important** |
| --- |
| Changing the CA configuration of the CA to permit subject alternative names in certificate requests will be a global setting and is not limited to a single template. Once this setting is enabled, the CA will accept attributes for subject alternative names for all certificate requests. |

To change the CA configuration to accept subject alternative names in requests, perform the following steps.

1. Log on to the CA as Administrator.

2. At a command-line prompt, type

   ```
   CERTUTIL -setreg policy\EditFlags +EDITF_ATTRIBUTESUBJECTALTNAME2
   ```

   This enables the CA to accept the "Subject Alternative Name" to be submitted in the request. If you submit more offline domain controller requests to this CA, you do not have to set the parameter again. It persists until it is manually reset to the default setting by an administrator. To reset the CA to the default setting, type the following at a command-line prompt.

   ```
   CERTUTIL -setreg policy\EditFlags -EDITF_ATTRIBUTESUBJECTALTNAME2
   ```

   | **Note** |
   | --- |
   | This setting will affect all certificate requests that are submitted to your CA. Any certificate request that provides a SubjectAltName2 will be recognized and processed by the CA. |

3. The following command will display the configuration parameters (EditFlags) that have been set before and after the change. You can verify the parameters explicitly with the following command.

   ```
   CERTUTIL -getreg policy\EditFlags
   ```

4. To enable the changes in all subsequently issued certificates, restart the certification authority service. To restart the CA, type the following at a command prompt, and then press Enter.

   ```
   NET STOP certsvc & NET START certsvc
   ```

**Issuing Domain Controller Certificates with a Windows 2000 CA**
A CA that is installed on a Windows 2000 computer can issue domain controller certificate requests for both Windows 2000 and Windows Server 2003 domain controllers.

With a Windows 2000 CA, no option is available to customize the *Domain Controller* certificate template. However, as a limited option, you may set the validity time of a domain controller certificate on a specific CA. For information about how to change the validity time, see the Microsoft Knowledge Base article *HOW TO: Change the Expiration Date of Certificates That Are Issued by a Windows Server 2003 or a Windows 2000 Server Certification Authority* at http://support.microsoft.com/default.aspx?id=254632

**Windows 2000 Stand-alone CA**
To issue domain controller certificates, it does not matter if the stand-alone CA is a domain member or a member of a workgroup. With both configurations, domain controller certificates can be issued. A stand-alone CA does not support certificate templates, therefore, no choice is required in this regard. A stand-alone CA will process a certificate request according to the information supplied in the request.

To issue a certificate for domain controllers from a Windows 2000 CA, you can use one of two approaches.

- Prepare a certificate request with the Windows Server 2003 version of certreq.exe that includes the domain controllers

GUID and its DNS name in the subject alternative name.

- Use a generic certificate request and add the certificate extensions to the certificate request while it is pending at the CA.

In the first case where you have included the subject alternative name in the certificate request, it is not required to set the certificate request status to pending before issuing the certificate.

Since this white paper illustrates how to include the subject alternative name in the certificate request in **Certificate Template Configuration**, the following section explains how to manipulate a pending request. You may use the following procedure with a different set of command-line parameters for other certificate types as well.

| **Note** |
| --- |
| From a technical viewpoint, both methods result in the same certificate being issued. However, it is more convenient to include extensions in the certificate request because no additional manipulation of a pending request is required. This method, however, does require the Windows Server 2003 version of certreq.exe to be used. |

**Windows 2000 CA Configuration**

Once you have set the *EditFlag* (see Windows 2000 Server CA Configuration), you should verify that the policy module will put all certificates into a pending mode before they are issued. To confirm the request handling of the CA, perform the following steps.

1. Log on to the computer where the Windows Server 2000 stand-alone CA is installed.

2. Open the Certification Authority MMC Snap-In.

3. In the left pane, select the CA object and select Properties on the Action menu.

4. In the Policy Module tab, click Properties.

5. Verify that the policy module of the stand-alone CA is set to the following value.

   *Set the certificate request status to pending*.

   | **Note** |
   | --- |
   | A stand-alone CA sets the certificate request status to pending by default. |

6. Click **OK** twice to confirm the setting and close the Properties page.

7. Close the Certification Authority MMC Snap-In.

**Issuing a Domain Controller Certificate**

Compared to a Windows 2003 CA, it is more complicated to issue certificates that require a given set of subject alternative names in the certificate. Unfortunately, unlike a Windows Server 2003 CA, you cannot specify certificate extensions such as the subject alternative name when you submit the certificate. The Windows 2000 CA does not support such functionality. To work around this limitation, you must include the certificate extensions in the certificate request or perform the certificate enrollment process in three distinct steps, with an optional fourth step.

1. The certificate request is submitted.

2. Certificate extensions are set in the pending certificate request.

3. The certificate is approved and issued.

4. The certificate can be manually verified for accuracy.

The following steps show how to submit the request, process the request, verify the request, and issue the certificate. In this case, the certificate request does not include the certificate extensions.

**Submit the Certificate Request**

1. Log on to the computer where the Windows Server 2000 stand-alone CA is installed.

2. Copy the certificate request (<dcname>.req) and the batch script (<dcname>-req.bat) that were previously created on the domain controller (see Creating an Offline Certificate Request) into a working file folder on the CA.

3. At a command-line prompt, use the <dcname>-req.bat script to run the required certreq command. The batch file will simply submit the certificate request to the CA with the following command.

   ```
   certreq -attrib "CertificateTemplate:DomainController" <dcname.req>
   ```

4. A window will appear where you can select the CA that will issue the certificate. Select the Windows 2000 issuing CA and click OK.

5. Note the RequestID that is shown after the command has finished.

**Process the Certificate Request**

The next step is to set the certificate extensions in the pending certificate request using either the Windows 2000 or the Windows Server 2003 version of certutil.

| **Important** |
| --- |
| The following command will override any existing information in the certificate request that matches the given object identifier. If you have specified, for example, a subject alternative name as part of the certificate request, the subject alternative name will be overridden with this command. |

1. Copy the <dcname>.asn file from the domain controller to the CA computer.

2. At a command-line prompt, run the following command.

   ```
   certutil -setextension <RequestID> 2.5.29.17 1 @<dcname>.asn
   ```

   The subject alternative name, which is identified by the object identifier 2.5.29.17, is set with the attributes that are defined in the <dcname>.asn file. The fourth parameter that is set to "1" marks the extension as critical. For a description of the file structure of the ASN file, see Appendix 5: ASN.1 File Structure.

**Verify the Pending Certificate Request**

You may verify the pending certificate request to validate that the extensions are properly inserted in the certificate request. If something is not correct or if the certificate request does not meet your requirements, you can validate the information at this point to ensure accuracy. Unfortunately, the Windows 2000 CA does not support viewing the properties of a pending certificate request in the Certification Authority MMC Snap-In. To verify that the certificate will be issued with the correct certificate template, you can use either the Windows 2000 or Windows Server 2003 version of certutil.

1. From a command-line prompt, run the following command.

   ```
   certutil -view -restrict RequestID=<RequestID> -out RequestAttributes
   ```

   Replace the <RequestID> with the RequestID that was recorded previously.

   The command output should look similar to the following:

   ```
   Row 1:
   ```

```
Request Attributes: "CertificateTemplate:DomainController"
```

2. To view the request attributes of all pending certificate requests, run the following command.

```
certutil -view -restrict disposition=9 -out RequestID,RequestAttributes
```

3. Verify that the certificate extensions have been set correctly. Type the following command at a command-line prompt.

```
certutil -view -restrict RequestID=<RequestID> -out ext:2.5.29.17
```

   Replace the <RequestID> with the RequestID that was recorded previously. The “2.5.29.17” value represents the object identifier of the certificate extension that you are referencing. If you do not know the exact object identifier of your extension, use “all” instead of the specific object identifier. For example:

```
certutil -view -restrict RequestID=<RequestID> -out ext:all
```

   Ensure that the extension you have configured in the previous section appears in the pending certificate request.

| **Note** |
| --- |
| All of the certutil -view commands may be used to query the certification authority database on a Windows 2000 or Windows Server 2003 CA. Once you understand the schema, you can query the database providing the appropriate field names. You can also use certutil -view -? for more samples to query the database. |

**Issue and Retrieve the Certificate**

Next, you must issue the pending certificate. For this section, you can use either the Windows 2000 or Windows Server 2003 version of certutil.

1. To issue the pending request, open the MMC snap-in. Run certsrv.msc at a command-line prompt, and then press Enter.

2. In the left pane, click the Pending Certificates container.

3. In the right pane, select the certificate that corresponds to the RequestID recorded previously.

4. On the Action menu, select All Tasks – Issue.

   Alternatively, you can issue certificates from the command line with the following command.

```
certutil -resubmit <RequestID>
```

   Replace <RequestID> with the RequestID value that was recorded previously by the certreq command.

5. Once the certificate has been issued, you must store the certificate as a file to transfer it to the domain controller. The following command will create two certificate files. The CER file contains only the domain controller certificate; the P7B file contains the domain controller certificate and all of its parent certificates. At a command-line prompt, run the following command.

```
CERTREQ -retrieve <RequestID> <dcname>.cer <dcname>.p7b
```

   Replace <RequestID> with the RequestID that was used in the previous commands.

   A window appears where you can select the CA that has issued the certificate.

6. Select the issuing CA and click OK.

7. Store the retrieved certificates on a diskette or other medium to transfer to the domain controller.

8. Log off the CA.

To install the certificate on the domain controller, see Domain Controller Certificate Installation.

**Windows 2000 Enterprise CA**
Unfortunately, domain controller certificates cannot be issued manually from a Windows 2000 enterprise CA for the following reasons.

- A Windows 2000 CA supports only hard-coded certificate templates so that you cannot duplicate and customize the default certificate template. If the original domain controller certificate was manipulated, it would affect all other domain controllers that are able to connect to the CA and use auto-enrollment to request certificates.

- A Windows Server 2000 CA issues certificates immediately without pending. Since the submission interface on the CA has limited functionality in Windows 2000 and, therefore, certificate manipulation is required in a pending state, support for offline domain controllers is particularly problematic.

Therefore, if support for offline certificate request processing is required, it is recommended that you install a Windows 2000 stand-alone CA or a Windows Server 2003 CA.

**Issuing Domain Controller Certificates with a Windows Server 2003 CA**
A Windows Server 2003 enterprise CA may support V2 templates and pending requests on a per template basis, as well as support for submitting request attributes in enrollment request from both enterprise and stand-alone CAs. Therefore, the following sections document the unique procedures for each CA type. V2 templates are only available if the CA was installed on Windows Server 2003, Enterprise Edition.

**Windows Server 2003 Stand-alone CA**
A stand-alone CA issues certificates based on fixed rules similar to those in templates. As described previously, a stand-alone CA issues certificates similar to the *Domain Controller* certificate template; thus, you cannot enroll *Directory Email Replication* or *Domain Controller Authentication* certificates with this CA type.

When issuing certificates manually, it does not matter if the stand-alone CA is a member of a domain or a workgroup. Both configurations are supported, and since the subject alternative name information was included in the certificate request when reqdccert.vbs was run, it is not required to place the certificate requests in a pending state to process them correctly.

To issue a domain controller certificate from a stand-alone Windows Server 2003 CA, perform the following steps.

1. Log on to the CA computer.

2. Copy the certificate request and the batch script (<dcname>-req.bat) that was created on the domain controller previously into a working folder on the CA.

3. From a command-line prompt, run the <dcname>-req.bat script to perform the certreq command. The script will request a certificate based on the *DomainController* certificate template because no other template exists for this purpose.

   The bat-file contains the following command.

   ```
   CERTREQ -attrib "CertificateTemplate:DomainController" <requestfile>
   ```

4. A window will appear where you can select the CA that will issue the certificate. Select the issuing CA and click OK.

5. Make a note of the RequestID that is shown after the command has finished. This value will be needed later.

6. If the enrollment handling is set to the default configuration on a stand-alone CA, you will have to approve and issue the pending certificate. If the CA is configured to issue certificates automatically, continue to step 15.

7. To verify and issue the pending request, open the MMC snap-in.

8. In the left pane, click the *Pending Certificates* container.

9. In the right pane, select the certificate that corresponds to the RequestID noted in step 5.

10. On the Action menu, select All Tasks - View Attributes/Extensions.

11. A window opens that displays the request properties. Click the Extensions tab.

12. Verify the value of the Subject Alternative Name tag. It should display the hexadecimal encoded GUID and the FQDN of the domain controller.

13. Click OK to close the window.

14. With the certificate request still selected in the right pane, choose All Tasks - Issue on the Action menu.

    Alternatively, you can issue certificates from the command-line prompt with the following command.

    ```
    certutil -resubmit <RequestID>
    ```

    Replace the <RequestID> variable with the RequestID that was noted in step 5.

15. Once the certificate has been issued, you will have to store the certificate as a file to transfer it to the domain controller. The following command will create two certificate files. The CER file contains only the domain controller certificate; the P7B file contains the domain controller certificate and all of its parent certificates. At a command-line prompt, run the following command.

    ```
    CERTREQ -retrieve <RequestID> <dcname>.cer <dcname>.p7b
    ```

    Replace the <RequestID> variable with the RequestID that was used in the previous commands.

16. A window will appear where you can select the CA that has issued the certificate. Select the issuing CA and click OK.

17. Store the retrieved certificates on a diskette or other medium to transfer to the domain controller.

18. Log off the CA.

Next, continue to Domain Controller Certificate Installation.

**Windows Server 2003 Enterprise CA**
An enterprise CA maintains and uses certificate templates in Active Directory for all certificate request processing and issuance. Therefore, domain controller certificates are formatted and issued based on the templates that are available and assigned to a CA. In the case of offline domain controller certificates, modification of the default certificate templates in Active Directory is necessary to support the enrollment processing.

Since the following section requires V2 templates, it is assumed that the enterprise CA was installed on a server with Windows Server 2003, Enterprise Edition.

**Certificate Template Creation**
In the following steps, duplicates of the existing *Domain Controller* certificate templates are created to support offline request processing. The following are the two primary reasons for modifications.

- By default, the offline *Directory Email Replication* certificate template publishes certificates in Active Directory. Normally, this would be satisfactory; however, the CA publishes an issued certificate into the certificate requestors Active Directory object and not into the certificate subject's Active Directory object. When a certificate request is submitted manually, the requestor is always the account of the user who created the certificate request. Thus, the CA would publish a domain controller certificate in the administrator's Active Directory user object. To work around this issue, a new certificate template is created that does not require the CA to publish the domain controller certificate in Active Directory. For information about manual certificate publication, see Publishing Domain Controller Certificates.

- Both *Directory Email Replication* and *Domain Controller Authentication* certificate templates require a special template flag to enable offline request processing. To leave the existing templates intact for all normal domain controller certificates processing, duplicates are made of both templates with the special settings.

| **Note** |
| --- |
| It is recommended that you do not manipulate the *Directory Email Replication* and *Domain Controller Authentication* default templates. They are used for auto-enrollment by Windows Server 2003 domain controllers that can connect to the enterprise CA. Modification of these templates may cause an interruption of service for auto-enrollment of connected domain controllers. |

Perform the following steps to duplicate the default *Domain Controller* certificate templates.

1. Log on with Enterprise Admin permissions to a domain computer that has Windows Server 2003 Administration Tools (AdminPak.msi) installed and is a member of the forest where the enterprise CA is installed. Any computer joined to the Active Directory forest can be used to maintain certificate templates since they are stored in Active Directory. Connectivity to a CA is not required at this point. By default, only members of the Enterprise Administrators group have permission to change certificate templates.

2. Click the Start button, and then point to Run. Type *certtmpl.msc* and press Enter.

3. The certificate Templates MMC Snap-In opens. In the right pane, select the Directory Email Replication template.

4. On the Action menu, select Duplicate template.

5. The Properties window of the new template appears. On the General tab, type *Offline Directory Email Replication* as Template display name. Click to clear the Publish certificate in Active Directory check box.

   Technically, any template name may be used; however, a meaningful label is recommended.

6. Click the Subject Name tab. Click to select the Supply in the request option and click OK.

7. In the right pane, select the Domain Controller Authentication template.

8. On the Action menu, select Duplicate template.

9. The Properties window of the new template appears. In the General tab, type *Offline Domain Controller Authentication* as Template display name. The Publish certificate in Active Directory check box is already clear because, by default, authentication certificates are not published in Active Directory.

10. Click the Subject Name tab. Click to select the Supply in the request option and click OK.

11. Close the Certificate Templates MMC Snap-In.

**Certificate Template Configuration**

Note that the template change is not required for CAs running Windows Server 2003 Service Pack 1 or later. If you have installed Windows Server 2003 Service Pack 1 or a later version on your CA, continue to **Issuing a Domain Controller Certificate**.

Typically, an enterprise CA will read information that is stored in several certificate attributes from the requestor's object in Active Directory. For example, the domain controller's common name or its GUID are derived from the domain controller's computer object and inserted into a certificate when a new domain controller certificate is manually or automatically enrolled through normal processes. If a domain controller certificate is requested manually through an offline or asynchronous process, all information that is required in the certificate must be explicitly specified in the certificate request.

When the certificate request is submitted to the CA, the request contains a field with the certificate template's common name, which is subsequently used by the CA to determine the enrollment and issuance policies. One such policy is whether the request may define the subject and the subject alternative name. By default, these attributes must not be set in a certificate

request, and the CA will ignore such information in a request. It is important to note that auto-enrollment requires that the request not contain the subject information to process requests properly.

To configure the CA to allow the subject alternative name to be specified in certificate requests, the certificate templates that have been created in a previous section must be modified. Fortunately, this is a one-time operation, and it is not necessary to undo the change after a domain controller certificate has been enrolled. The template change will replicate normally such as any other attribute value change in your Active Directory environment and will not generate any schema changes.

To configure and apply the template modification before issuing an offline domain controller certificate, perform the following steps.

1. Log on as the Enterprise Administrator to a computer that is a member of the forest where the enterprise CA was installed.

2. Make the script available to your local computer as shown in FixDCtemplate.vbs.

3. Run the following script with the specified parameters.

   ```
   fixdctemplate.vbs <Templatename>
   ```

   Replace <Templatename> with the template's common name *OfflineDirectoryEmailReplication*. (Do not use blank spaces.)

   For more information about all the steps performed by the script, see FixDCtemplate.vbs.

4. Run the following script again with the specified parameters.

   ```
   fixdctemplate.vbs <Templatename>
   ```

   In this case, replace <Templatename> with the template's common name *OfflineDomainControllerAuthentication*. (Do not use blank spaces.)

5. Log off the computer.

**Windows Server 2003 CA Configuration**

In the previous section, the certificate templates have been created and configured. Once the changes in Active Directory have been replicated throughout the forest, the CA will be able to access and use these templates. However, in order for the CA to use and issue certificates based on the templates, the templates must be manually published on each CA before they will be available.

Perform the following steps to publish a template in an enterprise CA.

1. Log on to the computer where the CA was installed as a local computer administrator.

2. Open the MMC snap-in.

3. Expand the CA object in the right pane and select Certificate Templates.

4. On the Action menu, select New - Certificate Template to Issue.

5. The template selection window appears. Press and hold the <CTRL> key and select the templates Offline Directory Email Replication and Offline Domain Controller Authentication.

6. Click OK to add the templates to the CA.

   Both templates will appear in the right pane of the MMC snap-in.

