If you intend to place sensitive data on your FTP site or if communication between clients and your FTP server is important, consider using FTP over an encrypted channel, such as a virtual private network (VPN) secured with Point-to-Point Tunneling Protocol (PPTP) or Internet Protocol security (IPSec). To learn how to set up a private network over the Internet using PPTP or how to set up IP communications with a VPN and IPSec, see the PPTP, VPN, and IPSec topics in Help and Support Center for Windows Server 2003.

If you need to authorize users or host sensitive content, WebDAV is a good alternative to FTP because WebDAV can take advantage of SSL encryption for communications. For more information about WebDAV, see Securing WebDAV Publishing Directories.

# Securing WebDAV Publishing Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

WebDAV is an extension of the HTTP 1.1 protocol that facilitates file and directory manipulation over an HTTP connection. Through the use of WebDAV *verbs*, or commands, properties can be added to and read from files and directories. Files and directories can also be remotely created, deleted, moved, or copied. Additional access control can be configured through both Web server permissions and NTFS.

Just as with a standard Web site, you can use the **Directory Security** tab in the **Web Site Properties** dialog box to configure WebDAV authentication, Web site access control, and IP address and domain name restrictions, and to enable secure communications. Furthermore, for security reasons and to enable WebDAV custom search properties, your WebDAV publishing directory must reside on an NTFS file system partition. For more information about NTFS partitions, see "Choosing a file system: NTFS, FAT, or FAT32" in Help and Support Center for Windows Server 2003.

**Setting the Client Authentication Method**

Because WebDAV is an HTTP-based protocol, the same authentication methods are available for your WebDAV publishing directory as for your Web sites. When you create a WebDAV virtual directory, the authentication settings will be set by default to Anonymous authentication and Integrated Windows authentication.

| **Important** |
| --- |
| Change the default authentication settings for your WebDAV site. Anonymous authentication and Integrated Windows authentication are appropriate for Web sites, but not for resources on a WebDAV publishing directory. |

Use the following best practices as guidelines when configuring client authentication for WebDAV. For more information about authentication, see Authentication in IIS 6.0.

**Anonymous authentication**

Turn off Anonymous authentication to your WebDAV publishing directory. Without controlling access, your directory might be vandalized by unknown clients.

**Basic authentication**

Turn on Basic authentication only if you encrypt passwords through SSL. Basic authentication sends passwords over the connection in plaintext, so passwords can be intercepted and read. For more information about SSL, see Configuring SSL on a Web Server or Web Site.

**Digest authentication**

Turn on Digest authentication if users access your WebDAV publishing directory over the Internet and through firewalls because Digest authentication sends the passwords over the network as an MD5 hash. However, passwords are stored as plaintext in the Active Directory® directory service.

**Advanced Digest authentication**

Turn on Advanced Digest authentication if users access your WebDAV publishing directory over the Internet and through firewalls. Advanced Digest authentication is the best choice because, in addition to sending passwords over the network as an MD5 hash, the passwords are also stored in Active Directory as an MD5 hash rather than as plaintext.

**Integrated Windows authentication**

Turn off Integrated Windows authentication unless users access your WebDAV publishing directory only from an intranet.

**.NET Passport authentication**

Turn off .NET Passport authentication. Microsoft® .NET Passport authentication uses cookies to validate user credentials against a central .NET Passport server. However, the central .NET Passport server does not authorize or deny the access of a specific user to individual .NET Passport–enabled sites.

**Configuring Access Control**

You can control access to your WebDAV publishing directory by coordinating permissions in IIS and Windows Server 2003. The following information can help you set the correct permissions depending on what kind of content your WebDAV publishing directory contains and what you want to allow users to do with that content. For step-by-step instructions for setting permissions, see Securing Sites with Web Site Permissions.

**Read, Write, Directory browsing enabled**

Set these permissions if you want clients to see a list of resources, modify them (except for resources that do not have Write

permission), publish their own resources, or manipulate files.

**Write enabled; Read and Directory browsing disabled**
Set these permissions if you want clients to publish private information on the directory, but you do not want others to see what has been published. This configuration works well if clients are submitting ballots or performance reviews.

**Read and Write enabled; Directory browsing disabled**
Set these permissions only if you want to obscure file names as a security method. However, be aware that security by obscurity is a low-level security precaution because an attacker or a malicious user can guess file names by trial and error.

**Index this resource enabled**
Enable Indexing Service if you plan to let clients search directory resources.

You can also control access to your WebDAV publishing directory through discretionary access control lists (DACLs). When you set up a WebDAV publishing directory on an NTFS file system disk, the server running Windows Server 2003 is configured with a secure set of defaults that can be too restrictive for Web publishing. If you change the defaults, assign Write permission only to the specific users or groups that absolutely need Write permission. (Whenever possible, assign permissions to groups rather than users.) By default, the Users group is assigned only Read permission for most portions of the file system.

If you have script files in your WebDAV publishing directory that you do not want users to access, you can deny access to these files by verifying that the Script Source Access permission is not assigned. The extensions of your script files are listed in the Applications Mapping list. All other executable files, including files with .exe extensions, are treated as static HTML files unless the Scripts and Executables permission is assigned to the directory.

You can prevent users from downloading and viewing .exe files as HTML files but still allow clients to run them by assigning the Scripts and Executables permission. To do so, on the **Virtual Directory** tab of the publishing directory, on the **Execute permissions** list, click **Scripts and Executables**. When you assign the Scripts and Executables permission to the directory, all of the executable files are subject to the Script Source Access permission setting. You can assign the Script Source Access permission on the **Home Directory** tab of the **Web Site Properties** dialog box of the Web site that you are configuring. When the Script Source Access permission is assigned, clients with Read permission can see all the executables, and clients with Write permission can edit and run all the executables.

If you want clients to be able to write to an executable file that does not appear in the Application Mapping list, assign the Write permission and the Scripts Only Execute permission to the directory.

If you want clients to be able to write to any executable file, regardless of whether it appears in the Application Mapping list, assign the Script Source Access permission and the Scripts and Executables Execute permission to the directory.

# Controlling Access to a Database on a Web Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For Web applications that communicate with a database, controlling access to the database is a critical element of Web server security. There are several ways to control access to a database that is published on an IIS 6.0 Web server:

- Use the built-in security permissions of the database application or the database management system. Many of the integrated user authentication methods in your database provide control access at a fine level of granularity. For example, the Database Results Wizard in Microsoft FrontPage 2002 allows you to create a Web page that can access a database, and to use password protection on the database connection. For more information about Microsoft SQL Server security, see the Help topics in SQL Server Enterprise Manager. For more information about Microsoft Access 2002 Security, see the Help topics that are accessible from the Help menu.

- Use the data source name (DSN). The DSN that you create on the Web server is used by an external program or an ASP page to refer to the database that you want to publish on your Web site. For more information about how to determine the DSN password setting for a database or database management system, consult the application's help.

- Use NTFS permissions. Windows Server 2003 NTFS permissions can restrict access to specific folders and files on your Web site. For more information about NTFS, see Help and Support Center for Windows Server 2003.

- Use subwebs to restrict access to a section of the Web site. For example, if you use FrontPage to create a Web site, you can create security boundaries by using subwebs. Each subweb can maintain separate security settings, so you can store database results pages or ASP pages that reference the database in a subweb with unique permissions. For more information about creating subwebs and assigning unique permissions, see Knowledge Base article 301432, How to Create a Subweb and Add Permissions Using FrontPage 2000.

- Use an appropriate Web server authentication method. Database user authentication can depend on the protocol that is used for the database connection. For example, if you decide to use the Named Pipes default connection protocol for SQL Server, Windows user account credentials might be authenticated with SQL Server authentication.

# Encryption in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Encryption is the process of scrambling information by applying a mathematical function in such a way that it is extremely difficult for anyone other than an intended recipient to retrieve the original information. Central to this process is a mathematical value, called a *key*, which is used by the function to scramble the information in a unique and complex way.

Your Web server uses essentially the same encryption process to secure communication links with users. After establishing a link, a special *session key* is used by both your Web server and the user's Web browser to both encrypt and decrypt information. For example, when an authenticated user attempts to download a file from a Web site requiring a SSL–secured channel, your Web server uses a session key to encrypt the file and related HTTP headers. After receiving the encrypted file, the Web browser then uses a copy of the same session key to recover the file.

This method of encryption has an inherent drawback: During the process of creating a link, a copy of the session key might be transmitted across an unsecured network. This means that a malicious user can compromise the link by intercepting and stealing the session key. To safeguard against this possibility, however, your Web server implements an additional method of encryption.

# About Secure Sockets Layer

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 uses the Secure Sockets Layer (SSL) protocol, which provides a way of establishing an encrypted communication link with users. SSL is a public key-based security protocol that is used by Internet services and clients to authenticate each other and to establish message integrity and confidentiality. SSL uses certificates for authentication, and it uses encryption for message integrity and confidentiality. To establish encrypted communications using SSL, you must have a valid server certificate installed.

SSL confirms the authenticity of your Web site and, optionally, confirms the identity of users that are accessing restricted Web sites. You can use the SSL encryption features of your Web server to cryptographically encode information transmitted and received by your Web server. When you enable SSL encryption, you can prevent unauthorized individuals from decoding the original content of your transmissions. For example, you can use encryption to help protect the private information that clients exchange with your server, such as credit card numbers or phone numbers.

When you set security properties for a specific Web site, you automatically set the same security properties for directories and files belonging to that site, unless the security properties of the individual directories and files have been previously set.

Your Web server will prompt you for permission to reset the properties of individual directories and files when you attempt to set security properties for your Web site. If you choose to reset these properties, your previous security settings will be replaced by the new settings. The same condition applies when you set security properties for a directory containing subdirectories or files with previously set security properties.

To maintain the performance level of your Web server, consider using SSL encryption only for sensitive information, such as financial transactions. Encrypted transmissions can significantly reduce transmission rates and server performance.

# Session Keys and Browsers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

During the exchange of information that establishes a SSL–secured connection, the server creates a *session key*, also called an encryption key. IIS and the browser use the session key to encrypt and decrypt information that is exchanged during a session. The required encryption strength is measured in bits (for example, 40-bit encryption or 128-bit encryption). The encryption strength provides the degree of confidentiality that is deemed necessary for the application. A large number of bits indicates greater encryption strength because attackers who do not have the session key find it difficult to decrypt larger encrypted strings. Although greater encryption key strengths offer greater security, they also require more server resources to implement. The session key for your Web server is typically 128 bits long. The session key is not the same as an SSL key pair, which is used to negotiate and establish a communication link.

You can configure your Web server to require a 128-bit minimum session-key strength, the default for Microsoft Windows .NET, for all SSL–secured communication sessions. If you set a minimum 128-bit key strength, however, users attempting to establish a SSL–secured communications channel with your server must use a browser capable of communicating with a 128-bit session key.

You can require users to establish an encrypted channel (https:// rather than http://) with your server before accessing a restricted Web site, directory, or file. The use of an encrypted channel, however, requires that the user's Web browser and your Web server both support the encryption scheme used to secure the channel. Specifically, when you enable your Web server's default communication security settings, you require the user's Web browser to support a session key strength of 40 bits, or greater.

# Session Key Encryption Strength

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A session key's *strength* is proportional to the number of binary *bits* that comprise the session key file. This means that session keys with a greater number of bits have a greater degree of security, and are considerably more difficult to forcibly decode.

When a user attempts to establish an encrypted communication channel with your Web server, the user's browser must negotiate the strongest possible level of encryption—that is, session key strength—that can be used to secure communications over that channel. This means that both your Web server and the user's browser must be equipped with compatible session key encryption and decryption capabilities. For example, when you configure your Web server to require a session key with a minimum of 40-bit (default) encryption strength, a user attempting to secure a connection must have a Web browser capable of processing information with a 40-bit session key. If you require 128-bit key encryption, your users must use Web browsers that support 128-bit encryption.

# Public Key Encryption

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Your Web server's SSL security feature uses *public key* encryption to shield the session key from interception during transmission. Public key encryption involves the use of two additional keys: a *private* and a *public* key.

Figure 5.6 shows how public key encryption works, and the steps that follow describe the process in more detail.

1. The user's Web browser establishes a communication link with your Web server by using the https:// protocol.

2. The user's Web browser and your server engage in negotiation to determine the degree of encryption to use for securing communications.

3. Your server sends the browser its certificate, which includes a public key.

4. The user's Web browser generates a session key, encrypts it with the server's public key, and sends it to your server.

5. Using the private key, your server decrypts the message and retrieves the session key sent by the Web browser.

6. Your Web server and the browser both use the session key to encrypt and decrypt transmitted data.

The private key plays an important role in ensuring that your communication link remains secured. You should take every reasonable precaution to protect the private key from loss or theft. If you suspect that your private key has been compromised, notify your certification authority and then use the Web Server Certificate Wizard to create a new certificate request so you can obtain a new server certificate.

# Kernel-Mode SSL

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

In Windows Server 2003 Service Pack 1 (SP1) and later, you can run SSL in *kernel mode* instead of the default *user mode*. Kernel mode operation means that components or processes run in the core address space of the operating system.

Running SSL in kernel mode improves SSL performance by moving encryption and decryption operations to the kernel, thereby reducing the number of transitions between kernel mode and user mode.

The following restrictions apply to running SSL in kernel mode:

- Client certificates are not supported.
- RC2 ciphers are not supported.
- The Private Communications Technology (PCT) 1.0 protocol is not supported.
- Configuration changes to server certificates require a restart of the HTTP service.
- ISAPI GetServerVariable calls for certificate information do not work.
- Bulk encryption offload is not supported.
- ISAPI filters do not get READ RAW notifications regardless of the security of the connection. This restriction affects only IIS 5.0 compatibility mode, because IIS 6.0 worker process isolation mode does not support READ RAW DATA filters regardless of the setting for kernel-mode SSL.

For information about enabling kernel-mode SSL, see Enabling Kernel Mode SSL.

# SSL and SF_NOTIFY_READ_RAW_DATA Filters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In IIS 6.0, SSL communication must use the SF_NOTIFY_READ_RAW_DATA notification in worker process isolation mode. However, these notifications are not supported in IIS 6.0 in worker process isolation mode. For this reason, IIS creates a new SSL service that is associated with worker process isolation mode. This service runs entirely outside of any IIS process; currently, it runs as lsass.exe, although it can be configured to run as an instance of Svchost.exe. For raw, unencrypted SSL data, Http.sys uses this new SSL service in much the same way it uses Inetinfo.exe in IIS 5.0 isolation mode for raw data filter support. However, in IIS 5.0 isolation mode, the SSL code runs in Inetinfo.exe instead of in its own service.

For more information about how SF_NOTIFY_READ_RAW_DATA notifications are handled in IIS 6.0 isolation modes, see Application Isolation Modes.

# SSL and Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Certificates* are digital identification documents that allow both servers and clients to authenticate each other. If you want the server and client browser to set up an SSL connection over which encrypted information can be sent, certificates are required. Certificates include keys that are used to establish an SSL-encrypted connection. A *key* is a unique value that is used to authenticate the server and the client in establishing an SSL connection. A public key and a private key form an *SSLkey pair*. The World Wide Web Publishing Service (WWW service) on your Web server uses this key pair to negotiate an encrypted connection with the client browser.

The certificate-based SSL features in IIS consist of a server certificate, a client certificate, and various digital keys. You can use Certificate Services to create certificates, or you can obtain certificates from a mutually trusted third-party organization called a certification authority (CA). For more information about obtaining, installing, and managing certificates, see Certificates_IIS_SP1_Ops.

*Server certificates* provide a way for users to confirm the identity of your Web site before they transmit personal information, such as a credit card number. A server certificate contains detailed identification information, such as the name of the organization that is affiliated with the server content, the name of the organization that issued the certificate, and a public key that is used to establish an encrypted connection. This information helps to assure users of the authenticity of Web server content and the integrity of the SSL–secured connection.

With SSL, your Web server also has the option of authenticating users by checking the contents of their *client certificates*. A typical client certificate contains detailed identification information about a user and the organization that issued the certificate, as well as a public key. You can use client certificate authentication, along with SSL encryption, to implement a method for verifying the identity of your users.

Use the Web Server Certificate Wizard to either generate a certificate request file (NewKeyRq.txt, by default) that you can send to a certification authority, or to generate a request for an online certification authority, such as Microsoft® Certificate Services. For more information, see Obtaining Server Certificates.

If you are not using Microsoft Certificate Services to issue your own server certificates, a third-party certification authority must approve your request and issue your server certificate. Depending on the level of identification assurance offered by your server certificate, you can expect to wait anywhere from several days to several months for the certification authority to approve your request and send you a certificate file. You can have only one server certificate per Web site.

After you receive a server certificate file, use the wizard to install it. The installation process attaches, or *binds*, your certificate to a Web site. For more information about installing certificates, see Requesting a New Server Certificate from an Online CA.

**Certification Authorities**

You can obtain a certificate from a mutually trusted, third-party commercial organization called a *certification authority* (CA). The primary responsibility of the CA is to confirm the identity of the party that is seeking a certificate, thus ensuring the validity of the identification information that is contained in the certificate.

Before issuing a certificate, the CA requires you to provide identification information, such as name, address, and organization. The extent of this information can vary with the identification assurance requirements of the certificate. If you need a certificate to provide absolute assurance about your identity, the CA will require substantial information from you; gathering this information might require a personal interview with the CA as well as the endorsement of a notary.

Ultimately, the success of certification authentication depends on whether the party receiving a certificate trusts the authority who issued the certificate, and that the authority correctly verified the certificate owner's identity. However, beyond this trust, certificates do not provide conclusive proof of the identity, trustworthiness, or intentions of the user or server.

**Certificate Trust Lists**

You can configure computers running Windows Server 2003 with IIS 6.0 to accept certificates from a predefined list of certification authorities (CAs). For example, you might create a different list of trusted certification authorities for each department on your network. IIS would accept only client certificates supplied by certification authorities in the CTL for that department. Each Web site can be configured to accept certificates from a different list by using certificate trust lists (CTLs). You can automatically verify client certificates against the CTL. You can use the Certificate Trust List Wizard to create and edit CTLs and to add new root certificates to your CTLs.

**Certificate Revocation Lists**

Certification authorities (CAs) cannot physically revoke your users' client certificates. However, they might publish Certificate

Revocation Lists (CRLs) that are copied onto your computer, where they can be searched for client certificates that are in revoked status. This process, called CRL checking, allows IIS to reject client certificates that do not meet the CA criteria for validity. CRLs pair subscribers and revocation status, along with a description of the reason for the revocation. Most CRL services also include a prospective date for the next CRL to be published. Frequent updates help you stay current with subscribers' status with the CA. When determining the schedule for CRL publishing, there is a trade-off between performance and security. The more often CRLs are published, the more current clients can be with the list of revoked CRLs and the less likely they are to accept recently-revoked certificates. However, frequent publishing can negatively impact network and client performance. To help mitigate this trade off, delta CRLs can be used if the environment supports them. For more information about certificate revocation and CRLs, see Revoking Certificates and Publishing CRLs.

CRL checking is managed by setting metabase properties. The metabase properties that control CRL checking can be set or viewed using a COM object, or WMI scripts, or ADSI scripts.

**Enabling and Disabling CRL Checking**

You can enable and disable CRL checking by setting the CertCheckMode Metabase Property. CRL checking is enabled by default. The CRL will be refreshed by the CA whenever a new CRL is issued, unless you set a different CRL refresh interval by specifying a value other than 0 for the CertCheckMode metabase property.

**Configuring CRL Refreshes**

Optionally, you can refresh the CRL on your computer with the CRL on the CA server even when the cached CRL on your computer is valid, by changing the setting of the RevocationFreshnessTime Metabase Property.

You can change the length of time allocated for downloading a CRL to a time, in seconds, by setting the RevocationURLRetrievalTimeout Metabase Property.

# Server Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To activate your Web server's SSL security features, you must obtain and install a valid server certificate. Server certificates are digital identifications containing information about your Web server and the organization that is sponsoring the server's Web content. A server certificate enables users to authenticate your server, check the validity of the Web content, and establish an encrypted connection. The server certificate also contains a public key, which is used in creating an encrypted connection between the client and server.

The success of a server certificate as a means of identification depends on whether the user trusts the validity of the information that is contained in the certificate. For example, a user logging on to your company's Web site might be hesitant to provide credit card information, despite having viewed the contents of your company's server certificate. This might be especially true if your company is new and not well known. If this is the case, consider obtaining a server certificate from a certification authority.

Alternatively, depending on your organization's relationship with its Web site users, you can issue your own server certificates. For example, in the case of a large corporate intranet handling employee payroll and benefits information, corporate management might decide to run a certificate service assuming responsibility for validating identification information and issuing server certificates. For more information see Obtaining and Installing Server Certificates.

# Using Certificate Wizards

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 includes the following wizards that simplify the tasks necessary to establish and maintain communications for a Web site using server certificates:

- Web Server Certificate Wizard. Obtain and manage server certificates, which are used in negotiating a link between your server and a user's browser.
- Certificate Trust List Wizard. Manage certificate trust lists (CTLs), which are lists of certification authorities that are trusted by each Web site or virtual directory.

**The Web Server Certificate Wizard**

In IIS, you can obtain, configure, and renew server certificates using the Web Server Certificate Wizard. The wizard detects whether a server certificate has already been installed and whether it is about to expire. Use the wizard to perform the following tasks:

- Create a certificate request.
- Replace the server certificate with another one from a certification authority (CA), from an online CA, such as Microsoft Certificate Services, or from a file previously obtained in Key Manager.
- Reassign a certificate from one Web site to another Web site.
- View certificates.

When creating a new certificate, the Web Server Certificate Wizard allows you to choose the strength of encryption, the type of certificate, and a cryptographic service provider for your certificate.

Online requests for server certificates can be made only to local and remote Enterprise Certificate Services and remote Stand-alone Certificate Services. The IIS Web Server Certificate Wizard does not recognize a stand-alone installation of Certificate Services on the same computer when requesting a certificate. To get around this, use the offline certificate request to save the request to a file and then process as an offline request. For more information about offline requests, see "Certificate Services Help" in Help and Support Center for Windows Server 2003.

If you are not using an online certification authority, you will need to save the request file generated by the Web Server Certificate Wizard to disk and send it to the CA. When the response is received, you can start the wizard and it will begin where it left off. If you are replacing a certificate, IIS will continue to use the old certificate until the new request is completed.

**The Certificate Trust List Wizard**

Use the Certificate Trust List Wizard to obtain and manage certificate trust lists (CTLs). A CTL is a list of trusted certification authorities (CA) for a particular Web site. By configuring your CTL, you can allow client certificates issued by one CA to be used but not from another CA. CTLs are especially useful for Internet Service Providers (ISPs) who have several Web sites on their server and who need to have a different list of approved certification authorities for authenticating clients at each site. CTLs are available only at the Web site level and are not available for FTP sites.

# Obtaining and Installing Server Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can obtain server certificates from an outside certification authority (CA), or you can issue your own server certificates by using Microsoft Certificate Services.

Use Microsoft Certificate Services to create a customizable service for issuing and managing certificates. You can create server certificates for the Internet or for corporate intranets, giving your organization complete control over certificate management policies.

**Obtaining Server Certificates from a certification authority**

If you are replacing your current server certificate, IIS will continue to use the old certificate until the new request has been completed.

When you are choosing a certification authority (CA), consider the following questions:

- Will the CA be able to issue a certificate that is compatible with all of the browsers used to access my server?
- Is the CA a recognized and trusted organization?
- How will the CA provide verification of my identity?
- Does the CA have a system for receiving online certificate requests, such as requests generated by the IIS Web Server Certificate Wizard?
- How much will the certificate cost initially, and how much will renewal or other services cost?
- Is the CA familiar with my organization or my company's business interests?

**Issuing Your Own Server Certificates**

When deciding whether to issue your own server certificates, consider the following:

- Microsoft Certificate Services accommodates different certificate formats and provides for auditing and logging of certificate-related activity.
- Compare the cost of issuing your own certificates against the cost of buying a certificate from a certification authority.
- Remember that your organization will require an initial adjustment period to learn, implement, and integrate Certificate Services with existing security systems and policies.
- Assess the willingness of your connecting clients to trust your organization as a certificate supplier.

**Assigning Resources to Server Certificates**

Use the following guidelines when assigning IP addresses, Web sites, and SSL ports to your server certificates:

- Each Web site can have only one server certificate assigned to it.
- One certificate can be assigned to multiple Web sites.
- You can assign multiple IP addresses per Web site.
- You can assign multiple SSL ports per Web site.

**Installing Server Certificates**

After obtaining a server certificate from a CA, or after issuing your own server certificate using Certificate Services, use the Web Server Certificate Wizard to install it. When you use the Server Certificate Wizard to obtain and install a server certificate, the process is referred to as *creating* and *assigning* a server certificate. For instructions on how to install your server certificate, see Requesting a New Server Certificate from an Online CA.

**Backing Up Server Certificates**

The Web Server Certificate Wizard is used to back up server certificates. Because IIS works closely with Windows, you can also use Certificate Manager, which is called "Certificates" in Microsoft Management Console (MMC), to export and back up your server certificates.

# Managing Certificates Programmatically

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 includes the new certificate object, **IISCertObj**, which allows you to use scripts to process SSL certificates on your local computer or on a remote computer. You can use scripts in conjunction with **IISCertObj**, a COM object, to perform the following tasks:

- Import copies of a certificate from a .pfx file (a file containing a PFX-encrypted certificate and a private key) from one server onto multiple servers.
- Save backup copies of certificates on a central site.
- Copy a certificate from one server onto multiple servers.

You can use **IISCertObj** to perform the following tasks:

- Import copies of a server certificate from a .pfx file (a file containing a PFX-encrypted server certificate and a private key) from a server to multiple servers.
- Save backup copies of server certificates on a central site.
- Copy a server certificate from one server to multiple servers.

When using **IISCertObj**, you must set properties for the methods that you call. The following sections outline the necessary properties and the methods that you need to manage server certificates.

**Setting IISCertObj Properties**

Because a method will return an error message if the required properties for that method are not available when the method is called, you should set properties before you call methods. Table 5.11 lists the **IISCertObj** properties that you need to generate server certificate requests.

**Table 5.11 IISCertObj Properties Required for Server Certificate Requests**

| Property Attribute | Name Attribute | Value | Description |
|---|---|---|---|
| ServerName | Data Type | String, write only | Contains the name of the computer on which server certificate operations are executed. |
| UserName | Data Type | String, write only | Specifies the user name that is used to log on to the remote computer. If UserName is empty, the credentials of the user that is currently logged on are used. |
| UserPassword | Data Type | String, write only | Specifies the password that is used for logging onto the remote computer. |
| InstanceName | Data Type | String, write only | Identifies the targeted metabase instance. W3svc/1 is an example. |

**Applying IISCertObj Methods**

You can apply the following methods to the **IISCertObj** object: **Copy**, **Export**, **GetCertInfo**, **Import**, **ImportToCertStore**,

**IsExportable**, **IsInstalled**, **Move**, and **RemoveCert**.

**Copy**

The **Copy** method allows you to copy a server certificate from one instance of IIS to another and from one computer to another. Use the following syntax with the **Copy** method:

```
Copy bAllowExport, bOverwriteExisting, DestinationServerName,
DestinationServerInstance, DestinationServerUserName, DestinationServerPassword
```

Table 5.12 lists the parameters that the **Copy** method uses.

**Table 5.12 Copy Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| *bAllowExport* | Boolean | Indicates whether the imported server certificate will be exportable (**true**) or not exportable (**false**). |
| *bOverwriteExisting* | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (**true**) or not overwritten (**false**). |
| *DestinationServerName* | String | Specifies the computer name of the server to which the server certificate will be moved. |
| *DestinationServerInstance* | String | Specifies the IIS metabase instance at which the server certificate will be pointed. For example, w3svc/1. |
| *DestinationServerUserName* | String | Specifies the user name for the destination server. If empty, the user name of the user who is currently logged on will be used. |
| *DestinationServerPassword* | String | Specifies the password for the destination server when the *DestinationServerUserName* parameter is used. |

**Export**

The **Export** method exports a copy of a server certificate to a file. The target file can be on a local or remote computer. Use the following syntax with the **Export** method:

```
Export FileName, Password, bPrivateKey, bCertChain, bRemoveCert
```

Table 5.13 lists the parameters that the **Export** method uses.