7. Close the MMC snap-in.

**Issuing a Domain Controller Certificate with a Windows Server 2003 CA**

The steps to issue a domain controller certificate from a Windows Server 2003 enterprise CA are similar to the Windows Server 2003 stand-alone CA procedures. However, since the Windows Server 2003 enterprise CA supports the new *Directory Email Replication* and *Domain Controller Authentication* certificate templates, these templates are used instead of the *Domain Controller* template.

Depending on the specific certificate template that is used, different attributes are specified as the subject alternative name. The *Directory Email Replication* requires the domain controllers GUID and its fully qualified DNS name (FQDN) in this extension. The *Domain Controller Authentication* template requires the FQDN only to be included in the subject alternative name extension. Therefore, you will find that the INF file and the certificate request look different for both certificate types.

| **Important** |
| --- |
| For offline domain controller certificate requests, never use the *Domain Controller* certificate template because a Windows Server 2003 CA supersedes that template with the *Directory Email Replication* and *Domain Controller Authentication* certificate templates. You will receive error 0x80094803 if you use the *Domain Controller* certificate template. |

To issue a domain controller certificate from a Windows Server 2003 enterprise CA, perform the following steps.

1. Log on to the CA computer.

2. Copy the certificate request and the batch script (<dcname>-req.bat) that was created on the domain controller in a previous step into a working folder on the CA.

3. From a command-line prompt, use the <dcname>-req.bat script to run the certreq command. The script will request a certificate based on the given certificate template.

   The bat file contains the following command if the *Directory Email Replication* certificate template is used.

   ```
   CERTREQ -attrib "CertificateTemplate:<TemplateName>" <requestfile>
   ```

   A window will appear where you can select the CA that will issue the certificate.

4. Select the issuing CA and click OK.

5. If you have changed the default enrollment handling in one of the *Domain Controller* certificate templates or in the CA policy module configuration, make a note of the RequestID that is shown after the previous command has finished to issue the pended certificate. Otherwise, a Save window appears where you can set the name of the certificate file. Type the name of the certificate and click OK. Continue to step 9.

6. If the certificate request was pended, run the following command at a command-line prompt. Otherwise, continue to step 7.

   ```
   certutil -resubmit <RequestID>
   ```

   Replace <RequestID> with the RequestID that was recorded previously.

7. Once the certificate is issued, you have to store it as a file to transfer it to the domain controller. The following command will create two certificate files. The CER-file contains only the domain controller certificate; the P7B file contains the domain controller certificate and all of its parent certificates. At a command-line prompt, run the following command.

   ```
   CERTREQ -retrieve <RequestID> <dcname>.cer <dcname>.p7b
   ```

   Replace <RequestID> with the RequestID that was used in the previous commands.

8. A window will appear where you can select the CA that has issued the certificate. Select the issuing CA and click OK.

9. Store the retrieved certificates on a diskette or other medium to transfer to the domain controller.

10. Log off the CA.

# Domain Controller Certificate Installation

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Installing a certificate on a domain controller implies that the certificate and associated private key are available to the local system (computer) account. Since the key material has been previously generated and the certificate request is still pending at the domain controller, the certificate must be accepted (installed). Acceptance refers to the operation whereby the certificate and the key material are linked, and the certificate request is deleted from the *Certificate Enrollment Requests* container.

When an Administrator accepts a certificate, certreq will look into the *Certificate Enrollment Requests* container of the local machine store first, and if no corresponding request is found, it looks into the current user's (Administrator) *Certificate Enrollment Requests* container. Thus, you can accept machine certificate requests as Administrator.

**Installing Domain Controller Certificates**

The following procedure will install the domain controller certificate locally in the local system profile but not in Active Directory. To install the certificate on the target domain controller, perform the following steps with the Windows Server 2003 version of certreq and certutil. On a Windows 2000 domain controller, you must add a prefix to the commands. The prefix is the path you have copied the commands to. In this white paper, the *%HOMEDRIVE%\W2K3AdmPak* path is used.

1. Log on to the target domain controller.

2. Make the CER- and P7B-file from the previous section available to the domain controller.

3. From a command-line prompt, run the following command.

   ```
   CERTREQ -ACCEPT <dcname>.p7b
   ```

   Replace <dcname> with the name of the target domain controller. The command will not report any confirmation of success.

4. Verify that the certificate has been installed in the local system personal certificate store by running the following command at a command-line prompt:

   ```
   certutil -viewstore My
   ```

   A window will appear that displays all certificates that are available in the local computer personal store.

5. Log off your domain controller.

**Publishing Domain Controller Certificates**

As mentioned previously, a stand-alone CA is not capable of publishing certificates in Active Directory. However, SMTP replication requires the use of domain controller certificates published in Active Directory. For certificates that are enrolled asynchronously through an offline process, you must manually publish these certificates in Active Directory.

The following steps instruct you to examine the certificates that reside in the domain controller's local machine certificate store before the new certificate is published in Active Directory. The new certificate is published and you will be able to verify that the certificate was published properly.

Publishing certificates into computer objects in Active Directory requires write permissions for the userCertificate attribute that is part of any computer object. Administrators and members of the built-in domain group "Cert Publishers" have this permission by default.

The reqdccert.bat script creates a file called <dcname>-vfy.bat that contains the correct certutil command to verify the domain controller's certificate in Active Directory. You can use this batch file instead of typing the certutil –viewstore commands manually as described in the following steps.

Perform the following steps to manually view and publish a domain controller certificate in Active Directory.

1. Log on as domain administrator or a member of the Cert Publishers global group for the target domain controller. Technically, the publication can be performed at any computer that is a domain member, but for convenience, the domain controller is used in this scenario.

2. Verify that there are no certificates already published on the domain controller's Active Directory object.

   **Note**

   The following steps work only with the Windows Server 2003 version of certutil.exe. Thus, if you perform the following steps from a Windows 2000 domain controller, you must add a prefix to the certutil command. The prefix is the path you have copied the certutil command to. In this white paper, *%HOMEDRIVE%\W2K3AdmPak* is used.

   Run the following command from a command-line prompt.

   ```
   certutil -viewstore "ldap:///cn=<dcname>,ou=domain controllers,dc=<domainname>,dc=
   <com>?usercertificate"
   ```

   Replace the <dcname> variable with the name of the target domain controller and <domainname> and <com> variable names with the appropriate domain suffix.

   A window should appear with no certificates displayed. This is expected since no certificates have been published yet.

3. Click Cancel to close the window.

4. The certificate is published in Active Directory using the *userCertificate* attribute on the machine account object for the domain controller. Run the following command to write the certificate to the domain controller's Active Directory object.

   ```
   certutil –f –dspublish <dcname>.cer machine
   ```

   Replace the <dcname> variable with the name of the target domain controller.

   The command determines the proper Active Directory object by the subject information in the certificate. The publication will fail if no object can be found based on the subject information.

   **Note**

   The use of the "machine" parameter is a mandatory requirement in the previous command example.

5. To verify that the certificate was published successfully, perform the following steps from a command-line prompt.

   ```
   certutil -viewstore "ldap:///cn=<dcname>,dc=<domainname>,dc=<com>?usercertificate"
   ```

   If the domain controller's computer object has no certificates in the *userCertificate* attribute, the certutil output will display an empty list in the window. If "?userCertificate" was omitted from the command line parameters or an invalid object class was specified, an error message will appear such as the following:

   ```
   CertUtil: -viewstore command FAILED: 0x80092009 (-2146885623)
   CertUtil: Cannot find the requested object.
   ```

**Note**

It is always a good practice to verify the certificates in the requestor's Active Directory object as well. If the certificate templates have not been configured correctly and the certificate template was configured to publish certificates in Active Directory, these certificates may be published to the user account that created the certificate request. To examine certificates in the domain administrator's Active Directory user object, run the following command.

```
certutil -viewstore "ldap:///cn=Administrator,cn=Users,dc=<domainname>,dc=<com>"
```

If computer certificates are found in this object, follow the instructions to remove them in Removing Certificates from an Active Directory Computer Object.

# Removing Domain Controller Certificates

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Occasionally, it may be necessary to remove or delete unwanted certificates locally in a certificate store, or remotely in Active Directory, to either correct mistakes or to perform periodic system cleanup. The following section describes the procedures to perform these activities. However, removing a certificate from a certificate store or an Active Directory object is not specific to domain controller certificates. The procedures are the same for any user or computer certificate type.

**Removing Certificates from a Local Certificate Store**

It may be necessary to remove certificates locally from a domain controller to ensure that only valid certificates are used by the domain controller or other applications. Expired or revoked certificates may be removed from a domain controller since the purpose of domain controller certificates is to encrypt replication traffic. Once replication has been performed, the replication data is discarded and there are no requirements to decrypt this information again. Therefore, such certificates may be safely deleted from the local machine profile.

To remove certificates from a dedicated domain controller, perform the following steps.

1. While logged on as a member of the local Administrators group, start the Microsoft Management console.
2. Add the Certificates MMC Snap-In.
3. Select Computer Account when prompted to select an account to manage.
4. In the Certificates MMC Snap-In, navigate to Personal in the left pane.
5. In the right pane, determine the domain controller certificate(s) by the template name as shown in the Certificate Templates column or select the certificate(s) by their intended purpose.
6. Delete the certificate(s) by selecting Delete on the Action menu.
7. Close the MMC Snap-In and log off.

**Removing Certificates from an Active Directory Computer Object**

In some cases, it may be necessary to remove certificates that are stored in an Active Directory object explicitly. Usually, this is the case if certificates have been enrolled manually. The auto-enrollment functionality in Windows XP and Windows Server 2003 can remove certificates from Active Directory objects when it determines that certificates in the Active Directory object have expired or are revoked. Also, the CA removes expired certificates when it publishes a new certificate in an object in Active Directory. For more information about the functionality performed by auto-enrollment, see the Certificate Autoenrollment in Windows Server 2003 white paper at

http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/autoenro.mspx

To manually remove a certificate from a domain controller object in Active Directory, perform the following steps.

1. Log on as a domain or enterprise administrator to a computer in your domain where the Windows Server 2003 version of certutil is installed and available.

   | **Note** |
   | --- |
   | The following steps work only with the Windows Server 2003 version of certutil.exe. Thus, if you perform the following steps from a Windows 2000 domain controller, you must add a prefix to the certutil command. The prefix is the path you have copied the certutil command to. In this white paper, the *%HOMEDRIVE%\W2K3AdmPak* path is used. |

2. At a command-line prompt, run the following command and press Enter.

```
certutil -viewdelstore "ldap:///cn=<dcname>,ou=domain controllers,<domainname>?
```

```
usercertificate"
```

The command contains the distinguished name of the object and specifies the LDAP attribute explicitly. If the LDAP attribute is missing or an invalid attribute was specified, the command will fail with an “Access denied” error message.

In the case of domain controller certificates, certificates are always stored in the *userCertificate* attribute. However, user objects may also have certificates in the *usercert* or *userSMIMEcertificate* attribute from other applications such as Outlook, which use these attributes as the preferred attribute for storing certificates.

A window will appear displaying the array of certificates on the user object. If the specified object contains certificates in the given attribute, the certificates are shown in the window. If no certificates are available, the list in the window will be empty.

3. To remove a specific certificate, select the certificate and click OK.

   The window will close and a status message will be displayed at the command-line prompt similar to the following: “Deleted certificate <certificate subject name>” where the <certificate subject name> displays the subject name of the certificate.

4. To close the window without deleting a certificate, click Cancel.

# Troubleshooting (Advanced Certificate Enrollment and Management)

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Despite the level of detail and documented procedures in this white paper, some scenarios and environments may encounter problems that require troubleshooting. This section contains some of the common errors and troubleshooting tips for the procedures in this white paper to assist in resolving potential problems in your environment.

The first troubleshooting tool shows the full descriptive text for an error code displayed by an application or tool. If an unexpected error appears, you can display the corresponding error message text with the following command.

```
certutil -error <Hexadecimal_Error_ID>
```

For example, to see the error text for error 0x80094800, run the following command at a command-line prompt.

```
certutil -error 0x80094800
```

**Domain Controller Certificates Appear in User Objects**
If a certificate template is configured for the CA to publish a certificate in Active Directory during the enrollment and issuance process, the CA will choose the requestor's Active Directory object instead of the domain controller's computer object. To correct this issue, follow the steps in Removing Certificates from an Active Directory Computer Object.

**Certreq –new fails with error 0x80092023**
This error may occur if the subject name was not specified in an X.500 format. You cannot specify just the raw string as the common name. You must at least add the prefix "CN=" to the string.

**Certreq –submit fails with error 0x80094800**
This common error occurs when the template is not available on the CA where the certificate request was submitted. To correct this issue, make sure that the template name is spelled correctly in the certificate request or as an –attrib parameter. Also, it is important to verify that you have performed the steps in **Windows Server 2003 CA Configuration**.

**Certreq –submit fails with error 0x80094001**
This error occurs if you have performed the steps described in Issuing Domain Controller Certificates with a Windows Server 2003 CA where the request uses the V1 *Domain Controller* certificate template and includes a subject or subject alternative name. The V1 domain controller template instructs an enterprise CA to read the subject name of the requestor from Active Directory, but this fails with manual certificate requests. An administrator's user object in Active Directory will obviously never have the appropriate subject name for a domain controller.

You must not enroll manual certificate requests with V1 certificate templates on an enterprise CA.

**Certreq –submit fails with error 0x80094803**
This error typically occurs when a certificate template does not allow the subject or subject alternative name to be explicitly specified in the certificate request. By default, a template only allows information to be retrieved from Active Directory when building the subject or subject alternative name in a certificate. To correct this error for offline certificate enrollment, modify the specific template by running the fixdctemplate.vbs script in Appendix 2.

To verify the mandatory attributes of a subject alternative name in a template, run the following command at a command-line prompt with the Windows Server 2003 versions of certutil. On a Windows 2000 computer, you must add a prefix to the commands. The prefix is the path you have copied these commands to. In this white paper, the *%HOMEDRIVE%\W2K3AdmPak* path is used. You must be logged on as a member of the Authenticated User group in the Active Directory forest.

```
Certutil -v -dstemplate {CertificateTemplate_commonname}
```

For example, type

```
certutil -v -dstemplate OfflineDomaincontrollerauthentication
```

The command will display the properties of the specified template. Examine the parameters following *msPKI-Certificate-Name-Flag* in the output. Parameters that are indented in the output are disabled. Ensure that you have specified all attributes in the certificate request that are not indented in the output of the template properties.

**Certreq –submit fails with error 0x8009480e**
This error most commonly occurs when the template is not available on the CA to which you have submitted the request. This

situation may also be corrected by running the fixtemplate.vbs script in Appendix 2. See also Certreq –submit fails with error 0x80094803.

**Certutil –viewstore displays an empty dialog with no certificates**

This error most commonly occurs when an invalid object class was specified in the command-line parameter(s). You can use ADSIedit from the Windows Server 2003 Support Tools on the Windows Server 2003 CD-ROM to identify the correct object class and its distinguished name.

# Appendix 1: Identifying a Domain Controller GUID

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Identifying the correct domain controller GUID for an SMTP replication certificate may pose a challenge for some administrators who are unfamiliar with the nuances of Active Directory and domain controller objects in the directory. To determine a specific domain controller GUID from a Windows XP or Windows Server 2003 computer joined to the Active Directory forest, perform the following steps.

| **Note** |
| --- |
| The dsquery utility is part of the Windows Server 2003 Administration Tools Pack and is not available on Windows 2000 computers. |

1. Log on to the computer with a domain account.

2. From a command-line prompt, run the following command.

   ```
   dsquery * "CN=<hostname>,OU=Domain Controllers,DC=<yourdomain>,DC=<yourdomain>" -
   scope base -attr objectguid
   ```

   You must replace the <hostname> variable with the name of the specific domain controller you want and the <yourdomain> variable with the domain name of your specific domain. For example:

   ```
   dsquery * "CN=DC01,OU=Domain Controllers,DC=contoso,DC=com" -scope base -attr
   objectguid
   ```

   The command will result in output similar to the following:

   ```
   Objectguid
   {57A8AAF4-686E-4128-8712-B6CA89FBF5BC}
   ```

3. Log off the computer.

# Appendix 2: Sample Scripts

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

This section contains two sample Visual Basic scripts that may be used to simplify or customize the various processes described in previous sections.

**Reqdccert.vbs – Generates Domain Controller Certificate Requests**
The reqdccert.vbs script makes it easier to create the correct INF file that is required to submit a certificate request to a Windows 2000 or Windows Server 2003 CA. Since it is fairly complicated to determine the GUID of a computer and create an ASN.1 file that contains both the GUID and the DNS name, the script generates the ASN.1 file automatically. In addition, a batch file is created that contains the certreq –submit command(s), which are required to submit the certificate request to the CA. Finally, a validation script is generated that allows you to verify the certificate(s) on a domain controller's computer object after you have published the domain controller certificate(s) in Active Directory.

If you plan to submit a certificate request to a Windows 2000 or a Windows Server 2003 stand-alone CA, run the script without any command-line parameters. If you plan to submit the certificate request to a Windows Server 2003 enterprise CA, you must specify the name of the certificate template that will be used to enroll the domain controller certificate.

| **Note** |
| --- |
| Since the script requires the Windows Server 2003 version of certutil for an internal encoding operation, it is highly recommended, on a Windows 2000 domain controller, to put this script in the same directory as the Windows Server 2003 version of certutil and certreq.exe. |

```
Set oArgs = WScript.Arguments
Set oShell = WScript.CreateObject("WScript.Shell")

    else
        sLength = "0" & Hex(iStrLen)
    end if
    if iStrLen > 127 then
        ComputeASN1 = Hex (128 + (Len(sLength) / 2)) & sLength
    else
        ComputeASN1 = sLength
    End If
End Function
```

**FixDCtemplate.vbs**

The fixDCtemplate.vbs script simplifies a change that is required for any certificate template that needs to accept the subject and subject alternative name as part of a certificate request. To change the *msPKI-Certificate-Name-Flag* in the certificate templates object, Active Directory Service Interfaces (ADSI) is used.

The *msPKI-Certificate-Name-Flag* attribute is actually a bit field, where the first bit determines whether the template accepts the subject and subject alternative name. Before changing the bit, the script determines if the bit is already set.

```
Set oArgs = WScript.Arguments
'
' Parse command line
'
if oArgs.Count <> 1 then
    Wscript.Echo "fixdctemplate {templatename}"
    WScript.Quit 1
end if
Set objRoot = GetObject("LDAP://rootDSE")
Set objTemplate = GetObject("LDAP://CN=" & oArgs(0) & _
                              ",CN=Certificate Templates," & _
                              "CN=Public Key Services,CN=Services," & _
                              objRoot.Get("configurationNamingContext"))
iNameFlag = objTemplate.Get("msPKI-Certificate-Name-Flag")
if iNameFlag = 1 then
    Wscript.Echo "Flag is already set"
else
    objTemplate.Put("msPKI-Certificate-Name-Flag"), 1
    objTemplate.SetInfo
    Wscript.Echo "Flag was set"
end if
```

# Appendix 3: Certreq.exe Syntax

Updated: May 20, 2013

Applies To: Windows Server 2003 with SP1

Certreq.exe is a command-line tool that is included in Windows 2000 Server, Windows XP, and Windows Server 2003 as well as in the Windows Server 2003 Administration Tools Pack. The version available with Windows XP and Windows Server 2003 is different from the version that is included in Windows 2000 Server. When using certreq.exe, you must distinguish between these versions.

| **Important** |
| --- |
| This document was written for Windows XP and Windows Server 2003. Some, but not all of the settings discussed in this article will apply to newer operating system. See Certreq as the reference for newer operating system versions. |

| **Tip** |
| --- |
| Several readers have asked for an actual example and mentioned that certreq is more difficult than using a graphical user interface. Microsoft KB article 931351 provides an example of how to perform a certificate request using a web interface as well as using Certreq. |

You can perform the following tasks with certreq.exe.