**Table 5.13 Export Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| *FileName* | String | Specifies the name of the targeted file. For example, C:\Mydir\Mycert.pfx. |
| *Password* | String | Specifies the password that is used to secure the file specified as *FileName*. |
| *bPrivateKey* | Boolean | Indicates whether the private key is exported (**true**) or not exported (**false**). |
| *bCertChain* | Boolean | Indicates whether the certificate trust chain is exported (**true**) or not exported (**false**). |
| *bRemoveCert* | Boolean | Indicates whether the binding of a server certificate is removed (**true**) or not removed (**false**). |

**GetCertInfo**

The **GetCertInfo** method allows you to acquire information on a server certificate that is installed on the computer specified by the **IISCertObj** properties, **ServerName** and **InstanceName**.

The **GetCertInfo** method uses no parameters.

**Import**

The **Import** method imports a copy of a server certificate from a file to a local or remote computer. Use the following syntax with the **Import** method:

```
Import FileName, Password, bAllowExport, bOverwriteExisting
```

Table 5.14 lists the parameters that the **Import** method uses.

**Table 5.14 Import Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| *FileName* | String | Specifies the name of the server certificate file to import. |
| *Password* | String | Specifies the password that is used to secure the file specified as *FileName*. |
| *bAllowExport* | Boolean | Indicates whether the imported server certificate is exportable (**true**) or not exportable (**false**). |
| *bOverwriteExisting* | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (**true**) or not overwritten (**false**). |

**ImportToCertStore**

The **ImportToCertStore** method imports a copy of a server certificate from a file to the certificate store on a local or remote computer. Use the following syntax with the **ImportToCertStore** method:

```
ImportToCertStoreFileNamePasswordbAllowExportbOverwriteExisting
```

Table 5.15 lists the parameters that the **ImportToCertStore** method uses.

**Table 5.15 ImportToCertStore Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| *FileName* | String | Specifies the name of the server certificate file to import. |
| *Password* | String | Specifies the password that is used to secure the file specified as *FileName*. |
| *bAllowExport* | Boolean | Indicates whether the imported server certificate is exportable (**true**) or not exportable (**false**). |
| *bOverwriteExisting* | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (**true**) or not overwritten (**false**). |

**IsExportable**

The **IsExportable** method allows you to determine whether a server certificate is exportable from a computer that is specified by the IIS **ServerName** and **InstanceName** properties.

The **IsExportable** method uses no parameters.

**IsInstalled**

The **IsInstalled** method allows you to determine whether a server certificate is installed on a computer that is specified by the **IISCertObj** properties, **ServerName** and **InstanceName**.

The **IsInstalled** method uses no parameters.

**Move**

The **Move** method allows you to move a server certificate from one instance of IIS to another, and from one computer to another. Use the following syntax with the **Move** method:

```
Move bAllowExport, bOverWriteExisting, DestinationServerName,
DestinationServerInstance, DestinationServerUserName, DestinationServerPassword
```

Table 5.16 lists the parameters that the **Move** method uses.

**Table 5.16 Move Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| *bAllowExport* | Boolean | Indicates whether the imported server certificate is exportable (**true**) or not exportable (**false**). |
| *bOverWriteExisting* | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (**true**) or not overwritten (**false**). |
| *DestinationServerName* | String | Specifies the computer name of the server to which the server certificate will be moved. |

| | | |
|---|---|---|
| *DestinationServerInstance* | String | Specifies the IIS metabase instance at which the server certificate will be pointed. For example, w3svc/1. |
| *DestinationServerUserName* | String | Specifies the user name for the destination server. If no user name is entered, the user name of the user that is currently logged on will be used. |
| *DestinationServerPassword* | String | Specifies the password for the destination server when the *DestinationServerUserName* parameter is used. |

**RemoveCert**

The **RemoveCert** method allows you to delete a server certificate from a certificate store. Use the following syntax with the **RemoveCert** method:

```
Copy bRemoveFromCertStore, bPrivateKey
```

Table 5.17 lists the parameters that the **RemoveCert** method uses.

**Table 5.17 RemoveCert Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| *bRemoveFromCertStore* | Boolean | Indicates whether the server certificate is removed (**true**) or not removed (**false**). |
| *bPrivateKey* | Boolean | Indicates whether the private key of the server certificate is removed (**true**) or not removed (**false**). |

**Sample Server Certificate Management Scripts**

In IIS, if you use Windows Script Host or ASP, you can execute scripts that communicate with **IISCertObj** programmatically to import, archive, or export server certificates.

**Importing server certificates to multiple servers**

Large sites often need to use one server certificate for user logon to multiple servers. It would be time-consuming to use the Microsoft Management Console (MMC) to add copies of the server certificate to each server. By using the **Import** method of **IISCertObj**, you can install copies of the same server certificate on all of the targeted servers.

To import a server certificate from a certificate store on one server to other servers, first save the following script in your text editor as CertImport.vbs.

**Important**

You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /User:***MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters).

```
Option Explicit
Dim iiscertobj, pfxfile, pfxfilepassword, InstanceName, WebFarmServers, IISServer
Set iiscertobj = WScript.CreateObject("IIS.CertObj")
pfxfile = WScript.Arguments(0)
pfxfilepassword = WScript.Arguments(1)
InstanceName = WScript.Arguments(2)
WebFarmServers = split(WScript.Arguments(3), ",")
iiscertobj.UserName = WScript.Arguments(4)
iiscertobj.UserPassword = WScript.Arguments(5)
For Each IISServer in WebFarmServers
  iiscertobj.ServerName = IISServer
  iiscertobj.InstanceName = InstanceName
  iiscertobj.Import pfxfile, pfxfilepassword, true, true
Next
```

After you save the script as CertImport.vbs, run this command:

```
Certimport.vbs cert.pfx pfxPassword w3svc/1 iisserver1,iisserver2,iisserver3
Administrator aal34290
```

**Saving backup copies of server certificates in a central archive**

Using the **Export** method of **IISCertObj**, you can archive a backup of each server certificate on your server farm to a central site.

To export copies of server certificates to the central site, first save the following script in your text editor as Save_all_certs.vbs.

```
Option Explicit
Dim iiscertobj, targetServer, targetServers, pfxbasename, pfxpassword, InstanceName
Set iiscertobj = WScript.CreateObject("IIS.CertObj")
pfxbasename = WScript.Arguments(0)
pfxpassword = WScript.Arguments(1)
InstanceName = WScript.Arguments(2)
targetServers = split(WScript.Arguments(3), ",")
iiscertobj.UserName = WScript.Arguments(4)
iiscertobj.UserPassword = WScript.Arguments(5)
iiscertobj.InstanceName = InstanceName
For Each targetServer in targetServers
  iiscertobj.ServerName = targetServer
  iiscertobj.Export pfxbasename + targetServer + ".pfx", pfxpassword, true, false,
false
Next
```

After you save the script as Save_all_certs.vbs, run this command:

```
Save_all_certs.vbs C:\certbackup\ pfxpassword w3svc/1 iisserver2,iisserver3,iisserver4
Administrator aal34290
```

**Copying a server certificate from an existing server to a new server**

Using the **Copy** method of **IISCertObj**, you can copy a server certificate to a new server after you add the server to a server farm.

To copy a server certificate from an existing server to a new server, first save the following script in your text editor as Certcopy.vbs.

```
Option Explicit
Dim iiscertobj, targetServer, targetServers, targetInstance
Set iiscertobj = WScript.CreateObject("IIS.CertObj")
iiscertobj.ServerName = WScript.Arguments(0)
iiscertobj.Instancename = WScript.Arguments(1)
targetServers = split(WScript.Arguments(2), ",")
targetInstance = WScript.Arguments(3)
iiscertobj.UserName = WScript.Arguments(4)
iiscertobj.UserPassword = WScript.Arguments(5)
For Each targetServer in targetServers
  iiscertobj.Copy true, true, targetServer, targetInstance
Next
```

After you save this script as Certcopy.vbs, run this command:

```
Certcopy.vbs iisServer1 w3svc/1 iisServer2 w3svc/1 Administrator asdf-0324
```

Listing 5.4 provides a customizable text file that you can use to import a certificate from a .pfx file and assign it to the desired site.

| **Important** |
| --- |
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /***User:MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

# Server-Gated Cryptography

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Server-Gated Cryptography (SGC) offers financial institutions a solution for worldwide financial transactions by using 128-bit encryption. SGC is an extension of SSL that enables financial institutions with export versions of IIS to use strong encryption.

SGC does not require an application to run on the client browser and will enable export clients to connect with 128-bit strength. Although SGC capabilities are built into IIS 4.0, 5.0, and 6.0, an SGC certificate is required to use SGC. Contact your CA for availability information.

If you want to support clients that run software without strong encryption support, you need only SGC certificates. On January 14, 2000, the United States government eliminated the remaining export controls for most computer hardware and software products that incorporate *strong encryption*, which was defined as products that implemented symmetric key encryption with key lengths of over 64 bits. Windows 2000 Server was the first platform to be shipped internationally under the new regulations with 128-bit+ encryption. For information about United States export regulations, see United States Commerce Department Bureau of Industry and Security. For more information about exporting Microsoft products, see Exporting Microsoft Products.

| **Note** |
| --- |
| If you are running Windows 2000 and you open your SGC certificate, you might receive the following notice on the **General** tab: **"The certificate has failed to verify for all its intended purposes."** This notice is issued because of the way SGC certificates interact with Windows 2000 Server and does not necessarily indicate that the certificate does not work correctly. |

# Cryptographic Service Provider

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Cryptographic service provider (CSP) allows you to select a Microsoft or third-party cryptographic provider to handle cryptography and certificate management. Each cryptographic provider can create a public and private key to encrypt the data that is sent to and from the Web server. The private key is stored at the server on hardware, on a Peripheral Component Interconnect (PCI) card, on a smart card, or in the registry, as it is for the two default providers that Microsoft installs: Microsoft DH SChannel Cryptographic Provider and Microsoft RSA SChannel Cryptographic Provider.

IIS certificate storage is now integrated with the Microsoft Cryptographic API (Crypto API). The Crypto API contains identical methods and properties for every cryptographic provider. This allows you to switch between cryptographic providers without having to rewrite code.

# Client Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Client certificates are electronic documents that contain information about clients. These certificates, like server certificates, contain not only this information but also public encryption keys that form part of the SSL security feature of IIS. The public keys, or encryption codes, from the server and the client certificates facilitate encryption and decryption of transmitted data over an open network, such as the Internet.

The typical client certificate contains several items of information: the identity of the user, the identity of the certification authority, a public key that is used for establishing encrypted communications, and validation information, such as an expiration date and serial number. Certification authorities offer different types of client certificates, which contain differing amounts of information, depending on the level of authentication that is required.

Your Web server cannot process client certificates unless you have previously installed a server certificate and enabled your server's communication securityfeatures.

# Obtaining Client Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can obtain a client certificate from a trustworthy, third-party organization, called a *certification authority* (CA). Before issuing a certificate, the CA might need to verify your identity. The identification information required by the CA varies, depending on the type of certificate that you want to obtain. How these certificates are obtained and implemented depends upon the browser that is being used.

When you choose a CA to issue client certificates, consider the following questions:

- Is the CA a well-known and trusted organization?
- What kind of information will the CA require from you to verify your identity? Most CAs require you to provide detailed identifying information, such as your name, address, organization name, and e-mail address.
- Does the CA have a Web site you can use to request your client certificate?
- Are the certificates issued by the CA compatible with your browser and server?

# Enabling Client Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can require users attempting to access your Web site to log on with a client certificate. Requiring a client certificate, however, does not reliably protect your content from unauthorized access. Any user with a valid and trusted client certificate can establish a connection and access your resource. To protect your Web content from unauthorized access you must do one of the following:

- Use Basic, Digest, or Integrated Windows authentication, in addition to requiring a client certificate.
- Create a Windows account mapping for client certificates. For more information, see Mapping Client Certificates to User Accounts in IIS 6.0.

When you attempt to set properties for a specific Web site, your Web server prompts you for permission to reset the properties of individual directories and files in the Web site. If you choose to reset these properties, your previous settings are replaced by the new settings. This is also true when you are setting properties for a directory containing subdirectories or files with previously set security properties.

# Client Certificate Mapping

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can authenticate users who log on with a client certificate by creating *mappings*, which relate the certificate information to a Windows user account. After you create and enable a certificate mapping, each time a user logs on with a client certificate, your Web server automatically associates that user with the appropriate Windows user account. This way, you can automatically authenticate users who log on with client certificates, without requiring the use of other supported authentication methods such as Basic, Digest, or Integrated Windows authentication. There are three ways to map client certificates: Directory Service (DS) mapping, one-to-one mapping, and many-to-one mapping.

**Directory Service Mapping**
*Directory Service (DS) certificate mapping* uses native Windows Active Directory features to authenticate users with client certificates. There are advantages and disadvantages to using DS mapping. For example, an advantage is that the client certificate information is shared across many servers. A disadvantage, however, is that wildcard matching is not as advanced as it is in the IIS mapper.

You can enable DS mapping only at the **Master** properties level, and only if you are a member of a Windows domain. Activating DS mapping will exclude the use of one-to-one and many-to-one mapping for the entire World Wide Web Publishing Service (WWW service).

**One-to-One Mapping**
*One-to-one mapping* maps individual client certificates to accounts. The server compares the copy of the client certificate it holds with the client certificate that is sent by the browser. The two must be absolutely identical for the mapping to proceed. If a client gets another certificate containing all of the same user information, it must be mapped again.

**Many-to-One Mapping**
*Many-to-one mapping* uses wildcard matching rules that verify whether a client certificate contains specific information, such as issuer or subject. This mapping does not compare the actual client certificate, but rather accepts all client certificates that fulfill the specific criteria. If a client gets another certificate containing all of the same user information, the existing mapping will work.

# Mapping Strategies

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Client certificate mapping is very flexible because any of the three mapping methods can be used to map client certificates to user accounts. You can map a client certificate to any number of user accounts. Likewise, you can map any number of client certificates to a single user account.

Certificate mapping can be used in several situations, including the following:

- Large Networks. Networks with a large number of client certificates can use many-to-one or Directory Service (DS) mapping. You can create one or more matching rules to map certificates to one or more Windows user accounts.

- Small Networks. Networks with very few users can use one-to-one mapping to provide greater control of certificate usage and revocation, or use many-to-one mapping to facilitate easier administration.

- Additional Security. For resources that have few users and that require additional security, you can use one-to-one mapping. In this way, you can be sure that only selected certificates are used. This allows more stringent certificate revocation policies to be enforced.

- Internet. Internet sites that use certificate authentication can use many-to-one mapping by accepting a wide range of certificates and mapping them all to an account with rights that are similar to the IUSR_*ComputerName* account.

- By certification authority. To map all users who log on with a client certificate that was issued by a particular organization, you can use many-to-one mapping. Then you can define a matching rule that automatically maps any certificate issued by that organization to a user account.

If you are using mapping to integrate your Web sites into a Windows domain, the Windows Directory Service mapper will best suit your purpose. For more information, see "Mapping certificates to user accounts" in Help and Support Center for Windows Server 2003.

# TCP/IP Port Filtering

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*TCP/IP port filtering* is the practice of selectively enabling or disabling Transmission Control Protocol (TCP) ports and User Datagram Protocol (UDP) ports on computers or network devices. When used in conjunction with other security practices, such as deploying firewall software at your Internet access point, applying port filters to intranet and Internet servers insulates those servers from many TCP/IP-based security attacks, including internal attacks by malicious users.

An Internet or intranet host, such as a computer or network device on a TCP/IP-based network, uses a combination of an IP address and port number to communicate with an application or service running on another Internet or intranet host. Together, an IP address and port number make up a *socket*. Because TCP/IP hosts are assigned a unique IP address, and standard TCP/IP-based applications and services typically use a specific TCP or UDP port number, sockets can direct communications between specific applications or services running on specific hosts.

A port number is identified in a TCP or UDP packet header and represents the transport protocol address of a specific application and service that uses TCP or UDP. For example, HTTP services use TCP port 80 by default, Telnet uses TCP port 23 by default, and Simple Network Management Protocol (SNMP) uses UDP port 161 by default.

The Internet Assigned Numbers Authority (IANA) categorizes TCP and UDP ports into three categories. Table 5.18 lists these categories.

**Table 5.18 IANA Categories of TCP and UDP Ports**

| Port Category | Port Number | Range Description |
|---|---|---|
| Well-known ports | 0–1023 | Typically used by standard system processes or programs that are executed by users with administrator credentials. Assigned by IANA. |
| Registered ports | 1024–49151 | Used by ordinary user processes or programs that are executed by ordinary users. IANA does not assign these ports, but registers use of them as a convenience for the TCP/IP community. |
| Dynamic or private ports | 49152–65535 | Unassigned and unregistered ports used for private applications, client-side processes, or other processes that dynamically allocate port numbers. |

Typically, the server side of a TCP or UDP process listens to the associated well-known port number. The client side of the process uses either the well-known port number or, more commonly, a dynamically allocated port number that is assigned only for the duration of the process.

To enable communications with the applications and services that your servers use, you must ensure that the associated ports are enabled. However, because malicious users on your internal network can attempt to exploit enabled ports to attack your servers, you should disable the TCP and UDP ports on your servers that are not used. This reduces the avenues of attack to your servers and improves the security of hosts that connect to your servers.

| **Important** |
|---|
| Server-based port filtering is not the only method you should use to secure your servers and network from TCP/IP-based security attacks. To provide a more complete network security solution, you should also deploy network firewall software at your Internet access point. |

Table 5.19 lists some of the default TCP port numbers for processes that are commonly used with Internet services.

**Table 5.19 TCP Ports and Associated Services**

| Default TCP Port Number | Internet Service |
|---|---|
| 20 | FTP Data Channel |
| 21 | FTP Control Channel |
| 23 | Telnet (enabled on some intranet or Internet servers) |

| | |
|---|---|
| 25 | Simple Mail Transfer Protocol (SMTP) |
| 80 | HTTP for World Wide Web |
| 119 | Network News Transfer Protocol (NNTP) |
| 443 | Hypertext Transfer Protocol over TLS/SSL (HTTPS) for secure World Wide Web |
| 563 | Network News Transfer Protocol over TLS/SSL (NNTPS) |

Notes

- Windows Media Services can provide streaming media services over unicast or multicast IP through a variety of static or dynamic UDP and TCP ports, or through a single port, depending on the configuration. You can also configure Windows Media Services to provide HTTP streaming media services through the default HTTP port, which is TCP port 80. For more information about Windows Media Services, see Help and Support Center for Windows Server 2003, and search for Using Windows Media Services.

- SSL 3.0 and Transport Layer Security (TLS) provide a way for clients and servers to exchange encrypted information. SSL 3.0 and TLS also provide a way for the server to verify the identity of the client before a user logs on to a server.

Table 5.20 lists the well-known UDP port numbers for the processes that are commonly used with Internet services.

**Table 5.20 UDP Ports and Associated Services**

| UDP Port Number | Service |
|---|---|
| 53 | DNS name queries (supports some Internet services) |
| 161 | SNMP |

For a list of TCP and UDP port numbers that are used by Windows Server 2003, see the services.txt file in the *systemroot*\System32\Drivers\Etc folder.

**Related Information**

For more information about network firewalls, see Microsoft Internet Security and Accelerations Server.

# Using Isolation to Secure Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Network Service built-in user account is the default worker process identity for application pools in IIS 6.0. You can have more than one application pool running with this process identity. However, if you use the Network Service account to configure ACLs on application pool resources, every application pool will then have access to every other application pool's resources.

**Configuring an Application Pool Identity to Isolate Applications**
To isolate applications effectively, each application pool should have its own account identity. That account identity must be added to the IIS_WPG local group so the account can launch the worker process associated with the application pool. However, you should not use the IIS_WPG group itself to configure ACLs on content files and directories. In addition, if you configure any accounts to be used either for anonymous access or for site authors or owners, you should not add them to the IIS_WPG group. Doing so would give those accounts access to directories that are shared among application pools, such as the compression cache and the ASP template cache. For more information about configuring an application pool identity, see Configuring Application Pool Identity in IIS 6.0.

To configure applications with a high level of isolation, create a unique user account for anonymous access, and then make this account the anonymous user account for your Web site. For step-by-step instructions, see Changing the Account Used for Anonymous Authentication. A unique anonymous user identity combined with a designated account for the application pool identity provides two of the essential elements needed for constructing an effective security boundary for the application. In addition, having a unique anonymous user identity allows you to configure authorization so that applications launched by the anonymous user can access only the required resources.

**Configuring Authorization to Isolate Applications**
Authorization uses the authenticated identity of the user, including the anonymous user, to limit access to resources. In this context, an application pool identity can be considered a user. You can use the application pool identity to configure ACLs to file system resources, the IIS metabase, and registry keys.

Use an ACL to permit or deny specific users access to an application's directories and files. When you configure ACLs on content, use groups to contain application pool identities and assign ACLs to those groups. Your groups can represent various user functions or actions, such as authoring or anonymous access, or specific permissions such as Browse or Read. Then, assign NTFS permissions to file system resources to allow permissions where the application pool identity requires access, for example, logging directories or script caches.

Use the Metabase Explorer tool in the IIS 6.0 Resource Kit Tools or the Meta-Data Edit Tool to view and set ACLs on metabase keys. Default ACLs on application pools give the IIS_WPG, Network Service, and Local System accounts the ability to query metabase properties for all application pools. You can increase isolation by:

- Removing metabase entries for IIS_WPG.
- Assigning the application pool identity Read permission.
- Assigning any Web site author or administrators Read permission.
- Giving the Administrators group and any other system administrators Full Control.

To configure ACLs on registry keys, you can use templates from the Windows Server 2003 Security Guide to restrict permissions on the registry. In addition, you can specifically restrict access to portions of the registry that contains information about Component Object Model (COM) objects used by your applications.

For more information about isolating applications, see Configuring Application Isolation using Windows Server 2003 and IIS 6.0.

# Secure Code

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

No matter how strong the security of your server is, if the applications that it hosts are not programmed according to best security practices, your network might be vulnerable to attacks. As part of a defense-in-depth strategy, IIS administrators should work with developers to ensure that the code hosted on the server running IIS is as secure as possible. For example, developers can reduce the risk of certain types of attacks, such as cross-site scripting and SQL injection, by validating user input.

*Cross-site scripting* occurs when an attacker sends a link in e-mail to a user or otherwise points the user to a Web site, and the link actually contains malicious script code, which can be VBScript or JScript. As a result of cross-site scripting, an attacker potentially can perform such actions as reading cookies, instantiating browser plug-ins or native code and scripting it with untrusted data, and intercepting user input. Potential targets are any browsers that support scripting and any Web servers that support HTML forms.

In a *SQL-injection attack*, an attacker finds a way to modify a SQL command that is used in a dynamic Web page. The attacker typically crafts user input in a way that modifies the logic of the SQL command, so that the attacker is able to obtain information that would otherwise be unavailable.

Developers who write the applications that are hosted on your Web site must know how to include safeguards against these types of attacks. It is paramount that all user input be validated thoroughly. The book *Writing Secure Code* covers these and other Web application security issues in depth. For more information about *Writing Secure Code*, see Additional Resources for IIS 6.0 Security.

# MIME Types

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To reduce the available attack surface, IIS serves only a small number of default static file types unless you add an approved extension to the MIME types list in IIS Manager. MIME types instruct a browser or mail application about how to handle the files received from a server. For example, when a browser requests an item on a server, the browser also requests the MIME type of the object. When IIS delivers a Web page to a client browser, IIS also sends the MIME type of the data it is sending. If there is an attached or embedded file in a specific format, IIS also tells the client application the MIME type of the embedded or attached file. The client application then knows how to process or display the data being received from IIS.

A MIME type consists of two required parts (the media-type and sub-type) and one optional part (the parameter-list) in the following format:

```
media-type/sub-type;parameter-list
```

| **Important** |
| --- |
| IIS does not support the optional parameter-list. Instead, IIS attempts to match the entire string that follows the media-type/. |

Known extensions are handled somewhat differently for static pages and for dynamic content, but you can add, change, or remove allowable extensions for both static and dynamic content. For more information about enabling dynamic content, see Enabling Dynamic Content.

If a user requests a file with an extension that is not permitted, the user receives a 404 error (File not found), rather than a 403 error (Access is denied). This reduces the amount of information that is supplied to a would-be attacker. For more information about interpreting substatus error codes, see Analyzing Log Files.

**Inheritance and Merge Behavior**

IIS merges the MIME type mappings that it finds on different levels into one in-memory representation. For example, when IIS receives a request, it searches for the **MimeMap** property for the level, such as lm/w3svc/1/root/MimeMap, and the closest inherited level. If the MIME type for an extension is not in the resulting array, IIS looks for the MIME type in the registry (HKEY_CLASSES_ROOT*extension*). If no matching MIME type is found, IIS can use a wildcard mapping if one is configured. Otherwise, the user receives a 404 error. The default wildcard for IIS is .*, application/octet-stream.

| **Important** |
| --- |
| Using a wildcard mapping can pose a security risk, and is recommended for troubleshooting only. By default, wildcard mapping is not configured in IIS, and only extensions that are defined at the **MimeMap** node in the IIS metabase are served. |

If you use IIS Manager to remove a MIME type mapping, you must also verify that the MIME type does not exist in the registry. If the MIME type continues to exist in the registry, files with that extension continue to be served. Be aware, however, that removing MIME type mappings from the registry may affect other applications, because the registry database is shared by multiple applications.

**Merge considerations**

When you configure MIME types, be aware of the restrictive MIME merge behavior of IIS 6.0. Values that are set on nodes are inherited by default by child nodes, but values that are set on child nodes do not propagate back up to parent nodes. For example, if you allow the .ini MIME type on *LocalComputer*/Directory, but you do not allow this MIME type on the root directory, users might not receive the files that you expect. In this situation, if a user requests http://server/directory/default.ini, the user receives the file. However, if the user requests http://server/default.ini, the user does not receive the file because IIS uses the **MimeMap** property for *LocalComputer*/Directory and does not merge it with entries in *LocalComputer*/Root. Instead, the user receives a 404 error.

# Auditing Server Activity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can use security auditing techniques to monitor a broad range of user and Web server security activity. You should routinely audit your server configuration to detect areas where resources might be susceptible to unauthorized access and tampering. For example, you can audit the following user activities:

- Logon attempts, both successful and unsuccessful
- Attempts to access restricted accounts
- Attempts to execute restricted commands

You can use the integrated Windows utilities, or the logging features built into IIS, or use Active Server Pages (ASP) applications to create your own auditing logs.

# Standards Implemented

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Many of the security features in IIS implement Internet community standards. These standards help to facilitate uniformity and cross-platform utilization of applications and information. Microsoft is committed to working with the Internet and computer communities both in assisting to structure good standards, but also in its implementation of those standards. The following standards are implemented by IIS security features:

- Secure Sockets Layer (SSL) 3.0. SSL 3.0 is a public key-based security protocol implemented by the Secure Channel (Schannel) security provider. SSL security protocols are used widely by Internet browsers and servers for authentication, message integrity, and confidentiality.

- Basic authentication. This authentication method is a part of the HTTP 1.1 protocol, as defined in RFC 2617 HTTP Authentication: Basic and Digest Access Authentication, and sends passwords over networks in Base64 encoded format. Most browsers support this specification.

- Digest authentication. This authentication method uses the MD5 message-digest algorithm as defined in RFC 1321, The MD5 Message-Digest Algorithm, and sends authentication information over networks as a *hash* and is compatible with proxy servers.

- Public-Key Cryptography Standard (PKCS) #7. This security standard describes the format of encrypted data such as digital signatures or digital envelopes that contain information. Both of these are involved in the certificate features of IIS.

- PKCS #10. This security standard describes the format of requests for certificates that are submitted to certification authorities.

# Additional Resources for IIS 6.0 Security

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to Managing a Secure IIS 6.0 Solution.

**Related Information**

# Optimizing IIS 6.0 Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you monitor your application servers to maintain a baseline of performance data, you can spot performance trends as they develop, take steps to prevent unsatisfactory performance, decide how to best tune or upgrade your servers, and determine whether your changes are beneficial. By tuning your Internet Information Services (IIS) version 6.0 application servers, you improve the client experience, help avoid bottlenecks, and can extend the interval between hardware upgrades.

**In This Section**

Overview of Performance Monitoring and Tuning

Controlling Memory Usage

Preventing Processor Bottlenecks

Improving Application Performance

Balancing Performance and Security

Optimizing Performance Through Design

Additional Resources for IIS 6.0 Performance

# Overview of Performance Monitoring and Tuning

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Performance monitoring* is the process of capturing and analyzing performance data from different areas of your server environment, which include applications, memory, processors, hardware, and your network. You obtain performance data to help you recognize trends as they develop, prevent unsatisfactory performance, and optimize the use of your system resources. Monitoring also helps you decide when to upgrade your hardware and whether upgrades are actually improving your servers performance.

Although some performance problems and their solutions are immediate and obvious, others develop over time and require careful monitoring and tuning. First, monitor to establish a performance baseline against which to judge and compare the performance of your server; without a baseline, your tuning efforts might not give you optimal performance.

By monitoring performance and analyzing performance data, you can identify performance patterns to help you locate bottlenecks and to identify underused or overused resources. After locating a bottleneck, you can make changes to the component to improve performance. Bottlenecks can occur anywhere in your server environment at any time, so you must regularly monitor performance to capture baseline information about your system.

To get started with performance monitoring, familiarize yourself with the tools used, which include System Monitor, Performance Logs and Alerts, and Network Monitor; with the counters that are available for monitoring performance objects; and with the basics of setting up monitoring in order to collect useful data.

# Using Performance Tools to Obtain a Baseline

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Using the appropriate tools, you can monitor your application server to collect data on performance, make specific changes in order to tune your server and its Web applications, evaluate the results of changes, and plan additional changes to help your application server run optimally. Which tools you should use, and when you should use them, depends on the data you need and your purpose in collecting it.

The Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; or Windows® Server 2003, Web Edition operating system provides the Performance console, which includes System Monitor, Performance Logs and Alerts, and Task Manager. System Monitor and Performance Logs and Alerts are Microsoft Management Console (MMC) snap-ins. In addition, you can access these tools through the **Run** dialog box by using the **perfmon** command.

From the Performance console, you can examine the output of *performance counters*, which monitor the activity of *performance objects*. Each performance counter is named based on the object from which it collects data (for example, a processor, process, or thread) and the type of data that it collects (for example, the Processor\% Processor Time performance counter reports the average percentage of processor time in use for the Processor performance object).

Windows Server 2003 provides several command-line tools that you can use to monitor performance. This section cites two command-line tools for performing event tracing. For more information about using command-line tools to monitor performance, see "Monitoring performance from the command line" in Help and Support Center for Windows Server 2003.

# System Monitor

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

System Monitor enables you to collect and display real-time performance data for a local computer or remote computers according to criteria that you define. System Monitor can also display data that is collected in counter logs.

You can use System Monitor to monitor your server's activity and summarize its performance at selected intervals. You can display performance data in real-time charts or reports, collect data in files, and generate alerts when critical events occur. Use the data to determine the cause of system bottlenecks and to fine-tune system and application performance.

By default, the System Monitor graph is plotted on a scale of 0 through 100. For counters that register small values, you might need to change the scale. When interpreting the counters, remember that most of them show the most recently observed value, not a long-term average. Use Performance Logs and Alerts to log data over time and determine average values.

**Related Information**

For more information about using System Monitor, see Setting Up Monitoring, and "System Monitor overview" in Help and Support Center for Windows Server 2003.

# Performance Logs and Alerts_IIS_SP1_TechRef

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

Use Performance Logs and Alerts to automatically collect performance data in logs and to send alerts based on criteria that you set:

- Create custom log files that automatically log the values for specified counters based on the start and stop times that you provide.
- Set an alert on a counter that defines what action you want the system to take (for example, send an alert, run a program, make an entry in a log file, or initiate logging) when the alert condition is met.
- View counter data during or after collection. After collecting data in logs, use System Monitor to view the data, or export the data to a spreadsheet or database application.

A binary log file format is provided for circular logging or for logging instances, such as threads or processes, that begin after the system starts logging data. (*Circular logging* is the process of continuously logging data to a single file, overwriting previous data with new data.)

| **Note** |
| --- |
| You can also monitor your server by examining IIS logs. For information about IIS logs, see Analyzing Log Files. |

# Task Manager

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use Task Manager to monitor key indicators of your computers performance.

The **Performance** tab displays a dynamic overview of your computers performance, including usage history for CPU and memory; the total number of handles, threads, and processes currently running on the computer; and physical memory, kernel memory, and commit memory usage.

The **Processes** tab shows information about the processes running on your computer. You can select columns to display. For example, display information about CPU and memory usage, page faults, handle count, and a number of other parameters.

# Event Tracing with Log Manager and Trace Report

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A Web request goes through many layers of the operating system, most of which can be tuned. By tracing IIS and kernel events, you can pinpoint Web bottlenecks on the server, and can often determine where to tune your server for improved performance. You can use the trace data with performance monitors, capacity planning tools, and applications that analyze information relating to system resource usage.

Use the Log Manager and Trace Report command-line tools in Windows Server 2003 to collect and report trace data relating to IIS and kernel events:

- Use the Log Manager tool (Logman.exe) to collect trace data for specified IIS and kernel events.
- Then use the Trace Report tool (Tracerpt.exe) to process the event trace log and to generate trace analysis reports and comma-delimited files for the events.

For information about Logman.exe and Tracerpt.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click **Command-line reference A-Z**. For information about using Log Manager and Trace Report with IIS 6.0, including syntax examples and analysis of output reports, see Troubleshooting IIS 6.0 with Tracing.

# Network Monitor_IIS_SP1_TechRef

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

Network Monitor is a useful tool for conducting a network analysis of your Web applications. Use this tool to document the number of roundtrips that are required for a client to download a specific Web page from your server. Make adjustments to your applications, such as the changes recommended in Optimizing Application Design and Administration, and then rerun Network Monitor to verify that the adjustments improved performance.

Network Monitor collects data about the network traffic that flows to and from the network adapter of the computer on which it is installed. By capturing and analyzing that data, you not only can improve performance, you can prevent, diagnose, and solve many types of network problems.

You can configure Network Monitor to provide only the information that is most relevant to you. For example, you can configure *capture triggers*, which cause Network Monitor to start or stop capturing data when a circumstance or set of circumstances occurs, and you can configure *capture filters* to control the types of data that Network Monitor captures or displays.

Network Monitor monitors the frames in which data is sent over the network, which, in addition to the data, contain the addresses of the source and destination computers and the protocols in use.

Because using Network Monitor can affect server performance, you might want to run this tool when usage is low or for short periods during peak usage. Use capture filters so that you collect only the data that you need, then repeat each network capture one or more times to verify that the data you obtained accurately reflects network activity.

# Monitoring with Performance Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Both System Monitor and Performance Logs and Alerts allow you to examine the output of *performance counters*, which monitor the activity of specific *performance objects*. Each performance counter is named for the object for which it collects data and the type of data that it collects. For example, the Processor\% ProcessorTime counter is the primary indicator of processor activity, displaying the average percentage of busy time observed during the sample interval.

A performance object often offers a choice of more than one *instance*. Using the Processor object as an example, if you are monitoring a dual-processor computer, the first processor instance is 0 and the second processor instance is 1. A commonly used instance is the _Total instance, which monitors the sum of the values of a specific counter's instances.

**Components of a counter path**
The counter path contains the computer name, and the performance object, instance, and counter.It is typically represented in the following way:

```
\\ComputerName\Object(Instance)\Counter
```

The computer name is optional. If you do not designate a computer name, the counter monitors the local computer.

Again, using the Processor object as an example, if you want to monitor the percentage of processor time that your #0 processor uses, your selection is represented in the following way:

```
Processor (#0)\% ProcessorTime
```

**Sampling methods for counters**
Performance counters collect and display their data in one of two ways:

- Instantaneous counters. These counters display the most recent measurement of an aspect of resource use. For example, the Process\Thread Count counter shows the number of threads for a particular process as of the last time it was measured. An instantaneous counter might have a name containing the word Current. Unless the server has a steady workload, these counters might not provide meaningful data.

- Averaging counters. Based on the previous two measurements, averaging counters derive an average value for the interval between the measurements. These counters typically calculate a percentage or the number of occurrences per second. For example, the Memory\Pages/sec counter shows the number of memory pages read over the sample interval, divided by the number of seconds in the interval. When you start one of these counters, no value is displayed until the second measurement is taken.

# Counters Provided by Windows and by IIS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003 provides hundreds of counters. Frequently used performance objects include cache, memory, process, and server. For more information about Windows performance objects and counters, see "Performance objects and counters" in Help and Support Center for Windows Server 2003.

When you install IIS, you automatically install the IIS performance counters, which include the following:

- Web Service counters to monitor the World Wide Web Publishing Service (WWW service).
- Web Service Cache counters to monitor the WWW service cache.
- FTP Service counters to monitor the File Transfer Protocol (FTP) service.
- Active Server Pages counters to monitor applications that run as Active Server Pages (ASP pages).

If you use Simple Network Management Protocol (SNMP) services to monitor your Web services, IIS makes available a set of counters by means of SNMP. They include SNMP FTP service counters and SNMP HTTP service counters, which you can use to monitor an SNMP WWW service. However, you cannot view the SNMP counters in System Monitor or Performance Logs and Alerts; you must use Windows Management Instrumentation (WMI) or a management information base (MIB) browser tool instead. For more information about specific IIS counters, including how to locate and view the SNMP counters, see IIS 6.0 Performance Counters.

# Suggested Performance Counters to Watch

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table 6.1 and Table 6.2 list some of the counters that are typically used for monitoring application servers. The tables include the preferred value of each counter and suggest values that might indicate performance problems.

Most of the values provided in this section are relative: Optimal values vary with the Web application, system, and network architecture. For example, data collected by the PhysicalDisk\Avg Disk Bytes/Transfer counter is different for different kinds of controllers and drives. Some counters may not be relevant to your applications. For example, data collected by the Active Server Pages\Transactions/sec counter is not relevant to a Web site with only static content.

In Table 6.1 and Table 6.2, *ComputerName* is omitted to conserve space. For example, the first counter in Table 6.1 is actually *ComputerName*\Memory\Pages/sec.

**Table 6.1 Preferred Values for Frequently Used Performance Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Memory\Pages/sec | 0–20. (Unhealthy if greater than 80; probably indicates not enough RAM.) |
| Memory\Available Bytes | 10% of physical memory. |
| Memory\Committed Bytes | No more than 75 percent of physical memory. |
| Memory\Pool Nonpaged Bytes | A steady value. (A slow rise might indicate a memory leak.) |
| Processor\% Processor Time | Less than 75 percent. |
| Processor\Interrupts/sec | Depends on the processor, and on network hardware and drivers. Up to 3,500 for a 90–megahertz (MHz) Pentium; more than 19,000 for a 500–MHz Pentium or more than 58,000 for a 1.5–gigahertz (GHz) Pentium. Lower is better. If the value is too high, try moving some hardware devices to a different server. |
| Processor\System Processor Queue Length | 4 or less. |
| LogicalDisk\% Disk Time<br><br>PhysicalDisk\% Disk Time | As low as possible. |
| LogicalDisk\Avg. Disk Queue Length<br><br>PhysicalDisk\Avg. Disk Queue Length | Less than 4. |
| LogicalDisk\Avg. Disk Bytes/Transfer<br><br>PhysicalDisk\Avg. Disk Bytes/Transfer | As high as possible. |
| System\Context Switches/sec | Compare this value with the value of Web Service\Total Method Requests/sec. Context switches per request (Context Switches/sec divided by Total Method Requests/sec) should be low. |
| System\System Calls/sec | As low as possible. |

| | |
|---|---|
| Web Service\Bytes Total/sec | As high as possible. |
| Web Service\Total Method Requests/sec | As high as possible. |
| Web Service\Current Connections | As high as possible. |
| Web Service Cache\File Cache Hits % | As high as possible for static content.<br><br>**Note**: This value might be low if the Kernel URI cache hits percentage is high. |
| Web Service Cache\Kernel:URI Cache Flushes | As low as possible, relative to the number of requests.<br><br>**Note**: This number increases every time a file is flushed from the HTTP.sys response cache (HTTP.sys is the kernel-mode device driver in IIS 6.0), which means that the content has not been accessed in the past 2–4 minutes. The only way to decrease this number is to flush the cache less often, although frequent flushing can cause HTTP.sys to use more memory for content that is not being accessed. |
| Web Service Cache\Kernel:URI Cache Misses | As low as possible. (Each request for dynamic content increases the value of the counter by one.) |
| Web Service Cache\Kernel:URI Cache Hits % | As high as possible. (Applies to static unauthenticated content and dynamic content that is marked as cacheable.) |
| Active Server Pages\Request Wait Time | As low as possible. |
| Active Server Pages\Requests Queued | As low as possible. |
| Active Server Pages\Transactions/sec | As high as possible.<br><br>**Note**: ASP transactions degrade overall server performance because each transaction requires interaction with a database. If you are concerned about server performance, use ASP transactions sparingly. |

The counters listed in Table 6.2 are useful for monitoring your FTP servers.

**Table 6.2 Preferred Values for Useful FTP Performance Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| FTP Service\Bytes Sent/sec | As high as possible. |
| FTP Service\Bytes Received/sec | As high as possible. |
| FTP Service\Bytes Total/sec | As high as possible. |

In addition to the counters in Table 6.1 and Table 6.2, the following system counters are useful for monitoring your servers use of system resources:

- System\Threads
- System\Processes
- System\Context Switches/sec

For a discussion of system-related counters and how their data relates to the performance of your Web server, see Identifying Processor Bottlenecks.

# Setting Up Monitoring

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the counters listed in Table 6.1 and Table 6.2 to generate a baseline log that typifies your server's performance under ordinary conditions. Be sure to obtain multiple logs so that your baseline data contains enough information to give you a good sense of your server's behavior. For example, you might log the recommended counters for one week of typical operation. Shorter logs, which you need to periodically create, can help you monitor how changes in network activity are affecting your system performance.

For information about selecting performance objects and counters to view in System Monitor, see Viewing Counter Data in the Performance Console.

# Using the Predefined System Overview Log

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To get started quickly, use the predefined System Overview log that Windows Server 2003 provides under Counter Logs. The System Overview log is configured to create a binary log in the *systemroot*\Perflogs folder that, after manual startup, is updated every 15 seconds until the log reaches a maximum size. To minimize the system resources used during logging, the System Overview log provides *circular logging*, which overwrites older data with new data.

By default, the log includes three counters: Memory\Pages/sec, PhysicalDisk(_Total)\Avg. Disk Queue Length, and Processor(_Total)\% Processor Time.

Interpreting the data from a binary log requires the use of a parser, such as the Log Parser tool (LogParser.exe), to extract the data and convert it to formatted text. You can obtain the Log Parser tool by downloading the IIS 6.0 Resource Kit Tools from the Microsoft Download Center.

For information about creating counter logs, including baseline IIS logs, see Microsoft Knowledge Base article 313064, Monitor Web Server Performance by Using Counter Logs in System Monitor in IIS.

For information about using Performance Logs and Alerts to create custom logs, see the "Performance Logs and Alerts overview" in Help and Support Center for Windows Server 2003. For information about analyzing log data and a list of acceptable values for counters, see "Analyzing performance data" in Help and Support Center for Windows Server 2003.

# Troubleshooting System Monitor when IIS Host Thousands of Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you add IIS Web service counters to a Performance Monitor log, either by right-clicking the System Monitor details pane and clicking **Add Counters** or by clicking the plus sign (+) on the tool bar, Performance Monitor may take a long time to enumerate the list of available instances on the server. If you are hosting a very large number of Web sites, for example more than 20,000, Performance Monitor may appear to stop responding (hang).

To work around this behavior, use Typeperf.exe to display all counters currently available on a particular local or remote computer and then use Logman.exe to create, start, stop, and schedule performance counter trace logs and collections on local and remote systems. For more information about these command line tools, see Help and Support Center.

# Collecting Useful Data

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you set up performance monitoring, keep the following guidelines in mind:

- Be selective when choosing which counters to run, because several counters running at the same time can cause a small decrease in performance and can consume disk space.

- For routine monitoring, start by sampling data every 15 minutes.

- If you are monitoring for a specific problem, try varying the length of the interval until you find the optimal setting for obtaining the data that you need.

  For example, if you are monitoring the activity of a specific process at a specific time, set a frequent update interval; however, if you are monitoring a problem that reveals itself slowly, such as a memory leak, use a longer interval.

- When deciding the logging interval, consider the overall length of time over which you want to monitor.

  For example, you might sample data every 15 seconds for monitoring that is 4 hours or less. If you plan to monitor for 8 hours or more, set an interval longer than 300 seconds.

When you decide to change your system in any way, such as by tuning settings, adding hardware, or upgrading your system, follow these guidelines:

- Always make changes one at a time. Unsatisfactory performance that appears to relate to a single component might be the result of bottlenecks involving multiple components. However, if you make multiple changes simultaneously, it is often impossible to assess the impact of each change. For this reason, even when you are troubleshooting performance problems that involve multiple components, you might need to address each problem individually, making changes one at a time.

- Repeat monitoring after every change. Because tuning one resource can affect other resources, it is recommended that you monitor after every change that you make, being sure to monitor not only the area you changed but also more globally. Unless you monitor after you make a change, you cannot determine whether your change improved performance.

- Review event logs. Sometimes poor or unsatisfactory performance generates output in event logs. Use Event Viewer to monitor events that appear in event logs, such as application, system, and security logs. In addition, IIS logs can provide you with information about your changes. For more information about Event Viewer, see Event Viewer in Help and Support Center for Windows Server 2003. For more information about IIS logs, see Analyzing Log Files.

- Test your changes in a lab. When your changes are significant, test them in a performance lab before making the changes in a production environment.

- Periodically, obtain a new performance baseline. After making several changes, monitor again to update your performance baseline. Compare the new baseline to previous logs to observe the actual effects your changes are having on performance and capacity.

# Managing Network Activity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Creating and maintaining a Web site involves using hardware, software, and network bandwidth to manage network traffic. Servers send out pages in response to requests. In order to issue a request, a browser first establishes a Transmission Control Protocol (TCP) connection with the server and then sends the request through the connection. Network traffic, as the term applies to Web servers, is the mixture of incoming requests and outgoing responses.

Network traffic typically occurs in bursts and clumps that are only partly predictable. For example, many intranet sites have activity peaks at the beginning and end of the day, and around lunchtime. However, the exact size of these peaks varies from day to day, and the actual traffic load changes from moment to moment. There is a direct relationship between the amount of traffic and the network bandwidth needed. *Network bandwidth* is the capacity of the transmission medium stated in bits per second (bps). On computer networks, greater bandwidth means faster data-transfer capability. The more visitors your site has and the larger the pages the site provides, the more network bandwidth your server requires.

# Estimating Bandwidth Requirements and Connection Speed

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Data traveling on a network is split into packets. In addition to the data that it carries, each packet includes about 20 bytes of header information and other network protocol information (this extra information is known as *overhead*). The amount of data in a packet is not fixed, and thus the ratio of overhead to data can vary. Most incoming HTTP requests are small. A typical request (for example, `GET http://www.microsoft.com/default.asp`), including the TCP/IP overhead, consists of no more than a few hundred bytes as it travels across the network.

Overhead can become an important consideration when you are estimating your sites bandwidth requirements and deciding how fast a connection you need. If current usage is close to the limits of your connections capacity, an extra 20 percent for overhead might mean that you need the next faster type of connection.

Think of a server that displays static Hypertext Markup Language (HTML) text-only pages that average 5 kilobytes (KB), which is nearly equivalent to a full page of printed text. The server is connected to the Internet through a DS1/T1 line, which can transmit data at 1.536 megabits per second. Inherent overhead makes it impossible to use the full-rated T1 bandwidth of 1.544 megabits per second. For this 5-KB file, protocol overhead is significant, amounting to about 30 percent of the files size. For larger files, the overhead accounts for a smaller percentage of network traffic.

Table 6.3 shows the traffic generated by a typical request for a 5-KB page. Note that all the figures for overhead are estimates. The precise number of bytes sent varies with each request.

**Table 6.3 Network Traffic Generated by a Request for a 5-KB Page**

| Traffic Type | Bytes Sent |
|---|---|
| TCP connection | 180 (approx.) |
| GET request | 256 (approx.) |
| 5-KB file | 5,120 |
| Protocol overhead | 1,364 (approx.) |
| **Total** | **6,920** |

To calculate the number of bits for this 5-KB page, multiply the total number of bytes sent by 8 bits per byte:

6,920 8 = 55,360

As stated previously, a T1 line can transmit 1.536 megabits per second. Dividing bits per second by bits per page (1,536,000/55,360) indicates a maximum transmission rate of just under 28 pages per second. (Because modems add a start bit and a stop bit to each byte, the transmission rate through a modem is slower than the raw numbers appear to indicate.) For this small text-only page, Table 6.4 shows the relative speed for connections to several types of network interfaces and an estimated page delivery rate for each connection type.

**Table 6.4 Relative Network Interface Speeds to Request a 5-KB Page**

| Connection Type | Connection Speed | 5-KB Pages Sent per Second |
|---|---|---|
| Dedicated PPP/SLIP via modem | 28.8 kilobits per second (Kbps) | About half of 1 page |
| Frame Relay or fast modem | 56 Kbps | Almost 1 page |
| Integrated Services Digital Network (ISDN) | 128 Kbps | Just over 2 pages |
| Typical DSL | 640 Kbps | Almost 11 pages |
| DS1/T1 | 1.536 megabits per second (Mbps) | 26 pages |

| | | |
|---|---|---|
| 10-megabit Ethernet | 8 Mbps (best case) | (Up to) 136 pages |
| DS3/T3 | 44.736 Mbps | 760 pages |
| OC1 | 51.844 Mbps | 880 pages |
| 100-megabit Ethernet | 80 Mbps (best case) | (Up to) 1,360 pages |
| OC3 | 155.532 Mbps | 2,650 pages |
| OC12 | 622.128 Mbps | 10,580 pages |
| 1-gigabit/sec Ethernet | 800 Mbps (best case) | (Up to) 13,600 pages |

If you add a small graphic to the 5-KB page, the results are considerably different. An image, in the form of a .jpg file that appears on-screen as a 1-inch by 2-inch rectangle (the actual physical size depends on monitor settings), takes up about as much disk space as the original text file. Adding one such image file to each page nearly doubles the average page size and also the number of requests that are needed. This increased size reduces the number of pages that the server can send to the Internet on a DS1/T1 line to a maximum of about 15 pages per second, regardless of how fast the computer itself runs.

If a page contains several images, if the images are relatively large, or if the page contains multimedia content, the page can take much longer to download. You can often find simple solutions for improving download time, such as consolidating, removing, sizing down, or compressing images or converting images to a more compact graphics format. You might also connect to the network by using a faster interface (this change can improve performance for the server, but not necessarily for the client, as is discussed later in this section).

A site that serves primarily static HTML pages, especially pages with a simple structure, is likely to run out of network bandwidth before it runs out of processing power. In contrast, a site that performs a lot of dynamic page generation, or that acts as a transaction or database server, uses more processor cycles and can create bottlenecks in its processor, memory, disk, or network.

For more information about how to create more efficient Web pages, see Creating a More Efficient Web Site.

**Browser Download Time**

Up to this point, the bandwidth discussion has focused on the number of pages that a *server* can send in a specified amount of time. The second part of this discussion focuses on how long it takes a *browser* to download a page.

Consider how much time a browser needs to download a page that, including overhead, amounts to 90 KB, which equals about 720 kilobits. If you ignore *network latency*, which is the amount of time required for a packet or signal to travel from one point on a network to another (latency typically adds a few seconds before any of the data arrives), and if everything is working perfectly, a 720-kilobit page downloads over a 28.8-Kbps connection in about 25 seconds. The download takes longer if any blocking or bottlenecks occur at the server, if the network is overloaded and slow, or if the users connection is slower than 28.8 Kbps (due to poor line quality, for example).

If the client computer has a higher bandwidth connection on an intranet, the download time is usually much shorter. If your Web site is on the Internet, however, you cannot count on a majority of users having faster connections.

**Server-Side Request Processing**

It takes about 52 connections at 28.8 Kbps to saturate a DS1/T1 line. Not accounting for delays (which are fairly typical), if no more than 52 clients simultaneously request the page used in the preceding example, and if the server can keep up with the requests, the clients all receive the 90-KB page in the 25 seconds calculated in the example.

If 100 clients simultaneously request that same page, however, the total number of bits to be transferred is 100 737,280 (720 kilobits). It takes between 47 and 48 seconds for that many bits to travel over a DS1/T1 line. When that many bits are involved, the network connection for the server, not the client, becomes the limiting factor.

A DS3/T3 line carries nearly 45 Mbps, about 30 times the capacity of a DS1/T1 line, and it takes more than 1,500 clients at 28.8 Kbps to saturate its bandwidth. Moreover, the increase in download time for each new client is much smaller on a DS3/T3 line. When there are 2,000 simultaneous 28.8-Kbps connections, for example, it still takes less than 33 seconds for a client to download the page.

This example assumes that the server is capable of performing the relevant processing and handling of 2,000 simultaneous connections, which is not the same as handling 2,000 simultaneous users: users occasionally stop to read or think, and typically

spend only a small percentage of their time downloading, except while receiving streaming multimedia content. Because of this difference between users and connections, IIS 6.0 can support more users than the figures appear to indicate. A Web server on a DS1/T1 line can typically handle several hundred users connecting at 28.8 Kbps, and with a DS3/T3 line the number typically climbs to 5,000 or more. Although these numbers are derived from actual servers, you can expect performance to vary with differing content types and user needs, and with the number and type of services that a particular computer is performing.

These network performance differences scale linearly, and the scaling continues at higher data-transfer rates. Two DS3/T3 lines, for example, can serve approximately twice as many clients as one line can, provided that processor power is sufficient to keep up with user demand and no bottlenecks prevent your servers from operating at maximum processing power. Connecting to the network by using a faster interface often resolves any performance problems for the server, but not necessarily for the client, as is shown later in this section.

**Perceived Delay, Acceptable Delay, and Site Performance**

The amount of time in which a user perceives that a Web page appears, known as *perceived delay*, is not identical to the actual time that is required to fully display the page. If the first thing that the user sees when opening a page is a set of buttons that allow further navigation, the user might never know or care that the rest of the page takes longer than a minute to download. If, on the other hand, the page takes longer than a minute to download, and the navigation buttons do not appear until after the rest of the page, users might not wait for the download.

The length of an *acceptable delay* depends partly on the kind of information that the page provides, but no more than 30 seconds is usually considered acceptable. If the information is important, users are more likely, but still reluctant, to wait.

As a best practice, set minimum performance goals that specify the acceptable performance for each of your sites. For example, the managers of certain Microsoft e-commerce Internet sites test their site performance against the following minimum performance goals:

- All pages must load within 10 seconds.
- Average CPU usage for each server must be less than 70 percent.
- Available memory must remain stable throughout the test period.
- The site must maintain 10 customer checkouts per second.

# Monitoring Network Activity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The primary functions of IIS 6.0 are to establish connections for clients, to receive and interpret requests, and to deliver files — all as quickly as possible. The pace at which these vital functions are performed depends, in large part, on two factors: the effective bandwidth of the link between the server and the network, and the capacity of this link and the server to support network resources.

The speed of the network interfaces also affects the pace. Some servers have two or more network interfaces, which are frequently called front-end and back-end servers. *Front-end servers* are client-accessible Web servers that run application server software, such as IIS, to handle traffic coming from the Internet. Front-end servers can add a layer of protection for your *back-end servers*, which include database servers, file servers, domain controllers, and WINS servers. Different interfaces do not necessarily run at the same speed. This is the case, for example, if a Web server is connected to a database server by means of a private network.

If more bandwidth is needed, the network must be upgraded or — in the case of shared-resource networks such as Ethernet — the network must be broken into subnets.

**Bandwidth and Capacity**

The main purpose of most Web servers is to manage input/output (I/O): Requests come in, and pages go out. Handling I/O requires a certain amount of bandwidth and other server resources as well. In addition to IIS 6.0, network I/O involves TCP/IP, which is implemented by Windows Server 2003 TCP/IP.

Network capacity is measured, in part, by the number of connections that the server establishes and maintains. Bandwidth is measured in several ways:

- By the rate at which bytes are transferred to and from the server.
- By the rate at which the server sends data packages, which include frames, packets, segments, and datagrams.
- By the rate at which the server sends and receives files.

Effective bandwidth varies widely and depends upon the transmission capacity of the link, the server configuration, and the server workload. The values for a single server also change as it operates in response to demand and to competition for shared network resources.

To ensure that your network has sufficient bandwidth and capacity for the network activity it must support, monitor the following performance indicators:

- Data transmission rates at the different Open Systems Interconnection (OSI) layers, because the components that transmit data reside in different layers.
- File transfer rates, because a Web page often requires multiple file transfers.
- TCP connections, because a plateau in connections established, or increases in connection failures and connection resets, can indicate insufficient bandwidth.

# Monitoring Data Transmission Rates at Different OSI Layers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The simplest measure of the effective bandwidth of a server is the rate at which the server sends and receives data. System Monitor displays counts of data transmissions that are collected by many components of the server computer.