- Create new certificate requests. This includes the generation of key material that corresponds to the certificate request.
- Apply policies to a certificate request. This applies to CA certificates where various constraints are required. Since you cannot include certificate policies in the certificate request that is created by a CA, you have to apply the policy to the CA certificate request explicitly.
- Submit certificate requests to a certification authority. This feature also works with remote certification authorities, so that you can submit a request via the network to a remote CA.
- Retrieve certificates from a CA. Based on the certificate request ID, you can retrieve any certificate from a CA and save it to a file.
- Accept (and install) certificates or responses. This command is intended to accept a certificate or a response that contains a certificate. Once you have created a certificate request with certreq.exe, it remains in a pending state on your computer until you install the certificate that corresponds to the request.
- Sign certificate requests. In the case where the certificate template administrator has set the number of certificate enrollment agent signatures to a value greater than zero, you can sign certificate requests with this option.

The Windows 2000 version of certreq.exe can only submit certificate requests and retrieve issued certificates. All other options require the certreq.exe version that comes with Windows XP or Windows Server 2003. For more information about the command-line syntax, run certreq,exe with the following parameters to display all available syntax and parameter information.

```
Certreq.exe -v -?
```

**Creating Certificate Requests**

The –new parameter with certreq.exe is used to construct new certificate requests. Certreq.exe uses an INF file as an input option that defines the certificate request parameters. When the certificate request is constructed based on the INF file, key material is also generated. A certificate request process can be divided into the following elements.

- Read the INF file.
- Create the private and public key based on the information in the INF file, and store the private key in the local key store of the user or computer profile as appropriate.

- Create the certificate request based on the information in the INF file and store the request in a Base64-encoded file or, optionally, in binary form if the –binary option is selected.

**Certreq.exe INF File Structure**
Since the INF file allows for a rich set of parameters and options to be specified, it is difficult to define a default template that administrators should use for all purposes. Therefore, this section describes all the options to enable you to create an INF file tailored to your specific needs.

The following key words are used to describe the INF file structure.

- A *section* is an area in the INF file that covers a logical group of keys. A section always appears in brackets in the INF file.
- A *key* is the parameter that is to the left of the equal sign.
- A *value* is the parameter that is to the right of the equal sign.

For example, a minimal INF file would look similar to the following:

```
[NewRequest]
; At least one value must be set in this section
Subject = "CN=W2K3-BO-DC.contoso2.com"
```

| **Note** |
|---|
| You can remark lines by putting a semi-colon (;) in front of the line. |

The following are some of the possible sections that may be added to the INF file.

**[Version]**
This section is optional and is not required in an INF file. If present, it must contain the Signature key.

**Signature**
The signature key must be equal to the fixed string "$Windows NT$".

**[NewRequest]**
This section is mandatory for an INF file that acts as a template for a new certificate request. If this section is missing, the following error message will be displayed.

"INF file line not found 0xe0000102 (INF: -536870654)"

This section requires at least one key with a value. If this section is empty and has no keys, the following error message will be displayed.

"Incorrect function. 0x1 (WIN32: 1)"

**EncipherOnly**

| | |
|---|---|
| Syntax | EncipherOnly={Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `EncipherOnly = TRUE` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | Yes (through the key usage extension) |

This parameter has an impact on the functional capabilities of the public-private key pair. If the value is set to TRUE, the key can exclusively be used for "encipherment" (encryption). If it is set to FALSE, the key can be used for "encipherment" and other purposes. This parameter refers only to the key type in CryptoAPI and has an indirect relationship only to the key usage

extension that may be included in an issued X.509 certificate. The default value of the certificate enrollment control is set to FALSE. This setting only affects AT_KEYEXCHANGE key types and then correspondingly limits the key usage to key Encipherment, data Encipherment, or both. The digital signature and non-repudiation key usage(s) will be disallowed.

**Exportable**

| | |
|---|---|
| Syntax | Exportable = {Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `Exportable = TRUE` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

This parameter is ignored when the "UseExistingKeySet" key is set to TRUE because you can set the exportable flag only when a new key is created. You cannot change this flag for an existing key. If this attribute is set to TRUE, the private key can be exported with the certificate. To ensure a high level of security, private keys should not be exportable; however, in some cases, it might be required to make the private key exportable if several computers or users must share the same private key. For example, a Web server that runs SSL and is published with Internet Security and Acceleration (ISA) to the Internet requires a certificate with an exportable key because the certificate and key must be installed on the Web server and the ISA server as well. Also, if it is required that the keys be managed and backed up, they must be exportable to provide for this functionality.

This setting correlates with the template configuration if a Windows Server 2003 enterprise CA is used. A certificate template administrator can explicitly define if private keys should be exportable.

| **Note** |
|---|
| The template setting for exportable has no affect on the exportability properties of a key generated through certreq.exe -new. |

**KeyContainer**

| | |
|---|---|
| Syntax | KeyContainer = {Key_containerName} |
| Values | Random string value (GUID) |
| Default value | None |
| Sample | `KeyContainer = {C347BD28-7F69-4090-AA16-BC58CF4D749C}` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

It is not recommended to set this parameter for new requests where new key material is generated. The key container is automatically generated and maintained by the system.

For requests where the existing key material should be used, this value can be set to the key-container name of the existing key.

Use the certutil –key command to display the list of available key containers for the computer context.

Use the certutil –key –user command for the current user's context.

If you need to find the key container for a specific certificate, use the certutil –store my command for machine certificates.

To find the key container for a specific certificate in the current user's certificate store, use the certutil –store –user my command.

If the "UseExistingKeySet" key is set to TRUE, the key container must be set explicitly in the INF file or in the renewal certificate.

**KeyLength**

| | |
|---|---|
| Syntax | KeyLength = {integer} |
| Values | Any valid key length that is supported by the cryptographic service provider |
| Default value | 1024 [depends on the certificate service provider (CSP)] |
| Sample | `KeyLength=2048` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

The key length defines the length of the public and private key. The key length has an impact on the security level of the certificate. Greater key length usually provides a higher security level; however, some applications may have limitations regarding the key length.

**KeySpec**

| | |
|---|---|
| Syntax | KeySpec = {integer} |
| Values | AT_KEYEXCHANGE: 1<br>AT_SIGNATURE: 2 |
| Default value | 2 |
| Sample | `KeySpec=1` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

| **Warning** |
|---|
| The KeySpec determines if the key can be used for signatures, for Key Exchange (encryption), or for both. If the KeySpec is set to a value of 2, the EncipherOnly key is ignored. Starting with Windows Vista and Windows Server 2003 R2, specifying EncipherOnly= in the INF will cause an error. |

**KeyUsage**

| | |
|---|---|
| Syntax | KeyUsage = {hexadecimal_value} |
| Values | CERT_DIGITAL_SIGNATURE_KEY_USAGE 0x80<br>CERT_NON_REPUDIATION_KEY_USAGE 0x40<br>CERT_KEY_ENCIPHERMENT_KEY_USAGE 0x20<br>CERT_DATA_ENCIPHERMENT_KEY_USAGE 0x10<br>CERT_KEY_AGREEMENT_KEY_USAGE 0x08<br>CERT_KEY_CERT_SIGN_KEY_USAGE 0x04<br>CERT_OFFLINE_CRL_SIGN_KEY_USAGE 0x02<br>CERT_CRL_SIGN_KEY_USAGE 0x02<br>CERT_ENCIPHER_ONLY_KEY_USAGE 0x01 |

| | |
|---|---|
| Default value | 0xC0 for AT_SIGNATURE (default)<br><br>For AT_KEYEXCHANGE, EncipherOnly = TRUE: 0x30<br><br>For AT_KEYEXCHANGE, EncipherOnly = FALSE: 0xf0 |
| Sample | `KeyUsage=0xa0` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | Yes |

The key usage defines what the certificate key should be used for. The value is a bit field that is composed of the key usage flags as they are defined in the Windows Platform Software Development Kit (SDK). (See the include file wincrypt.h.) Caution should be used in defining the correct key usage for the certificate request based on the intended application usage.

| **Note** |
|---|
| The key usage extension has an indirect dependency with the enhanced key usage extension. For example, if you specify "Encrypting File System" as the enhanced key usage, you should also specify "Key Encipherment" as the key usage. |

To combine multiple key usages, summarize the values of the individual key usages by performing hexadecimal arithmetic. The default key usage is set to Digital Signature (0x80) and Non-Repudiation (0x40). The hexadecimal sum of 0x80 and 0x40 is in 0xC0.

The key usage parameter is primarily useful if certificate requests are submitted to stand-alone CAs. Only enterprise CAs have certificate key usages predefined through certificate templates. The key usage extension is set to critical by default.

**MachineKeySet**

| | |
|---|---|
| Syntax | MachineKeySet = {Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `MachineKeySet = TRUE` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

This key is important when you need to create certificates that are owned by the computer and not a user. The key material that is generated is maintained in the security context of the security principal (user or computer account) that has created the request. When an administrator creates a certificate request on behalf of a computer, the key material must be created in the computer's security context and not the administrator's security context. Otherwise, the computer could not access its private key because it would be in the administrator's security context.

You must set this key to TRUE if you are creating requests for domain controllers, a Web server, or any other service that runs in the computer's security context.

**PrivateKeyArchive**

| | |
|---|---|
| Syntax | PrivateKeyArchive = {Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `PrivateKeyArchive = TRUE` |

| | |
|---|---|
| Supported with CA type | Windows Server 2003 |
| Can be manipulated in a pending request | No |

The *PrivateKeyArchive* setting works only if the corresponding RequestType is set to "CMC" because only the Certificate Management Messages over CMS (CMC) request format allows for securely transferring the requester's private key to the CA for key archival. Only the Windows Server 2003 enterprise CA supports private key archival. The Windows Server 2003 enterprise CA must be online and accessible to retrieve the CA encryption certificate directly during this process.

**ProviderName**

| | |
|---|---|
| Syntax | ProviderName = {CSP_stringname} |
| Values | The descriptive name of the certificate service provider |
| Default value | Microsoft Strong Cryptographic Provider |
| Sample | `ProviderName="Microsoft RSA SChannel Cryptographic Provider"` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

The provider name is the display name of the CSP. If you do not know the provider name of the CSP you are using, run certutil –csplist from a command line. The command will display the names of all CSPs that are available on the local system.

**ProviderType**

| | |
|---|---|
| Syntax | ProviderType = {integer} |
| Values | The number that describes the provider type |
| Default value | 12 |
| Sample | `ProviderType=13` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

The provider type is used to select specific providers based on specific algorithm capability such as "RSA Full". If you do not know the provider type of the CSP you are using, run certutil –csplist from a command-line prompt. The command will display the provider type of all CSPs that are available on the local system.

**RenewalCert**

| | |
|---|---|
| Syntax | RenewalCert={CertificateHash} |
| Values | The certificate hash of any certificate that is available at the computer where the certificate request is created |
| Default value | n/a |
| Sample | `RenewalCert=4EDF274BD2919C6E9EC6A522F0F3B153E9B1582D (must use double quotation marks if white space is used between pairs of hexadecimal values)` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |

| | |
|---|---|
| Can be manipulated in a pending request | No |

If you need to renew a certificate that exists on the system where the certificate request is generated, you must specify its certificate hash as the value for this key. If you do not know the certificate hash, use the Certificates MMC Snap-In and look at the certificate that should be renewed. Open the certificate properties and see the "Thumbprint" attribute of the certificate. Certificate renewal requires either a PKCS#7 or a CMC request format.

| **Note** |
|---|
| You can only renew certificates that are time valid. Expired certificates cannot be renewed and must be replaced with a new certificate. |

**Requestername**

| | |
|---|---|
| Syntax | Requestername=samAccountName in Active Directory |
| Values | |
| Default value | n/a |
| Sample | `Requestername = "DOMAINNAME\username"` |
| Supported with CA type | Windows 2000 (with a PKCS#7 request type only)<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

The requester name can be specified for certificate requests if the *RequestType* is set to PKCS7 or CMC. If the *RequestType* is set to PKCS10, this key will be ignored. The *Requestername* can only be set as part of the request. You cannot manipulate the *Requestername* in a pending request.

**RequestType**

| | |
|---|---|
| Syntax | RequestType={string value} |
| Values | CMC<br>PKCS10<br>PKCS10-<br>PKCS7 |
| Default value | PKCS10 |
| Sample | `RequestType = CMC` |
| Supported with CA type | Windows 2000 (except CMC request type)<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

The RequestType determines the standard that is used to generate and send the certificate request.

**Silent**

| | |
|---|---|
| Syntax | Silent={Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `Silent = TRUE` |

| | |
|---|---|
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

By default, this option allows the CSP access to the interactive user desktop and request information such as a smart card PIN from the user. If this key is set to TRUE, the CSP must not interact with the desktop and will be blocked from displaying any user interface to the user.

**SMIME**

| | |
|---|---|
| Syntax | SMIME = {Boolean} |
| Values | TRUE \| FALSE |
| Default value | False (when KeySpec = AT_SIGNATURE) |
| Sample | `SMIME = TRUE` |
| Supported with CA type | Windows 2000 (if the policy module is configured in the registry to ignore the extension in the request)<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | Yes |

If this parameter is set to TRUE, an extension with the object identifier value 1.2.840.113549.1.9.15 is added to the request. The extension contains up to four object identifiers, depending on the CSP capability, which refer to symmetric encryption algorithms that may be used by Secure Multipurpose Internet Mail Extensions (S/MIME) applications such as Outlook.

When an S/MIME encrypted e-mail is sent, the sender's computer does not know exactly what encryption algorithms are supported by the receiver. Thus, the weakest encryption algorithm was chosen by default to ensure a high level of interoperability. Today, the majority of computers support encryption algorithms that can handle stronger keys than 40-bit. To give the sender of an S/MIME message a hint as to which encryption algorithms might be supported by the receiver, identifiers of supported symmetric algorithms are inserted in the certificate. Alternatively, Outlook can be configured through the registry to always use the default encryption algorithm. For more information, see the Knowledge Base article at http://support.microsoft.com/?id=307472

This functionality is supported with Outlook XP SP2 or a later version.

If the CA administrator has added the object identifier for S/MIME capabilities to the CA configuration parameter "*DisableExtensionList*", the CA will ignore the S/MIME capabilities in the request. For more information about how to add entries to the "*DisabledExtensionList*", see the Windows Server 2003 PKI Operations Guide at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/ws03pkog.mspx

**Subject**

| | |
|---|---|
| Syntax | Subject={String} |
| Values | Relative Distinguished Name string values |
| Default value | n/a |
| Sample | `Subject="CN=computer1.contoso.com"`<br>`Subject="CN=John Smith,CN=Users,DC=Contoso,DC=com" x` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | Yes |

Several applications rely on the subject information in a certificate. Thus, it is recommended that a value for this key be specified. If the subject is not set here, it is recommended that a subject name be included as part of the subject alternative name certificate extension.

**UseExistingKeySet**

| | |
|---|---|
| Syntax | UseExistingKeySet={Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `UseExistingKeySet=TRUE` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

This parameter is used to specify that an existing key pair should be used in building a certificate request. If this key is set to TRUE, you must also specify a value for the *RenewalCert* key or the KeyContainer name. You must not set the *Exportable* key because you cannot change the properties of an existing key. In this case, no key material is generated when the certificate request is built.

**UserProtected**

| | |
|---|---|
| Syntax | UserProtected={Boolean} |
| Values | TRUE or FALSE |
| Default value | FALSE |
| Sample | `UserProtected=TRUE` |
| Supported with CA type | Windows 2000<br>Windows Server 2003 |
| Can be manipulated in a pending request | No |

If this key is set to TRUE, a CryptoAPI password window is displayed when the key is generated during the certificate request build process. You can optionally protect the key with a password in the window or choose to display only a window when the key is used within an application. Once the key is protected with a password, you must enter this password every time the key is accessed. For more information about strong private key protection, see http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/autoenro.mspx

**[EnhancedKeyUsageExtension]**

The enhanced key usage extension determines for what purposes a certificate can be used. To see a list of object identifiers that are supported by your CA, run the following command at a command-line prompt.

```
certutil -oid [OID string value]
```

| **Note** |
|---|
| You can add custom object identifiers to the CA configuration. Thus, the default list of object identifiers that is supplied with a Windows Server 2003 CA can be extended according to your requirements. |

For a list of object identifiers that are supported with the Microsoft PKI, see the Knowledge Base article "Object IDs Associated with Microsoft Cryptography" at http://support.microsoft.com/?id=287547.

**Object Identifier**

| | |
|---|---|
| Syntax | OID={OID_String} |
| Values | Any valid object identifier |
| Default value | n/a |

| | |
|---|---|
| Sample | `OID = 1.3.6.1.5.5.7.3.1` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | Yes |

The object identifier is specified as a value that will be added to the enhanced key usage of the certificate. To specify multiple object identifiers, add a new line for every object identifier required. For example:

```
OID = 1.3.6.1.5.5.7.3.1
OID = 1.3.6.1.5.5.7.3.2
```

**[Extensions]**
Instead of specifying extensions in this section, you can set extensions at the time you submit the certificate request to a Windows Server 2003 CA or a Windows 2000 CA if the request is initially made pending.

**{OID}**

| | |
|---|---|
| Syntax | {OID} = {Base64Text} |
| Values | any valid object identifier that appears in the certificate |
| Default value | n/a |
| Sample | `2.5.29.17=MDmCFlcySy1CTy1EQy5jb25`<br>`_continue_=0b3NvMi5jb22gHwYJKwYBB`<br>`_continue_=AGCNxkBoBIEENKgYHzc`<br>`_continue_=F4dJmg+HRCPkkQ0=` |
| Supported with CA type | Windows 2000<br><br>Windows Server 2003 |
| Can be manipulated in a pending request | Yes |

Certificate extensions can be added to a request through this parameter. The value must be a Base64-encoded string. To split the string into several lines, use the _continue_ key word.

**Critical**

| | |
|---|---|
| Syntax | Critical = {coma-separated OIDList} |
| Values | Any valid object identifier that appears in the certificate [Extensions] section |
| Default value | n/a |
| Sample value | `Critical = 2.5.29.17,2.5.29.15` |
| Can be manipulated in a pending request | Yes |

This parameter carries the list of object identifiers of certificate extensions where the extension is set to critical. A certificate extension can also be set to critical with the certutil –setextension command during the time a certificate request is pending. For more information, see the section "certutil -setextension".