The components that collect data reside in different layers of the OSI reference model:

- Counters on the Web, FTP, and Simple Mail Transfer Protocol (SMTP) services performance objects measure data transmitted at the OSI application layer.
- Counters on the TCP object measure data transmitted at the transport layer.
- Counters on the IP object measure data at the network layer.
- Counters on the Network Interface object measure data at the data-link layer.

As a result of their different positions in the OSI stack, the counters collect different data. For example, the counters at the application layer measure data in the form in which the application sends it, counting the bytes sent before the data is divided into packets and prefixed with protocol headers and control packets. Counters at the application layer do not include retransmitted data.

In addition, the counters display the data in units native to the component being measured. For example, the Web Service object displays data in bytes, and the TCP object displays data in segments.

For more information about TCP/IP and about the OSI reference model, see Additional Resources for IIS 6.0 Performance.

Tables 6.5 through 6.8 list and describe some of the counters that can be used to measure transmission rates. These counters display the transmission rates observed during the last sample interval; they do not display a rolling or cumulative average of the rate.

**Counters for Monitoring Data Transmission Rates at the Application Layer**

Table 6.5 lists counters at the application layer. As with all the Web Service counters, these collect data that shows the rate at which the WWW service (a user-mode service) is sending and receiving bits. These counters do not measure the transmittal rates for HTTP.sys.

**Table 6.5 Counters for Measuring Data Transmission Rates at the Application Layer**

| Object\Counter | Value |
|---|---|
| Web Service\Bytes Sent/sec | The rate at which the WWW service is sending data, in bytes per second. |
| Web Service\Bytes Received/sec | The rate at which the WWW service is receiving data, in bytes per second. |
| Web Service\Bytes Total/sec | The rate at which the WWW service is sending and receiving data, in bytes per second (the sum of Web Service\Bytes Sent/sec and Web Service\Bytes Received/sec). |
| FTP Service\Bytes Sent/sec | The rate at which the FTP service is sending data, in bytes per second. |
| FTP Service\Bytes Received/sec | The rate at which the FTP service is receiving data, in bytes per second. |
| FTP Service\Bytes Total/sec | The rate at which the FTP service is sending and receiving data, in bytes per second (the sum of FTP Service\Bytes Sent/sec and FTP Service\Bytes Received/sec). |

| | |
|---|---|
| SMTP Server\Bytes Sent/sec | The rate at which the SMTP server is sending data, in bytes per second. |
| SMTP Server\Bytes Received/sec | The rate at which the SMTP server is receiving data, in bytes per second. |
| SMTP Server\Bytes Total/sec | The rate at which the SMTP server is sending and receiving data, in bytes per second (the sum of SMTP Service\Bytes Sent/sec and SMTP Service\Bytes Received/sec). |

**Analyzing the data**

The IIS 6.0 service counters listed in Table 6.5 display the number of bytes transmitted on behalf of each service that runs on the server. To calculate the total number of bytes sent or received by all IIS 6.0 services, calculate the sum of the values for each service. To determine the proportion of bytes transmitted by each service, compute the ratio of bytes for one service to the sum of bytes for all services or for the network.

Data collected by the IIS 6.0 service counters underestimates the total number of bytes that the IIS 6.0 services actually transmit to the network. Because these values are collected at the application layer, they measure data only. They do not measure protocol headers, control packets, or retransmitted bytes. In general, the bytes counted by the services represent 60 to 70 percent of the total number of bytes transmitted by the services on the network. If the sum of bytes for all services accounts for two-thirds or more of total network bandwidth, you can assume that your network is running at or near the total capacity of its communications link.

If you are using bandwidth throttling to limit the amount of bandwidth that the WWW service or an individual Web site uses, or you want to evaluate whether bandwidth throttling might be useful, monitor the Web Service\Bytes Total/sec and the Web Service\Bytes Sent/sec counters. These counters can indicate whether your Web server has sufficient bandwidth to handle its load. If it does not, consider using bandwidth throttling to redistribute network availability.

For information about using bandwidth throttling, see Throttling Bandwidth to Manage Service Availability.

**Counters for Monitoring Data Transmission Rates at the Transport and Network Layers**

Table 6.6 lists the counters on the TCP object. These counters monitor *TCP segments* — the unit of data that TCP sends down the protocol stack to IP. Windows Server 2003 provides two TCP objects, TCPv4 and TCPv6. Choose the counter that monitors the version of TCP that your server uses.

**Table 6.6 Counters for Measuring Data Transmission Rates at the Transport Layer**

| Object\Counter | Value |
|---|---|
| TCPv4\Segments Sent/sec<br><br>TCPv6\Segments Sent/sec | The rate at which TCP segments are sent by using the TCP protocol. |
| TCPv4\Segments Received/sec<br><br>TCPv6\Segments Received/sec | The rate at which TCP segments are received by using the TCP protocol. |
| TCPv4\Segments/sec<br><br>TCPv6\Segments/sec | The rate at which TCP segments are sent and received by using the TCP protocol (the sum of Segments Sent/sec and Segments Received/sec). |
| TCPv4\Segments Retransmitted/sec<br><br>TCPv6\Segments Retransmitted/sec | The rate at which segments are transmitted that contain one or more bytes that TCP recognizes as having been transmitted before. Segments Retransmitted/sec is a subset of Segments Sent/sec and Segments/sec. To determine the proportion of transmissions caused by failed transmission attempts, divide Segments Retransmitted/sec by Segments Sent/sec. |

Table 6.7 describes lists some of the datagram counters for the IP object. These counters monitor *IP datagrams*, which are the units of data that IP sends down the protocol stack to the network interface, such as a network adapter. The sum of IP\Datagrams/sec and IP\Datagrams Forwarded/sec represents the rate at which the server handles all IP datagrams.

**Table 6.7 Counters for Measuring Data Transmission Rates at the Network Layer**

| Object\Counter | Value |
|---|---|

| | |
|---|---|
| IPv4\Datagrams Sent/sec<br><br>IPv6\Datagrams Sent/sec | The rate at which IP datagrams are sent to the network interfaces. This counter does not include datagrams forwarded to another server. |
| IPv4\Datagrams Received/sec<br><br>IPv6\Datagrams Received/sec | The rate at which IP datagrams are received from the network interfaces. This counter does not include datagrams forwarded to another server. |
| IPv4\Datagrams/sec<br><br>IPv6\Datagrams/sec | The overall transmission rate for IP datagrams being sent and received over the network interfaces (the sum of IP\Datagrams Sent/sec and IP\Datagrams Received/sec). |
| IPv4\Datagrams Forwarded/sec<br><br>IPv6\Datagrams Forwarded/sec | The rate, in incidents per second, at which the server attempts to find routes over which to forward IP datagrams to their final destination. |

**Analyzing the data**

Counters on the TCP and IP performance objects display the rate at which data is sent and received over a TCP/IP connection at the transport and network layers, but the rate is not expressed in bytes. Counters on the IP performance object display data in datagrams, and counters on the TCP performance object display data in segments. It is difficult to convert segments to bytes because bytes per segment can vary from 8 KB to 64 KB (the size can increase to 1 gigabyte [GB] if a window scaling option is in effect), depending upon the size of the TCP/IP receive window and the maximum segment size negotiated when each connection is established.

**Counters for Monitoring Data Transmission Rates at the Data-Link Layer**

Table 6.8 lists several counters on the Network Interface performance object that might be useful for obtaining data about the network adapters on the server. The first instance of the Network Interface object that you see in System Monitor represents the *loopback* — a local path through the protocol driver and the network adapter; all other instances represent installed network adapters.

**Table 6.8 Counters for Measuring Data Transmission Rates at the Data-Link Layer**

| Object\Counter | Value |
|---|---|
| Network Interface (*Adapter ID*)\Bytes Sent/sec | The rate, in seconds, at which bytes are sent over this network adapter. The counted bytes include framing characters. This counter is a subset of Network Interface\Bytes Total/sec. |
| Network Interface (*Adapter ID*)\Bytes Received/sec | The rate, in seconds, at which bytes are received over this network adapter. The counted bytes include framing characters. This counter is a subset of Network Interface\Bytes Total/sec. |
| Network Interface (*Adapter ID*)\Bytes Total/sec | The rate, in bytes per second, at which bytes are sent and received over this network adapter (the sum of Network Interface\Bytes Sent/sec and Network Interface\Bytes Received/sec). |
| Network Interface\Packets Sent/sec | The rate, in seconds, at which packets are sent over the network adapter. |
| Network Interface\Packets Received/sec | The rate, in seconds, at which packets are received over the network adapter. |

**Analyzing the data**

Counters for the Network Interface performance object display the rate at which bytes are transmitted over a TCP/IP connection by monitoring the counters on the network adapter at the data-link layer. The values of these Network Interface counters include all prepended frame header bytes and bytes that have been retransmitted. They provide a relatively accurate estimate of the number of bytes transmitted over the network, but do not measure the bytes transmitted by a specific IIS 6.0 service.

It is useful to compare the data produced by these counters with other performance measures, such as the total number of connections served at a given bandwidth or processor use at different throughput rates.

# Monitoring File and Message Transfers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Most static Web pages include multiple files, such as a file of text and one or more graphics files. File counters are available for each IIS 6.0 service. The counters for the WWW and FTP services count the total number of files that the services send and receive. The counters for the SMTP service tally total messages sent and total messages received, but not total messages sent and received.

Table 6.9 lists the counters for monitoring file and message transfers.

**Table 6.9 Counters for Monitoring IIS 6.0 File and Message Transfers**

| Object\Counter | Value |
|---|---|
| Web Service\Total Files Sent<br>FTP Service\Total Files Sent<br>SMTP Server\Messages Sent Total | For the WWW and FTP services, the total number of files sent by the service since service startup.<br>For the SMTP service, the total number of outbound messages sent since service startup. |
| Web Service\Files Received<br>FTP Service\Total Files Received<br>SMTP Server\Messages Received Total | For the WWW and FTP services, the total number of files received by the service since service startup.<br>For the SMTP service, the total number of inbound messages received since service startup. |
| Web Service\Total Files Transferred<br>FTP Service\Total Files Transferred | For the WWW and FTP services, the sum of Total Files Sent and Total Files Received by the service since service startup.<br>The SMTP service does not provide a sum total counter. |

# Analyzing the Data

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The file counters for a particular service are an indicator of the network activity generated by that service. This data can also be associated with other performance measures to determine the effects of high and low file activity on server components.

The file counters in Table 6.9 display a cumulative total for all traffic since the service was started, regardless of when System Monitor was started. These counters do not display the current value or the rate at which files are transmitted. In IIS 6.0, the Web Service object (but not the FTP Service object) provides counters to measure the rate, in seconds, at which files are sent and received. The SMTP service provides similar counters that measure the rate at which messages are received and sent.

To calculate file transmission rates for the FTP service, you can use Performance Logs and Alerts to log the values for the file counters and the times at which measurements are taken. To derive the transmission rates, you can export the log files to a spreadsheet that associates the time of the measurement with the file count.

# Monitoring TCP Connections

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the bandwidth of your server is insufficient to handle its workload, clients usually become aware of this before the server does. Client requests to the server might be rejected or time out or the response might be delayed. On the server side, the indicators are less clear because the server continues to establish connections, receive requests, and transmit data.

Bandwidth shortages are not uncommon. You can detect one on your server (perhaps even before clients do) by monitoring the success and failure of connections established and rejected by TCP. With ample bandwidth, the server can establish and serve connections before they time out. If bandwidth is insufficient, the connections fail.

Table 6.10 lists the counters that monitor the success and failure of connections to TCP. Windows Server 2003 provides two TCP objects, TCPv4 and TCPv6; choose the counter that monitors the version of TCP that your server is using.

**Table 6.10 Counters for Monitoring the Success or Failure of TCP Connections**

| Object\Counter | Value |
|---|---|
| TCPv4\Connections Established<br><br>TCPv6\Connections Established | The number of simultaneous connections supported by TCP. This counter displays the number of connections last observed to be in the ESTABLISHED or CLOSE-WAIT state. This counter displays the last observed value (indicating the current state); its value is not an average. |
| TCPv4\Connection Failures<br><br>TCPv6\Connection Failures | The number of connections that have failed since the service was started (regardless of when you started System Monitor). TCP counts a connection as having failed when it goes directly from sending (SYN-SENT) or receiving (SYN-RCVD) to CLOSED, or from receiving (SYN-RCVD) to listening (LISTEN). |
| TCPv4\Connections Reset<br><br>TCPv6\Connections Reset | The number of connections reset since the service was started (regardless of when you started System Monitor).<br><br>TCP counts a connection as having been reset when it goes directly from ESTABLISHED or CLOSE-WAIT to CLOSED. |

The counters on the TCPv4 and TCPv6 objects are the best indicators of the success of connection requests. The counters on the Web Service and FTP Service performance objects monitor connections maintained by each IIS 6.0 service, but display only successful connection requests, not failed attempts. Like all counters at the application layer, they do not have information about connections until the connections are established.

For a discussion of performance counters that display the number of simultaneous connections maintained by IIS 6.0, see Preventing Processor Bottlenecks.

**Analyzing the Data**

If your server does not support current or increasing demand, look for the following patterns when you analyze the data from the TCP\Connections counters:

- Look for a plateau in the Connections Established counter value. If the counter value of TCP\Connections Established often reaches, but rarely exceeds, a maximum value (that is, the line in the graph rises and then reaches a plateau), the peak value is likely to indicate the maximum number of connections that can be established with the current bandwidth and application workload. If you observe such a pattern, the server probably cannot support any greater demand.

- Look for consistent increases of the Connection Failures and Connections Reset counter values. An increasing number of failures and resets, or a consistently increasing rate of failures and resets, can indicate a bandwidth shortage. The counters that monitor failures and resets show cumulative values, but you can use Performance Logs and Alerts to set alerts on the values or to log values over time. You can then use a spreadsheet to calculate the rates at which connections are rejected and reset.

**Note**

Be cautious when interpreting the number of reset connections shown by the TCP\Connections Reset counter. Resets do not always indicate dropped or failed connections. To minimize connection overhead, many browsers routinely close connections by sending a TCP reset (RST) packet rather than by using a normal close operation. The TCP\Connections Reset counter does not distinguish between connections that are reset because they are dropped and those that are reset in order to be closed abruptly.

# Administering Network Resources

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 provides a set of Quality of Service (QoS) features to help you maintain acceptable service levels of data transmission on your network. The goal of QoS is to ensure that particular sites or applications do not monopolize server resources, such as memory or CPU cycles, which can adversely affect performance. QoS helps administrators control how IIS components — such as sites, application pools, or the WWW service as a whole — use resources.

If the bandwidth on your server is not sufficient to support demand, you can increase overall server bandwidth. You can also increase the effective bandwidth of existing communication links. Some suggestions on how to do so follow; many involve setting parameters that can only be modified by editing the Windows registry or the IIS 6.0 metabase.

It is frequently possible to reduce your use of bandwidth by optimizing Web application scripts or content. This option is worth looking into as an interim solution, partly because it can also improve response time and the user experience; however, if your client base is growing, you might eventually have to increase the bandwidth of your network connection anyway.

You can sometimes effectively increase existing bandwidth by limiting connections, by increasing the length of the connection queues, or by enabling HTTP Keep-Alives.

QoS in IIS provides the following methods for managing and maintaining network performance:

- Limiting Connections to Manage Resources: Set limits on the number of connections allowed to a Web or FTP server or to specific sites. Use this feature to ensure that all your services remain active during periods of peak use and to protect against malicious attack.

- Enabling HTTP Keep-Alives to Keep Connections Open: To maintain an open connection when browsers send multiple requests to download a Web page, be sure that HTTP Keep-Alives are enabled.

- Setting Connection Timeouts to Save Resources: To reduce the loss of processing resources consumed by idle connections, set connection timeouts on your Web server.

- Using HTTP Compression for Faster Downloads: To provide faster transmission time between IIS and compression-enabled browsers, use HTTP compression.

- Throttling Bandwidth to Manage Service Availability: Limit the bandwidth used by your Web server so that the server remains available for other services, such as e-mail or news, even during periods of peak use.

- Using Other Features to Enhance Performance: In addition to the QoS features, use other IIS features, including Web gardens, idle timeout, CPU monitoring, and processor affinity, to help you manage system resources and enhance performance.

# Limiting Connections to Manage Resources

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Connection limits restrict the number of simultaneous connections to your Web sites and your Web server. If the number of connections reaches the maximum allotted, all subsequent connection attempts return an error and then are disconnected.

By limiting connections, you can conserve bandwidth for other uses, such as e-mail servers, news servers, or another Web site running on the same installation. Limiting connections also conserves memory and protects against malicious attacks designed to overload your Web server with thousands of client requests.

To determine whether you need to limit connections, use System Monitor to log the Current Connections, Maximum Connections, and Total Connection Attempts counters on the Web Service and FTP Service objects. Continue logging until you have a good sense of the normal range; typically, logging can take several days to a week or more and must be repeated at regular intervals. For more information about performance logging, see Enabling Logging and Analyzing Log Files.

You can establish global WWW service or FTP service connection limits for all Web and FTP sites, or you can establish connection limits on individual Web or FTP sites. IIS checks for a global connection limit before checking for connection limits on individual sites. If the global connection limit is exceeded, IIS returns error message 403.9 (Forbidden - Too Many Users) regardless of the connection limit set for individual sites. (You can customize the connection limit error message in IIS 5.0; however, IIS 6.0 does not offer that option.) For information about limiting connections for the WWW service, the FTP service, a Web site, or an FTP site, see Limiting Connections.

Another way to limit connections to your Web server is through bandwidth throttling. For information about using this feature, see Throttling Bandwidth to Manage Service Availability. For a list of counters related to performance, see IIS 6.0 Performance Counters. For information about connection timeouts, see Setting Connection Timeouts to Save Resources.

# Enabling HTTP Keep-Alives to Keep Connections Open

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A browser typically makes multiple requests in order to download an entire Web page. To enhance server performance, most Web browsers request that the server keep the connection open across these multiple requests, which is a feature known as *HTTP Keep-Alives*.

Without HTTP Keep-Alives, a browser that makes numerous requests for a page containing multiple elements, such as graphics, might require a separate connection for each element. These additional requests and connections require extra server activity and resources, decreasing server efficiency. The additional connections also make a browser much slower and less responsive, especially across a slow connection.

HTTP Keep-Alives are enabled by default in IIS 6.0, which complies with the HTTP/1.1 specification for HTTP Keep-Alives. IIS holds open an inactive connection for as long as the **ConnectionTimeout** metabase property specifies (the default value is 120 seconds).

If you disable HTTP Keep-Alives, the server ignores a clients request to keep the connection open. Therefore, disable HTTP Keep-Alives only for a specific reason and if you clearly understand how this change affects your server.

HTTP Keep-Alives are required for integrated security or connection-based authentication services, such as Integrated Windows authentication. If you disable HTTP Keep-Alives for Web sites that use Integrated Windows authentication, requests to the Web site may fail.

To verify that your server is running with HTTP Keep-Alives enabled, or to enable HTTP Keep-Alives if this feature is disabled, see Enabling HTTP Keep-Alives.

# Setting Connection Timeouts to Save Resources

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Connection timeouts help reduce the amount of memory resources that are consumed by idle connections. Time-out settings also allow you to specify how long server resources are allocated to specific tasks or clients. When you enable connection timeouts, IIS 6.0 enforces the following types of connection timeouts at the connection level:

- A *connection timeout*, in which the client has sent data to the server, but the client is now idle. Use the **ConnectionTimeout** metabase property to set a connection timeout limit for the WWW, FTP, Network News Transfer Protocol (NNTP), and SMTP services.

- A *request timeout*, which prevents clients from issuing unreasonably slow requests to the server (for example, 1 bit per second). Use the **HeaderWaitTimeout** metabase property to set a request timeout for the WWW service.

- A *response timeout*, which prevents malicious or malfunctioning clients from consuming resources by holding a connection open with minimal data. Use the **MinFileBytesPerSec** metabase property to set a response timeout for the WWW service.

**Monitoring with Counters to Evaluate Connection Limits**

In IIS 6.0, the default connection timeout settings are more restrictive than in earlier versions of IIS, which helps prevent denial of service attacks on the server. To determine whether you can improve performance by changing a default connection timeout setting or by adding an optional setting, begin by obtaining a baseline of how your server performs with the current connection limits. For example, use System Monitor to log the Current Connections, Maximum Connections, and Total Connection Attempts counters on the Web Service and FTP Service objects. Continue logging until you have a good sense of the normal range; typically, logging can take several days to a week or more and must be repeated at regular intervals.

After obtaining baseline performance data for the default configuration, make incremental changes to the connection timeout settings, and then collect additional performance data by using these same counters. Compare the results to determine if changing the connection limits improves performance, keeping in mind that more aggressive limits can increase protection against malicious attacks.

**Setting Connection Timeouts by Using IIS Manager**

You can set global connection timeouts for the WWW or FTP service, or for individual Web sites and FTP sites. You can also set global connection timeouts on SMTP and NNTP servers. For more information about setting connection timeouts, see Setting Connection Timeouts.

**Setting Connection Timeouts by Editing the Metabase**

IIS 6.0 provides three metabase properties, **ConnectionTimeout**, **HeaderWaitTimeout**, and **MinFileBytesPerSec**, which you can use to set different types of connection timeouts. In IIS 6.0, these properties replace the **ServerListenTimeout** metabase property, which is no longer used for the WWW service but can be used for the FTP, SMTP, and NNTP services.

**Setting connection timeouts**

The **ConnectionTimeout** metabase property specifies the amount of time (in seconds) that the server waits before disconnecting an inactive connection. IIS applies this timeout limit after the client sends the first request to the server and the client is idle. The default value is 120 seconds for the WWW and FTP services (global settings); 120 seconds for individual Web and FTP sites; and 10 minutes for the SMTP and NNTP services. (In IIS Manager, when you change the value of the **ConnectionTimeout** property, you change this setting.)

For security reasons, the **ConnectionTimeout** property cannot be disabled. Thus, if you try to set the **ConnectionTimeout** property to 0, the property retains its previous setting.

**Setting request timeouts**

The **HeaderWaitTimeout** metabase property specifies the amount of time (in seconds) that the server waits for the client computer to send all HTTP headers for a request (indicated by a double carriage return) before HTTP.sys resets the connection. The purpose of this property is to help impede a type of denial of service attack that attempts to exhaust connection limits and keep those connections connected. You can apply this connection timeout only at the WWW service level.

For security reasons, the **HeaderWaitTimeout** property cannot be disabled. Thus, if you try to set the **HeaderWaitTimeout** property to 0, the property retains its previous setting.

**Setting response timeouts**

The**MinFileBytesPerSec**metabase property determines the length of time that the client has to receive the server's entire response to its request. If the client computer does not receive the entire HTTP response within the interval set by the time-out value (by default, 240 bytes per second), HTTP.sys terminates the connection. You can apply this connection timeout only at the WWW service level.

Configuring the **MinFileBytesPerSec** metabase property prevents a client computer from sending a request for a large response (such as a file download) and then receiving the response at a maliciously slow rate that is meant to consume resources on the server and potentially interrupt service for other client computers.

The time-out period is calculated by dividing the size of the entire response (including headers) by the value of the **MinFileBytesPerSec** property to obtain a maximum allowable response time, in seconds. For example, a 2-KB response (2,048 bytes) is allowed 8.5 seconds to complete if **MinFileBytesPerSec** has the default value of 240 bytes per second.

To accommodate very slow applications, you can disable the **MinFileBytesPerSec** property by setting the value to 0.

**Reference to Default Time-out Settings**

Additional IIS 6.0 metabase properties set time-out values for ASP, Common Gateway Interface (CGI) scripts, and Internet database connection pooling. Table 6.11 gives a summary of the metabase properties for setting timeouts and the default time-out limit for each property. For information about configuration options, see Code Examples to Configure Metabase Properties. The final column of the table indicates which properties can alternatively be updated in IIS Manager.

**Table 6.11 Default Time-out Values for IIS 6.0**

| Metabase Property | Default Time-Out Value | Configured in IIS Manager |
|---|---|---|
| **AspQueueTimeout** | Unlimited | |
| **AspScriptTimeout** | 90 seconds | Yes |
| **AspSessionTimeout** | 20 minutes | Yes |
| **CGITimeout** | 300 seconds | Yes |
| **ConnectionTimeout** | 120 seconds (Web and FTP);<br>10 minutes (SMTP and NNTP) | Yes |
| **HeaderWaitTimeout** | None (Turned off by default.) | |
| **MinFileBytesPerSec** [1] | 240 bytes per second | |
| **PoolIdcTimeout** | None (Turned off by default.) | |

[1] This metabase property cannot be modified in IIS Manager, but it can be modified by adding the **MinFileBytesPerSec** entry to the Windows registry.

For more information about ASP–related properties and counters, see Monitoring ASP Performance. For information about the registry path for the **MinFileBytesPerSec** entry, see Global Registry Entries.

Another way to limit connections to your Web server is to use bandwidth throttling. For information, see Throttling Bandwidth to Manage Service Availability. A related way to manage resources is to limit the number of simultaneous connections to your sites and server. For information about limiting connections, see Limiting Connections to Manage Resources.

# Using HTTP Compression for Faster Downloads

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If your Web sites use large amounts of bandwidth or if you want to use bandwidth more effectively, consider enabling HTTP compression, which provides faster transmission times between IIS and compression-enabled browsers regardless of whether your content is served from local storage or a UNC resource. If your network bandwidth is restricted, HTTP compression can be beneficial unless your processor usage is already very high.

IIS provides the following compression options:

- Static files only.
- Dynamic application responses only.
- Both static files and dynamic application responses.

Dynamic processing can affect CPU resources because IIS does not cache compressed versions of dynamic output. If compression is enabled for dynamic responses and IIS receives a request for a file that contains dynamic content, the response that IIS sends is compressed every time it is requested. Because dynamic compression consumes considerable CPU time and memory resources, use it only on servers that have slow network connections but CPU time to spare.

Compressed static responses can be cached and therefore do not affect CPU resources like dynamic responses do.

**How HTTP Compression Works**

When IIS receives a request, it checks whether the browser that sent the request is compression-enabled. (Recent versions of Microsoft® Internet Explorer and most other browsers typically send the following header if they are compression-enabled: Accept-Encoding: gzip, deflate.) IIS then determines whether the request is for a static file or for dynamic content.

If the content of the file is static, IIS checks whether the file has previously been requested and is already stored in a compressed format in the temporary compression directory. If a compressed version of the requested file is not found, IIS sends an uncompressed version of the requested file to the client browser while a background thread compresses the requested file. The newly compressed file is then stored in the compression directory, and subsequent requests for that file are serviced directly from the compression directory. In other words, an uncompressed version of the file is returned to the client unless a compressed version of the file already exists in the compression directory.

If the file contains dynamic content, IIS compresses the response as it is generated and sends the compressed response to the browser. No copy of the file is cached by the Web server.

The performance cost of compressing a static file is modest and is typically incurred only once, because the file is then stored in the temporary compression directory. The cost of compressing dynamically generated files is somewhat higher because the files are not cached and must be regenerated with each request. The cost of expanding the file at the browser is minimal. Compressed files download faster, which makes them particularly beneficial to the performance of any browser that uses a network connection with restricted bandwidth (a modem connection, for example).

When you enable HTTP compression, compressed files are given a default expiration date of Jan. 1, 1997. This expiration date prevents proxy servers from serving cached copies of compressed files to browsers that are not compression-enabled. This expiration date also forces browsers to return to the server for a fresh copy of the file when the user makes a new request instead of displaying a cached copy of the file. When you enable HTTP compression, the default settings for the **HcExpiresHeader**, **HcCacheControlHeader**, and **HcSendCacheHeaders** metabase properties ensure that older clients and proxy servers do not attempt to cache compressed files. Before you change these settings, see Metabase Property Reference for information about these and related metabase properties.

**Determining Whether HTTP Compression Will Improve Performance**

If your server generates a large volume of dynamic content, consider whether the additional processing cost of HTTP compression is one that you can reasonably afford. If the % Processor Time counter is already 80 percent or higher, enabling HTTP compression is not recommended.

To evaluate how much of your processor is typically being used, follow these steps:

1. Establish a baseline for your processor usage by using System Monitor to log the following counters over several days. If

you use Performance Logs and Alerts, you can log the data to a database and then query the data, examining the results in detail.

- Processor\% Processor Time. This counter has a total instance and a separate instance for each processor in the system. If your server has more than one processor, you need to watch the individual processors as well as the total to discover any imbalance in the workload.
- Network Interface\Bytes Sent/sec. Counters for the Network Interface performance object display the rate at which bytes are transmitted over a TCP/IP connection by monitoring the counters on the network adapter. For information about additional counters to monitor for this object, see Table 6.8.

2. Enable compression, and continue to log the values for these counters for an extended period — preferably for several days — so you have a good basis for comparison.

   Collect a broad sample to determine how compression affects various aspects of performance. Conduct the following tests:

   - Enable static compression only, dynamic compressions only, and both.
   - Change the list of files that you use for compression testing for both static and dynamic content.
   - Vary the compression level. Try this on all content types.

3. Compare the data from monitoring with and without compression, and with different types of compression, different compression levels, and different files.

| **Important** |
|---|
| If you see signs of blocking or bottlenecking during the preceding testing, promptly stop the test. A significant drop in the value of either counter indicates that performance with compression enabled has decreased relative to performance without compression enabled. |

**Choosing Compression Options**

When you configure HTTP compression by using IIS Manager, IIS 6.0 automatically applies the default settings shown in Table 6.12. You can configure custom settings for each compression option by editing the metabase or alternatively — in the case of the compression directory — by using IIS Manager.

**Table 6.12 Default Settings When HTTP Compression Is Enabled**

| Compression Options | File Type | Default Configuration | Configuration Method |
|---|---|---|---|
| File types compressed | Static | .txt, .htm, and .html | Metabase |
| | Dynamic | .exe, .dll, and .asp | Metabase |
| Compression schemes | Static | Both gzip and deflate | Metabase |
| | Dynamic | Both gzip and deflate | Metabase |
| Compression level | Static | 10 | Metabase |
| | Dynamic | 0 | Metabase |
| Compression directory | Static | Size: 95 MB<br>Location[1]: %Windir%\IIS Temporary Compressed Files | Metabase or IIS Manager |
| | Dynamic | No directory[2] | N.A. |

[1] The compression directory must reside on an NTFS file system volume.

[2] When dynamic files are compressed, they are not cached.

If the default HTTP compression configuration does not meet the needs of your organization, you can make the following changes to the configuration:

- Specify additional file types to compress. Edit the **HcFileExtensions** metabase property (for static files) and the **HcScriptFileExtensions** metabase property (for dynamic files) to apply compression to additional file types. Add only compressible files types to your compression scheme because trying to compress an already compressed file — such as .jpg, .mp3, or .zip files — wastes processing time.

- Enable or disable the gzip or deflate compression scheme. When you use IIS Manager to enable compression, IIS enables both compression schemes (gzip and deflate), so that IIS can apply whichever compression scheme the client requests. You can edit the metabase to specify that only a particular compression scheme is used. If you disable the only compression scheme that a client supports, the server replies with an uncompressed file.

  | **Note** |
  | --- |
  | Disabling either the gzip or deflate compression schemes can have unintended consequences, such as not compressing responses to a particular browser. For maximum compatibility, it is recommended that you leave both compression schemes enabled. |

- Change the level of compression for static or dynamic files. Compression levels range from 0 through 10. Higher compression levels produce smaller compressed files but use more CPU and memory. Lower compression levels produce slightly larger compressed files, but with less impact on CPU and memory usage. To configure a compression level other than 10 for static files and other than zero for dynamic files, edit the **HcOnDemandCompLevel** and **HcDynamicCompressionLevel** metabase properties.

  For dynamic compression, increasing the compression level can significantly increase CPU usage. The default compression level of zero uses the least amount of CPU resources and can increase performance if network bandwidth is adequate. Raise the dynamic compression level above zero only if you need more network bandwidth and have sufficient CPU capacity to handle the extra load.

- Change the location or size of the compression directory. To change the location and size of the compression directory for static files, edit the **HcCompressionDirectory**, **HcDoDiskSpaceLimiting**, and **HcMaxDiskSpaceUsage** metabase properties.

**Compression Strategies**

When the CPU of your server is not heavily loaded, the simplest compression strategy is to enable static and dynamic compression for all of the sites and site elements (directories and files) on the server. This is known as global HTTP compression. However, when the CPU load of your server is high, you might not want to enable compression for all of the sites and site elements on the server.

Depending on CPU usage, there are two strategies for fine tuning which sites and site elements are compressed:

- Enable compression globally, and then disable compression selectively for specific sites or site elements.

- Leave global compression disabled, and then enable compression selectively for specific sites or site elements.

**Enabling Global HTTP Compression**

When you enable HTTP compression by using IIS Manager, IIS applies compression according to the default settings shown in Table 6.12. With the exception of the location and size of the compression directory, you cannot change the default settings by using IIS Manager. Instead, you must edit the metabase to change the default settings.

| **Important** |
| --- |

After enabling HTTP compression (either by using IIS Manager or by editing the metabase), you must restart IIS for the change to take effect.

For more information about enabling global HTTP compression by using IIS Manager and through Adsutil.vbs, see Enabling HTTP Compression.

**Configuring HTTP Compression for Individual Sites and Site Elements**

All of the compression configurations discussed so far are located under W3SVC/Filters/Compression in the metabase and are used to apply global HTTP compression, which is applied by using IIS Manager or by using one of the metabase properties that are used for global compression (beginning with Hc). IIS 6.0 offers two new metabase properties, **DoStaticCompression** and **DoDynamicCompression**(beginning with Do), which can be used to enable or disable compression at the individual site and site element levels. Use these two new properties to apply compression to individual namespaces. Hence, you can enable global compression by using IIS Manager or the Hc global properties and then disable one of the Do properties (or vice versa) to obtain compression at a specific location in the IIS metabase.

For more information about enabling compression for individual Sites and Site elements, see Enabling HTTP Compression.

**Specifying File Types and Compression Schemes by Editing the Metabase**

After enabling HTTP compression, you can use the Adsutil.vbs command-line utility (located in the *systemroot*\Inetpub\AdminScripts folder) to edit the metabase, specifying which static or dynamic file types to compress and which compression scheme to apply.

Using Adsutil.vbs, you can customize HTTP compression in the following ways:

- Apply the gzip or deflate compression scheme, or both. To apply both schemes, you must execute a separate **set** command for each compression scheme.

- Customize the file types to which both static and dynamic compression are applied. You must execute a separate **set** command for each compression type. If you use IIS Manager to enable compression and you then use Adsutil.vbs to specify specific static or dynamic file types, you replace any default values that were applied by IIS Manager.

**Note**

For compression to be performed, the **HcDoStaticCompression** metabase property must be set to **true** (for static compression) and the **HcDoDynamicCompression** metabase property must be set to **true** (for dynamic compression). You can set these by using IIS Manager or Adsutil.vbs. For instructions, see the procedures in the preceding section.

The following syntax enables compression at the W3SVC level (which means it is applied to all Web sites and virtual directories on the Web server):

```
cscript.exe adsutil.vbs set W3svc/Filters/Compression/{GZIP|DEFLATE}/
{HcFileExtensions "StaticFileType" ...}|{HcScriptFileExtensions "DynamicFileType" ...}
```

You must restart the WWW service before any changes take effect. For information about restarting a service, see Common IIS 6.0 Administrative Tasks. Table 6.13describes the parameters for customizing file types and compression schemes.

**Table 6.13 Parameters for Setting Compression Schemes and File Types for HTTP Compression**

| Parameter | Description |
|---|---|
| `GZIP\|DEFLATE` | Specifies which compression scheme (either gzip or deflate) to apply to the specified file types. To enable both compression schemes, you must run this command once for each compression scheme. For maximum compatibility, leave both compression schemes enabled. |
| `HcFileExtensions "StaticFileType" ...` | Specifies which static file types to apply the compression scheme to — for example, .txt, .js, .css, .doc, or .xls files. To specify a file type, enclose the file name extension (without the leading period) in quotation marks. Separate multiple file types with a space. This parameter cannot be executed together with the `HcScriptFileExtensions "`*DynamicFileType*`"` parameter. |

| | |
|---|---|
| `HcScriptFileExtensions "DynamicFileType" ...` | Specifies which dynamic file types to apply the compression scheme to — for example, .exe, .dll, or .asp files. To specify a file type, enclose the file name extension (without the leading period) in quotation marks. Separate multiple file types with a space. This parameter cannot be executed together with the `HcFileExtensions "StaticFileType"` parameter.<br><br>**Important** Setting the `HcScriptFileExtensions` parameter to an empty string can adversely affect your servers performance. If this parameter is empty, all dynamic responses are sent compressed. In addition, any static file type not specified in `HcFileExtensions` is dynamically compressed and therefore not cached. |

For example, the following command uses a deflate compression scheme to apply static compression at the W3SVC level to text files (.txt) and cascading style sheets (.css):

```
cscript.exe adsutil.vbs set w3svc/Filters/Compression/DEFLATE/HcFileExtensions "txt"
"css"
```

#### Specifying the Location and Size of the Compression Directory for Static Compression

Three metabase properties enable you to change the location of the default directory for static compression and to limit its size.

#### Changing the location of the compression directory

The **HcCompressionDirectory** metabase property specifies the folder where compressed versions of static files are temporarily cached. By default, the compression directory is at %Windir%\IIS Temporary Compressed Files.

Due to a number of differences between NTFS and FAT volumes — such as differences in time stamping and access control mechanisms, and the efficiency with which NTFS handles directories that contain large numbers of files — the compression directory must reside on an uncompressed and unshared NTFS volume. In addition, the access control lists (ACLs) for the folder must include Full Control access to the identity of the application pool or to the IIS_WPG group. If a requested file resides on an NTFS volume and the compression directory is on a FAT volume, IIS does not perform HTTP compression on that file.

#### Setting a size limit for the compression directory

In addition, you can configure the **HcDoDiskSpaceLimiting** and **HcMaxDiskSpaceUsage** metabase properties to limit the amount of disk space that all files in the compression directory can occupy. **HcDoDiskSpaceLimiting** enables disk space limiting. If it is set to **true**, IIS limits compressed files to no more than the number of bytes specified by **HcMaxDiskSpaceUsage**. After the limit is reached, compressed files are removed from the compression directory on a least recently used basis. If **HcDoDiskSpaceLimiting** is set to **false**, no disk space limit is enforced for the compression directory.

**HcDoDiskSpaceLimiting** is relevant only if you have set the property **HcDoOnDemandCompression** to **true**. For more information about these metabase properties, see Metabase Property Reference.

| **Important** |
|---|
| Limiting the use of disk space has a significant impact on performance because additional overhead is required to check for the limit. Use this feature only when you lack adequate disk space to cache all content files on your Web server. |

#### Disabling HTTP Compression for Requests That Come Through Certain Proxy Servers

Certain HTTP proxy servers, including some advertised as HTTP 1.1–compliant, do not handle the caching of compressed objects correctly. The **HcNoCompressionForProxies** metabase property allows you to disable the HTTP 1.1 response for compression requests that come through proxy servers.

In addition, you can use the **HcNoCompressionForHttp10** metabase property to disable compression for requests that contain an HTTP 1.0 version number. HTTP 1.0, as described in RFC 1945, Hypertext Transfer Protocol — HTTP/1.0, provides a minimal level of support for certain types of compression. However, some confusion exists concerning HTTP 1.0 compression, especially with regard to proxy servers. To minimize the chance of inappropriately returning a compressed file to a client that cannot decompress it, you can use the **HcNoCompressionForHttp10** metabase property to disable compression in questionable scenarios.

For more information about the many metabase properties that you can set when configuring HTTP 1.1 compression, including a complete list of all the properties you can set, see IIsCompressionSchemes (ADSI) in the IIS 6.0 SDK.

# Throttling Bandwidth to Manage Service Availability

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the network or Internet connection used by your Web server is also used by other services, such as e-mail or news, you can limit the bandwidth used by your Web server so that the server is available for those other services. If your Web server hosts more than one Web site, you can individually throttle the bandwidth used by each site. However, keep in mind that the IPv6 network traffic handled by your Web sites is not throttled. Bandwidth throttling uses Packet Scheduler to manage when data packets are sent.

**Determining When and Where to Use Bandwidth Throttling**
Before enabling bandwidth throttling, determine your Web server's typical load by using System Monitor to log the following counters over several days:

- Bytes Total/sec or Current Bandwidth counter on the Network Interface object. To compare incoming and outgoing traffic, examine both Bytes Sent/sec and Bytes Received/sec.

- Compare the values from the Network Interface object counters with the total bandwidth of your network connection.

If you use Performance Logs and Alerts, you can log the data to a database and then query the data, examining the results in detail.

For a typical load, your server should use no more than 50 percent of its total available bandwidth. If your server is subject to large peaks in use, keep your typical load lower than 50 percent. The remaining bandwidth can be used during peak periods.

If testing of your servers' typical loads shows that a server or a particular site is consistently using more than 50 percent of the available bandwidth, use the procedures that follow to throttle bandwidth.

In addition, before you set global bandwidth throttling, be sure that you understand the following:

- Individual sites throttle bandwidth according to their established maximum; the global setting limits the total network bandwidth that is available for all unthrottled Web sites on a server. Setting a global WWW service maximum bandwidth does not override established bandwidth maximums for individual Web sites on the server.

- Global bandwidth throttling settings for the WWW service do not affect FTP sites or the FTP service as a whole.

**Related Information**

- For more information about bandwidth throttling, including enabling packet scheduler, and enabling and disabling bandwidth throttling, see Throttling Bandwidth.

# Using Other Features to Enhance Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0, when running in worker process isolation mode, offers several features that you can use in addition to the QoS feature to better manage your systems resources:

- Use Web gardens to enhance performance.
- Conserve processor resources by using idle timeout.
- Enable CPU monitoring to conserve processing time.
- Assign processor affinity to better use CPU caching.

**Using Web Gardens to Enhance Performance**

If the server is running in worker process isolation mode, you can configure an application pool to be supported by multiple worker processes. An application pool that uses more than one worker process is called a *Web garden*. Creating a Web garden for an application pool enhances performance and reliability by providing the following enhancements:

- Robust processing of requests. When a worker process in an application pool is tied up (for example, when a script engine stops responding), other worker processes can accept and process requests for the application pool.
- Reduced contention for resources. When a Web garden reaches a steady state, each new TCP/IP connection is assigned, according to a round-robin scheme, to a worker process in the Web garden. The round-robin scheme smoothes out workloads and reduces contention for resources that are bound to a worker process.

For more information about Web gardens, including how to configure them, see Running IIS 6.0 as an Application Server.

**Conserving Processor Resources by Using Idle Timeout**

If the server is running in worker process isolation mode, you can conserve system resources by terminating idle worker processes; that is, you can configure an application pools worker process to shut down after a specified period of inactivity. Use this feature to better manage your resources when the processing load is heavy, when identified worker processes are consistently idle, or when new processing space is not available. If an application pool times out because the inactivity of its worker process exceeds a configured limit for idle timeout, and if HTTP.sys then receives a request for the idle application pool, the WWW service starts a new worker process to replace the one that timed out.

For more information about configuring idle timeout for a worker process, see Running IIS 6.0 as an Application Server.

**Enabling CPU Monitoring to Conserve Processing Time**

Through CPU monitoring of application pools, you can monitor the CPU usage of worker processes and, if you configure it to do so, automatically shut down worker processes that consume large amounts of CPU processing time. CPU monitoring logs and throttles only the applications that are isolated in a process that is separate from IIS; hence, this feature is only available when your server is running in worker process isolation mode.

When you configure CPU monitoring for an application pool, you can choose from two monitoring options:

- Perform only event logging. When the CPU usage for an application pool exceeds the Maximum CPU use limit, the WWW service writes an error to the Windows event log. The log entry identifies the specific worker process and the application pool that exceeded the CPU limit.
- Log events, and also shut down the unhealthy application pool. After an application pool reaches the configured Maximum CPU use limit, CPU monitoring writes an error to the event log and shuts down the application pool. The application pool remains down until the **CPUResetInterval** time limit expires, at which time the application pool restarts. If any requests are received while the application pool is stopped, HTTP.sys returns a 503 error (Server Too Busy).

For more information about CPU monitoring, including how to configure it, see Running IIS 6.0 as an Application Server.

**Obtaining more detailed CPU monitoring**

If your Web server is running the Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, operating system, you can use the Windows System Resource Manager to monitor different types of CPU activity more closely. With this feature, you can control how CPU and memory resources are allocated to applications, services, and processes. However, Windows System Resource Manager cannot manage system resources correctly if the computer is already being managed by another resource manager, such as IIS CPU monitoring. For best results, if you use Windows System Resource Manager, do not use any other resource manager on that computer.

**Related Topics**

For more information about Windows System Resource Manager, see Windows System Resource Manager — Fast Facts.

# Controlling Memory Usage

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

With memory, more is almost always better. However, just adding more RAM to your server does not optimize performance. You must first determine whether you are making good use of the memory that the server has.

The biggest performance gains with IIS occur when you resolve issues related to insufficient memory. Before changing your hardware configuration, rule out memory problems. Monitor memory first to verify that your server has enough memory, and then move on to other parts of your server environment. Problems caused by memory shortages can often appear to be problems in other parts of the system.

**Minimum Memory Requirements for IIS 6.0**
To run IIS 6.0 with the Windows Server 2003 operating system, a dedicated Web server must have a minimum of 128 MB of RAM. However, your server might require more RAM to handle the resource needs of custom applications. If your custom applications require large amounts of memory, provide 256 MB or more of RAM. Additional memory is particularly beneficial for e-commerce sites, sites with a lot of content, and sites with a high volume of traffic.

**Memory Management and Memory Allocation in Windows Server 2003**
In order to use memory most efficiently, the Windows Server 2003 memory system is largely self-tuning. Similarly, IIS 6.0 regulates the size of the IIS object cache. Therefore, the primary purpose of monitoring memory on a Windows Server 2003–based server running IIS 6.0 is not to adjust the size of each memory component, but rather to make sure that the system as a whole has enough memory and is using it efficiently.

The largest chunk of activity in Windows Server 2003 is a *process*. The physical RAM available to a process is known as its *working set*. If the needs of a process exceed its working set — that is, if the process is not able to store all its code and frequently used data in RAM — some of the information is stored elsewhere, usually on disk as virtual memory.

Storing information on disk, instead of in memory, increases disk activity, which slows down the server. Some memory contains information that is frequently used, and sending that data to disk instead of retaining it in memory can degrade performance.

In addition, a section of system memory, known as *pool memory*, is reserved for use by the operating system. Pool memory is either *paged* or *nonpaged*. Nonpaged pool is the section of pool memory that is not pageable. Data in a nonpaged pool is always stored in physical memory and never saved to the disk. This section usually reserved for device drivers or other critical system components that cannot wait for memory to be paged. Paged pool is the section of pool memory that can be managed in the same way as other virtual memory - that is, it is pageable in the inactive memory can reside on the disk, and the current or active memory can reside in physical memory.

Within each process, Windows Server 2003 uses threads to accomplish particular tasks. The memory occupied by threads is part of the working set of the process, except for some special threads that run in nonpageable memory. Threads that service connections in IIS 6.0, for example, cannot be paged.

This section tells how to monitor various aspects of overall server memory — available memory, paging, use of the file system cache, the size of paging files, the IIS working set, and disk I/O — and, based on your observations, how to optimize memory usage.

# Monitoring Overall Server Memory

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use System Monitor to check the values of the counters described in the following sections. This will help you determine if the current amount of memory on your server is sufficient for your needs.

To evaluate memory usage on your Web server, look at available memory, paging, the size of the file system cache, the size of the paging files, the size of the components of the IIS 6.0 working set, and disk I/O.

# Monitoring Available Memory

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Monitor the counter in Table 6.14 to determine whether the server has performance bottlenecks associated with memory.

**Table 6.14 Counter for Monitoring Available Memory**

| Object\Counter | Value |
|---|---|
| Memory\Available Bytes | The amount of physical memory, in bytes, available to processes running on the computer. This counter displays the last observed value only; it is not an average. |

Compare the total physical memory that is available to Windows Server 2003 with the available memory remaining when all server services are running. To gather reliable data, log this value over time, being sure to include periods of peak activity. Try to reserve at least 10 percent of available memory for peak use.

# Monitoring Paging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If a process requests a page in memory and the system cannot find the page at the requested location, a page fault occurs. If the page is elsewhere in memory, the fault is a *soft page fault*. If the page must be retrieved from disk, the fault is a *hard page fault*. Most processors can handle large numbers of soft page faults without consequence. However, hard page faults can cause significant delays. Continuous high rates of disk paging indicate a memory shortage.

Table 6.15 lists the counters that are available for monitoring hard and soft page faults.

**Table 6.15 Counters for Monitoring Page Faults, Pages Input, and Page Reads**

| Object\Counter | Value |
|---|---|
| Memory\Page Faults/sec | The overall rate at which the processor handles both hard and soft page faults. |
| Memory\Pages Input/sec | The total number of pages read from disk to resolve hard page faults. |
| Memory\Page Reads/sec | The number of times that the disk was read to resolve hard page faults. |
| Memory\Transition Faults/sec | The rate at which page faults are resolved by recovering pages without incurring additional disk activity. *Transition faults*, which measure soft page faults, are counted in numbers of faults because only one page is faulted in each operation; the number of transition faults is equal to the number of pages faulted. |

Hard page faults increment the Page Faults/sec counter (which reports the rate of hard and soft page faults combined) in addition to the Pages Input/sec and Page Reads/sec counters (which report the rate of hard page faults only). The Transition Faults/sec counter is only incremented by soft page faults.

The value of the Memory\Pages Input/sec counter (the number of pages read from disk as a result of hard page faults) will be greater than or equal to the value of Page Reads/sec (the number of times the disk was read as a result of hard page faults), and can give you a good idea of your hard page fault rate. If these numbers are low, your server is responding to requests quickly. If these numbers are high, investigate whether you have dedicated too much memory to the caches, leaving too little memory for the rest of the system. If reducing cache sizes does not improve system performance, you might need to increase the amount of RAM on your server.

# Monitoring the File System Cache

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Monitor the counters in Table 6.16 to determine whether a server has a performance bottleneck associated with the size of the file system cache. These counters display the last observed value only; they do not display an average value.

**Table 6.16 Counters for Monitoring the File System Cache**

| Object\Counter | Value |
|---|---|
| Memory\Cache Bytes | The current size, in bytes, of the file system cache. By default, the cache uses up to 50 percent of available physical memory. The counter value is the sum of Memory\System Cache Resident Bytes, Memory\System Driver Resident Bytes, Memory\System Code Resident Bytes, and Memory\Pool Paged Resident Bytes. |
| Memory\System Cache Resident Bytes | The current size, in bytes, of the pageable operating system code in the file system cache. This value includes only current physical pages and excludes any virtual memory pages not currently resident. |
| Memory\System Driver Resident Bytes | The current size, in bytes, of the pageable physical memory in use by device drivers. This represents the *working set* (physical memory area) of the drivers. This value is a component of Memory\System Driver Total Bytes. |
| Memory\System Code Resident Bytes | The current size, in bytes, of the operating system code currently in physical memory that can be written to disk when it is not in use. This value is a component of Memory\System Code Total Bytes. |
| Memory\Pool Paged Resident Bytes | The current size, in bytes, of the paged pool. The paged pool is an area of *system memory* (physical memory used by the operating system) reserved for objects that can be written to disk when they are not in use. The space that is used by the paged and nonpaged pools is taken from physical memory; thus, a pool that is too large denies memory space to processes. |

The value of the Memory\System Cache Resident Bytes counter equals the System Cache value shown on the **Performance** tab in Task Manager. As a result, this value can be smaller than the actual amount of virtual memory in use by the file system cache.

Windows Server 2003 automatically trims the cache when memory is scarce and enlarges the cache when memory is ample. Use the Memory\Cache Bytes counter to monitor the size of the file system cache. A log of cache size readings reveals how the size of the file system cache changes over time. Compare the log data to a measure of general memory availability, such as data from the Memory\Available Bytes counter. By monitoring these counters and watching the trends, you can expose memory shortages in a server.

When examining the logs, note when the cache is smallest. Track how small the cache gets and how often its size is reduced. Also, note how much system memory is available when the cache size is reduced. By watching these trends, you can begin to associate the size of the cache with the servers performance. For example, if performance degrades when the cache is large, consider adding RAM. If performance degrades when the cache is small, consider increasing the time interval during which objects remain in the cache before being flushed. For more information about monitoring and tuning IIS file cache, see Web Server Scalability.

# Monitoring the Size of the Paging Files

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The counters in Table 6.17 are useful in examining paging file usage. *Paging files* store pages of memory used by a process that are not contained in other files. Paging files are shared by all processes, and the lack of space in paging files can prevent processes from allocating memory.

**Table 6.17 Counters for Monitoring Page Files**

| Object\Counter | Value |
|---|---|
| Process\Page File Bytes | The current amount of virtual memory, in bytes, that this process has reserved for use in the paging files. |
| Process\Page File Bytes Peak | The maximum amount of virtual memory, in bytes, that this process has reserved for use in the paging files. |
| Paging File\% Usage | The percentage of the Page File instance that is in use. |
| Paging File\% Usage Peak | The peak usage of the Page File instance, expressed as a percentage of total file size. |

Windows Server 2003 creates a paging file (with the file name Page File) on the system drive. You can create a paging file on each logical disk. By striping a paging file across separate physical drives, you can improve paging file performance by using drives that do not contain your sites content or log files.

You can change the sizes of existing paging files. The larger the paging file, the more memory the system commits to it. Be sure that the paging file on the system drive is at least twice the size of the physical memory, so that the system can write the entire contents of RAM to disk if the system unexpectedly locks up or shuts down.

# Monitoring the IIS 6.0 Working Set

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If free memory on the computer is above a threshold, pages are left in the working set of a process even if they are not in use. When free memory falls below that threshold, pages are trimmed from working sets. If the trimmed pages are later needed, they are soft-faulted back into the working set before leaving main memory.

When available memory falls below about 4 MB, the system attempts to make more memory available by taking memory away from the working sets of processes. This strategy increases the rate of page faults, because each process must now retrieve data that was once in its working set either from disk or from elsewhere in memory. When the rate of page faults for a particular process rises, however, the system attempts to expand the working set of that process to lower the page fault rate. As the system tries to maintain this balance, the size of the working set of each process fluctuates accordingly.

The Process\Working Set counters measure the number of memory pages that each process uses. If the system has sufficient memory, it can maintain enough space in the working set so that IIS 6.0 rarely must perform disk operations. One indicator of memory sufficiency is how much the size of the process working set fluctuates in response to general memory availability on the server. Significant fluctuation can indicate a lack of available memory.

The systems memory pools hold objects created and used by applications and the operating system. The contents of the memory pools are accessible only in privileged mode — that is, only the kernel of the operating system can directly use the memory pools; user processes cannot.

Table 6.18 describes the counters that are available for monitoring the IIS 6.0 working set.

**Table 6.18 Counters for Monitoring the IIS 6.0 Working Set**

| Object\Counter | Value |
|---|---|
| Memory\Pool Paged Bytes<br>Memory\Pool Non-paged Bytes | Pool Paged Bytes and Pool Non-paged Bytes monitor the pool space for all processes on the server. |
| Process(W3wp1)\Virtual Bytes<br>Process(Inetinfo)\Virtual Bytes | The amount of virtual address space, in bytes, reserved directly by IIS, either by the Inetinfo.exe process (where IIS runs when set to IIS 5.0 isolation mode) or by the W3wp.exe process (where isolated or pooled applications run when IIS is set to worker process isolation mode) instantiated on your server. |
| Process(W3wp1)\Working Set<br>Process(Inetinfo)\Working Set | Size, in bytes, of the working set of the W3wp.exe or Inetinfo.exe process. These counters display the last observed value, not an average over time. |

Monitor the W3wp instance if you are running your Web server in worker process isolation mode. If you are running your server in IIS 5.0 isolation mode, monitor either the Inetinfo instance (for in-process applications) or the Dllhost instance (for out-of-process applications).

**Important**

You can run IIS6.0 in one of two request processing models: *worker process isolation mode* and *IIS 5.0 isolation mode*. IIS typically performs better while running in worker process isolation mode, although results depend on a variety of factors, including the design of your applications. Also note that each mode uses different instances of a counter to monitor performance. For more information about the two request processing models, see Running IIS 6.0 as an Application Server.

Be sure that you monitor Process\Working Set counters for all instances of W3wp.exe (the component that hosts the worker process when IIS runs in worker process isolation mode) on your server; otherwise, you might obtain an inaccurate reading of the virtual memory used by IIS.

You can use the Memory\Available Bytes counter (in Table 6.14) as an indicator of memory availability and the

Process\Working Set counters (in Table 6.18) as an indicator of the size of the IIS 6.0 working set. These counters display the last value observed, rather than an average, so be sure to examine data collected over time.