**[RequestAttributes]**
All keys from this section can be specified as part of the certreq -submit -attrib command. For example, instead of specifying the CertificateTemplate in the INF instruction file, you could use the following command at a command-line prompt.

```
certreq -submit -attrib "CertificateTemplate:Domaincontroller" dcname.req
```

**CertificateTemplate**

| | |
|---|---|
| Syntax | CertificateTemplate = {Templatename} |
| Values | Any valid certificate template name |

| | |
|---|---|
| Default value | n/a |
| Sample value | Critical = "DomainController" |
| Can be manipulated in a pending request | Yes |

The value of this key instructs the CA as to which certificate template should be used in processing the certificate request. The name must be specified as the common name of the certificate template or the object identifier of the template, not the template display name. A list of valid certificate template common names can be determined with the following command.

```
certutil -template
```

**SAN**

| | |
|---|---|
| Syntax | SAN = ["{tag}={value}&{tag}={value}]..."<br><br>To see an example of how to compose a request for a SAN see the "How to use the Certreq.exe utility to create and submit a certificate request that includes a SAN" section in Microsoft KB article 931351. |
| Values | A list of valid subjectalternatename2 extension tags.<br><br>*email, upn, dns, guid, url, ipaddress, oid*<br><br>Alternatively, any valid object identifier can be specified. |
| Default value | n/a |
| Sample value | See below; should always include double quotation marks around value(s) |
| Can be manipulated in a pending request | Yes |

The subject alternative name can be specified in various ways. A service principal name (SPN) is specified as a user principal name (UPN) value. The value is a string type by default but can have a prefix of a tag in section brackets "{}" that determines the data type of the value explicitly as exemplified in the following table.

| **SAN string** | |
|---|---|
| `2.5.29.17={octet}MBmCF1cySzMtQk8tREMuY29udG9zbzIuY29t` | An ASN.1 string is inserted in the subject alternative name with one or several encoded extensions.<br><br>The octet is a wrapper around a Base64 string encoded in binary format. |
| `1.2.3.4={utf8}SomeReadableText` | An ASN.1 string is inserted in the subject alternative name with one or several encoded extensions.<br><br>The value is a string encoded with a UTF8 wrapper. |
| `2.5.29.17={asn}=3019821757...` | An ASN.1 string is inserted in the subject alternative name with one or several encoded extensions. |
| `email=John.Smith@contoso.com` | The user's e-mail address is inserted in the subject alternative name. |
| `dns="w2k3bodc.contoso.com"` | The DNS name is set to the computer's FQDN. |
| `dn="CN=W2K3BODC,OU=Domain Controllers,DC=contoso,DC=com"` | The distinguished name is set to the domain controller's distinguished name. |

| | |
|---|---|
| `url="http://www.contoso.com/default.html"` | The URL is set to an http URL. |
| `ipaddress=172.134.10.134` | The IP is inserted in the subject alternative name. |
| `oid=2.5.29.17` | A given object identifier is inserted in the subject alternative name. |
| `upn=John.Smith@contoso.com` | The UPN name represents the user. |
| `guid=f7c3ac41-b8ce-4fb4-aa58-3d1dc0e36b39` | A GUID is inserted in the subject alternative name. |

Multiple tags and values must be combined with an ampersand (&). For example, to set the UPN and the GUID, you would have to set the subject alternative name as follows at a command-line prompt.

```
-attrib "SAN:upn=John.Smith@contoso.com&guid=f7c3ac41-b8ce-4fb4-aa58-3d1dc0e36b39"
```

If you insert the subject alternative name in the INF file, the syntax would look like this.

```
SAN="upn=John.Smith@contoso.com&guid=f7c3ac41-b8ce-4fb4-aa58-3d1dc0e36b39"
```

**-policy**
For a detailed description and examples of this option, see the "Planning and Implementing Cross-Certification and Qualified Subordination Using Windows Server 2003" white paper at http://www.microsoft.com/technet/prodtechnol/windowsserver2003/technologies/security/ws03qswp.mspx.

**-submit**
This is the default option for certreq.exe. If no option is specified explicitly at the command-line prompt, certreq.exe attempts to submit a certificate request to a CA. You must specify a certificate request file when using the –submit option. If this parameter is omitted, a common File Open window is displayed where you can select the appropriate certificate request file. For more information about the available command-line parameters for this option, see Certreq –submit fails with error 0x80094800 or type certreq -submit -? from a command line.

Certificate attributes from the RequestAttributes section in the INF instruction file can be alternatively specified as a command-line parameter for Windows 2000 Server and Windows Server 2003. For a list of valid subject alternative tags that may be used with the –submit parameter, see **SAN**. It is important to separate attribute types with "\n". Use an ampersand (&) to separate each specific subject alternative name attribute value.

The following are samples of certreq.exe commands.

```
certreq -attrib "SAN:email=John.Smith@contoso.com" -submit myreq.req
certreq -submit -
attrib "CertificateTemplate:Domaincontroller\nSAN:DNS=w2k3bodc.contoso.com" dcname.req
dcname.cer dcname.p7b
certreq -submit -attrib "SAN:UPN=admin@contoso.com&email=sample@bar.com&guid=f7c3ac41-
b8ce-4fb4-aa58-3d1dc0e36b39"
```

**-retrieve**
This option allows you to retrieve an issued certificate from the CA. Certificate owners or submitters can retrieve their certificate(s) from a Windows 2000 or 2003 CA. The certificate manager can retrieve all certificates from a Windows Server 2003 CA. This is not a security issue because certificates that are made available through the CA database contain only public information and only the original requestor may retrieve an issued certificate.

**-accept**
The final and most important step of the certificate enrollment process is to accept a certificate or response after it has been issued and retrieved from the CA. Certificates that are auto-enrolled or requested through the MMC Snap-In are accepted using the automation built into these applications. However, manual certificate requests, such as those submitted using certreq.exe, must be accepted and installed manually. The -accept parameter of certreq.exe links the previously generated private key with the issued certificate and removes the pending certificate request from the system where the certificate is requested. Accepting a CMC full response is required when archiving a private key on the CA.

**-sign**
Once the template administrator has configured the template to require one or more signatures on a certificate request, you must add these signatures to the request in order for the CA to process it correctly. The default Certificate Services Web enrollment pages can add only one signature to a certificate request, specifically when an Enrollment Agent certificate is used

to request a smart card certificate on behalf of another user. If more than one signature is required, you must add these signatures with certreq.exe –sign from the command line to the raw certificate request, one at a time.

# Appendix 4: Certutil -setextension

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

This option allows an administrator to manipulate pending requests on a CA. In some cases, it is not possible to specify every possible certificate extension in the certificate request. For example, if a request for a user certificate is submitted to the CA with the MMC snap-in, additional information is not allowed in the enrollment process.

Unfortunately, to apply an extension to a pending certificate, you have to create the ASN.1-encoded extension manually. Once you have constructed the ASN.1 binary large object (BLOB) information you want, you can add the extension to the certificate request that is pending. Encoding data into ASN.1 is not straightforward, and you have to understand the basic concept of this macro language used by certutil.exe. It is usually easier to find an existing request or certificate with the extensions you want, and then use certutil -v -dump to display the extensions as a hexadecimal dump.

For more information about ASN.1 encoding, see Appendix 5: ASN.1 File Structure.

The -setextension option is similar to the *[Extensions]* section in the INF file used by certreq.exe. This implies that the critical flag on certificate extensions can be set for distinct object identifiers and that specific value(s) can be set for these object identifiers using the command-line options.

| **Note** |
| --- |
| With an enterprise CA, template settings will always override certificate extension conflicts that have been set manually. But this is only true for the extensions that are explicitly set through the template. |

The syntax of the command line looks similar to the following example.

```
certutil.exe -setextension <RequestID> <ExtensionName> Flags {Long|Date|String|@InFile}
```

| Option | Description |
| --- | --- |
| Request-ID | The ID of the pending request. It can be determined with the MMC snap-in. |
| ExtensionName | The object identifier of the extension that should be modified. If you are unsure which object identifier is appropriate, dump an existing certificate and find the object identifier from there. |
| Flags | Used to set a certificate extension to critical. flag = 0 means the extension is non-critical; flag = 1 means the extension is critical. |
| {Long \| Date \| String \| @InFile} | Only the @InFile option applies. All other parameters should not be used. The @InFile can be Base64-encoded or a file in hexadecimal format. If the file contents could be interpreted as either Base64 or hexadecimal, hexadecimal is used. To force Base64 interpretation, use the "----- BEGIN -----" and "----- END -----" header. The content of the file depends on the extensions that should be manipulated. |

The following examples illustrate how to use the certutil -setextension command to set the key usage of a pending certificate on the CA to critical and constrain the key usage to certificate and certificate revocation list (CRL) signing.

```
echo 03 02 01 06>ku.txt
certutil.exe -setextension <Request-ID> 2.5.29.15 1 @ku.txt
```

# Appendix 5: ASN.1 File Structure

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

Compiling an ASN.1 BLOB requires advanced knowledge about ASN.1 encoding. When developing your own applications, it is highly recommended that you use an encoding function such as CCertEncodeAltName to create the ASN.1 BLOB. See ICertEncodeAltName (http://go.microsoft.com/fwlink/?LinkID=116167).

Manually developing and parsing such ASN.1 data structure(s) is time-consuming and prone to error due to the overall complexity of the data encoding rules.

The following is a sample ASN.1 BLOB that was used to add a server's GUID and its DNS name to the subject alternative name extension of a certificate. The first line in both boxes is the actual ASN.1 BLOB; the lines following explain per column what the field in the BLOB actually represents. Note that the full ASN.1 BLOB is the following sequence.

30468223636B696E64657230312E6575726F70652E636F72702E6D6963726F736F66742E636F6D
A01F06092B0601040182371901A0120410633035303536343461613133364326338

The following boxes explain in greater detail the breakdown of the ASN.1.

```
30468223636B696E64657230312E6575726F70652E636F72702E6D6963726F736F66742E636F6D
Sequence
  Total length of ASN.1 string
    ContextSpecificPrimitiveType
     Generalname see http://www.ietf.org/rfc/rfc2459.txt for a list of General
      Lenth of DNS name -------------------------------------------------------|

 Generalname see http://www.ietf.org/rfc/rfc2459.txt
  Length of othername -------------------------------------------|
    Other name OID-------|
                          ContextSpecificConstructedType
                           Generalname see http://www.ietf.org/rfc/rfc2459.txt
                            Length of datatype and othername
                              Other name datatype see
                              http://asn1.elibel.tm.fr/en/resources/tags.htm
                                Length of othername
                                  GUID -------------------------|
```

For more information about ASN.1 encoding, see the MSDN article, Example C Program: Converting Names from Certificates to ASN.1 and Back (http://go.microsoft.com/fwlink/?LinkID=116166).

# Appendix 6: Encoding and Decoding with Hexadecimal, Binary, and Base64

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

In many cases, data that must be inserted in a certificate or certificate request must be converted from a human-readable format into a computer-readable format. The most important formats to understand when working with X.509 certificates are hexadecimal, binary, and Base64. Since it is time-consuming to perform data conversions manually, this capability is natively provided with certutil.exe.

As mentioned previously, certutil.exe comes in two versions. In the following table, V1 represents the Windows 2000 version and V2 represents the Windows Server 2003 version.

| From | To Hexadecimal | To Binary | To Base64 |
|---|---|---|---|
| Hexadecimal | n/a | V1: -decodehex<br>V2: -decodehex | n/a |
| Binary | V1: n/a<br>V2: -encodehex | n/a | V1: -encode<br>V2: -encode |
| Base64 | n/a | V1: -decode<br>V2: -decode | n/a |

The table illustrates that you cannot convert data directly from Base64 into hexidecimal, and vice versa. However, you can use binary as an intermediate format to perform this kind of conversion. The reqdccert.vbs script in Appendix 2: Sample Scripts leverages the conversion capabilities of certutil.exe to perform the work on behalf of the administrator, without requiring programming knowledge. For example, to convert an ASN.1 BLOB into a Base64 format (which is required for the certreq.exe INF instruction file), the script uses certutil.exe to automate the following commands.

```
certutil –decodehex <dcname>.asn <dcname>.bin
certutil –encode <dcname>.bin <dcname>.b64
```

# Summary (Advanced Certificate Enrollment and Management)

Updated: June 30, 2010

Applies To: Windows Server 2003 with SP1

As the white paper thoroughly demonstrates, Windows Server 2003 provides a robust and flexible platform for supporting even the most complex or demanding deployment environments. Although the primary focus of the white paper is to demonstrate the procedures for supporting offline domain controller X.509 certificate enrollment in a disconnected or branch-office deployment, the procedures directly apply to all complex application environments. Administrators may apply the concepts presented to support any type of network and infrastructure services. These include directory servers (ADAM), radius servers (IAS), Web servers (IIS), and other stand-alone applications that require X.509 certificate enrollment or provisioning to provide or enable secure protocols, messaging, or application services.

# Administering Group Policy with Group Policy Management Console Abstract

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In conjunction with Windows Server 2003, Microsoft has released a new Group Policy management solution that unifies management of Group Policy. Microsoft Group Policy Management Console (GPMC) provides a single solution for managing all Group Policy-related tasks. GPMC lets administrators manage Group Policy for multiple domains and sites within one or more forests, in a simplified user interface (UI) with drag-and-drop support. Highlights include new functionality such as backup, restore, import, copy, and reporting of Group Policy objects (GPOs). These operations are fully scriptable, which lets administrators customize and automate management. Together these advantages make Group Policy much easier to use and help you manage your enterprise more cost-effectively.

For more information about this topic, see Administering Group Policy with Group Policy Management Console.

# Introduction (Administering Group Policy with Group Policy Management Console)

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Microsoft Group Policy Management Console (GPMC) is the new tool for Group Policy management that helps administrators manage an enterprise more cost-effectively by improving manageability and increasing productivity. It consists of a new Microsoft Management Console (MMC) snap-in and a set of scriptable interfaces for managing Group Policy.

GPMC simplifies the management of Group Policy by providing a single place for managing core aspects of Group Policy. It addresses the top Group Policy deployment requirements, as requested by customers, by providing the following functionality:

- A user interface (UI) that makes Group Policy much easier to use.
- Backup/restore of Group Policy objects (GPOs).
- Import/export and copy/paste of GPOs and Windows Management Instrumentation (WMI) filters.
- Simplified management of Group Policy-related security.
- HTML reporting of GPO settings and Resultant Set of Policy (RSoP) data.
- Scripting of policy related tasks that are exposed within this tool (not scripting of settings within a GPO).

**GPMC System Requirements**

GPMC helps you manage both Windows 2000 and Windows Server 2003-based domains with the Active Directory® service. In either case, the computer on which GPMC runs must be running one of the following operating systems:

- Windows Server 2003.
- Windows XP Professional with Service Pack 1 (SP1) and the Microsoft .NET Framework. In addition, a post-SP1 hotfix (Q326469) is required. This hotfix updates your version of gpedit.dll to version 5.1.2600.1186, which is required by GPMC. This hotfix is included with GPMC, and GPMC setup will prompt you to install it. However, if the language of GPMC does not match the language of your operating system, GPMC will not install the hotfix, and you will need to separately obtain and install this hotfix. This hotfix will be included in Windows XP Service Pack 2.

**Installing GPMC**

Installing GPMC is a simple process that involves running a Windows Installer (.MSI) package. All necessary files are installed to the \Program Files\GPMC folder.

1. Double-click the **gpmc.msi** package, and click **Next**.
2. Accept the End User License Agreement (EULA), and click **Next**.
3. Click **Close** to complete the installation.

Upon completion of the installation, the Group Policy tab that appeared on the Property pages of sites, domains, and organizational units (OUs) in the Active Directory snap-ins is updated to provide a direct link to GPMC. The functionality that previously existed on the original Group Policy tab is no longer available since all functionality for managing Group Policy is available through GPMC.

To open the GPMC snap-in directly, use any of the following methods:

- Click **Start**, click **Run**, type **GPMC.msc**, and then click **OK**.

- Click the **Group Policy Management** shortcut in the **Administrative Tools** folder on the Start Menu or in the Control Panel.

- Create a custom MMC console - Click **Start**, click **Run**, type **MMC**, and then click **OK**. Point to **File**, click **Add/Remove Snap-in**, click **Add**, highlight **Group Policy Management**, click **Add**, click **Close**, and then click **OK**.

To repair or remove GPMC, use **Add or Remove Programs** in Control Panel. Alternatively, run the gpmc.msi package, select the appropriate option, and click **Finish**.

# Group Policy Management Console Overview (Administering Group Policy with Group Policy Management Console)

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

In the past, administrators have been required to use several Microsoft tools to manage Group Policy, such as the Active Directory Users and Computers, Active Directory Sites and Services, and Resultant Set of Policy snap-ins. GPMC integrates the existing Group Policy functionality exposed in these tools into a single, unified console, along with several new capabilities.

Built-in to GPMC is support for managing multiple domains and forests, making it possible for administrators to easily manage Group Policy across an enterprise. Administrators have complete control of which forests and domains are listed in GPMC, making it possible to display only pertinent parts of an environment.

By default, the first time GPMC is started it loads the forest and domain containing the user object logged on to the computer. Administrators can then specify which forests and domains to display. When the console is closed, GPMC automatically saves the last view and will return to that view the next time the user opens that console.

The console tree on the left side of the snap-in contains GPMC's root node **Group Policy Management**. Each forest appears as a sub node of GPMC's root node, and is named after the forest root domain for that forest, pre-pended with the word "Forest." Each forest has either three or four sub nodes of its own: Domains, Sites, Group Policy Modeling, and Group Policy Results. The Group Policy Modeling node is only shown in a forest that has the Windows Server 2003 schema for Active Directory. To perform a Group Policy Modeling analysis, you must also have at least one domain controller that is running Windows Server 2003.

Figure 1 shows GPMC with two forests, Contoso.com and Tailspintoys.com, added to the console. Tailspintoys.com is a Windows 2000 forest so the Group Policy Modeling node is not available.

**Figure 1**

Below is a description of each of the four major sub node types within each forest:

- **Domains:** This node contains sub nodes corresponding to domains within the forest. The domain nodes are named after the DNS names of the domain. Users can choose which domains to display within the console, by right clicking this node and selecting the **Show Domains** context menu option. Domain nodes are always shown as peers of one another, regardless of the actual DNS relationship between them. This is because Group Policy is not inherited across domains. The list in the details pane of Figure 2 shows the name of the domain and the domain controller in that domain used during GPMC operations.

**Figure 2**

- **Sites:** This node contains sub nodes corresponding to sites within the forest. Users can choose which sites to display within the console, by right clicking this node and selecting the **Show Sites** context menu option. All sites are shown as peers of one another. As with forests and domains, the list of sites displayed is preserved for future use when the console is closed. No sites are displayed by default. This is done to speed up console performance by not enumerating a potentially large number of sites in the forest, unless explicitly requested by the user.

- **Group Policy Modeling:** This node allows you to access the Resultant Set of Policy (RSoP) – Planning Mode capabilities of Windows Server 2003. This is a powerful new Group Policy management feature that allows the user to simulate policy settings applied to users and computers via Group Policy before actually applying the policies. You can simulate the policy deployment for any user and computer in the forest. This feature, known as Resultant Set of Policies (RSoP) – Planning Mode in Windows Server 2003, is integrated into GPMC as Group Policy Modeling. This feature requires at least one domain controller in the forest running Windows Server 2003, since the simulation is performed by a service that is only present on domain controllers running Windows Server 2003. Each Group Policy Modeling simulation is displayed as an individual sub node.

- **Group Policy Results:** This node allows you to access the Resultant Set of Policy (RSoP) – Logging Mode capabilities. In contrast to Group Policy Modeling, which is a simulation, Group Policy Results represents the actual resultant set of policy that was applied to a given user and computer. This information is obtained by directly querying the target user/computer. Each sub node represents a different RSoP query for a given user/computer combination. You can only obtain Group Policy Results data from computers that are running Windows XP or Windows Server 2003 and later.

**Managing Multiple Forests**

Multiple forests can be easily added to the console tree:

1. Right-click the root node **Group Policy Management**, and select **Add Forest...**

**Figure 3**

2. Specify the DNS or NetBIOS name of the desired domain in a forest that is not already loaded in GPMC, and click **OK**. If you specify a NetBIOS name, GPMC will attempt to determine the corresponding DNS name and will prompt you with a dialog box to confirm the entry.