**Monitoring Disk I/O**

IIS 6.0 writes its logs to disk, so there is almost always some activity, even when requests are processed out of the cache 100 percent of the time. Under ordinary circumstances, disk activity other than that generated by logging might indicate a problem in other areas. For example, if your server has insufficient RAM, you see lots of disk activity because many hard page faults are occurring.

Under certain conditions, disk activity is normal. Examples include a large site that serves more content than your server can cache and any site that serves large amounts of static content that is not cacheable. You are also likely to notice lots of disk activity if your server hosts a database or if your users request many different Web pages.

Typically, you use the Physical Disk counters in Table 6.1 to watch for spikes in the number of disk reads when the server is busy. If the server has enough RAM, most connections result in cache requests, unless the server also hosts a database and clients are making dissimilar queries, which precludes caching.

If the server does not host any application or service that is obviously disk-intensive, but you see lots of disk activity anyway, you need to check RAM use immediately to make sure that the server has enough memory.

# Optimizing Memory Usage

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Servers running IIS 6.0 benefit from ample physical memory. Generally, the more memory that you add, the more the servers use and the better they perform. IIS 6.0 requires a minimum of 128 MB of memory; at least 256 MB is recommended. If you are running memory-intensive applications, your server might require much more memory to run optimally — more than the recommended 256 MB of memory.

Adding RAM to your system is not the only option, however. The following methods can be used to optimize memory performance without adding memory.

**Improve Data Organization**
To improve the performance of the file system cache, keep related Web files on the same logical partitions of a disk.

Use Disk Defragmenter to consolidate fragmented files and folders on the server's hard disk so that each occupies a single, contiguous space on the volume. As a result, the system can gain access to files and folders and save new ones more efficiently.

**Increase the Efficiency of High-Traffic Web Sites**
Evaluate your high-traffic Web sites to find ways to increase their efficiency. For more information about creating efficient Web sites, see Creating a More Efficient Web Site.

**Try Disk Mirroring or Striping**
The optimum configuration is to have enough physical memory to hold all static Web pages. However, if pages must be retrieved from disk, use mirroring or striping to make reading from disk sets faster. In some cases, a caching disk controller is helpful. For more information about mirrored or striped volumes, see "Using mirrored volumes" or "Using striped volumes" in Help and Support Center for Windows Server 2003.

**Add or Enlarge Paging Files**
Add paging files, or increase the size of existing ones. Windows Server 2003 creates one paging file on the system disk, but you can also create a new paging file on each logical partition of each disk. By striping a paging file across separate physical drives, you can improve paging file performance by using drives that do not contain your sites content or log files.

You can change the sizes of existing paging files. The larger the paging file, the more memory the system commits to it. Be sure that the paging file on the system drive is at least twice the size of the physical memory, so that the system can write the entire contents of RAM to disk if the system unexpectedly locks up or shuts down.

For information about resizing paging files, see "Change the size of the virtual memory paging file" in Help and Support Center for Windows Server 2003.

**Retime the IIS Object Cache**
Consider shortening the period of time that an unused object remains in the cache, or lengthening the time that a used object remains in the cache, by adding the ObjectCacheTTL entry to the registry.

| ⚠Caution |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see IIS 6.0 Registry Reference. |

The value of ObjectCacheTTL controls the static file cache by specifying the Time To Live (TTL), which sets the length of time that objects are held in cached memory. If an object in the memory cache has not been referenced for the defined period, that object is phased out of the cache.

The default value is 30 seconds. If system memory is limited or if the contents of the server are dynamic, you can use a lower TTL to prevent system memory from being used to cache a large number of volatile objects. Setting the ObjectCacheTTL entry to unlimited disables the object-cache scavenger and allows cached objects to remain in the cache until the cached object changes. Disabling the cache scavenger is useful if your server has ample system memory and your data is relatively static.

For more information about setting the time limit for the object cache, see Setting the IIS Object Cache Time Period.

**Change the Balance of the File System Cache to the IIS 6.0 Working Set**
By default, servers running Windows Server 2003 are configured to give preference to the file system cache over the working sets of processes when allocating memory (through the server property **Maximize data throughput for file sharing**). Although IIS 6.0–based servers benefit from a large file system cache, giving the file system cache preference often causes the IIS 6.0 pageable code to be written to disk, which results in lengthy processing delays. To avoid these processing delays, you can set server properties to maximize data throughput for network applications. For more information about setting the server properties to maximize throughput, see Maximizing Data Throughput for Network Applications.

**Limit Connections**
If your server does not have enough memory, limiting the number of connections on the server might help alleviate the shortage because some physical memory (about 10 KB per connection) is consumed by the data structures that the system uses to keep track of connections. For more information about limiting connections to save memory, see Limiting Connections to Manage Resources.

**Limit the Queue Length for Application Pools**
If you are running your server in worker process isolation mode, you can limit application pool queue lengths to prevent large numbers of requests from queuing up and overloading your server. When the queue length limits feature is enabled (it is enabled by default), IIS monitors the number of requests in a designated application pool queue before queuing a new request. Use IIS Manager to change the default limit of 1,000 requests for application pool request queues.

If adding a new request to the queue exceeds the maximum queue length, the server rejects the request and sends a 503 error (Server Too Busy) to the client. However, requests that are already queued remain queued even if the limit is changed to a value that is less than the current queue length.

For information about changing the queue length limit for an application pool by using IIS Manager, see Configuring Application Pool Queue-Length Limits. For information about configuring application pool queue length limits by using metabase properties, see the **AppPoolQueueLength** property in the Metabase Property Reference.

**Adjust Resource Allocation in Windows**
System processing is managed by Windows Server 2003, which can allocate processor and memory resources among tasks. If your server needs a temporary performance boost, you can temporarily adjust resource allocation in Windows to allocate the resources where you need them:

- To obtain a faster response time, you can set Windows to allocate more processor time to the program that you are currently running.

- If you want to run background programs, such as printing or disk backup, while you work, you can have Windows share processor resources equally between background and foreground programs.

For more information about changing the way that Windows allocates processor resources, see Change the performance of foreground and background programs in Help and Support Center for Windows Server 2003.

**Limit Performance Logging**
Always keep in mind that performance logging uses system resources. When you are not actively checking performance, disable performance-related logging to squeeze a bit more performance from your server.

# Preventing Processor Bottlenecks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Servers running IIS 6.0 rely on the speed and efficiency of their processors. IIS 6.0 code is multithreaded for efficient scaling on uniprocessor and multiprocessor computers, and is largely self-tuning. Even so, processor bottlenecks can occur on very active servers.

A *processor bottleneck* occurs when one or more processes consume the majority of the processor time. This forces threads that are ready to be executed to wait in a queue for processor time. Processor bottlenecks can occur on multiprocessor computers even when only a single processor is fully loaded, if the work in the queue cannot be — or is not — distributed to the other processors. Because a processor bottleneck is not centered in other components, such as memory, disks, or network connections, upgrading or adding to those components does not fix this performance problem, and can sometimes make it worse.

The processors on a server running IIS 6.0 must support the operating system and processes unrelated to Internet services, in addition to IIS 6.0 processes. The processors must also support applications related to Internet services, such as those that assemble data from Microsoft® SQL Server™ databases or generate dynamic Web pages.

To identify processor bottlenecks on the server, you need to monitor process activity, connections, and threads. After evaluating the data, determine the appropriate measures for improving processor performance through hardware upgrades, software configuration changes (limiting connections or allowing a higher thread count), or the redesigning of Web sites to reduce the processor workload.

# Identifying Processor Bottlenecks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The relationships among threads, connections, and requests are complex, especially in IIS 6.0, which uses the worker thread model rather than the simpler, and less efficient, thread-per-client model. Because of the complexity of the model, it is important to obtain a baseline from which to evaluate your system if a bottleneck occurs.

To identify performance bottlenecks, perform the following types of monitoring activity:

- Monitor processor activity by using performance counters and other tools.
- Monitor connections to determine how your server responds to managing different numbers of connections.
- Monitor threads, including context switches, interrupts, and deferred procedure calls.

# Monitoring Processor Activity

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Several tools are available for monitoring processor performance:

- Use the Web Capacity Analysis Tool (WCAT) to perform stress tests. For information about using WCAT, see Using WCAT as a Stress Client.
- To monitor process performance on servers running Windows Server 2003, you can use Task Manager, System Monitor, and Performance Logs and Alerts.

Remember that all monitoring tools use system resources. Monitor the processor use of the process in which the tool runs; then, before you analyze your data, subtract the processor time of the tool process from the data.

To collect data about processor activity, monitor the counters that are listed in Table 6.19. The % Processor Time counter is the primary indicator of processor activity, displaying the average percentage of busy time observed during the sample interval.

**Table 6.19 Counters for Monitoring Processor Activity**

| Object\Counter | Value |
|---|---|
| System\Processor Queue Length | The number of threads in the processor queue. Shows ready threads only, not threads that are running. Even multiprocessor computers have a single queue for processor time; thus, for multiprocessors, you need to divide this value by the number of processors servicing the workload. A sustained processor queue of less than two threads per processor is normally acceptable, depending upon the workload. |
| System\Context Switches/sec | The combined rate at which all processors on the computer are switched from one thread to another. |
| Processor (_Total)\% Processor Time | The average percentage of time that all processors are active. This counter is the primary indicator of average processor activity. This value is derived by calculating the percentage of time during the sample interval that all processors spent in executing their idle thread (which consumes cycles on a processor when no other threads are ready to run), and then subtracting the result from 100 percent. |
| Processor\% Processor Time | The average percentage of processor use for each processor (#0, #1, and so on). |
| Processor\% Privileged Time | The average percentage of processor time that is spent in privileged mode. In Windows Server 2003, only privileged mode code has direct access to hardware and memory. Application threads can be switched to privileged mode to run operating system services. |
| Processor\% User Time | The average percentage of processor time that is spent in user mode. *User mode* is a restricted processing mode designed for applications, environment subsystems, and integral subsystems. The alternative, *privileged mode*, is designed for operating system components, allowing direct access to hardware and memory. The operating system switches application threads to privileged mode to access operating system services. |
| Process\% Processor Time | The average percentage of processor use attributable to each processor, either for a particular process or for the total for all processes (shown in the list of instances). |

**Tip**

A memory bottleneck can sometimes look like a processor or disk bottleneck. If the system does not have enough physical memory to store the code and data that are needed, the processor spends substantial time paging. Before adding or upgrading processors or disks, you need to monitor the memory on your server. For more information about monitoring memory, see Monitoring Overall Server Memory.

**Analyzing Processor Activity Data**

Of the counters listed in Table 6.19, the System\Processor Queue Length counter is probably the most important for analyzing processor activity data. This counter displays the number of threads waiting to be processed in the single queue shared by all processors. Sustained high rates of processor activity, which leave little excess capacity to handle peak loads, are often associated with processor bottlenecks. Processor activity itself only indicates that the resource is being used, not that maximum use of the resource is a problem. However, a long, sustained queue indicates that threads are being kept waiting because a processor cannot handle the load assigned to it.

A sustained processor queue length of two or more threads (as indicated by the System\Processor Queue Length counter) typically indicates a processor bottleneck. You can set an alert in Performance Logs and Alerts to notify administrators when the processor queue length is unacceptably high.

The Processor\% Processor Time counter is most often used as a general measure of processor activity on both uniprocessor and multiprocessor computers. On a multiprocessor server, use this counter to reveal unequal distribution of processor load. You might have a processor bottleneck if % Processor Time numbers are high while usage of the network adapter and disk I/O remain well below capacity.

On multiprocessor computers, use the total instance of the Processor\% Processor Time counter — for example, Processor(_Total)\% Processor Time — to monitor system-wide processor use. For multiprocessor use, this counter represents the active time of all processors divided by the number of processors. If the server workload is shared equally among all processors, the total instance time is an excellent measure of processor activity.

Windows Server 2003 is designed for efficient scaling and includes several strategies for balancing processor load. An application, however, can create an imbalance by setting a processor affinity, which binds a process to a single processor. To identify processor bottlenecks related to processor affinity, chart Processor\% Processor Time for each processor on the computer.

| **Note** |
| --- |
| Though processor affinity can overload a single processor, it can improve performance by reducing the number of processor cache flushes as threads move from one processor to another. You will need to assess, through monitoring, whether the trade-off is acceptable. For information about assigning processor affinity to an application pool or Web garden, see Improving Processor Performance. |

**Optimizing Processor Activity**

If data shows a large processor queue with all processors busy, view a histogram of Process\% Processor Time for each process. To do this, click the **View Histogram** button on the toolbar in System Monitor. The histogram shows the processor time consumed by each process.

Based on the histogram readings, consider making the following adjustments to optimize performance:

- If a single bar in the histogram rises above all of the others, the process represented by the bar might be consuming a disproportionate share of processor time and causing a bottleneck. Consider replacing the application running in that process, or moving the process to another server.

- If the processors are being shared equally by several processes, consider upgrading or adding processors. (Multithreaded processes benefit most from additional processors.)

**Related Topics**

For more information about processor use by applications related to IIS, see Improving Application Performance.

# Monitoring Connections

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

It is important to determine how your server responds when it is managing different numbers of connections. After collecting data on connection trends, you can associate data about general server performance with the number of connections being served.

Each connection that an IIS 6.0 service establishes consumes processor time. The network adapter interrupts the processor to signal that a client has requested a connection. Further processing is required to establish and maintain the connection, to fulfill client requests sent over the connection, and — when the connection is closed — to delete the structures that serviced the connection. Each time a connection is established, the load on the server increases.

IIS 6.0 includes several features to optimize its handling of connections. For example, the HTTP Keep-Alives feature, which is enabled by default, maintains an open connection between the server and browser across multiple requests until an entire Web page is downloaded. This feature significantly improves bandwidth performance on most servers and improves response times for clients. For more information about HTTP Keep-Alives, see Enabling HTTP Keep-Alives to Keep Connections Open.

You can use IIS 6.0 logging to monitor the number of connections that your server makes and to track patterns of client demand for your server. Table 6.20 lists the counters that you can use with Performance Logs and Alerts to monitor connections to IIS 6.0.

Table 6.20 Performance Counters for IIS 6.0 service connections/p>

| Object\Counter | Value |
|---|---|
| Web Service\Current Connections FTP Service\Current Connections | The number of connections maintained by the service during the most recent sample interval. |
| Web Service\Maximum Connections FTP Service\Maximum Connections | The maximum level of simultaneous connections since the server started up. |

Because these counters display the last observed value, and not an average, you must log their values over time to get a reliable sample. These counters can exaggerate the number of simultaneous connections because, at any given moment, some entries may not have been deleted even though the connections on which they are based have been closed.

For more information about configuring and interpreting IIS 6.0 logs, see Analyzing Log Files.

**Analyzing Connection Data**

Identify patterns of client demand for your server by monitoring the number of connections. Log connection data at regular time intervals, and look at the number of connections served during each interval. Observe the size of the processor queue and the usage on each processor during periods of small, moderate, and large numbers of connections. This data shows how your configuration responds to each load level.

You can identify a processor bottleneck during a given time interval by observing one of the following:

- A long, sustained processor queue (with more than two threads).
- High usage rates on one or more processors.
- A curve in the graph of the Current Connections counter on any IIS 6.0 service performance object that reaches a high value and then plateaus. This pattern often indicates that additional connections are being blocked or rejected.

The Active Server Pages, Web Service, FTP Service, and SMTP Server counters collect data at the OSI application layer. If any connections are blocked, rejected, or reset between the transport and application layers, counts of TCP/IP connections might not equal the sum of HTTP, FTP, and SMTP connections. For information about monitoring connections at lower layers, see Monitoring Network Activity.

**Optimizing Connections**

To prevent processor bottlenecks, make certain that a lengthy processor queue is not forming when you serve large numbers of connections. You can usually avoid a bottleneck during peak usage by setting the connection limit to twice the average value of the Current Connections counter.

If the processor regularly develops a bottleneck when servicing large numbers of connections, consider upgrading or adding processors, or limit the maximum number of connections on the server. Limiting connections can cause the server to block or reject connections, but it helps to ensure that accepted connections are processed promptly.

For information about limiting connections, including how to configure this setting, see Limiting Connections to Manage Resources.

# Monitoring Threads

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 runs in a set of multithreaded processes designed for efficient scaling on uniprocessor and multiprocessor systems. *Threads* are the sequences of execution in each process that run the process code on the processor. In the IIS 6.0 process, there is no simple association between threads and connections or between threads and requests, nor is there an easily quantifiable relationship between the optimum number of threads in the process and the number of files served, the number of requests filled, or the number of connections maintained.

Because IIS 6.0 uses the worker thread model (rather than the simpler, thread-per-client model, which dedicates a thread to each connection or request), a pool of threads, known as the *worker threads*, is dedicated to accepting and monitoring all connections. This frees other threads to do the remaining work of the application, such as authenticating users; parsing client requests; locating, opening, and transmitting files; and managing internal data structures.

Even though you cannot associate individual threads with connections or requests, you can:

- Count the number of threads in the IIS 6.0 process.
- Measure the amount of processor time that each thread gets.
- Associate the number of threads (and processor activity) with the number of current connections, number of files served, and other measures of server activity and performance.

Several tools — including Performance Logs and Alerts, Task Manager, and System Monitor — monitor or enumerate the threads in a process. Individual threads are difficult to monitor, especially if they frequently start and stop. Monitoring threads is also costly. Be sure to monitor the overhead of the process in which your tool runs (by monitoring the Process\% Processor Time counter), and subtract this from the overall processor time for the data that you collect.

**Monitoring Threads and Context Switches**

Table 6.21 lists the counters that monitor threads and context switches. You can add to this list any counters that you use to associate numbers of threads with performance, such as Web Service\Current Connections, Web Service\Bytes/sec, or Server\Logon/sec.

**Table 6.21 Counters for Monitoring IIS 6.0 Threads**

| Object\Counter | Value |
|---|---|
| Process (W3wp1)\Thread Count | The number of threads created by the process. This counter does not indicate which threads are busy and which are idle. It displays the last observed value, not an average. |
| Thread (W3wp1:*Thread #*)\% Processor Time | The percentage of processor time that each thread of the worker process is using. |
| Thread (W3wp1/*Thread #*)\Context Switches/sec | The rate of switches from one thread to another. Thread switches can occur either inside of a single process or across processes. |
| System\Context Switches/sec | The combined rate at which all processors on the computer are switched from one thread to another. |

1 Monitor the W3wp instance if you are running your Web server in worker process isolation mode. If you are running your server in IIS 5.0 isolation mode, monitor either the Inetinfo instance (for in-process applications) or the Dllhost instance (for out-of-process applications).

Balancing threads against overall performance as measured by connections and requests can be difficult. Any time that you tune threads, follow up with overall performance monitoring to see whether performance increases or decreases.

You can chart the Process\Thread Count: W3wp value over time to see how many threads the worker process creates and how

the number of threads varies. Then, observe the processor time for each thread in the process (Thread\% Processor Time: W3wp/*Thread #*) during periods of high, medium, and low server activity (as indicated by the other performance measures).

To determine if you need to adjust the thread count, compare the number of threads and the processor time for each thread in the process to the total processor time. If the threads are constantly busy, but are not fully using the processor time, you might improve performance by allowing more threads. However, if all the threads are busy and the processors are operating at close to their maximum capacity, it is best to distribute the load across more servers instead of increasing the number of threads.

Context switch counters are provided for the System and Thread objects. If you decide to increase the maximum size of any of the thread pools, it is important to monitor the counters for context switches. *Context switches* occur when a running thread voluntarily relinquishes the processor, is preempted by a higher priority ready thread, or switches between user mode and kernel mode to use an Executive or subsystem service. Switching to the subsystem process causes one context switch in the application thread; switching back causes another context switch in the subsystem thread.

Increasing the number of threads can increase the number of context switches to the point that performance decreases rather than increases. Ten thousand or more context switches per second is high. If you see numbers in that range, consider reducing the maximum thread pool size.

You should also observe the patterns of context switches over time, which indicate that the kernel has switched the processor from one thread to another. A large number of threads is likely to increase the number of context switches. Although they allow multiple threads to share the processor, context switches also interrupt the processor and might interfere with its performance, especially on multiprocessor computers.

Controlling processor affinity can improve performance by reducing the number of processor cache flushes as threads move from one processor to another. For example, you might be able to reduce cache flushes for dedicated servers by assigning processor affinity. However be aware that dedicating a program to a particular processor might prevent other program threads from migrating to the least-busy processor.

**Monitoring Interrupts and Deferred Procedure Calls**

You also need to monitor the counters for interrupts and deferred procedure calls (DPCs). Table 6.22 lists the counters to use.

**Table 6.22 Counters to Monitor Interrupts and Deferred Procedure Calls**

| Object\Counter | Value |
|---|---|
| Processor\Interrupts/sec | The rate, in average number of interrupts in incidents per second, at which the processor received and serviced hardware interrupts. It does not include deferred procedure calls, which are counted separately. |
| Processor\% DPC Time | The percentage of time that the processor spent receiving and servicing deferred procedure calls during the sample interval. Deferred procedure calls are interrupts that run at a lower priority than standard interrupts. |

The value of the Processor\Interrupts/sec counter is an indirect indicator of the activity of devices that generate interrupts, such as the system clock, the mouse, disk drivers, data communication lines, network adapters, and other peripheral devices. These devices normally interrupt the processor when they have completed a task or require attention, suspending normal thread execution. The system clock typically interrupts the processor every 10 milliseconds, creating a background of interrupt activity.

Use the Processor\Interrupts/sec and Processor\% DPC Time counters to determine how much time the processor is spending on interrupts and deferred procedure calls. These two factors can be another source of load on the processor. Client requests can be a major cause of interrupts and deferred procedure calls. Some new network adapters include interrupt moderation, which accumulates interrupts in a buffer when the level of interrupts becomes too high.

**Optimizing Thread Values**

By default, the IIS 6.0 process creates as many as four threads per processor. IIS 6.0 continually adjusts the number of threads in its process in response to server activity. For most systems, this tuning is sufficient to maintain the optimum number of threads, but you can change the maximum number of threads per processor if your system requires this. If the threads in the IIS 6.0 process appear to be overworked or underutilized, consider these tuning strategies:

- If nearly all of the threads of the IIS 6.0 process are busy nearly all of the time, and the processors are at or near their maximum capacity, consider distributing the workload among more servers. You can also add processors.

- If nearly all threads appear busy, but the processors are not always active, consider increasing the maximum number of threads per processor. Do not increase the maximum number of threads unless you have processors with excess capacity. More threads on the same number of processors cause more interrupts and context switches, and result in less processor time per thread.

To adjust the maximum number of threads in the IIS 6.0 service process, use a registry editor to add the **MaxPoolThreads** entry to the following registry path:

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Inetinfo\Parameters

| ⚠**Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see Registry Reference. |

The **MaxPoolThreads** entry is calculated in units of threads per processor. Do not set this value below 2 or above 20. You can try setting the **MaxPoolThreads** entry to a higher value if back-end latency is higher; set the entry to a lower value for applications that are CPU-intensive. Continue monitoring the system carefully to make sure that changing the number of threads allowed achieves the effect that you want.

# Improving Processor Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If your data on processor performance indicates that processor queues are developing regularly or while a server is handling large numbers of connections, start by monitoring the server's memory. Rule out a memory bottleneck or add more memory before (or in addition to) adding or upgrading processors.

In addition to the methods for optimizing thread values (discussed in Monitoring Threads), consider making the following adjustments.

**Upgrade the L2 cache**
When you add or upgrade processors, choose processors with a large secondary (L2) cache. Server applications, such as IIS, benefit from a large processor cache because their instruction paths involve many different components. A large processor cache (2 MB or more if external, up to the maximum available if on the CPU chip) is recommended to improve performance on active servers running IIS 6.0.

**Add network adapters**
If you are administering a multiprocessor system that does not distribute interrupts symmetrically, you can improve the distribution of the processor workload by adding network adapters so that there is one adapter for every processor. Generally, you only add adapters when you need to improve the throughput of your system. Network adapters, like any additional hardware, have some intrinsic overhead. However, if one of the processors is nearly always active (that is, if Processor\% Processor Time = 100) and more than half of its time is spent servicing deferred procedure calls (if Processor\% DPC Time > 50), then adding an adapter is likely to improve system performance, as long as the available network bandwidth is not already saturated.

**Upgrade network adapters**
If you are adding or upgrading network adapters, choose those with drivers that support interrupt moderation cards, which can perform transfers in the background without processor help. Interrupt moderation prevents the processor from being overwhelmed by bursts of interrupts. Consult the driver manufacturer for details. Also, if at all possible, use adapters that support TCP checksum offloading.

**Upgrade to a multiprocessor computer**
A server-application environment, such as e-commerce sites running COM+ applications, is much more processor-intensive than a typical file or print server environment because much more processing is taking place at the server. For that reason, high-end multiprocessor computers can increase performance in server-application environments. IIS 6.0 introduces a new kernel-mode driver for HTTP parsing and caching that is tuned to increase Web server throughput and scalability of multiprocessor computers.

**Assign processor affinity to better use CPU caching**
To efficiently use CPU caches on multiprocessor servers, you can configure application pools to establish affinity between worker processes and the processors. *Processor affinity* forces worker processes to run on a specific microprocessor or CPU, and applies to all worker processes serving a particular application pool. You can also use processor affinity with Web gardens that run on multiprocessor computers where clusters of CPUs are dedicated to specific application pools.

Controlling processor affinity can improve performance by reducing the number of processor cache flushes as threads move from one processor to another. For example, you might be able to reduce cache flushes for dedicated servers by assigning processor affinity. However, the performance trade-off is that dedicating a program to a particular processor might prevent other program threads from migrating to the least-busy processor.

If you want to assign a particular process or program to a single processor to improve its performance — possibly at the expense of other processes — configure the SMPAffinitized Metabase Property and SMPProcessorAffinityMask Metabase Property. For more information about assigning processor affinity, including how to configure these metabase properties, see Running IIS 6.0 as an Application Server.

**Limit connections**
If you cannot upgrade or add processors, consider reducing the maximum number of connections that each IIS 6.0 service accepts. Limiting connections can result in connections being blocked or rejected, but it helps ensure that accepted connections are processed promptly.

**Adjust the maximum number of threads**
IIS 6.0 tunes the number of threads in its process dynamically. The dynamic values are usually optimal; in extreme cases of very

active or underused processors, however, it might help to adjust the maximum number of threads. If you change the maximum number of threads, continue careful testing to make sure that the change has improved performance. The difference is usually quite subtle.

**Redesign the Web site**

You can improve performance and reduce the processor workload by optimizing database use, calling compiled components from scripts in ASP pages, using Internet Server API (ISAPI) instead of ASP (and ASP or ISAPI instead of CGI applications), and eliminating large bitmapped images or optimizing them to reduce file size. For more information about optimizing Web site performance, see Improving Application Performance.

# Improving Application Performance

Updated: November 5, 2009

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Web applications continue to increase in popularity, constituting an ever larger proportion of the average Web server file base. The challenge for administrators is to preserve speed and efficiency while serving complex applications. By monitoring and tuning different types of applications, in addition to static HTML pages, you can estimate application overhead during periods of varying activity to ensure that your server is prepared for the workload.

Use the tools and counters that are included with IIS 6.0, such as those discussed here, to help you optimize application performance:

- Testing Applications with Stress Tools. Use a stress client like the Web Capacity Analysis Tool (WCAT) to test your applications under a variety of workloads.

- Monitoring and Tuning Applications in IIS 6.0. When you enable ASP.NET and ASP pages on a Web server, IIS provides application-specific counters for monitoring and tuning their performance.

# Testing Applications with Stress Tools

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If Web applications are an important part of your site, the performance of those applications is critical in determining the capacity of the site. In turn, testing is the only way to find out the capacity and performance of a Web application.

If you are unfamiliar with stress testing or need a refresher, look at the following sections:

- Measuring performance by using a stress client. Provides an introduction to performing stress testing.
- Using WCAT as a stress client. Details how to obtain the WCAT tool and its documentation. WCAT is a stress client provided in the IIS 6.0 Resource Kit Tools.
- Estimating baseline performance for applications. Compares the relative performance capabilities of specific application types to help you proactively develop applications that provide optimal performance.

# Measuring Performance by Using a Stress Client

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use a stress client to test different server and network configurations under a variety of workloads. For example, use a stress client to test how your server responds to different workloads or to test the same workload with varying configurations of the server. Some stress clients include prepared test workloads; optionally, you can create your own workloads.