The specified forest will appear as a sub node in the console tree and the forest is loaded into the console with the domain that was entered in the **Add Forest** dialog box.

To remove a forest node, simply right-click the node, and then select **Remove**.

By default you can only add a forest to GPMC if there is a 2-way trust with the forest of the user running GPMC. You can optionally enable GPMC to work with only 1 way trust or even no trust. To enable this functionality, clear the **Enable Trust Detection** check box on the **General** tab in the **Options** dialog box of GPMC.

If you need to add a forest to which you have no trust, you must also use the **Stored User Names and Passwords** tool to add credentials for the forest you want to connect to using the procedure below. For this procedure, assume you have no trust to a domain called "mydomain.myforest.contoso.com" and you want to manage that domain.

1. Start the Stored User Names and Passwords tool:

   - In Windows XP, click **Start**, click **Control Panel**, double-click **User Accounts**, click **Advanced**, and then click **Manage Passwords.**

   - In Windows Server 2003, click **Start**, click Control Panel, and then double-click **Stored User Names and Passwords**.

2. Add an entry for the forest containing the domain you want to manage. In this example, add the following entry:

   *.myforest.contoso.com

   For the user name and password, enter the name and password of an account that has the rights to access the domain you want to manage.

3. Start GPMC and disable trust detection by deselecting the **Enable Trust Detection** check box: on the **General** tab in the **Options** dialog box of GPMC.

4. Add the forest to the GPMC console by right-clicking **Group Policy Management** and then clicking **Add Forest**. Enter the name of the domain in the forest that you want to manage.

| **Note** |
| --- |
| When adding forests to which you have no trust, some functionality will not be available. For example, Group Policy Modeling is not available and it is not possible to open the Group Policy Object Editor on GPOs in the untrusted forest. The untrusted forest scenario is primarily intended to enable copying GPOs across forests. Microsoft will support the untrusted forest scenario on a limited basis, and will not be providing escalation support for issues arising from this scenario. |

**Domain Controllers in GPMC**

In each domain, GPMC uses the same domain controller for all operations in that domain. This includes all operations on the GPOs, OUs, security principals, and WMI filters that reside in that domain. In addition, when the Group Policy Object Editor is opened from GPMC, it always uses the same domain controller that is targeted in GPMC for the domain where that GPO is located.

In addition, GPMC uses the same domain controller for all operations on sites. Note that this domain controller is used to read and write information about what links to GPOs exist on any given site, but information regarding the GPO itself is obtained from the domain controller of the domain hosting the GPO.

Group Policy Management Console allows you to choose which domain controller to use for each domain, as well for all sites in a forest in Group Policy Management Console. You can choose from among these four options:

- Use the primary domain controller (PDC) emulator (default choice).

- Use any available domain controller.

- Use any available domain controller that is running a Windows Server 2003 family operating system. This option is useful is you are restoring a deleted GPO that contains Group Policy software installation settings. See *Restore* for more details.

- Use a specific domain controller that you specify.

Right-click the desired domain node and select **Change Domain Controller** to specify a particular domain controller to use for domain operations.

To specify a domain controller to use for operations on sites, right click the Sites node and click **Change Domain Controller**.

In either case, the **Change Domain Controller** dialog box appears. This dialog box provides four options for specifying a domain controller as shown in Figure 4. Selecting the **This domain controller:** radio button activates the list of domain controllers allowing GPMC to target any desired domain controller in a given domain.

| **Note** |
| --- |
| When choosing a domain controller for sites, you have the additional option of choosing which domain to use. Using the domain dropdown list, you can efficiently filter the list of domain controllers, and select a domain controller accordingly. |

**Figure 4**

**Selection of Domain Controllers**

By default, when you add a new domain to the console, GPMC uses the PDC emulator in that domain. For managing sites, GPMC uses the PDC emulator in the user's domain by default.

It is important to consider the choice of domain controller in order to avoid replication conflicts. This is especially important to consider since GPO data resides in both Active Directory and on SYSVOL, and two independent replication mechanisms must be used to replicate GPO data to the various domain controllers in the domain. If two administrators are simultaneously editing the same GPO on different domain controllers, it is possible for the changes written by one administrator to be overwritten by another administrator, depending on replication latency.

To avoid this situation, GPMC uses the PDC emulator in each domain as the default to help ensure that all administrators are using the same domain controller. However, it may not always be desirable to use the PDC. For example, if the administrator resides in a remote site, or if the majority of the users or computers targeted by the GPO are in a remote site, then the administrator may want to choose to target a domain controller at the remote location.

| **Important** |
| --- |
| If multiple administrators manage a common GPO, it is recommended that all administrators use the same domain controller when editing a particular GPO, to avoid collisions in File Replication Services (FRS). |

**Domain Contents Overview**

Within each domain, GPMC provides a policy-based view of Active Directory and the components associated with Group Policy, such as GPOs, WMI filters, and GPO links. The view in GPMC is similar to the view in Active Directory Users and Computers MMC snap-in in that it shows the OU hierarchy. However, GPMC differs from this snap-in because instead of showing users, computers, and groups in the OUs, it displays the GPOs that are linked to each container, as well as the GPOs

themselves.

Each domain node in GPMC displays the following items (see Figure 5):

- All GPOs linked to the domain.
- All top-level OUs and a tree view of nested OUs and GPOs linked to each of the OUs.
- The **Group Policy Objects** container showing all GPOs in the domain.
- The **WMI Filters** container showing all WMI Filters in the domain.

**Figure 5**

The **Group Policy Objects** container shows all of the GPOs for the domain. Each node in this container represents the actual GPO components from Active Directory and SYSVOL that collectively define that GPO. Figure 6 shows an expanded **Group Policy Objects** container for the Contoso.com domain containing 12 GPOs.

**Figure 6**

GPOs are not useful until they are linked to a site, domain, or OU (Scope of Management, or SOM). The settings defined in a GPO can only be applied when the GPO is linked to one or more of these SOMs. The link is not a component of the GPO; it is a component of the SOM to which it is linked. Therefore, the ability to manage links for a given SOM must be delegated on that SOM, not the GPO. In the GPMC tree view, GPO-links on a given SOM are shown as child nodes of that container.

This distinction between GPOs and GPO links was not readily apparent in Windows 2000, and a key goal for GPMC was to

make this distinction clearer. The GPMC user interface distinguishes between GPO-links and GPOs as follows:

- Location in the tree view. Actual GPOs are always shown under the **Group Policy Objects** node for a given domain, whereas links appear as child nodes of a site, domain, or OU. Note that the contents of the result panes for GPOs and GPO-links are identical.

- When you click a GPO-link, a confirmation dialog box is shown by default to indicate that you are viewing a GPO-link, not a GPO.

- The icons for GPO-links have a shortcut icon, to indicate that they are pointers to another object. For example, in Figure 5, note the Default Domain Policy GPO link at the domain level. The icon for this link has a shortcut icon to differentiate it from the icon for the actual Default Domain Policy GPO under the **Group Policy Objects** node (see Figure 6).

- The context menu that appears when you right click in the tree view is different depending on whether you are managing a GPO-link or a GPO. Right clicking a GPO exposes options that are primarily relevant for the actual GPO (such as backup and restore), whereas right clicking a GPO-link exposes options that are relevant to managing the link (such as "Enforced"). Note that some options, such as "Edit" are available on both context menus.

# Creating and Editing GPOs

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

A Group Policy object (GPO) is a collection of policy settings that can be applied to a given set of users and/or computers. The process of applying a GPO to a set of users and/or computers is known as "scoping the GPO", which is described later in this white paper.

With GPMC, you can create GPOs using any of the following methods:

- Right-click any domain or OU and choose **Create and Link**. This option simultaneously creates a new GPO and links that GPO to that domain or OU.
- Right-click the **Group Policy Objects** node in any domain in GPMC and click **New**. This will create a new unlinked GPO.
- Using a script. For example, GPMC includes a sample script called CreateGPO.wsf that can be run from the command line to create a new GPO.
- Using any of the methods for copying GPOs. Copy operations are described later in this white paper in the section on GPO operations.

When you create a new GPO, it initially has no settings defined. To edit the settings in a GPO, use Group Policy Object Editor (known previously as the Group Policy snap-in or GPedit). You can open Group Policy Object Editor by right clicking a GPO in GPMC and selecting **Edit**.

# Scoping GPOs

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Group Policy is a powerful tool for managing the Windows 2000 (and later) environment. The value of Group Policy can only be realized through properly applying the GPOs to the Active Directory containers you want to manage. Determining which users and computers will receive the settings in a GPO is referred to as "scoping the GPO". Scoping a GPO is based on three factors:

- The site(s), domain(s), or organization unit(s) where the GPO is linked.
- The security filtering on the GPO.
- The WMI filter on the GPO.

This section will discuss how to utilize GPMC to properly manage the scope of a GPO and the Active Directory components you want to manage. Figure 7 shows the GPO scope tab.

**Figure 7**

**Linking GPOs**

The primary mechanism by which the settings in a GPO are applied to users and computers is by linking the GPO to a site, domain, or OU in Active Directory. The location where a GPO is linked is referred to as the Scope of Management, or SOM (also sometime abbreviated as SDOU in previous white papers). There are three types of SOMs: sites, domains, and OUs. A GPO can be linked to multiple SOMs, and a SOM can have multiple GPOs linked to it. A GPO must be linked to a SOM for it to be applied.

| **Note** |
| --- |
| GPOs are not stored on a per-SOM basis, but rather per domain. Thus, if you link a GPO to an OU, the GPO does not actually reside in that OU. A GPO is a per domain object that can be linked anywhere in the forest (although performance issues may exist where cross-domain links are used). One of the goals for GPMC is to make the distinction between links and actual GPOs clearer. |

With GPMC, you can link a GPO to SOMs using any of the following methods:

- Right click a domain or OU node, and choose **Create and Link a GPO here**. This option is analogous to choosing **New** in the old Group Policy user interface prior to GPMC. (This old Group Policy interface was the Group Policy tab on the properties dialog box of a site, domain, or OU in Active Directory Users and Computers or Active Directory Sites and

Services snap-ins.). Although this operation is presented as one action to the user, there are actually two operations taking place. First, a GPO is created in the domain, and second, a link to that GPO is created on the domain or OU from where you started the shortcut menu.

- Right click a site, domain, or OU node, and choose **Link an existing GPO here**. This option is analogous to choosing **Add** in the old Group Policy user interface prior to GPMC. This requires that the GPO already exists in the domain.

- Using drag and drop, drag a GPO from under the **Group Policy objects** node to the OU. This drag and drop functionality can only be performed within the same domain.

| **Note** |
| --- |
| By default, new user and computer accounts are created in the CN=Users and CN=Computers containers. These containers are not actually OUs, so GPOs cannot be directly applied to these containers, however, objects in these containers do inherit GPOs linked to the domain and sites. It is possible to specify a different container in which to place either new user accounts, new computer accounts, or both. This allows you to have greater control for applying GPOs to newly created user and computer objects, before they are moved to their final locations in Active Directory. To specify new locations for user or computer accounts, use Redirusr.exe (for users) or Redircomp.exe (for computers) in the domain you want to manage. The domain administrator can use these tools to specify an OU in which to place all new user or computer accounts when they are created. Redirusr.exe (for user accounts) and Redircomp.exe (for computer accounts) are two new tools included with Windows Server 2003 and are located in the %windir%\system32 directory. For more information about redirecting containers for users and computers, see article Q324949, "Redirecting the Users and Computers Containers in Windows Server 2003 Domains," in the Microsoft Knowledge Base. To find this article, see the Microsoft Knowledge Base link on the Web Resources page at http://www.microsoft.com/windows/reskits/webresources. |

**Security Filtering**

By default all Authenticated Users that are located in the SOM (and its children) where a GPO is linked will apply the settings in the GPO.

You can further refine which users and computers will receive the settings in a GPO by managing permissions on the GPO. This is known as security filtering. In order for GPO to apply to a given user or computer, that user or computer must have both **Read** and **Apply Group Policy** permissions on the GPO. By default, GPOs have permissions that allow the **Authenticated Users** group both of these permissions. This is how all authenticated users receive the settings of a new GPO when it is linked to a SOM (OU, domain or site). These permissions can be changed however to limit the scope of the GPO to a specific set of users, groups, and/or computers within the SOM(s) where it is linked.

GPMC simplifies how administrators manage security filtering for a GPO. Without GPMC, administrators were required to use the ACL editor, to manually set the **Read** and **Apply Group Policy** permissions for various security principals (users, computers, and groups) to modify the scope of the GPO. In GPMC, this process is no longer necessary. The administrator can just add or remove security principals in the security filtering section in the **Scope** tab for the GPO or the GPO link. This will automatically set or remove the **Read** and **Apply Group Policy** permissions for that security principal on that GPO. In the example in Figure 7, the security filtering on the “Common Managed Settings” GPO has been modified so that only members of the “Managed Users” group can receive the settings. Note that members of this group that are not located in either the “Engineering – Offsite” or “User Accounts” OUs will not receive the settings in this GPO.

If the administrator needs to access the detailed permissions, they are still available using the ACL editor when you can access using the **Advanced** button on the **Delegation** tab for the GPO. For example, if you need to set permissions to **Deny**, you can do this using the ACL editor. Groups with Deny permissions will appear as having **Custom** permissions on the **Delegation** tab. In general, it is recommended that you avoid the use of Deny permissions for managing Group Policy.

**Linking WMI Filters**

WMI Filters allow an administrator to dynamically determine the scope of GPOs based on attributes (available through WMI) of the target computer. A WMI filter consists of one or more queries that are evaluated to be either true or false against the WMI repository of the target computer. The WMI filter is a separate object from the GPO in the directory. To apply a WMI filter to a GPO, you link the filter to the GPO. This is shown in the WMI filtering section on the Scope tab of a GPO. Each GPO can have only one WMI filter; however the same WMI filter can be linked to multiple GPOs.

When a GPO that is linked to a WMI filter is applied on the target computer, the filter is evaluated on the target computer. If the WMI filter evaluates to false, the GPO is not applied. If the WMI filter evaluates to true, the GPO is applied. Note that client support for WMI filters exists only on Windows XP and later operating systems. Windows 2000 clients will ignore any WMI filter and the GPO is always applied, regardless of the WMI filter.

# Group Policy Inheritance

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Group Policy can be applied to users and computers at a site, domain, or OU. GPOs from parent containers are inherited by default. When multiple GPOs apply to these users and computers, the settings in the GPOs are aggregated. For most policy settings, the final value of a given policy setting is set only by the highest precedent GPO that contains that setting. (However, the final value for a few settings will actually be the combination of values across GPOs.) Precedence of GPOs determined by the order of processing for the GPOs. GPOs processed last have highest precedence. GPOs follow the *SDOU* rule for processing; site first, then domain and followed by OU including nested OUs. A nested OU is one that has another OU as its parent. In the case of nested OUs, GPOs associated with parent OUs are processed prior to GPOs associated with child OUs. In this processing order, sites are applied first but have the least precedence. OUs are processed last and have the highest precedence.

There are several Group Policy options that can alter this default inheritance behavior. These options include:

- Link Order – the precedence order for GPOs linked to a given container. The GPO link with Link Order of 1 has highest precedence on that container.
- Block Inheritance – the ability to prevent an OU or domain from inheriting GPOs from any of its parent container. Note that Enforced GPO links will always be inherited.
- Enforcement – (previously known as "No Override") the ability to specify that a GPO should take precedence over any GPOs that are linked to child containers. Enforcing a GPO link works by moving that GPO to the end of the processing order.
- Link Status – determines if a given GPO link is processed or not for the container to which it is linked.

These items are described in more detail below.

If multiple GPOs are linked to the same container and have settings in common, there must be a mechanism for reconciling the settings. This behavior is controlled by the link order. The lower the link order number, the higher the precedence. Information about the links for a given container are shown on the **Linked Group Policy Objects** tab of a given container, as in Figure 8. This pane shows if the link is enforced, if the link is enabled, the status of the GPO, if a WMI Filter is applied, when it was modified, and the domain container where it is stored. An administrator or users that have been delegated permissions to link GPOs to the container can change the link order by highlighting a GPO link and using the up and down arrows to move the link higher or lower in the link order list.

**Figure 8**

GPOs are inherited from parent containers. For example, a GPO linked to an OU will be inherited by child OUs. The **Group Policy Inheritance** tab for a given container shows all GPOs (except for GPOs linked to sites) that would be inherited from parent containers, as shown in Figure 9. The precedence column on this tab shows the overall precedence for all the links that would be applied to objects in that container, taking into account both Link Order and the Enforcement attribute of each link, as

well as Block Inheritance on any SOMs. Note that the Group Policy Inheritance tab does NOT show the impact of GPOs linked to sites, because it is not possible to determine which site would apply, unless a particular target computer is identified.

**Figure 9**

It is possible to prevent containers from inheriting GPOs linked to parent containers by blocking the inheritance on the OU or domain. Blocking inheritance on a container will prevent all GPOs from parent containers from applying to the blocked container, except for GPOs that are marked as Enforced. Administrators can right-click the domain or OU and select **Block Inheritance** from the context menu to set GPO blocking on the container. If inheritance is blocked for an OU or domain, its icon will appear with a blue exclamation mark in the console tree.

An administrator can prevent the settings in a GPO linked to a container from being overwritten by settings linked to GPOs in child containers (which normally would have higher precedence) by setting the GPO link to **Enforced** (formerly known as No Override). This also will prevent the GPO link from being blocked at containers that have been set to **Block Inheritance**. GPO-links that are enforced appear with a gray padlock icon in both the console tree and in the details pane.

A GPO link can be set to **Enabled** to allow it to be processed. If the link is not set to Enabled, processing of the linked GPO is disabled. The GPO link can be either enabled or disabled by right-clicking the link and selecting the **Link Enabled** option. A check beside this option indicates that the link is enabled and will be processed.

# Delegating Group Policy (Administering Group Policy with Group Policy Management Console)

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Group Policy is an essential component of management in Windows 2000 and Windows Server 2003 environments. A portion of Group Policy's power lies in the ability to delegate certain Group Policy tasks to other administrators. For example, the creation, linking, and editing of GPOs are independent permissions that can be delegated separately.

Group Policy delegation covers these areas:

- The ability to create GPOs in a domain.
- Permissions on an individual GPO (for example, read access, edit access).
- Permissions on an individual SOM. There are three permissions related to policy:
    - The ability to link GPOs to a SOM.
    - The ability to perform Group Policy Modeling analyses for objects in that SOM.
    - The ability to collect Group Policy Results data for objects in that SOM.
- The ability to create WMI filters in a domain.
- Permissions on an individual WMI filter (for example, edit access)

One of the key goals for GPMC was to simplify the management of Group Policy related permissions. GPMC does this by abstracting the low-level permissions on the object and managing them as a single unit, based on the task that an administrator wants to perform. Using GPMC, delegation tasks for a given object can be performed by navigating to the Delegation tab for that object.

Using this new model in GPMC, an administrator may never need the traditional ACL Editor. However, for administrators that prefer the flexibility of that ACL editor, it is still available through GPMC by clicking the Advanced button on the Delegation tab.

**Delegating Creation of GPOs**

Creation of GPOs is a right of the Group Policy Creator Owners (GPCO) group by default but can be delegated to any group or user. There are two methods to grant a group or user this right:

- Add the group or user to the Group Policy Creator Owners group. This was the only method available prior to GPMC.
- Explicitly grant the group or user permission to create GPOs. This method is newly available with GPMC.