A stress client simulates clients and servers communicating over a network, and usually requires at least four primary subsystems:

- At least one computer that simulates a client, which runs one or more virtual clients.
- One computer that acts as a server.
- One computer, called a *controller*, which initiates and monitors the test.
- A network.

Both the client and controller components can run on one computer. (You can also run the server component on the same computer, but doing so might provide inaccurate results.)

To produce a more realistic test of your server, link it to client computers that are powerful enough to drive the server. The processors in the client computers must be fast enough to prevent a client bottleneck when accessing the server computer. If the client processors are slower than the server, you might need to link more client computers to each server.

Stress clients usually work best if the network that connects the computers has little or no traffic that is unrelated to the test. If possible, use a link dedicated only to the test, and run the tests on a 100 megabits per second — or faster — network.

Test different performance features to observe the effect they have on your server. To test a feature, first run a stress client test with the feature, then run the same test without it. Be sure to run the with feature and without feature versions of the test on varying workloads and multiple clients. For example, use a stress client to test the following features:

- Set different connection limits, such as HTTP Keep-Alives and connection timeouts.
- Test several compression combinations. For example, compress only static files, only dynamic files, or both. Compress at different compression levels for both file types. Also, check to see that the correct set of compressible file types is included in your compression configuration.
- Test bandwidth throttling at different times and on different services.
- Test different hardware combinations, including multiprocessor machines with and without processor affinity.
- Compare the benefits of running different health-monitoring features, such as rapid-fail protection and worker process recycling.
- Test security-related features, such as SSL.

Repeat each test several times, and average the results to eliminate the effects of unintended variations in the test conditions. Then compare the results of the with feature and without feature tests. Consistent differences in the results of the tests are likely to indicate the overhead associated with the feature. You can use these results for planning configuration changes.

# Using WCAT as a Stress Client

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Web Capacity Analysis Tool (WCAT) is a stress client available to IIS users. It is a script-driven command-line tool. WCAT includes a stress client tool (Wcclient.exe) to simulate the clients and a controller tool (Wcctl.exe) to initiate and monitor the testing.

Downloading the IIS 6.0 Resource Kit Tools performs a default installation of the WCAT client and controller files in the *LocalDrive*:\Program Files\IIS Resources folder.

A WCAT test begins with the controller locating and interpreting input files. A controller input file includes three required sections (Configuration, Script, and Distribution) and one optional section (Performance, for specifying which performance counters to monitor). The controller uses the input files to send instructions to the clients, including which tests to run. WCAT includes a prepared input file (Sample.ubr, in the *LocalDrive*:\Program Files\IIS Resources\WCAT Controller\Scenarios folder) that contains a test for stressing the default IIS Web page.

When a WCAT test is complete, the controller collects the test results and writes them to output files. Output files include a log file, which you can optionally configure as an XML-formatted file, and an optional performance results file, which contains data collected from performance counters on the server.

If you specify performance counters in the Performance section of the .ubr file, WCAT logs the counter data in its usual report but also produces a performance log file in a tab-separated format, so that you can import the logged counter data into a spreadsheet or data-processing application. The log of performance data that WCAT generates is stored, by default, in the WCAT Controller\Scenarios folder. You can open this log, which is a text file, by using any word processor.

# Estimating Baseline Performance for Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you develop a new application, it is useful to understand the performance capabilities of different types of Web applications. Table 6.23 provides a guide to the relative performance of different types of applications, where *n* represents the fastest application, and all other application types are rated relative to its performance.

**Table 6.23 Relative Performance of Different Application Types**

| Application Type | Relative Cost | Comments |
|---|---|---|
| Static page (kernel mode) | *n* | Fastest and simplest Web page. |
| Static page (user mode) | 2*n* | |
| ISAPI | 2*n* | Relative speed for a simple ISAPI application. |
| ASP.NET | 5*n* | Relative speed for a simple ASP.NET application. |
| ASP | 10*n* | Relative speed for a simple ASP application. |
| CGI | 100*n* | Slowest. |

Microsoft® Visual Studio® .NET provides Application Center Test (ACT) to help you test and monitor the performance of your Web application. ACT simulates a large group of users by opening multiple connections to a Web server and rapidly sending HTTP requests. ACT is designed to stress-test Web servers and to analyze performance and scalability problems with Web applications. For more information about ACT, see the Microsoft Application Center Test 1.0, Visual Studio .NET Edition documentation on MSDN.

**Related Topics**

For more information about Web application development, including ASP.NET and ASP applications, see Web Application Guide.

# Monitoring and Tuning Applications in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

To ensure that all of your Web applications run reliably and efficiently during peak hours as well as normal usage periods, you should monitor and tune your applications, obtaining baseline data to compare the performance of different types of applications. If you uncover applications or groups of applications that appear to run inefficiently, review the suggestions for improving application performance in Optimizing Application Design and Administration.

You can also improve application performance by using the connection timeout and HTTP compression features that IIS provides. Certain applications, such as ASP pages, provide metabase properties for customizing these features. For more information about using these features to improve application performance, see Administering Network Resources.

When you make changes to your applications or to the hardware on which your applications run, be sure to test the changes in a nonproduction environment before implementing them on production servers.

IIS provides application-specific counters that you can monitor to obtain performance data about different types of applications that run on your servers.

- Monitor applications that use the WWW service by observing counters that monitor ISAPI extensions, CGI requests, and so forth.
- Monitor ASP pages, and tune metabase properties for ASP.
- Monitor ASP.NET applications.

| **Note** |
| --- |
| If after installing Windows Server 2003 SP1 you see a decrease in performance, and investigation reveals a decrease in the CGI Requests/sec processed from what was typical before installing SP1, see Configuring the Maximum Number of Concurrent CGI Requests for information on increasing the value of MaxConcurrentCgisExecuting. |

# Monitoring Applications That Use the IIS 6.0 WWW Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Monitor the counters in Table 6.24 to determine how the WWW service is processing ISAPI, CGI, POST, and GET requests.

**Table 6.24 Counters That Provide Data About WWW Service Applications**

| Object\Counter | Value |
|---|---|
| Web Service\ISAPI Extension Requests/sec<br><br>Web Service\CGI Requests/sec | The rates at which the server is processing ISAPI and CGI application requests. If these values decrease due to increasing loads, you might need to redesign the applications.<br><br>**Note**: ASP is an ISAPI extension; therefore ASP requests are included in the first counter. |
| Web Service\Get Requests/sec<br><br>Web Service\Post Requests/sec | The rate at which these two common HTTP request types are made to the server. POST requests are generally used for forms and are sent to ISAPIs (including ASP) or CGIs. GET requests make up almost all other requests from browsers and include requests for static files, ASPs and other ISAPIs, and CGI requests. |

# Monitoring ASP Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you are running ASP pages on your server, the counters listed in Table 6.25 can help you determine how well the applications are performing. These counters provide the sum of the ASP performance counters for all processes hosting ASP; the data cannot be broken down by process. For information about monitoring the performance of your ASP.NET applications, see Monitoring ASP.NET Performance.

**Table 6.25 Counters Used to Monitor ASP Performance**

| Object\Counter | Value |
|---|---|
| Active Server Pages\Requests/sec | The number of ASP responses during the past second. This counter excludes requests for static files or other dynamic content, and can fluctuate considerably based on the complexity of the ASP pages and the capacity of your Web server. |
| Active Server Pages\Requests Executing | The number of ASP requests currently executing (for example, the number of active worker threads). |
| Active Server Pages\Request Wait Time | The number of milliseconds that the most recent ASP request was waiting in the queue. |
| Active Server Pages\Request Execution Time | The number of milliseconds that the most recent ASP request took to execute. This value can be somewhat misleading because it is not an average. |
| Active Server Pages\Requests Queued | The number of queued ASP requests that are waiting to be processed. The maximum number for this counter is determined by the metabase property **AspRequestQueueMax**. |

**Analyzing the Data**

The Active Server Pages\Requests/sec counter excludes requests for static files or other dynamic content, and can fluctuate considerably based on the complexity of the ASP pages and the capacity of your Web server. If this counter is low during spikes in traffic on your server, your applications might be causing a bottleneck.

It is difficult to give an ideal value for the Active Server Pages\Requests Executing counter. Some factors to consider include:

- If pages execute quickly and do not wait for I/O (for example, loading a file or making a database query), the number of ASP requests that are currently executing is likely to be low — little more than the number of processors when the computer is busy.

- If pages must wait for I/O, the number of pages executing is likely to be higher —up to the maximum thread count allowed for an ASP processor (set by the **AspProcessorThreadMax** metabase property) multiplied by the number of processors, multiplied by the number of processes hosting ASP. (The default **AspProcessorThreadMax** value is 25.)

- If the Requests Executing counter value equals the value of the **AspProcessorThreadMax** property, if Requests Queued is large, and if CPU usage is low, you might need to increase the value of the **AspProcessorThreadMax** metabase property.

| **Important** |
|---|
| The value of the AspProcessorThreadMax Metabase Property can significantly influence the scalability of your Web applications and the performance of your server. Before changing the setting, be sure to read about this property and its use. |

The Request Execution Time counter can be misleading because it is not an average. For example, if you regularly receive 30 requests for a page that executes in 10 milliseconds (ms) to every one request for a page that executes in 500 ms, the counter is likely to indicate 10 ms even though the average execution time is over 25 ms.

Ideally, the Requests Queued and Request Wait Time counters remain close to zero; however, they can vary under varying loads (depending on the application) while the server still provides good performance. If these numbers vary too much from their expected range, you might need to rewrite your ASP applications. If the queue size and wait time increase, or if the queue limit is reached, browsers display the message HTTP 500/Server Too Busy.

**Related Topics**

For more information about ASP performance counters, including additional ASP counters, see IIS 6.0 Performance Counters.

# Tuning ASP Metabase Settings

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If your Web server is running ASP applications, you can help optimize server performance by tuning the metabase properties described in this section. You can retrieve and change these properties by using WMI or ADSI, or by directly editing the metabase with a text editor. Changes to most of these properties do not take effect until you restart the WWW service.

**AppAllowDebugging**
The AppAllowDebugging Metabase Property specifies whether ASP debugging is enabled on the server. When this property is enabled, IIS application threads are serialized; only one thread can execute for each application at one time. Serialized threads adversely affect Web server performance. You should retain the default setting for this property, which is **false,** on all production servers. Set this property to **true** only on a test server when you are debugging an application during its deployment phase.

**AspBufferingOn**
The AspBufferingOn Metabase Property turns on buffering in ASP, so that all output from an application is collected in the ASP output buffer before the buffer is flushed to the client browser (default behavior). If this property is set to **false**, output from ASP scripts is written to the client browser as the client browser becomes available. Set this property to **true** on all production Web servers.

**AspProcessorThreadMax**
The AspProcessorThreadMax Metabase Property specifies the maximum number of worker threads per processor that IIS can create. To find out the maximum number of worker threads that IIS allows per ASP process, multiply this value by the number of processors on your server. If you decrease this value, monitor performance to make sure that the lower thread limit does not degrade performance. If it does, increase the value again.

**AspQueueConnectionTestTime**
The AspQueueConnectionTestTime Metabase Property specifies the maximum time, in seconds, that a request remains queued before ASP checks to determine whether a client is still connected. If a request is in the queue longer than the queue connection test time, the server checks whether the client is still connected before beginning execution.

This feature can help you handle impatient users who fill up the request queue with numerous attempts at the same page. Often, users do not wait more than a few seconds for ASP pages to process. Although the maximum waiting time varies from user to user, the generally accepted maximum is about 10 seconds; so set a small value — for example, 3 seconds.

This property is useful for making ASP processing efficient only up to the point at which ASP begins to process the script. After the script is running, your application should continue to check for client connection at appropriate times, by using the **IsClientConnected** method of the ASP built-in **Response** object. For long-running pages, make cautious use of **Response.Flush** to ensure that users perceive that the page is still alive and doing productive work.

**AspRequestQueueMax**
The AspRequestQueueMax Metabase Property specifies the maximum number of ASP requests that are permitted in a queue. The default value is 3,000, but the optimal setting depends on the behavior of the application. If the execution time of the request is very short and the time in the queue is short, it is reasonable to decrease this value.

**AspScriptEngineCacheMax**
The AspScriptEngineCacheMax Metabase Property specifies the maximum number of scripting engines that ASP pages keep cached in memory (excludes currently running script engines). The default value is 250. Adjust the value according to the type of content in the application. If you are serving thousands of unique pages, server performance might improve if you increase the cache size so that the most frequently requested pages are accessed easily. A hit in the script engine cache means that you can avoid recompiling the template into byte code.

**AspScriptFileCacheSize**
The AspScriptFileCacheSize Metabase Property specifies the number of precompiled script files that can be stored in the ASP template cache. If you set the property to 4,294,967,295 (unlimited), all requested script files are cached. The default value is 500. Increase the value if you have many ASP pages. Do not set the value of this property to zero, which turns off all ASP caching and can severely impair your servers performance.

**AspDiskTemplateCacheDirectory**
The AspDiskTemplateCacheDirectory Metabase Property specifies the name of the directory where ASP stores compiled ASP templates to disk when the in-memory cache overflows. If you change the default directory, you must ensure that the identity

of the processes running Asp.dll is assigned Full Control permission to the new directory. Typically, the identity of the worker processes running Asp.dll is the LocalSystem or Network Service account. You must specify a local path; ASP template caching fails if this property is set to a Universal Naming Convention (UNC) or mapped network path.

**AspSessionTimeout and AspSessionMax**

The AspSessionTimeout Metabase Property specifies, in minutes, the default amount of time that a session object is maintained after the last request associated with the object is received. The AspSessionMax Metabase Property specifies the maximum number of concurrent sessions that IIS permits. For applications that take advantage of sessions, you might want to decrease the session timeout in order to reduce server overhead. If decreasing the session timeout causes the number of concurrent sessions to increase too much, you might need to set a lower session maximum.

**AspTrackThreadingModel**

The AspTrackThreadingModel Metabase Property specifies whether IIS checks the threading model of any components that your application creates. ASP no longer uses this metabase property, although it is still in the metabase to provide compatibility with existing administrative scripts. It is recommended that you retain this property's default value, which is **false,** to avoid the overhead incurred by the ASP track threading model and to help improve performance of your ASP application.

**CacheISAPI**

The CacheISAPI Metabase Property indicates whether ISAPI extensions are cached in memory after first use. If the value of this property is **true** (the default setting), ISAPI extensions, after they are loaded, remain in the cache until the server is stopped. If the value is **false**, extensions are unloaded from memory after the ISAPI extension is no longer in use.

ISAPI extensions are cached or not cached based on the value of this property when they are loaded into memory. Thus, if this property is changed after an extension is loaded and cached, the change has no effect on that extension until the Web server is restarted.

Although you might temporarily set this property to **false** to help with debugging, you need to keep this value set to **true** on all production Web servers. Because the ASP.dll is an ISAPI extension, disabling this property — which requires that every request be reloaded — degrades performance.

# Monitoring ASP.NET Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP.NET includes a number of performance counters that you can use to track the execution of your Web applications. When you do steady-state running analysis, you might want to ignore the first request and also any one-time initialization costs for objects. For example, when an ASP.NET page is requested for the first time, there is always the cost of compiling an instance of the **Page** class. After the initial cost is incurred, performance improves for subsequent requests.

| **Note** |
| --- |
| You can also use the built-in ASP.NET tracing feature to track code execution for a page or an application. |

Two performance objects are defined for ASP.NET, supporting two types of performance counters:

- The ASP.NET performance object contains system counters that monitor events on the state server. These global counters are not bound to a particular application instance.
- The ASP.NET Applications performance object contains application counters.

For example, there is a significant difference between the State Server Sessions counters for the ASP.NET performance object, which apply only to the computer on which the state server is running, and the Sessions counters for the ASP.NET Applications performance object, which apply only to user sessions that occur in process.

Unlike the ASP performance counters discussed earlier, which are exposed globally for the entire server computer, most of the ASP.NET performance counters are exposed per application.

Use System Monitor to view the counters for ASP.NET. If your Web server serves multiple applications, you need to specify a particular application instance when selecting a counter to monitor. In addition, System Monitor provides a **__Total__** application instance, which aggregates the counter values for all applications on a server.

**Useful Counters for Monitoring ASP.NET Applications**

When monitoring the performance of your ASP.NET Web applications, try tracking the performance counters described in Table 6.26.

**Table 6.26 ASP.NET Performance Counters**

| Object\Counter | Value |
| --- | --- |
| ASP.NET\Application Restarts | The aggregate number of restarts for all ASP.NET applications during the Web servers lifetime. |
| ASP.NET\Requests Queued | The number of ASP.NET requests waiting to be processed. |
| ASP.NET\Worker Process Restarts | The number of times that a worker process has restarted on the computer. |
| ASP.NET Applications\Errors Total | The total number of errors that have occurred in ASP.NET applications. |
| ASP.NET Applications\Requests/Sec | The number of requests executed per second for ASP.NET applications. |

Application restarts, as reported by the ASP.NET\Application Restarts counter, are incremented with each **Application_OnEnd** event. An application restart can occur because changes were made to the Web.config file or to assemblies stored in the applications \Bin directory, or because too many changes occurred in Web Forms pages. A sudden increase in this counter can mean that your Web application is shutting down. If an unexpected increase occurs, be sure to investigate it promptly. This value is reset every time that IIS is restarted.

| **Note** |
| --- |
| The value of each ASP.NET performance counter is updated every 400milliseconds. |

**Useful Counters for Troubleshooting ASP.NET Performance Problems**

Table 6.27 describes some additional performance counters that you can use to troubleshoot performance problems with your Web applications.

**Table 6.27 Performance Counters for Troubleshooting ASP.NET Applications**

| Object\Counter | Indicates |
|---|---|
| ASP.NET Applications\Pipeline Instance Count | The number of active pipeline instances. |
| .NET CLR Exceptions\# of Exceps Thrown | The total number of exceptions thrown since the start of the application. Collects data both on .NET exceptions and on unmanaged exceptions that are converted to .NET exceptions. For example, a null pointer reference exception in unmanaged code is rethrown in managed code as a .NET SystemNullReferenceException. Exceptions that are rethrown are recounted. This counter collects data from both handled and unhandled exceptions. |
| System\Context Switches/sec | The rate at which thread contexts are switched by all CPUs in the Web server. A high number usually indicates either high contention for locks or many switches between user and kernel mode by the thread. Be sure to investigate these problems by using sampling profiles and other tools. |

Although exceptions occur infrequently, you might want to monitor the # of Exceps Thrown counter, because exceptions can have performance implications. Some code paths, however, rely on exceptions for their proper functioning. For example, the **HttpResponse.Redirect** method always throws an exception, **ThreadAbortException**. Therefore, it can be more useful to track the number of exceptions thrown by using the Errors Total counter to see if the exception generated an error for the application.

**Related Topics**

For more information about the ASP.NET performance counters discussed in this section, as well as other ASP.NET performance counters, see IIS 6.0 Performance Counters.

# Balancing Performance and Security

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Balancing performance with concerns about the security of your Web applications can be an important issue, particularly if you run an e-commerce Web site. Secure Web communications require more resources than do Web communications that are not secure, so you need to know when to use security techniques such as SSL certificates or any of the Windows authentication methods. Because SSL uses complex encryption, and encryption requires considerable processor resources, it takes much longer to retrieve and send data from SSL-enabled directories. Therefore, you should place only those files that contain or receive sensitive information in your SSL-enabled directory, keeping pages free of resource-consuming elements such as images.

If you use SSL, be aware that establishing the initial connection takes five times longer than reconnecting by using security information in the SSL session cache. The default time-out interval for the SSL session cache is 10 hours in Windows Server 2003. After secure data is deleted from the cache, the client and server must establish a new connection.

# Configuring ServerCacheTime for SSL Sessions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you plan to support long SSL sessions, consider lengthening the SSL cache time-out interval by adding the ServerCacheTime entry to the registry. If you expect thousands of users to connect to your site by using SSL, estimate how long you expect SSL sessions to last, and then set the value of the ServerCacheTime entry to a number slightly higher than your estimate. Do not set the value much higher than your estimate, because the resulting time-out interval might cause your server to retain stale data in the cache.

| **Caution** |
| --- |
| The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference. |

One reason for changing the default value for the SSL session cache is to force the client to authenticate more often. More frequent caching is sometimes useful, for example, if you know that the client is using a smart card and you want the Web page to be accessible only when the user inserts the smart card in the reader.

Before changing the SSL cache time-out interval, make sure that HTTP Keep-Alives are enabled (HTTP Keep-Alives are enabled by default). SSL sessions do not expire when you use them with HTTP Keep-Alives except when the browser closes the connection.

For information about adding the ServerCacheTime entry to the registry, see Setting the SSL Cache Time-out Interval. For more information about configuring SSL session caching, including how to set the ClientCacheTime registry setting, see Knowledge Base article 247658, How to Configure Secure Sockets Layer Server and Client Cache Elements.

**Related Topics**

For more information about editing the registry, see the Registry Reference.

# Testing How Security Features Affect Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The security services in Windows Server 2003 and IIS 6.0 are integrated into a number of operating system services. This means that you cannot monitor security features separately from other aspects of those services. Instead, the most common way to measure security overhead is to run tests that compare server performance with and without a security feature. Run the tests with fixed workloads and a fixed server configuration so that the security feature is the only variable.

In your tests of the effects of security services on performance, measure the following:

- Processor activity and the processor queue. Security features like authentication, certificates, encryption, and the SSL protocol require significant processing; so it is important to balance the performance costs associated with these security features with your performance objectives.

  When using security features, you are likely to see increased processor activity, in both privileged mode and user mode, and an increase in the rate of context switches and interrupts. If the processors on the server are not sufficient to handle the increased load, queues are likely to form.

  If the SSL protocol is being used, Lsass.exe might consume an unexpected amount of CPU resources because SSL processing occurs in the Lsass.exe process. Custom hardware, such as cryptographic accelerators that perform encryption, can help. When you create certificates by using the certificate wizards provided in IIS, you can select a cryptographic service provider that uses cryptographic accelerators.

- Physical memory used. Security features require that the system store and retrieve more user information.

- Network traffic. You are likely to see an increase in traffic between the IIS-based server and the domain controller that is used for authenticating logon passwords and verifying IP addresses.

- Latency and delays. The most obvious performance degradation resulting from complex security features like SSL is the time and effort involved in encryption and decryption, both of which use many processor cycles. Downloading files from servers by using the SSL protocol can be 10 to 100 times slower than downloading from servers that are not using SSL.

| **Important** |
| --- |
| It is recommended that you do not use a domain controller as a Web server. If a domain controller is running IIS, the proportion of processor use, memory, and network and disk activity consumed by domain services is likely to increase significantly. The increased activity can be enough to prevent IIS services from running efficiently. |

**Related Topics**

For more information about IIS certificate wizards, see Using Certificate Wizards.

# Measuring Security Overhead by Using a Stress Client

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To test a security feature like SSL, first run a stress client test with the security feature; then run the same test without it. Be sure to run the "with feature" and "without feature" versions of the test on varying workloads and multiple clients.

To eliminate the effects of unintended variations of the test conditions, repeat each test several times and average the results. Then, compare the results of the "with feature" and "without feature" tests. Consistent differences in the results of the tests are likely to indicate the overhead associated with the security feature. You can use these results for planning configuration changes to handle the security overhead.

For more information about testing with a stress client, see Testing Applications with Stress Tools.

WCAT is a particularly useful tool for determining security overhead. Run IIS 6.0 logging together with WCAT to count the number of logons and file accesses. In addition, you can use System Monitor, which includes a set of counters for monitoring user authentication.

**Related Topics**

For more information about obtaining and using WCAT, see Using WCAT as a Stress Client.

# Tracking Anonymous and Nonanonymous Requests

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Web Service and FTP Service performance objects include counters that report the number of anonymous and nonanonymous requests that are sent to each of these IIS 6.0 services. (The term *nonanonymous* is used instead of *authenticated* to account for custom authentication schemes that require data from the client other than, or in addition to, the user name and password, as is also the case with authentication.)

By themselves, these counters help you determine the number and proportion of each type of request. You can also use the counter values to estimate the effect of changing how you handle anonymous and nonanonymous users. For example, if most connections are anonymous, prohibiting anonymous requests has a more significant impact than if most requests are nonanonymous.

Analysis of data from these counters, together with general measures of server performance — such as the use and allocation of processor time, the size of processor queues, memory use, the number of disk reads and writes, and throughput — is even more useful. By analyzing the combined data, you can associate the effects of varying numbers and proportions of anonymous and nonanonymous users with changes in the performance of system components.

The counters that report the number of anonymous and nonanonymous requests are called Current Anonymous Users and Current NonAnonymous Users. In IIS 5.0, these counters actually displayed connections. In IIS 6.0, these counters count each request as a unique user.

Table 6.29 describes the counters for monitoring anonymous and nonanonymous requests. These counters are associated with the Web Service and FTP Service performance objects. The Anonymous Users and Nonanonymous Users counters display the number of anonymous and nonanonymous requests to the IIS 6.0 service when the values were last observed. They do not report averages or rates. These counters can exaggerate the number of requests because closed requests might not yet have been deleted when the counter is displayed.

**Table 6.29 Counters for Anonymous and Nonanonymous Users**

| Object\Counter | Indicates |
|---|---|
| Web Service\Anonymous Users/sec<br>Web Service\NonAnonymous Users/sec | The number of requests per second that anonymous or nonanonymous users sent to the IIS 6.0 service. (These counters provide an instantaneous value rather than an average.) Note that IIS 6.0 counts each request as a new user. |
| Web Service\Current Anonymous Users<br>Web Service\Current NonAnonymous Users<br>FTP Service\Current Anonymous Users<br>FTP Service\Current NonAnonymous Users | The number of requests from anonymous or nonanonymous users that the server is currently processing. Note that IIS 6.0 counts each request as a new user. |
| Web Service\Maximum Anonymous Users<br>Web Service\Maximum NonAnonymous Users<br>FTP Service\Maximum Anonymous Users<br>FTP Service\Maximum NonAnonymous Users | The maximum number of anonymous or nonanonymous users that made concurrent requests to the service since the service was started. Note that IIS 6.0 counts each request as a new user. |

| | |
|---|---|
| Web Service\Total Anonymous Users<br><br>Web Service\Total NonAnonymous Users<br><br>FTP Service\Total Anonymous Users<br><br>FTP Service\Total NonAnonymous Users | The total number of requests that anonymous or nonanonymous users sent to the service since the service was started. Note that IIS 6.0 counts each request as a new user. |
| Web Service\Total Logon Attempts<br><br>FTP Service\Total Logon Attempts | The total number of requests that both anonymous and nonanonymous users sent to the service since the service was started. |

**Related Topics**

If you prefer to use SNMP services to monitor the WWW and FTP services, IIS provides a set of SNMP counters that monitor anonymous and nonanonymous users. For more information about the SNMP Web counters, see IIS 6.0 Performance Counters.

# Watching 404 Not-Found Errors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Web Service performance object includes a counter that displays not-found errors. Not-found errors result from client requests that were not satisfied because they included a reference to a Web page or a file that does not exist. These errors are identified by their HTTP status code number, which is 404. Many not-found errors occur because Web pages and files have been deleted or moved to another location.

You can use the Web Service\Not Found Errors/sec counter, described in Table 6.30, to track the rate at which not-found errors are occurring on your server. Alternatively, set an alert in Performance Logs and Alerts to notify the administrator when the rate of not-found errors exceeds a threshold.

**Table 6.30 Counters for Not-Found Errors**

| Object\Counter | Indicates |
|---|---|
| Web Service\Not Found Errors/sec | The number of client read requests that were not satisfied because the URL did not point to a valid file. |

An increase in not-found errors might indicate that a file has been moved without its link being updated. However, it can also indicate failed attempts to access protected documents, such as user lists and file directories.

An increase in not-found errors might also be related to IIS 6.0 security measures. When you perform a clean installation of IIS 6.0, the default settings ensure that IIS is installed in a secure, locked mode. This default installation serves only static HTTP content, such as .htm files; the request handlers for dynamic content, such as ISAPI and CGI, are disabled.

IIS 6.0 provides new substatus error codes that can help you determine why an HTTP 404 error (file or directory not found) occurred. For example, if a request is denied because an ISAPI extension or CGI is locked, a 404.2 error is returned, and a 404.3 substatus code indicates a MIME map restriction policy.

**Related Topics**

For more information about analyzing substatus codes, see Troubleshooting IIS 6.0. For more information about unlocking dynamic content, see Common IIS 6.0 Administrative Tasks.

# Analyzing Security Data and Planning Upgrades

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you collect data to assess the effects of adding security features to your server configuration, use the results of your analysis to plan configuration changes that can help you handle the additional workload that is required to support security features. Consider the following options.

**Upgrade or add processors**
Security features in general and the SSL protocol in particular are usually processor-intensive. Because Windows Server 2003 security features are multithreaded, they can run simultaneously on multiple processors. Thus, adding processors can improve performance significantly and prevent the processors from becoming a bottleneck.

For best results, choose processors with large secondary (L2) cache space (up to 2 MB). When a security feature like SSL encrypts and decrypts data, much of the processors time goes to reading and writing small units of data to and from main memory. If your server can store this data in the processor cache, the data is retrieved much faster.

**Add memory**
If security features cause increased paging or shortages in virtual memory, adding more memory can help. The physical memory used to support the security service consumes space that can be used to cache files. To accommodate peak use, allow for twice as much memory as required during times of average use while still maintaining 10 MB of available memory.

| **Important** |
| --- |
| Avoid adding disk space for security-related activity. Do not add disk space solely to support security features. Any increased disk activity associated with security features is likely to result from a shortage of physical memory, not from an actual need for more disk space. Security features such as the SSL protocol rely primarily on processors and physical memory, as opposed to disk space. |

**Use custom hardware**
Custom hardware, such as cryptoaccelerator cards, can make a significant difference in the way that your server handles security overhead. Be sure to thoroughly test any nonstandard hardware to make sure that it is compatible with the other hardware and software that you use.

**Related Topics**

- For more information about IIS security features, see Configuring Advanced Security and Customization.
- For more information about setting up certificates and keys, see Configuring SSL on a Web Server or Web Site.
- For more information about enabling HTTP keep-alives, see Enabling HTTP Keep-Alives to Keep Connections Open.

# Optimizing Performance Through Design

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to monitoring and tuning your server, you can optimize performance by improving the design and administration of your Web applications, by optimizing Web page design to create efficient Web pages, and by partnering with other groups in your organization who share the same network.

# Optimizing Application Design and Administration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can often improve the performance of your Web server by paying attention to the design and administration of your Web applications and by upgrading hardware components to support fast application response times.

**Upgrading Hardware to Improve Application Performance**
Several types of hardware upgrade can significantly improve application response times on your Web servers:

- Upgrade or add processors. Web applications benefit from faster processors.

- Add memory. Adding memory can improve application response times if applications are running within their own processes.

**Optimizing Application Design**
Check this list for general application design guidelines that can optimize performance.

- Use static files wherever possible. Typically, static files require much less processor time than do files with dynamic content.

  If you are generating pages dynamically to satisfy user preferences, consider substituting as many as 10 or 20 static variations for a single dynamic page. If you are generating dynamic pages to provide frequently updated data, redesign your application so that it generates a single static page on a fixed schedule and stores that page for retrieval until the next update.

- Use managed code (C# or Microsoft® Visual Basic® .NET), Microsoft ASP.NET, or ISAPI applications. C# and Visual Basic .NET applications usually run faster than ASP applications because the run-time environment executes compiled code. All of these types of applications typically run faster than equivalent CGI applications.

- Enable ISAPI and ASP.NET output caching where possible, which allows HTTP.sys to cache the response and serve requests for the applications from the kernel instead of transitioning to user mode. For more information about tuning ISAPI output caching, see Tuning ASP Metabase Settings.

- Avoid transitions from managed code to unmanaged code in your applications, if possible.

- Enhance database-driven performance by using Microsoft SQL Server. Create and maintain good indexes to minimize I/O during database queries. Also, use stored procedures, which take much less time to execute and are easier to write than ASP scripts designed to do the same task.

- Design your site so that applications push the processing load onto the client.

  Client-side checks reduce roundtrips and help to avoid network latencies, conserve server-side resources, and allow changes to appear instantaneously to the user. For example, add client-side code to validate that forms are filled out with good data, such as checking that credit-card numbers have a correct checksum. However, the server must still validate the data, because malicious clients can send malformed data.

**Optimizing the Design of ASP Applications**
Check this list for ASP application design guidelines that can optimize performance.

- Turn off ASP debugging, and verify that both the **AppAllowDebugging** and **AppAllowClientDebug** metabase properties are set to false.

- Avoid storing apartment-threaded components in ASP application or session state. Remove Visual Basic objects from ASP Session state if they are apartment threaded.

- Cache output from ASP if possible; if not, cache inputs to ASP if possible.

- Convert scripts in ASP pages into COM objects. Scripts in ASP pages are interpreted; if a script involves one or more loops, converting it to a COM object can improve its performance considerably.

- ASP is now able to run all of its threads in a multithreaded apartment (MTA). If your COM components are primarily free-threaded or both-threaded, running the ASP threads as MTA can improve performance significantly. To enable all ASP applications to run in an MTA, you can use the metabase property **AspExecuteInMTA** at the application level. For more information about designing ASP to run its threads in MTA, see Configuring Applications to Use COM+ Services.

- If an ASP script is more than 100 lines (counting lines of code in included files), consider creating a COM+ component to provide the same function. If COM+ components are written efficiently and debugged properly, they can offer 20 to 30 times the processing speed of a script for the same dynamic page.

| **Tip** |
| --- |
| The easiest way to measure the size of an ASP script with **#include** directives is to change the file name extension of the page from .asp to .stm, and then open the .stm file by using your browser. Use your browser's **View Source** command to display the .asp file and lines of code from the included files. |

**Optimizing Network Administration and Design**

Check this list for network administration and design guidelines that can optimize performance.

- Set HTTP expire headers for all images and for HTML so that proxy servers and browsers make fewer calls to the Web server. For information about setting an expiration date for Web site content, see Using Content Expiration.

- Use SSL certificates only when needed and only for content that requires security. Because SSL uses complex encryption that consumes considerable processor resources, it takes much longer to retrieve and send data from SSL-enabled directories. Therefore, only secure the files that contain or receive sensitive information, such as credit-card numbers or medical information. Also, keep these pages free of other elements that consume resources, such as images. For more information about implementing an acceptable level of security while preserving performance, see Balancing Performance and Security.

- Minimize initialization processing wherever possible. For example, enable caching, when appropriate; on multiprocessor computers, assign processor affinity to better use CPU caching; and use HTTP compression for faster downloads. For information about caching, see Monitoring Overall Server Memory. For information about using compression on different file types, see Using HTTP Compression for Faster Downloads.

- Run IIS in worker process isolation mode, which allows you to periodically restart worker processes assigned to an application pool (either manually or automatically by using preconfigured settings). Recycling worker processes can help minimize problems attributed to faulty Web applications.

- Establish Web gardens, which are application pools that can run multiple worker processes.

- Stress-test applications in your lab before you place them on a production server.

- If you have a large installation with many FTP sites, each attached to a different IP port, your server might create too many backlog monitor threads (the system creates a thread for every 64 sites). The workaround for this is to disable the backlog monitor. To disable the backlog monitor, set the value of the DisableBacklogMonitor registry entry to 1 and then restart the FTP services. The DisableBacklogMonitor entry is located in the following registry subkey:

  HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Inetinfo\Parameters

| **Caution** |
| --- |
| The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference. |

- If you expect a large spike in traffic on a particular page or set of pages, you can change that page or set it to static HTML for a few days. Switching from a dynamic page to static HTML can involve some redesign, but the effort is often worthwhile. For example, when many thousands of people, during a short period, traverse three or four scripted pages to get to a particular download page, your server uses a lot more resources than it needs to. To save time for your users, you can instead provide a temporary static front page that has simple navigation.

**Related Topics**

For information about editing the registry, see the Registry Reference.

# Creating a More Efficient Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Creating a page-load performance profile provides a systematic way of looking at a Web page and recording its performance characteristics across a wide area network (WAN). A page-load performance profile incorporates the distance, congestion, and limited bandwidth that 99 percent of your users experience when accessing your site.

Page-load performance profiles can help you determine the following:

- The impact of not setting expiration dates.
- Which files are taking the longest to load.
- Whether you have unneeded file content.
- Where to reduce and consolidate files.
- How long your pages take to load (on first access and second access).
- Whether you need to enable or adjust your compression configuration.

To perform a page-load test, install the appropriate tools to collect data so that you can develop performance profiles by analyzing HTTP traffic. Network Monitor is a protocol analyzer that looks into packet-level detail. For more information about obtaining and using this tool, see Network Monitor overview in Help and Support Center for Windows Server 2003.

After obtaining page-load performance profiles for your Web pages, you can use the performance data to identify changes that you can make in order to optimize the performance of the Web pages.

# Obtaining a Page-Load Performance Profile

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To obtain an accurate picture of a Web pages performance during normal use, you must obtain page-load performance data for the second access to a Web page as well as the first access. The first-access load time is usually much longer in duration than second-access load times. When a first-time user visits a Web page, the user's computer does not hold cached files from previous visits; hence, the user's browser must load all the files that are a part of the Web page. The procedure for measuring a Web page's first-access load time differs slightly from the procedure for measuring second-access load times.

For information about measuring first-access and second-access page-load times for a Web page, see Measuring Load Time for a Web Page.

After you complete your own page-load performance profiles, perform a page-load test against your competitor's sites, compare the results with your own performance data, and ask:

- Which site is faster?
- Does speed contribute to ratings?
- Which sites will users choose to come back to?

# Optimizing a Page-Load Performance Profile

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By optimizing page-load performance profiles, you can provide more efficient Web sites for your users. Begin by making sure that HTTP Keep-Alives are enabled, enabling HTTP compression if appropriate for your Web sites, and setting expiration dates on the files associated with your Web pages. Then identify your slow-loading files, reviewing them for unneeded file content. Next measure your file quantity and size. Finally, determine port usage and minimize unneeded screen refreshes. After reviewing all these factors and optimizing your Web sites, obtain a new page-load profile to determine whether the changes significantly improve the efficiency of your Web site.

For additional tips for optimizing your Web sites, see Best Practices for Creating Efficient Sites. For instructions telling how to obtain a page-load profile, see Obtaining a Page-Load Performance Profile.

**Verify That HTTP Keep-Alives Are Enabled**

Another item to verify is the connection = keep-alive state for each TCP connection. If keep-alive connections are turned off, every file requires a new TCP connection. For small files, enabling HTTP Keep-Alives in IIS effectively doubles the number of roundtrips. For more information about HTTP Keep-Alives, see Enabling HTTP Keep-Alives to Keep Connections Open.

**Set HTTP Compression**

If you have Web sites that use large amounts of bandwidth, consider enabling HTTP compression to obtain faster transmission times between your server and compression-enabled browsers. The performance cost of compressing a static file is small and is typically incurred only once because the compressed file is stored in a compression cache.

The cost of expanding the file at the browser is minimal. Compressed files download faster, which makes them especially beneficial to the performance of any browser that uses a network connection with restricted bandwidth, such as a modem connection.

For more information about enabling HTTP compression, see Using HTTP Compression for Faster Downloads.

**Set Expiration Dates on Files**

A common performance mistake is forgetting to set the expiration dates on the files associated with Web pages. When a user returns to a Web page, Internet Explorer already has most of the files for the page in its cache, but it does not use these files if the expiration dates are in the past. Instead, Internet Explorer sends a GET request to the server for the file, indicating the date of the file in the cache. If the file has not changed, the server sends a Not Modified message. This GET/Not-Modified sequence costs the client a roundtrip. For small files of 3 KB or less, this roundtrip is as expensive as getting the original file.

For more information about setting expiration dates, see Using Content Expiration.

**Identify Slow-Loading Files**

Identifying which files are taking the longest to load often provides the best clues about what you need to improve. Causes of very long load times can include server capacity issues, network congestion, and large file content. Use the data that you collect from Network Monitor captures to identify how long each file takes to load. Visit a Web page several times and observe which files are regularly loaded most slowly. Multiple visits to a page help improve statistical veracity.

**Remove Unneeded File Content**

Files often contain clutter, such as tabs, spaces, new lines, and comments, which consumes up to 15 percent or more of a page. For production Web sites that are visited by millions of users, remove every bit of file content that is not absolutely necessary for the rendering of the page.

View the packet contents of your files with Network Monitor. Look for repetitive text such as <Option Value = data> statements that are used to insert text into drop-down lists. It takes much less space to add a few lines of code that sends an array (that reads the drop-down lists) to the client.

**Measure File Quantity and Size**

The number and size of files that you load on your Web site have a large impact on page-load times. Fewer large files load faster than many small files, as follows:

- Number of files. For each file, HTTP must perform a GET-File. Each GET-File is at least a single roundtrip. If the files are on a new server that the user has not previously connected to, HTTP must also make another roundtrip to create a new connection. Roundtrips across a modem cost 250 milliseconds or more.

The optimal minimum number of files for a Web site is about four. Consider consolidating like files; for example, have only one .js or .css file instead of two or three.

- Size of files. The TCP slow-start algorithm favors larger files. When a new connection is first opened, TCP sends a small number of packets in response to a GET-File. Thereafter, for each acknowledgement received by the server, TCP increases the number of response packets sent to the client.

  Small files of 3 KB or less are complete in one roundtrip. Files larger than 20 KB receive only about 16 KB of data per roundtrip. The size of a file can make the difference between a very small bit rate of 1 to 10 kilobits per second (Kbps) and a high bit rate of 40 to hundreds of Kbps.

**Determine Your Port Usage**

Using HTTP 1.1, Internet Explorer can open a maximum of two ports to any one server and a maximum of four ports total. The best performance occurs when four ports are opened and are kept open to be reused by all the files. Reusing a port is a good thing; when TCP slow-start increases the window size for a file, the next file that uses the same port can also use the increased window size.

View your Network Monitor capture summary to determine how many ports were used during your page-load tests, and by which files. Keep in mind that measuring Web pages through a proxy server hides the true number of ports being used. The best tests from your office are conducted by using a direct connection to the Internet without a proxy.

**Control Screen Refreshes**

In a refresh request, Internet Explorer (the client) tells the server the date stamp of the version of a file that it has in its cache by using the If-Modified-Since header. IIS 6.0 then determines whether the file has been modified since that time. If the file is unmodified, IIS 6.0 replies with a brief Not Modified response.

In routine file updates for your Web site, do not copy files that have not been modified. A static HTML page is not retrieved during a screen refresh if it has not been updated. Some publication processes copy files that have not been modified, which gives the files new time stamps and thus updates them as far as the system is concerned. These files are downloaded even though they are actually unchanged. When you set up your publication process, make every effort to avoid this waste of resources.

# Best Practices for Creating Efficient Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following best practices can help you improve the efficiency of important, often-used Web pages.

**Optimize settings**

- Set file expiration dates. By setting future expiration dates on each file at the IIS server, you can reduce second-access load times by 50 to 70 percent.
- Enable HTTP Keep-Alives in IIS.
- Author hyperlinks consistently because the Internet Explorer cache is case sensitive.
- Use cache-control extensions. Internet Explorer version 5 introduced support for two extensions to the cache-control HTTP response header: pre-check and post-check.
- Enable HTTP compression to increase efficiency of bandwidth use.

**Use design elements judiciously**

- Standardize images. For example, if your site uses two images that are slightly different from each other, either in size, color, or design, standardize to a single image.
- Reduce Graphics Interchange Format (GIF) image color depth or consider using Portable Network Graphics (PNG) format.
- Eliminate unnecessary images that appear below the scroll bar. Users view these images less frequently; so weigh their value against their performance cost. For example, use text rather than images for arrows, lines, and bullets. Incorporate several small images into one large graphic (or remove some of the images). Substitute smaller images for large ones.
- Use the most compact graphics format that supports the quality of image that you need. Images saved as a file type that is inherently large, such as a Tagged Image File Format (.tif), can increase download times; consider substituting a more compact format such as a Graphics Interchange Format (.gif) or a Joint Photographic Experts Group (.jpg) file. You might also consider compressing existing images.

**Ensure that developers design scripts and code that load quickly**

- Reduce clutter. Space characters, tabs, and remarks often consume more than 20 percent of an .htm or an .asp file. Delete this clutter before you load the files on production servers.
- Remove redundant tags. Consider using arrays to fill drop-down lists instead of repeating [<Option Value = data> data</Option>] again and again.
- Use JavaScript (.js) files to consolidate commonly used scripts.
- Reduce the number of small files. Build whole images instead of multiple component images. For tabs, use a single image map.
- Consolidate multiple images and adjacent images into a single file.
- Do not use nested <table> tags.

**Test load times for your pages**

You can use the following tools to test the load times for your Web pages:

- WAN simulators
- Network Monitor
- Load simulators for the Internet environment
- Reporting tools

# Partnering with Other Groups to Improve Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In enterprise organizations, where corporate intranets might be accessed by employees in far-reaching parts of the country or the world, IT administrators in areas that share the intranet must work together to ensure optimal performance for all users. Take time to find out how the performance of other areas is affecting the performance of your applications and systems; then work with IT administrators in other areas to coordinate efforts to improve performance.

If the systems and applications that you manage depend on the performance of other systems and applications, use this guide to help you collaborate with your IT partners:

1. Identify your partners:

   - Start early in the IT cycle to contact partners and find performance allies in other groups and on your own team. Obtain agreement to work together to maintain and improve performance, including upgrading, adding to, or changing your network components.

   - Determine how the performance of other systems and applications affects your systems and applications, and vice versa; then document the dependencies and share the data with your partners.

2. Before you begin your design, obtain information about your users. You must know your users in order to set realistic goals for response times and system preferences. If possible, conduct usability tests to discover the actual needs, behaviors, and preferences of real users.

3. Set performance goals for your group, and establish a timeline:

   - Set performance goals and test plans for your group.

   - Discuss key milestones in your timeline.

   - Identify competing priorities, especially conflicting priorities of partners outside your immediate group.

4. Coordinate your plans and goals with your partners plans and goals:

   - Share your goals, timeline, and milestones with your partners; then synchronize goals and timelines with them. Define terminology to ensure that everyone understands each goal and service level. Include a plan for communicating with your partners.

   - Write contracts, if needed, to set service level agreements for performance and to balance competing priorities so that other groups priorities do not adversely affect yours (and vice versa).

   - Establish baseline requirements for operating systems and hardware.

   - Establish guidelines for how to monitor any mutual performance dependencies. Establish minimum testing standards. Establish a system for logging bugs against performance problems.

5. Design the systems and applications for your group to minimize their impact on other components:

   - Design your client systems so they do not put unnecessary load on servers. For example, ensure that clients' browsers are compression-enabled, and enable HTTP compression of static files on your Web server to provide faster transmission times.

- Test to identify and minimize unnecessary client requests, such as requests from impatient users who make numerous attempts to access the same page. It is recommended that you set the AspQueueConnectionTestTime Metabase Property so that your server does not process abandoned requests, enable HTTP Keep-Alives, and set up caching to minimize requests from clients Web browsers.

# Additional Resources for IIS 6.0 Performance

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to this optimizing IIS 6.0 performance.

**Related Information**

- Analyzing Log Files for information about using IIS logs to monitor and tune performance.
- Common IIS 6.0 Administrative Tasks for step-by-step instructions to help you complete many of the tasks described in the performance topics.
- Troubleshooting IIS 6.0 for information about troubleshooting performance.
- Web Server Scalability for information about IIS 6.0 capacity planning and scalability.
- Article 247658, Configure Secure Sockets Layer Server and Client Cache Elements, in the Microsoft Knowledge Base for information about configuring SSL session caching, including how to set the ClientCacheTime registry setting.
- Article 313064, Monitor Web Server Performance by Using Counter Logs in System Monitor in IIS, in the Microsoft Knowledge Base for information about creating counter logs, including baseline IIS logs.
- The Windows System Resource Manager — Fast Facts site for information about using Windows System Resource Manager.
- Microsoft Application Consulting and Engineering (ACE) Team, *Performance Testing Microsoft .NET Web Applications*. Redmond, WA: Microsoft Press, 2003. Read this source for information about how to perform stress testing by using Microsoft Application Center Test (ACT), how to use System Monitor and Network Monitor, and how to conduct an application network analysis.

**Related IIS 6.0 Operations Guide Topics**

- Enabling Logging, which is accessible from IIS Manager, for information about performance logging.
- Limiting Connections for information about setting global and individual site connection limits.
- Administering Network Resources for information about the QoS features in IIS 6.0.
- Analyzing Security Data and Planning Upgrades for information about IIS 6.0 security features.
- Web Application Guide for information about Web application development, including ASP.NET and ASP applications.

**Related Windows Server 2003 Help Topics**

For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the **Search in title only** check box.

- Analyzing performance data in Help and Support Center for Windows Server 2003 for information about analyzing log data and a list of acceptable values for counters.
- Performance console overview in Help and Support Center for Windows Server 2003 for information about Windows performance monitoring tools.
- Monitoring performance from the command line in Help and Support Center for Windows Server 2003 for information about command-line tools that you can use to monitor performance.

- The TCP/IP model in Help and Support Center for Windows Server 2003 for information about how the OSI model relates to the TCP/IP reference model.

**Related Tools**

- The **logman** command

  Use the **logman** command to schedule performance counter and event trace log collections on local and remote systems. For more information about the **logman** command, see Logman in Help and Support Center for Windows Server 2003.

- Log Parser tool (LogParser.exe)

  Use the Log Parser tool to extract data from the raw file. The Log Parser tool and its accompanying user documentation are included in the IIS 6.0 Resource Kit Tools.

- The **start netmon** command

  Use the **start netmon** command to start the Network Monitor user interface from the command line. You can also specify parameters for capturing and filtering frames. For more information about using this command-line option, see Managing Network Monitor from the command line in Help and Support Center for Windows Server 2003.

- Web Capacity Analysis Tool (WCAT), which contains a stress client tool (Wcclient.exe) and a controller tool (Wcctl.exe).

  Use WCAT to perform stress testing. WCAT and its accompanying user documentation are included in the IIS 6.0 Resource Kit Tools.

# Web Server Scalability

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) 6.0, running on the Microsoft® Windows® Server 2003 operating system, includes a new architecture and new features to help your application server scale. *Scaling* is the ability of a system to handle increasing demands at an acceptable performance level. If an application server and the underlying infrastructure scale, the application can handle steady traffic growth, in addition to occasional peaks in traffic volumes, while maintaining good performance. If an application server and the underlying infrastructure do not scale, clients connecting to that application can experience poor response times, errors, or other problems that might ultimately frustrate end users.

# Scaling IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Changes in the Internet Information Services (IIS) 6.0 architecture have led to dramatic improvements in how IIS scales. During preliminary testing, IIS 6.0 scaled better than earlier versions of IIS. Those preliminary results showed that on a default installation, while running in worker process isolation mode, IIS 6.0 was capable of the following:

- Hosting as many as 20,000 static-content sites.
- Hosting as many as 2,000 application pools.
- Processing 25,000 requests per second for a 15-KB cached static file with Hypertext Transfer Protocol (HTTP) Keep-Alives enabled.
- Running hundreds — or potentially thousands — of simultaneous worker processes.

| **Note** |
| --- |
| Performance and scalability results vary depending on hardware and software configurations. Microsoft does not make any warranties or guarantees about these preliminary results. |

Additionally, processing throughput has greatly improved for installations with up to eight processors. Default thread pool, queue, and cache settings have all been tuned to increase throughput. Startup and shutdown times are faster than earlier versions. Simply put, your IIS Web server installation should scale better on a default installation of IIS 6.0 than on any earlier version of IIS. However, there are many variables in a Web server installation that can affect how IIS 6.0 scales. Scalability is dependent on the least scalable part in your server installation. Factors such as network latency, slow back-end processing, a shortage of RAM on your servers, or poorly designed and untested applications can all undermine how IIS 6.0 scales. If one part does not scale, the whole installation suffers.

This section provides a brief overview of the many changes and features that help IIS scale, and also describes some of the changes and features in the Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Web Edition; and Windows® Server 2003, Datacenter Edition operating systems that can increase the scalability of your server installation. Be aware that scaling an application server is a process much like tuning the performance of your server. Performance and scalability are intricately linked, and both goals require long-term planning, testing, and monitoring. For more information about performance monitoring and tuning, see Optimizing IIS 6.0 Performance.

# Scalability Features in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This section describes features in IIS 6.0 that can improve the scalability of your application server.

| **Important** |
| --- |
| Do not enable the features described in this chapter on a production server before you establish a performance baseline in a test environment. If enabling any of these features degrades performance, continue testing or disable the feature and return your server to the pre-change configuration. |

**Worker process isolation mode**

IIS 6.0 introduces worker process isolation mode, which runs all Web applications in an isolated environment. When you run IIS in worker process isolation mode, you can configure applications to run in separate application pools. An *application pool* is a grouping of URLs routed to one or more worker processes. An application pool allows specific configuration settings to apply to these worker processes.

Worker processes operate independently: if one fails, it does not affect other worker processes. The pooling of applications protects applications from the effects of worker processes that support other application pools. In this way, applications are protected from each other.

When a worker process enters an unhealthy state and stops processing requests, the HTTP protocol stack (HTTP.sys) continues to queue requests. The World Wide Web Publishing Service (WWW service) detects that the worker process is unhealthy and shuts it down, starting a new worker process if requests are waiting in the queue or if new requests arrive. Hence, even when a worker process fails, the WWW service, by means of HTTP.sys, continues to accept requests and shields the user from loss of service because the client can still connect to the WWW service.

For more information about IIS 6.0 application isolation modes, including how to enable and configure worker process isolation mode, see Running IIS 6.0 as an Application Server. For more information about how IIS 6.0 processes requests, see IIS 6.0 Architecture.

**On-demand process start**

IIS 6.0 does not allocate resources at initialization time; instead, it allocates resources as needed, which increases site scalability. In particular, IIS 6.0 application pools only start processes when the first request for a URL is served by the application pool.

**HTTP Keep-Alives**

IIS 6.0 supports HTTP Keep-Alives, an HTTP specification that can significantly improve server performance. Most Web browsers request that the server keep the connection open across multiple requests; this is called a *Keep-Alive*. Without this feature, a browser must make numerous connection requests for a page that contains multiple elements, such as graphics. A separate connection might need to be made for each element. HTTP Keep-Alives increase server efficiency by reducing server activity and resource consumption. HTTP Keep-Alives can also increase browser responsiveness across a slow connection. For more information about HTTP Keep-Alives, see Optimizing IIS 6.0 Performance.

**Web gardens**

When running in worker process isolation mode, IIS can be configured to have multiple worker processes servicing requests for an application pool. This configuration is known as a Web garden. When a worker process in an application pool is busy processing a request, other worker processes can accept and process requests for the application pool. For more information about Web gardens, including how to enable or configure this feature, see Running IIS 6.0 as an Application Server.

**Processor affinity**

To efficiently use resources on large multiprocessor servers, IIS 6.0 enables you to configure application pools to establish affinity between worker processes and individual processors. When set, processor affinity forces worker processes to run on specific microprocessors or CPUs. This affinity applies to all worker processes that serve the Web sites and applications of an application pool. For more information about processor affinity, including how to enable or configure this feature, see Optimizing IIS 6.0 Performance.

**Idle timeout for worker processes**

An IIS 6.0 application pool can be configured so that its worker processes request a shutdown if they are idle for a configurable amount of time. Shutting down worker processes frees up unused resources and reduces CPU load. For more information about idle timeout, including how to enable or configure this feature, see Running IIS 6.0 as an Application Server.

**Bandwidth throttling**
If the network or Internet connection used by your Web server is also used by other services, such as e-mail or news, you can limit the bandwidth used by your Web server so it is available for those other services. If your Web server hosts more than one Web site, you can individually throttle the bandwidth used by each site. For more information about bandwidth throttling, including how to enable or configure this feature, see Optimizing IIS 6.0 Performance.

**HTTP compression**
HTTP compression allows faster transmission of pages between the Web server and compression-enabled clients. In addition, HTTP compression makes the best use of available bandwidth and can significantly increase site performance. For more information about HTTP compression, including how to enable or configure this feature, see Optimizing IIS 6.0 Performance.

**64 GB cache capacity**
For workloads that require large amounts of cached data, the IIS 6.0 kernel-mode driver, HTTP.sys, can be configured to cache up to 64 gigabytes (GB) on an x86-based or compatible processor–based system. For more information about IIS caches, see Improving Scalability by Optimizing IIS 6.0 Caches.

**Centralized binary logging**
IIS 6.0 supports centralized binary logging, where multiple Web sites send binary, unformatted log data to a single log file. When many Web sites are hosted on the same server, the process of creating hundreds or thousands of formatted log files and writing the log data to disk can quickly consume valuable CPU and memory resources, thereby creating performance and scalability problems. Centralized binary logging in IIS 6.0 minimizes the server resources that are used for logging, while providing detailed log data for organizations that require it. For more