You can manage this permission using the delegation tab on the **Group Policy Objects** container for a given domain in GPMC. This tab shows the groups that have permission to create GPOs in the domain, including the GPCO group. From this tab, you can modify the membership of existing groups with this permission, or add new groups.

The ability to grant users or groups permissions to create GPOs without using GPCO was added to facilitate the delegation of GPO creation to users outside the domain. Because the Group Policy Creator Owners group is a domain global group, it cannot contain members from outside the domain. Thus, prior to GPMC, this task could not be delegated to members outside the domain.

It is recommended that for users and groups within the domain that you continue to use the GPCO group to grant them GPO creation rights. If you require that users outside the domain have the ability to create GPOs, consider using the following steps.

- Create a new domain local group in the domain ("GPCO – External" for example)

- Grant that group GPO creation rights in the domain
- Create a global group in the external domain ("GPCO in Domain X" for example)
- Add external domain groups or users to that group
- Add the global group ("GPCO in Domain X") to the local group ("GPCO – External")

Adding a user to the membership of GPCO, or granting the user GPO creation permissions directly using the new method available in GPMC, is identical in terms of permissions. Granting a user the ability to create GPOs in the domain does not give the user the ability to edit or delete existing GPOs or the ability to link the GPO to a SOM. Users have full control of GPOs that they created.

**Figure 10**

Figure 10 shows the results pane for the delegation tab of the Group Policy objects container in the Contoso.com domain. Domain Admins can add new delegations or remove existing delegations through the Add and Remove buttons on the delegation tab. The Properties button will display the object properties for the selected user or group.

**Delegating an individual GPO**

GPMC has simplified the ability to delegate rights on an individual GPO. Prior to GPMC, administrators needed to rely on the ACL editor and required an intimate knowledge of the low-level permissions on the GPO. GPMC abstracts this so the administrator can manage the permissions on the GPO at the task level.

There are five categories of Allowed Permissions on a GPO.

- Read
- Edit settings
- Edit, delete, modify security
- Read (from Security Filtering)
- Custom

These permissions are managed using the delegation tab of a GPO, as shown in Figure 11.

**Figure 11**

The options listed above represent predefined combinations of ACLs. The corresponding underlying permissions for each are shown in Table 1 below:

**Table 1**

| Option | Underlying Permissions |
|---|---|
| Read | Allow Read Access on the GPO |
| Edit settings | Allow Read, Write, Create Child Objects, Delete Child Objects |
| Edit, delete, and modify security | Allow Read, Write, Create Child Objects, Delete Child Objects, Delete, Modify Permissions, and Modify Owner. This essentially grants full control on the GPO, except that the "Apply Group Policy" right is not set. |
| Read (from Security Filtering) | This setting cannot be set directly, but appears if the user has Read and Apply Group Policy rights to the GPO (on the **Scope** tab of the GPO). |
| Custom | Any other combinations of rights, such as the use of deny permissions, will show up as **Custom** in the display. Custom rights cannot be set using the Add button, but they can be removed using the Remove button. They can be set only if using the ACL editor directly (which can be started with the Advanced button). |

You can grant users permissions on a GPO using the Add button. This opens the object picker so you can find the desired user or group to set the permission level. You can then set the permission level by selecting either "Read", "Edit", or "Edit, Delete, Modify Security" permissions.

Note that the Apply Group Policy permission, which is used for Security Filtering, cannot be set using the Delegation tab. Setting Apply Group Policy is used for scoping the GPO, so is managed on the Scope tab. Note that when you grant a user Security Filtering on the Scope tab, you are actually setting both the Read and Apply Group Policy rights.

**Delegating Policy-Related Permissions on SOMs**

GPMC enables you to easily set the following three permissions on SOMs that are related to Group Policy:

- The ability to link GPOs to a SOM.
- The ability to perform Group Policy Modeling analysis for objects in that SOM.
- The ability to collect Group Policy Results data for objects in that SOM.

These permissions are viewed and managed using the **Delegation** tab on a given SOM, and selecting the desired option from the permissions dropdown. You can add new delegations or remove existing delegations through the Add and Remove buttons on this tab. The Properties button will display the object properties for the selected user or group. The Advanced button will display the Security properties dialog box (the ACL Editor) for the SOM, from which you can view the actual

permissions for the individual attributes of the SOM.

When you grant permissions using the **Add** button, you will be prompted to specify whether the permission should apply only to the current container, or whether it should be inherited to child containers. Using the **Add** button only grants "Allow" permissions. It is strongly recommended that you avoid using "Deny". However, if you must set a "Deny" permission, you can do so by pressing **Advanced** button.

| **Note** |
| --- |
| The "Applies to" column is not present on sites as they can not have child containers.<br><br>Group Policy Modeling or Group Policy Results permissions cannot be delegated on sites so these options are not available in the permissions dropdown on site nodes. |

**Delegating Linking of GPOs**

The settings in a GPO are applied to users and computers by linking the GPO to a SOM (site, domain, or OU) that contains the user or computer objects, either as a direct child or indirectly through inheritance. The ability to link GPOs to a SOM is a permission that is specific to that SOM. At the lowest level, the permission equates to having read and write access to the gPLink and gPOptions attributes on the SOM. However, with GPMC, there should be no need to manage these attributes individually. GPMC abstracts this permission as a single permission called "Link GPOs." This permission also grants the ability to manage link order, block inheritance, and set the enforced attribute on GPO-links to this SOM.

This permission can be managed using the delegation tab on the SOM in GPMC when you select the **Link GPOs** option in the permission dropdown.

Figure 12 shows the **Link GPOs** permissions on the SOM delegation tab for the Child.Contoso.com domain.

**Figure 12**

**Delegating Group Policy Modeling**

Group Policy Modeling allows the user to simulate the resultant set of policy for objects in a domain or OU. This feature is described in more detail later in the white paper. This section discusses delegation aspects only for Group Policy Modeling.

This feature is only available to Domain Administrators by default but can be delegated to other users or groups. At its lowest level, this delegation equates to granting the user or group the "**Generate Resultant Set of Policy (Planning)**" permission on an OU or domain. This permission is available in any forest that has the Windows Server 2003 schema. Without GPMC, this attribute was available only on the advanced page of the ACL editor for a given domain or OU. GPMC simplifies the management of this permission by exposing this permission directly on the **Delegation** tab for any domain or OU. The administrator selects the "**Perform Group Policy Modeling Analyses**" setting from the Permissions drop-down box. This will display the Name, Applies To, Setting, and Inherited properties for the delegations. Figure 13 shows the **Perform Group Policy Modeling Analyses** permissions on Delegation tab for the Contoso.com domain.

**Figure 13**

**Delegating Group Policy Results**

Group Policy Results allows the user to read RSoP logging data for objects in the domain or OU. Group Policy Results is described in more detail later in the white paper. This section discusses delegation aspects only for Group Policy Results.

By default, only users with local administrator rights on the target computer can remotely access Group Policy results data; however this right can be delegated to other users or groups. Delegation is performed on either a domain or OU. Users with this permission can read Group Policy Results data for any object in that container, and in child containers if the permission is specified to be inherited.

At its lowest level, this delegation equates to granting the user or group the "**Generate Resultant Set of Policy (Logging)**" permission on an OU or domain. This permission is available in any forest with the Windows Server 2003 schema. Without GPMC, this attribute was available only on the advanced page of the ACL editor for a given container. GPMC simplifies the management of this permission by exposing this permission directly on the **Delegation** tab for the domain or OU. The administrator selects the "**Read Group Policy Results Data**" setting from the Permissions drop-down box. This will display the users and groups that have this permission for the domain or OU, if the setting applies to only this container or to the container and all child objects, if the setting is allowed, and if the permission is inherited from a parent container. Figure 14 shows the **Read Group Policy Results data** permissions on the Delegation tab for the Contoso.com domain.

**Figure 14**

**Delegating Creation of WMI Filters**

WMI filters are a new feature in Windows Server 2003. When a new WMI filter is created it is stored in the WMIPolicy container in the domain's System container in Active Directory. It is the permissions applied on this container that govern the rights a user has to create, edit, and delete WMI Filters. This section is limited to delegation aspects of WMI filters. For more information about WMI filters, see the WMI Filters section in this white paper.

There are two levels of permission for creating WMI filters, which can only be delegated by Domain Admins:

- Creator Owner: Allows the user to create new WMI Filters in the domain, but does not grant them permissions on WMI filters created by other users. This permission is analogous to the GPO creation permission.

- Full Control: Allows the user to create WMI filters, and grants them full control on all WMI Filters in the domain, whether they created them or not. There is no corresponding permission level for GPOs because permissions in the sysvol are not inherited, so it's not technically possible to guarantee full control to all GPOs

By default, Domain Admins and Enterprise Admins have Full Control and Group Policy Creator Owners have Creator Owner permissions.

To delegate either permission to a user or group, use the Add button on the delegation tab of the WMI Filters pane. Figure 15 shows the delegation tab for the **WMI Filters** container.

**Figure 15**

An administrator can **Add**, **Remove**, and view **Properties** for WMI Filter delegations from the **Delegation** tab. Selecting **Add** will prompt for a user or group before selecting the permission level (Creator Owner or Full Control) to assign to the user or group. Selecting **Remove** will prompt for confirmation that the delegation should be removed. Selecting **Properties** will display the user or group properties for that object.

**Delegating an individual WMI Filter**

GPMC has the ability to delegate rights on an individual WMI Filter. There are two levels of permissions that can be granted to a user or group on an individual WMI Filter.

- Edit – allows the user or group to edit the WMI Filter.

- Full Control – allows the user or group to edit, delete, and modify security on the WMI Filter.

These permissions are managed using the **Delegation** tab of an individual WMI Filter, as shown in Figure 16.

**Figure 16**

The **Delegation** tab shows the users and groups that have permissions on the WMI Filter, the permission level, and if the permission is inherited from a parent container. Buttons on this tab allow the user to Add or Remove users and groups to the delegation list for the WMI Filter.

Note that all users have **Read** access to all WMI filters. GPMC does not allow this permission to be removed. If the **Read** permission were removed, this could cause policy processing on the client to fail. Therefore, GPMC deliberately doesn't offer the capability to remove this permission.

# Reporting on GPO Settings

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

The Settings tab of the GPO or GPO link pane in GPMC shows an HTML report that displays all the defined settings in the GPO. Clicking this tab will generate a report of the settings in the GPO. Figure 17 shows a typical report. This report can be generated by any user with read access to the GPO.

Without GPMC, users that did not have write access to a GPO could not read and view the settings in that GPO. This is because the Group Policy Object Editor requires the user to have read and write permissions to the GPO to open it. Some examples of users that might need to read and view but not edit a GPO include security audit teams that need to read but not edit GPO settings, helpdesk personnel that are troubleshooting a Group Policy issue, and OU administrators that may need to read and view the settings from inherited GPOs. With GPMC, these users now have read access to the settings.

The HTML reports also make it easy for the administrator to view all settings that are contained in a GPO at a glance. By clicking the **Show All** option at the top of the report, the report is fully expanded and all settings are shown. Alternatively, administrators can expand and contract individual sections within the report by clicking the heading for each section.

For settings under the Administrative Templates section of the report, you can view a description of the setting by clicking the setting name in the report. This opens a new window with the Explain text for that policy setting.

GPMC also solves some common reporting requirements including the ability to document all the settings in a GPO to a file for printing or viewing. Using a context menu, users can either print the reports, or save them to a file as either HTML or XML. Note that saved reports include the contents of the Settings tab, as well as additional information that that is shown on the Scope, Details, and Delegation pages in the UI.

To view a saved report directly in a Web browser, you must use Internet Explorer 6 or Netscape 7. Netscape 7 does not support functionality that enables you to show or hide data in reports.

**Figure 17**

In addition, GPMC provides similar reports for Group Policy Modeling (Resultant Set of Policy – planning) and Group Policy Results (Resultant Set of Policy –logging). This is described later in the paper in those respective sections.

The reports generated by GPMC display all settings that are contained in a GPO, except:

- Within the IE Maintenance section of reports:
    - The reports indicate only whether Content Ratings and Connectoids are deployed, and do not report the details of those settings.
    - If Preference Mode is specified, this will be indicated, however the new settings that are only available in Preference mode will not be displayed.

- Settings for the following cookie settings which were available in IE 5.5 but not in IE 6 are not displayed:

  Allow per-session cookies (not stored)

  Allow cookies that are stored on your computer

- Within Security Zones and Privacy, the details of customized Java settings, if specified, are not shown. Customized Java settings will appear as "Custom."

- The core information for Wireless and IPSec settings is displayed, however some details for these settings are not displayed.

**Administrative Templates Background**
Administrative templates, (or .adm files), enable administrators to control registry settings using Group Policy. Windows comes with a predefined set of Administrative template files, which are implemented as text files (with an .adm extension), that define the registry settings that can be configured in a Group Policy object (GPO). These .adm files are stored in two locations by default: inside the GPO's folder on Sysvol and in the %windir%\inf folder on the local computer.

As new versions of Windows are released, new policy settings are added. In addition to supporting these new settings, each successive version of Windows supports all registry policy settings that were available in earlier versions of Windows. For example, the Windows Server 2003 family supports all registry policy settings available in Windows 2000 and Windows XP.

It is important to understand that .adm files are not the actual settings that are deployed to client operating systems. The .adm file is simply a template file that provides the friendly name for the setting and an explanation. This template file is used to populate the user interface. The settings that are deployed to clients are contained in the registry.pol file inside the GPO. On Windows XP and Windows Server 2003, each registry setting contains a "Supported on" tag that indicates which operating system versions support that policy setting. If a setting is specified and deployed to a client operating system that does not support that setting, the settings are ignored.

Because all successive iterations of .adm files include settings from earlier versions, and because there is no harm if a new setting is applied inadvertently to a computer running an earlier operating system that does not support that setting, it is recommended to always create and edit GPOs from a computer that has the latest .adm files available.

**Administrative Templates and GPMC**
GPMC uses administrative templates (.adm files) to display the friendly names of policy settings in the Administrative Templates section when generating HTML reports for GPOs, Group Policy Modeling, and Group Policy Results. The reports generated by GPMC can display settings based on custom .adm files as well.

GPMC handles administrative templates for GPOs differently than the Group Policy Object Editor. The change in behavior was a deliberate design decision to simplify the behavior with .adm files, to avoid complications with .adm file version conflicts, and to improve performance in GPMC.

To generate a report, GPMC looks by default in the following locations for .adm files:

- %Windir%\inf on the local computer where GPMC is running. If an .adm file is found, it is used, regardless of its timestamp.

- If the .adm file is not found, GPMC looks in the GPO's folder on SYSVOL

The user can specify an alternate path for where to find .adm files using the custom search location option on the Reporting tab of GPMC options. If specified, this takes precedence over the previous locations.

When searching for a given .adm file, GPMC will only use the first .adm file it finds in the listed search order. If there are policy settings in the GPO for which no .adm file can be found, these settings will be displayed in the report in a section called "Extra Registry Settings" which displays the registry keys and values for those settings.

As noted above, GPMC looks by default on the local computer for .adm files first, since the user-specified location is not specified by default. When running GPMC on Windows XP, this means that settings that were not available in Windows XP or Windows 2000 may be displayed in the report as "Extra Registry Settings." This situation only occurs if both of the following are true:

- You have set one of the settings in the Administrative Templates section of the GPO that is new for Windows Server 2003.

- You are generating a report of that GPO on a computer running Windows XP.

  The workaround here is to store the Windows Server 2003 versions of the .adm files somewhere, and specify that location in the custom search location mentioned above.

Unlike the Group Policy Object Editor, GPMC itself never transfers newer versions of .adm files to the SYSVOL. It simply reads the .adm files found using the algorithm described above in order to generate the report. However, when the Group Policy Object Editor is opened (either from GPMC or using other means) .adm files may be transferred to the sysvol, as described below.

**Administrative Templates and Group Policy Object Editor**

- The Group Policy Object Editor uses .adm files to display available policy settings in the Administrative Templates section of a GPO.

- By default it attempts to read .adm files from the GPO (from the Sysvol on the domain controller). Alternatively, the .adm file can be read from the local workstation computer. This behavior can be controlled by a policy setting.

- By default, if the version of the .adm file found on the local computer is newer (based on the time stamp of the file) than the version on the Sysvol, the local version is copied to the Sysvol and is then used to display the settings. This behavior can be controlled by a policy setting.

- If the GPO contains registry settings for which there is no corresponding .adm file, these settings cannot be seen in the Group Policy Object Editor. However, the policy settings are still active and will be applied to users or computers targeted by the GPO.

# GPO Details

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

There are a variety of details about GPOs that are useful for troubleshooting and other purposes. For example, since the data for a given GPO is stored in both Active Directory and Sysvol, it's important to have details about of these components. As shown in Figure 18, the **Details** tab of any GPO displays this type of information and other useful attributes.

**Figure 18**

The **Details** tab of a GPO shows the following information:

- The domain where the GPO is defined.
- The owner of the GPO. In most cases this is the user that created the GPO. However, if a member of the Domain Admins group creates the GPO, then Domain Admins will be the owner.
- The date and time when the GPO was created.
- The date and time when the GPO was last modified.
- The version number for the user configuration component of the GPO. This is broken out into a version number for the Active Directory component and the Sysvol component. In a healthy GPO, these numbers should match. However, the user version numbers need not match the computer version numbers.
- The version number for the computer configuration component of the GPO. This is broken out into a version number for the Active Directory component and one for the Sysvol component. In a healthy GPO, these numbers should match. However, the computer version numbers need not match the user version numbers.
- The unique ID of the GPO, also known as the GPO GUID.
- The GPO Status. This indicates whether either the user configuration or computer configuration of the GPO is enabled or disabled. It can have four possible values:
    - Enabled.
    - User configuration settings disabled.
    - Computer configuration settings disabled.

- All settings disabled.

**Ensuring consistency of permissions on a GPO**

Each Group Policy object (GPO) is stored partly in the Sysvol on the domain controller and partly in Active Directory. GPMC, Group Policy Object Editor, and the old Group Policy user interface provided in the Active Directory snap-ins present and manage a GPO as a single unit. For example, when you set permissions on a GPO in GPMC, GPMC is actually setting permissions on objects in both Active Directory and the Sysvol.

It is essential that the permissions in the Active Directory component are consistent with the Sysvol component for a given GPO. It is not recommended that you manipulate these separate objects independently outside of GPMC and Group Policy Object Editor. Doing so can potentially cause Group Policy processing on the client to fail, or certain users that should normally have access may no longer be able to edit a GPO. Furthermore, file system objects and directory service objects don't have the same available permissions since they are different types of objects. So in the event of a permissions mismatch, it might not be immediately apparent how to make them consistent.

To help you ensure that the security for the Active Directory and Sysvol component of a given GPO is consistent, GPMC will automatically check the consistency of the permissions of any GPO when you navigate to the GPO using GPMC. If it detects a problem with that GPO, you will be presented with one of the following dialog boxes, depending on whether you have permission to modify security on that GPO:

- "The permissions for this GPO in the SYSVOL folder are inconsistent with those in Active Directory. It is recommended that these permissions be consistent. To change the permissions in SYSVOL to those in Active Directory, click OK."

- "The permissions for this GPO in the SYSVOL folder are inconsistent with those in Active Directory. It is recommended that these permissions be consistent. Contact an administrator who has rights to modify security on this GPO."

If you have permission to modify security on the GPO, you should click OK in this dialog box. This action will reset the permission on the Sysvol component of the GPO to be consistent with the existing permissions on the Active Directory component of the GPO. Note that the information presented on the Delegation tab (and Security Filtering section) for a GPO is based on the Active Directory component of the GPO, so this will simply correctly ensure that the permissions you see in the GPMC UI are being applied to that GPO.

| **Note** |
| --- |
| When running GPMC in a Windows 2000 domain, clicking on either the Default Domain Policy or the Default Domain Controllers Policy opens the dialog box described above. This is the result of a bug in Windows 2000 that is expected to be fixed in Windows 2000 Service Pack 4. The issue occurs because the Access Control List (ACL) on the Sysvol portion of the GPO is mistakenly set to inherit permissions from the parent folder. If you have permissions to modify security on the default GPOs, you should click OK in this dialog box. This will correct the problem by modifying the ACLs on the Sysvol portion to make them consistent with the ACLs on the Active Directory component. In this case, it will remove the inheritance attribute in the Sysvol. |

# GPO Operations

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

GPO operations refer to the ability to **backup** (export), **restore**, **import**, and **copy** GPOs.

Backing up a GPO consists of making of copy of GPO data to the file system. Note that the **Backup** function also serves as the export function for GPOs. Backed up GPOs can be used either in conjunction with Restore or Import operations.

Restoring a GPO takes an existing GPO backup and re-instantiates it back in the domain. The purpose of a restore is to reset a specific GPO back to the identical state it was in when it was backed up. Since a restore operation is specific to a particular GPO, it is based on the GUID and domain of the GPO. Therefore, a restore operation cannot be used to transfer GPOs across domains.

Importing a GPO allows you to transfer settings from a backed up GPO to an existing GPO. You can perform this operation within the same domain, across domains, or across forests. This allows for many interesting capabilities such as staging of a test GPO environment in a lab before importing into a production environment.

Restoring and Importing a GPO will remove any existing settings already in the GPO. Only the settings in the backup will be in the GPO when these operations are complete.

Copying a GPO is similar to an export/import operation only the GPO is not saved to a file system location first. In addition, a copy operation creates a new GPO as part of the operation, whereas an import uses an existing GPO as its destination. These operations are discussed in additional detail in the following sections.

**Backup**

Backing up a GPO places a copy of all relevant GPO data into a specified file system location. The relevant data includes:

- The GPO GUID and domain.
- GPO Settings.
- The Discretionary Access Control List (DACL) on the GPO.
- WMI filter link (but not the filter itself).

A backup operation only backs up components of a GPO that are in the GPO in Active Directory and in the GPO file structure in SYSVOL. The operation does not capture items stored outside the GPO, such as WMI filters, links on a SOM to that GPO, and IP Security policies. These are separate objects with their own set of permissions, and it is possible that an administrator performing either a backup or restore operation may not have the required permissions on those other objects. In addition, in the case of WMI filters and IP Security policies, these can be used by multiple GPOs, so it is not necessarily desirable to restore these objects when restoring a single GPO. To avoid these complications, the backup and restore operations only handle the contents of the GPO itself.

Note that the link to a WMI filter is actually an attribute of the GPO, so the link is included as part of the GPO backup and restore operation; even though the WMI filter itself is not. Customers who want to backup and restore WMI filters should use the import and export capabilities that are available on the WMI filter node in GPMC. Similarly, a backup operation only includes the link to any IP Security policy set in a GPO, because IPSec policies are stored outside the GPO. You must use the **Export Policies** and **Import Policies** commands of the IP Security Policy Management snap-in to back up and restore the IPSec policies themselves.

The backup also contains an XML report of the GPO settings, a date and time stamp, and the user supplied description. The report can be viewed as HTML from within GPMC. Each backup is given a unique ID. This allows for multiple GPOs and/or multiple versions of the same GPO to be backed up to the same file system location. With GPMC, users can identify backups stored in a given file system location based on GPO GUID, the GPO friendly name, the date and time stamp of the backup, the domain name, and the description of the backup. You can manage backups from within GPMC using the Manage Backups dialog box, described later in the "Managing Backups" section.

Administrators can backup one or more GPOs using the following methods:

- Right click a GPO under the **Group Policy objects** node and choose **Back up...** from the context menu.

- Right click one or more GPOs in the **Contents** tab of the **Group Policy objects** node and choose **Back up...** from the context menu. This will backup the selected GPO(s).

- On the **Group Policy Objects** node, right click and choose the **Back Up All...** option. This will backup all GPOs in the domain. This is shown in the figure below.

- Use GPO backup scripts. You can either write your own scripts, or you can use the sample scripts included with GPMC in the GPMC\scripts folder. There are two scripts **BackupGPO.wsf** and **BackupAllGPOs.wsf** that are included with GPMC that you can use to back up GPOs.

When you backup a GPO, you must supply the file system location, and optionally, a description for the backup.

| **Important** |
| --- |
| The administrator should take precautions to secure this location to trusted administrators only. This should be done to protect the GPO backups from malicious or accidental tampering that could compromise the environment if they were used as the basis for a restore or import operation. |

**Figure 19**

Backing up a GPO requires read access to the GPO and write access to the file system location where the backup will be stored.

**Managing Backups**

GPMC provides a way to manage the GPO backups. This feature can be accessed in 2 ways:

- Right-clicking on the **Domains** container and selecting **Manage Backups** from the context menu. This will show backed up GPOs for all domains and forests in the specified file system location.

- Right-clicking on the **Group Policy Objects** container in a domain in GPMC and selecting **Manage Backups**. This will only show GPOs backed up for that domain in the specified file system location.

Either method of starting **Manage Backups** will provide a dialog box for selecting the location of your stored GPO backups. Select a file system location containing valid GPO backups. Figure 20 shows the **Manage Backups** dialog box.

**Figure 20**

In the Manage Backups dialog box, you can sort, delete, restore, and view the backup settings for GPOs. Note the check box that gives the user an option to only show the latest version for each backed up GPO. The dialog box displays the originating domain for the GPO, the display name of the GPO, the timestamp when the GPO was backed up, a user supplied description when the backup was taken, and the GPO GUID.

Upon selecting either the "Restore" or "Delete" buttons, the user is presented with a confirmation dialog box before the operation is performed. Selecting the "View Settings..." button opens a new instance of the user's default web browser which displays a report of the settings in the selected GPO. Selecting "Browse" allows the user to choose the backup location. It is possible to select multiple GPOs for deleting but not for viewing or restoring.

GPO backups can also be managed from script. The sample script QueryBackupLocation.wsf, in the GPMC\Scripts folder, will display information about backups stored in a particular file system location.

**Restore**

Restoring a GPO restores the GPO to a previous state. A restore operation can be used in both of the following cases: the GPO was backed up but has since been deleted, or the GPO is live and you want to roll back to a known previous state. A restore operation retains the original GPO GUID even if the restore is recreating a deleted GPO. This is a key difference between the restore operation and the import or copy operations discussed in later sections of this white paper.

A restore operation replaces the following components of a GPO:

- GPO Settings.
- ACLs on the GPO.
- WMI filter links (but not the filters themselves).

The restore operation does **not** restore links to a SOM (Scope of Management). Any existing links will continue to be used, for example, when restoring an existing GPO to a previous state. However, if the user has deleted a GPO and all links to the GPO, the user must add these links back after restoring the GPO. To facilitate recreating these links, you can view the report in the backup to identify all links in the domain of the GPO.

You can restore GPOs using any of the following methods:

- To restore an existing GPO, right-click the GPO in the **Group Policy objects** container and select **Restore from Backup...** This opens the **Restore Group Policy Object Wizard.**

- To restore a GPO that has been deleted since it was backed up, use the **Manage Backups** dialog box (refer to Figure 20 in the Managing Backups section).

- Use GPO restore scripts. You can either write your own scripts, or you can use the sample scripts included with GPMC in the GPMC\scripts folder. There are two scripts **RestoreGPO.wsf** and **RestoreAllGPOs.wsf** that are included with GPMC that you can use to restore GPOs.

There is also an option to view the settings in the backup before restoring.

The permissions necessary to perform a restore of a GPO are different for restoring an existing GPO or if you are restoring a GPO that has been deleted since it was backed up.

**Table 2**

| GPO State | Permissions needed |
|---|---|
| Existing GPO | The user must have **Edit settings, delete, and modify security** permissions on the GPO in order to restore it, as well as read access to the file system location where the backup is stored. Notice that this does NOT require GPO creation rights. |
| Deleted GPO | The user must have the right to create GPOs in the domain, as well as read access to the file system location where the backup is stored. The person that performs the restore will become the new creator owner for the GPO. |

When restoring a GPO, GPMC will handle the GPO version number differently depending on the type of restore.

- Restore of existing GPO: The GPO version number is incremented by one over the existing version number of the live GPO. This is done to guarantee that clients will apply the GPO.

- Restore of a previously deleted GPO: The GPO version number in the GPO backup is retained in the restored GPO.

**Special Considerations for Software Installation GPOs**

When restoring a deleted GPO that contains Software Installation settings, some side effects are possible depending on the circumstances under which the GPO is restored. This section describes those side effects and how you can avoid them.

When restoring a GPO that has been deleted, it is possible that:

- Cross-GPO upgrade relationships that upgrade applications in the GPO being restored, if any, are not preserved after restore. A cross-GPO upgrade is one where the administrator has specified that an application should upgrade another application, and the two applications are not deployed in the same GPO. Note that cross-GPO upgrade relationships are preserved when applications—in the GPO being restored—upgrade applications in other GPOs.

- If the client has not yet seen that the GPO has been deleted (either because the user has not re-logged on or rebooted since the deletion of the GPO), and the application was deployed with the option to “Uninstall this application when it fall out of scope of management,” then the next time the client logs on:

    - Published apps that the user has previously installed will be removed.

    - Assigned applications will be uninstalled before re-installation.

This behavior occurs because when the GPO is restored, the object in Active Directory that represents the application (the "deployment object") is assigned a new GUID. Because the GUID is different than the GUID of the original deployment object, Windows interprets this as a different application.

The solution is to restore the GPO using the original GUID for the deployment object. However, because the GUID is controlled by Active Directory, the only way to re-use the original GUID is to re-animate the tombstone of the deleted deployment object. Tombstone re-animation is a new feature of Windows Server 2003.

GPMC automatically attempts to re-animate these objects when performing a restore. Re-animation will succeed if each of the following is true:

- GPMC is targeting a domain controller that is running Windows Server 2003.

- The user performing the restoration has permissions to re-animate objects in the domain. By default, only Domain Admins and Enterprise Admins have this permission. You can delegate this right to additional users at the domain level using the ACL editor.

- The time elapsed between deletion and restoration of the GPO does not exceed the tombstone lifetime specified in Active Directory.

If re-animation fails, a new deployment object will be created and the previously mentioned side effects will occur.

Therefore, as a general rule, if you deploy software using Group Policy, it is recommended that you perform the restoration of GPOs that contain application deployments using a domain controller running Windows Server 2003 and that you grant the tombstone re-animation right to the users who will be performing restoration of those GPOs.

**Considerations for Domain Rename**
GPO Backups taken prior to a domain rename operation cannot be restored after a renaming a domain. If you are renaming a domain, be sure to backup your GPOs as soon as you complete the rename procedure. For more details on domain rename, see the documentation on Domain Rename at
http://www.microsoft.com/windowsserver2003/downloads/domainrename.mspx.

**Import**
The Import operation transfers settings into an existing GPO in Active Directory using a backed up GPO in the file system location as its source. Import operations can be used to transfer settings across GPOs within the same domain, cross-domain in the same forest, or cross-domain in a separate forest.

Import operations are ideally suited for migrating Group Policy across environments where there is no trust. For example, if you have separate test and production forests with no trust, you can use import operations to migrate GPOs that you develop and verify in the test forest to the production environment. You need to be able to access a file system location from the production environment where the backed up GPOs are stored. Depending on the settings in the GPO, you may also want to use a migration table (described later in this paper) to effectively transfer the settings.

The target of an import operation is an existing GPO. The target GPO's ACLs, links to any SOMs, and link to a WMI filter are not modified during an Import operation. Importing a GPO requires edit permissions on the target GPO.

Import operations can be performed using either of the following methods:

- Right click a GPO under the Group Policy Objects node and click Import Settings. This starts a wizard that guides you through the process of selecting a backup and optionally specifying a migration table if appropriate.

- Using either the **ImportGPO.wsf** or **ImportAllGPOs.wsf** scripts that are included with GPMC.

**Copy**
A copy operation transfers settings using an existing GPO in Active Directory as the source and creates a new GPO as its destination. A copy operation can be used to transfer settings to a new GPO either in the same domain, cross-domain in the same forest, or cross-domain in a separate forest. Since a copy operation uses an existing GPO in Active Directory as its source, trust is required between the source and destination domains, or you must use the **Stored User Names and Passwords** tool as described earlier in the section "Managing Multiple Forests," to gain access to the untrusted forest. Copy operations are ideally suited for migrating GPOs between production environments, as well as for migrating Group Policy that has been staged and tested in a test domain or forest to a production environment.

Copying a GPO requires GPO creation rights in the target domain and read access to the source GPO.

When copying a GPO, the administrator has two options for specifying the DACL to use on the destination GPO:

- Use the default permissions that are used when creating new GPOs.

- Preserve the DACL from the source GPO. Note that if a migration table (described in the next section) is specified during the copy operation, the migration table will apply to any security principals in the DACL.

There are some minor differences between same-domain and cross-domain copy operations.

- When copying a GPO within the same domain, any link to a WMI filter is preserved. However, when copying a GPO to a new domain, the link is dropped because WMI filters can only be linked to GPOs within the same domain.

- When copying a GPO within the same domain, any link to an IPSec policy is preserved. However, when copying a GPO to a new domain, the link is dropped because it is unknown whether a corresponding IPSec policy exists in the new domain, and it is not always desirable to link to the original IPSec policy in the original domain.

- When copying a GPO within the same domain, the user is presented with a simple choice of choosing the DACL. However, for cross-domain copy operations, GPMC presents a wizard to facilitate the operation. In the cross-domain case, the user has the ability to specify a migration table (described below).

Copy operations can be performed using any of the following methods:

- Right-click the source GPO and choose copy, and then right-click the **Group Policy Objects** container in the desired destination domain and choose the paste option.

- Using drag and drop to drag the source GPO to the **Group Policy Objects** container in the destination domain.

- Using the **CopyGPO.wsf** command-line script that is included with GPMC.

**Using migration tables to facilitate cross-domain import and copy operations**
This section discusses the use of migration tables to facilitate cross-domain import and copy operations.

The key challenge when migrating GPOs from one domain to another is that some information in the GPO is actually specific to the current domain where the GPO is defined. When transferring the GPO to a new domain, it may not always be desirable, or even possible, to use the exact same settings. Items that can be specific to a domain include references to security principals (users, groups, and computers) and UNC paths. The solution is to modify these references in the GPO that are domain-specific, during the import or copy operation, so that the settings in the destination GPO are written with the appropriate information for the destination domain. GPMC supports this capability using migration tables.

A migration table is a file that maps references to users, groups, computers, and UNC paths in the source GPO to new values in the destination GPO. The migration table consists of one or more mapping entries. Each mapping entry consists of a source type, source reference, and destination reference. If you specify a migration table when performing an import or copy, each reference to the source entry will be replaced with the destination entry when writing the settings into the destination GPO. Note to use a migration table, the security principals specified in the destination entries of the migration table must already exist when you perform the import or copy operation.

The migration table will apply to any references in the settings within a GPO, whether you are performing an import or copy operation. In addition, during a copy operation, if you choose the option to preserve the ACL on the GPO, the migration table will also apply to both the ACL on the GPO and the ACLs on any software installation settings in the GPO.

Migration tables have their own file name extension, .migtable. The mapping information is stored as XML. You can create and edit migration tables using the Migration Table Editor (MTE) described later in this section. A sample migration table file is included with GPMC installation at "%ProgramFiles%\GPMC\Scripts" as SampleMigrationTable.migtable.

**Which settings are impacted by Migration Tables:**
There are two types of settings that may not transfer well across domains:

1. Users, groups, and computers (security principals) that are referenced in the settings of the GPO, and optionally for copy operations, in the DACL for the GPO itself and the DACL for any software installation settings in the GPO. Security principals don't transfer well for several reasons:

    - Domain local groups are never valid in external domains.

    - If there is no trust between source and destination domains, then none of the security principals in the source domain will be available in the destination domain.

    - Even in situations with trust between source and destination domains, it may not always be appropriate to use the exact same group in the new domain.

2. UNC paths. When you are migrating GPOs from test to production, users in the production environment may not have access to paths in the test environment, and vice versa.

The following items can contain security principals and can be modified using a migration table:

- Security policy settings of the following types:
    - User rights assignment
    - Restricted groups
    - System services
    - File system
    - Registry
- Advanced folder redirection policy settings.
- The GPO DACL, if you choose to preserve it during a copy operation.
- The DACL on software installation objects – only preserved if the option to copy the GPO DACL is specified.

The following items can contain UNC paths, which can be updated to new values as part of the migration process:

- Folder redirection policy settings.
- Software installation policy settings (for software distribution points).
- Pointers to scripts deployed through Group Policy (startup, shutdown, logon, and logoff) that are stored outside the GPO. Note that the script itself is not copied as part of the GPO copy operation, unless the script is stored inside the source GPO.

Note that security principals and UNC paths referenced in other types of settings not mentioned above, such as Administrative Templates and Software Restriction Policies, cannot be mapped using migration tables.

**Options for specifying migration tables**

Migration tables are specified when performing import and copy operations. There are three options for using migration tables with import and copy:

- Do not use a migration table. This option will copy all references in the source GPO exactly as is.
- Use a migration table. This option will map any references in the GPO that are in the migration table. References in the source GPO that are not contained in the migration table will be copied as is.
- Use a migration table exclusively. This option requires that all references to security principals and UNC paths be specified in the migration table. If a security principal or UNC path is referenced in the source GPO and is not included in the migration table, the import or copy operation will not proceed. This option is useful to ensure you have accounted for all security principals and UNC paths in your migration table.

In addition, cross-domain copy operations will apply the migration table to the DACL on the GPO (and any software installation settings) if you choose the option to “Preserve or migrate the existing permissions” and you specify a migration table.

When performing a copy or import, the wizard will scan the source GPO or backup to determine if there are any references to

security principals or UNC paths in the GPO. If there are, you will have the opportunity to specify an existing migration table or to create a new migration table. Note that during cross-domain copy operations, if you specify the option to "Preserve or migrate the permissions on the GPO", the wizard will always present the opportunity to specify a migration table, since a DACL by definition contains security principals.

**Creating Migration Tables**

The Migration Table Editor (MTE) in GPMC allows the user to create and edit migration tables .You can open the MTE using any of the following methods:

- From either the Import Settings or Cross Domain Copying wizards
- By right clicking the **Group Policy Objects** node in any domain and choosing **Open Migration Table Editor**.
- From the **Domains** node in any forest and choosing **Open Migration Table Editor**.
- By double clicking an existing .migtable file in Explorer.
- By manually running the program at %programfiles%\gpmc\mtedit.exe.

A migration table consists of one or more mapping entries, as shown in Figure 21 below. Each mapping entry has three pieces of information: Source type, source name, and destination name.

- Source Type: The type of domain-specific information in the domain for the source GPO. Migration tables support the following types:
    - User
    - Computer
    - Domain Local Group
    - Domain Global Group
    - Universal Group
    - UNC Path
    - Free Text or security identifier (SID). Note: This category is only for use with security principals that are specified as free text and raw SIDs.
- Source Name: The exact name of the User, Computer, Group or UNC Path referenced in the source GPO. The type of the source name in the source GPO or backup must match the source type specified in the migration table. Security principals can be specified using any of the following formats:
    - UPN. For example, "someone@example.com".
    - SAM. For example, "example\someone".
    - DNS. For example, "example.com\someone".
    - Free text. For example, "someone". You must specify the type as Free Text or SID in this case.
    - SID. For example, S-1-11-111111111-111111111-1111111111-1112. You must specify the type as Free Text or SID in this case.
- Destination Name: The destination name specifies how the name of the User, Computer, Group or UNC Path in the

source GPO should be treated upon transfer to the destination GPO. There are four choices:

- *Same as source*. Copy without changes. Equivalent to not putting the source value in the migration table at all. If specified, the destination entry will appear as <Same As Source> in the MTE.
- *None*. Removes the User, Computer or Group from the GPO. If specified, the destination entry will appear as <None> in the MTE. This option cannot be used with UNC paths.
- *Map by relative name*. For example, map SourceDomain\Group1 to TargetDomain\Group1. If specified, the destination entry will appear as <Map by Relative name> in the MTE. This option cannot be used with UNC paths.
- *Explicitly specify value*. In the destination GPO, replace the source value with the exact literal value specified in the migration table. The same format for destination entries is supported as for source names, except that raw SIDs cannot be specified.

| Source Name | Source Type | Destination Name |
|---|---|---|
| testdomain3.com\Computer3$ | Computer | testdomain4.com\Computer4$ |
| Computer5$@testdomain5.com | Computer | Computer6$@testdomain6.com |
| testdomain1\Computer1$ | Computer | testdomain2\Computer2$ |
| testdomain1\Group02 | Domain Global Group | <Map by Relative name> |
| testdomain1.com\Group1 | Domain Global Group | testdomain2.com\Group2 |
| Group01@testdomain1.com | Domain Global Group | <None> |
| testdomain3\Group3 | Domain Local Group | Group4@testdomain4.com |
| S-1-1-11-111111111-111111111-1111111111-11 | Free Text or SID | testdomain1\Group02 |
| Group05 | Free Text or SID | Group06 |
| EVERYONE | Free Text or SID | <None> |
| S-1-1-11-111111111-111111111-1111111111-11 | Free Text or SID | <Same As Source> |
| \\domain01\Share1\Script1.bat | UNC Path | \\domain02\share2\Script2.bat |
| \\domain01.test.com\share1\FolderRedirect1 | UNC Path | \\domain02.test.com\share2\FolderRedirect2 |
| \\domain01\deploy1 | UNC Path | \\domain02\deploy2 |
| Group03@testdomain3.com | Universal Group | <Same As Source> |
| Group5@testdomain5.com | Universal Group | Group6@testdomain6.com |
| testdomain1\User1 | User | testdomain2\User2 |
| User5@testdomain5.com | User | User6@testdomain6.com |
| testdomain3.com\User3 | User | testdomain4.com\User4 |

**Figure 21**

To add entries in the migration table using MTE, you can either manually type in the appropriate information or you can scan an existing GPO or GPO backup to auto-populate existing security and UNC paths in the source column. When using the auto-population methods, the destination will be set to <Same as Source> by default. The user must then adjust the destination entries in the MTE.

GPMC users can also create migration table files using the **CreateMigrationTable.wsf** script included with GPMC. This script performs an auto-populate operation that is available in the MTE. The user must then edit the file manually to set the target ACLs and paths. Alternatively, you can create a migration table manually using any XML editor.

**Scenarios for Copy and Import**

There are two key scenarios GPMC enables with the copy and import operations .

- Test-to-production migration.
- Production-to-production migration.

### Test-to-production migration

The test-to-production scenario is usually a multi-forest environment with separate forests for test and production which are often physically isolated. In this scenario, all groups, users, and computers in all domains will likely need to be mapped.

Sometimes there is a trust between the forests while other times there is not. GPMC handles either scenario, and typically a

migration table will be required. In cases with no trust, all security principals and UNC paths must be mapped using a migration table. Also, if there is no trust, you must either use import, or if using copy, you must supply alternate credentials using the **Stored User Names and Passwords** tool as described earlier in the section "Managing Multiple Forests," to gain access to the untrusted forest.

Assume for this scenario that the administrator wants to copy or import GPO X in domain B in the TEST forest to Domain E in the PRODUCTION forest. GPO X contains security settings such as the Log on locally setting under User Rights Assignment that reference security principals throughout the TEST forest. These security principals may reside in the same domain as the GPO or potentially in different domains in the TEST forest. In the drawing above, these security principals are represented as A\user, A\group, etc, where "A" is the domain, and "user" is the relative name of the security principal.

In this scenario, when copying GPO X to the new domain, the administrator will want to map all security principals that are referenced in the GPO. At a minimum, the domain prefix will need to change and potentially the relative names as well.

This scenario can be handled by using a migration table.

**Production-to-production migration**

The production-to-production scenario has all domains in production environments and there is a trust between the source and target domains. The diagram below assumes A, B, and C are all production domains in the same forest. Note that you could also have this scenario across forests provided there was a trust in place.

Assume for this scenario that the administrator wants to copy GPO X from production domain B to production domain C. There are potentially two alternative behaviors that are desired in this scenario:

- Retain all references to security principals in the copied GPO. Functionally, this would be equivalent to cross-linking GPO X to domain C (in terms of the settings that are applied from the GPO). This scenario is handled when you choose no migration table.

- Map some or all of the security principals to new values. For example for security principals defined in domain B, it may make sense to map them to domain C when copying the GPO from B to C. In particular, and domain local groups must be mapped. However, it probably makes sense to leave references defined in domain A as is. This scenario can also be handled using a migration table.

**Creating a Staging Environment**

Most administrators will want to deploy Group Policy to a test environment before introducing it to their production environment. Deploying Group Policy ideally requires the following steps:

- Gather management requirements for the target platform.
- Determine what management tasks can be done through Group Policy.
- Test Group Policy in staging environment.
- Use GPMC to migrate Group Policy to production environment.

GPMC can be used for planning, creating, testing, and migrating the Group Policy environment.

For best results, you should have a test environment that closely resembles the production environment, in terms of domains, OUs, GPOs, and groups. Using this test environment, you can test and validate changes to your policy deployment in a controlled, isolated manner that does not impact production users. Once the change has been validated, you can use the import and/or copy functions to migrate the GPOs to production.

Creating a staging environment that closely resembles the production environment is essential for this task. GPMC facilitates this by providing two sample scripts that help you create a new test environment, based on an existing environment.

- **CreateXMLFromEnvironment.wsf**: This script uses the information in a live domain to generate an XML file and a set of GPO backups that represent the policy information for that domain. The XML file captures information such as OU structure, groups and users, GPOs and the settings contained in them, links to GPOs, security on GPOs, and WMI filters. By running this script against a production domain, you can capture the essential policy information for that domain for later re-use.

- **CreateEnvironmentFromXML.wsf**: This script populates a domain with policy information such as OU structure, groups, and users, GPOs and the settings contained in them, links to GPOs, security on GPOs, and WMI filters using an XML file and a set of GPO backups referenced in the XML. The XML file required as the input for this script can be generated using the previous script. By using this second script in conjunction with the XML file previously generated, you can replicate the contents of one domain to another.

For more details on using these two scripts, see the chapter, “Staging Group Policy Deployments” in the Windows Server 2003 Deployment Kit.

# WMI Filters

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

WMI Filters are a new feature in Windows Server 2003 and Windows XP. WMI Filters allow an administrator to dynamically determine the scope of GPOs based on attributes of the target computer. This provides the administrator with the potential to dramatically extend the filtering capabilities for GPOs well beyond the previously available security filtering mechanism.

A WMI filter is a separate object that can be linked to a GPO. When the GPO is applied on the target computer, the filter is evaluated on the target computer. A WMI filter consists of one or more queries that are evaluated against the WMI repository of the target computer. If the total set of queries evaluates to false, the GPO is not applied. If all queries evaluate to true, the GPO is applied. Each query is written using the WMI Query Language (WQL), which is a SQL-like language for querying the WMI repository.

Note that client support for WMI filters exists only on Windows XP and later operating systems. Windows 2000 clients will ignore any WMI filter and the GPO is always applied, regardless of the WMI filter.

Each GPO can have only one WMI filter. However, the same WMI filter can be linked to multiple GPOs. Like GPOs, WMI filters are per domain objects.

Figure 7 in the Scoping GPOs section shows a GPO scope pane with a link to the GPO for the "XP Systems" WMI filter. WMI filters are only available in domains that have the Windows Server 2003 configuration. Although none of the domain controllers need to be running Windows Server 2003, you must have run **ADPrep /DomainPrep** in this domain. ADPrep is a utility included on the Windows Server 2003 CD and must be run before upgrading an existing Windows 2000 domain to Windows Server 2003. If ADPrep /DomainPrep has not been run in a Windows 2000 domain, the **WMI Filters** node will not be present, and the **GPO scope** tab will not have a WMI filters section.

The user can create new WMI filters from the **WMI Filters** container in the GPMC console. Right-clicking either the **WMI Filters** container or the Contents pane for this node allows the user to create a new WMI filter or to import a filter that was previously exported. Selecting **New** will present the user with the dialog box in Figure 22.

**Figure 22**

The user enters a name for the WMI filter, an optional description, and then one or more WQL queries using the Add button. Note that for each query, you must specify the WMI namespace where the query is to be executed. The default namespace is root\CIMv2, which should be appropriate for most scenarios. When the user presses the **Save** button, the query syntax is checked before the WMI filter can be saved.

There are three methods for linking a WMI filter to a GPO:

1. On the **Scope** tab of the GPO, use the **WMI filtering** dropdown to select a WMI filter to link to the GPO.

2. On the **General** tab of a WMI filter, right-click the **GPOs that use this WMI Filter** section and select **Add** (shown below in Figure 23). Selecting **Add** will present the user with a list of GPOs in the domain to which the user can link the WMI filter. You can only link to one GPO at a time from this pane.

3. Using drag and drop, drag a WMI filter onto a GPO.

**Figure 23**

There is no option to link to a GPO in another domain because WMI filters can not be linked to GPOs in a different domain. Note that the ability to link a WMI filter to a GPO requires edit access to the GPO, as the link to the WMI filter is an attribute of the GPO.

The General tab on the WMI filter pane allows the user to edit a WMI filter. If the user does not have write access to the WMI filter, the **Edit Filter** button is grayed out. The user can modify the WMI Filter name, description, and the WMI query from this dialog box.

# Searching for GPOs

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

GPMC provides extensive capabilities to search for GPOs within a domain or across all domains shown in a forest. This search feature allows you to search for GPOs based on:

- Display name of the GPO.
- Whether or not a specific domain contains links to the GPO.
- The permissions set on the GPO.
- The WMI filter that is linked to the GPO.
- The *type* of policy settings that have been set in the User Configuration or Computer Configuration in the GPO, such as folder redirection or security settings. Note that you cannot search based on the individual settings configured in a GPO.
- GUID of the GPO.

Figure 24 shows the GPO Search dialog box.

**Figure 24**

The GPO search by name and by GUID functions allow the user to search for a GPO by the GPO display name or by GUID associated with the GPO. The search by User Configuration or Computer Configuration allows the user to find GPOs that contain certain types of Group Policy settings. Refer to Table 3 for a list of the Group Policy settings allowed in this search feature.

The search by security group feature allows the user to find GPOs that have certain permissions applied to them. You can search for GPOs that either explicitly have these permissions (or explicitly do not have these permissions) or that have these permissions effectively applied to them (or not). An explicit permission on a GPO means the security principal is directly referenced in the ACL on the GPO. An effective permission means the security principal has permissions on the GPO either as

the result of an explicit ACE, or because of its group membership. These factors combine to give a security principal the merged or effective set of permissions they have on the GPO.

Searching by GPO-Link allows the user to find unlinked or cross-domain linked GPOs. For example, if you are searching for GPOs in a given domain and you perform a search where GPO links do NOT exist in that domain, this search type will return the list of unlinked GPOs.

Searching by GPOs that link to a WMI filter allows the user to find all GPOs that link to a specified WMI filter.

Table 3 summarizes the GPO search actions and how they can be used.

**Table 3**

| Search Item | Search Condition | Value |
|---|---|---|
| GPO name | Contains<br>Does not Contain<br>Is Exactly | GPO Display name |
| GPO-Link | Exist in<br>Does not Exist in | Domain name(s)<br>[All Sites] |
| Security Group | Has this explicit permission<br>Does not have this explicit permission<br>Has this effective permission<br>Does not have this effective permission | Apply Settings<br>Edit Settings<br>Edit Settings, Delete, Modify Security<br>Read Settings |
| Linked WMI filter | Is<br>Is not | WMI Filter name |
| User Configuration | Contains<br>Does not Contain | Folder Redirection<br>Internet Explorer Branding<br>Registry<br>Scripts<br>Software Installation |
| Computer Configuration | Contains<br>Does not Contain | EFS Recovery<br>IP Security<br>Microsoft Disk Quota<br>QoS Packet Scheduler<br>Registry<br>Scripts<br>Security<br>Software Installation<br>Wireless Group Policy |
| GPO GUID | Equals | GUID |

**Note**

When searching based on user or computer configuration, if a setting is enabled, and then all the settings in that extension are removed, there can be false-positive search for certain types of settings. This happens because the GPO has the extension listed as active. The extensions with this behavior are Security Settings, Software Installation, Folder Redirection, Internet Explorer Maintenance, and Encrypting File System (EFS).

# Group Policy Modeling

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

Windows Server 2003 has a powerful new Group Policy management feature that allows the user to simulate a policy deployment that would be applied to users and computers before actually applying the policies. This feature, known as Resultant Set of Policy (RSoP) – Planning Mode in Windows Server 2003, is integrated into GPMC as Group Policy Modeling. This feature requires a domain controller that is running Windows Server 2003 in the forest, because the simulation is performed by a service that is only present on Windows Server 2003 domain controllers. However, with this feature, you can simulate the resultant set of policy for any computer in the forest, including those running Windows 2000.

In Figure 25, note that the Contoso.com Windows Server 2003 forest has a **Group Policy Modeling** container in the tree pane and the Tailspintoys.com Windows 2000 forest does not have this container.

**Figure 25**

The contents tab on the **Group Policy Modeling** node displays a summary of all Group Policy Modeling queries that the user has performed. This is shown in Figure 25. For each query, GPMC shows the following data:

- Name – This is the user-supplied name of the modeling results.
- User – This is the user object (or the OU where the user object is located) that forms the basis of the modeling query.
- Computer – This is the computer object (or the OU where the computer object is located) that forms the basis of the modeling query.
- Last refresh time – This is the last time the planning query was refreshed.

The Group Policy Modeling Wizard can be opened from the Group Policy Modeling container, the domain node, or from any OU. When the Group Policy Modeling Wizard is started from one of the SOM containers, the wizard automatically passes the SOM data to the wizard and pre-populates the User and Computer Selection page of the wizard.

| **Note** |
| --- |
| For users that are familiar with the RSoP MMC snap-in in Windows Server 2003, the Group Policy Modeling Wizard is a newer version of the RSoP wizard, running in Planning mode. Because all RSoP functionality provided by the RSoP MMC snap-in is included in GPMC, along with new functionality such as HTML reporting of RSoP data, it is recommended that users access all RSoP functionality primarily through GPMC, rather than the standalone RSoP MMC snap-in. |

Figure 26 shows the Group Policy Modeling Wizard's Summary of Selections dialog box prior to running the modeling analysis. The settings in the summary pane are the answers supplied by the user while running the modeling wizard.

**Figure 26**

Once the user completes the Group Policy Modeling Wizard, a new node in the console is created to display the results. These nodes are persistent across GPMC console sessions. The user must manually remove any Group Policy Modeling nodes that are no longer desired.

For a given Group Policy Modeling query, the node contains three tabs as shown in Figure 27.

- Summary - this contains an HTML report of the summary information including the list of GPOs, security group membership, and WMI filters.
- Settings - this contains an HTML report of the simulated policy settings that would be applied in this simulation.
- Query - this lists the parameters that were used to generate the query.

Using the context menu on this new node, the user is able to:

- Save the results report to the file system. This saves the contents of both the Summary and Settings tabs as a single file (either HTML or XML).
- Re-run the query. Choosing the option to re-run the query will re-run the simulation and re-generate the data displayed in the report.
- Create a new query using the original as a template.
- Start the RSoP MMC snap-in, by choosing the "Advanced View" option. The RSoP snap-in includes the same data that is shown in the HTML report, but also shows precedence information. For example, if three GPOs set the same setting, only 1 GPO will actually set that setting. The HTML will tell you the final value and which GPO actually set it, whereas the traditional RSoP snap-in will also identify all GPOs that attempted to set that setting and the corresponding value of that setting. This is shown on the precedence tab when you double click a setting in the RSoP MMC snap-in.

The summary tab (shown in Figure 27) shows a summary of the RSoP data for the user configuration and computer configuration. For both sections, the following information is shown:

- General information including the name of the user, computer, and/or SOM for which the RSOP data was gathered.
- A list of GPOs that are in scope for the given user, computer, computer, and/or container, and the SOM to which each GPO was linked. This includes a list of GPOs that would be applied, as well as GPOs that were in scope, but would not be

applied on the target.

- Simulated security group membership of the targeted user and/or computer.
- List of WMI filters that are linked to the GPOs and whether they were assumed in the query to be true or not.

**Figure 27**

The settings tab (shown in Figure 28) displays a report of the final value of all policy settings that would be applied, and the GPO (for example, "Winning GPO") that would be responsible for setting each value.

**Figure 28**

The query tab displays the parameters of the query entered by the user that were used to generate the data. This tab includes data that the user entered in the wizard to generate the query such as:

- Last time the query was refreshed.
- Domain controller on which the simulation was run.
- User name or SOM name for user settings.
- Computer name or SOM name for computer settings.

- If slow link processing was simulated.
- The site that the computer is assumed to be in, for this simulation.
- Whether Loopback processing was assumed, and if so, the mode (“none”, “merge mode”, or “replace mode”).
- Simulated alternate user location.
- Simulated alternate computer location.
- Simulated security group membership of user object.
- Simulated security group membership of computer object.
- WMI filters that were assumed to be true for the computer object
- WMI filters that were assumed to be true for the user object

# Group Policy Results (Administering Group Policy with Group Policy Management Console)

Updated: April 7, 2003

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

This feature allows administrators to determine the resultant set of policy that was applied to a given computer and (optionally) user that logged on to that computer. The data that is presented is similar to Group Policy Modeling data, however, unlike Group Policy Modeling, this data is not a simulation. It is the actual resultant set of policy data obtained from the target computer. Unlike Group Policy Modeling, the data from Group Policy Results is obtained from the client, and is not simulated on the DC. The client must be running Windows XP, Windows Server 2003 or later. It is not possible to get Group Policy Results data for a Windows 2000 computer. (However, with Group Policy Modeling, you can simulate the RSoP data).

| **Note** |
| --- |
| Technically, a Windows Server 2003 DC is not required to access Group Policy Results. However, by default, only users with local admin privileges on the target computer can remotely access Group Policy Results data. This can be delegated to additional users (as previously described), however, the ability to delegate RSoP data is only available in Active Directory forests that have the Windows Server 2003 schema (for example, you have run ADPrep /ForestPrep) in that forest. |

Each Group Policy Results query is represented by a node in the tree view under the Group Policy Results container. Each node has three tabs:
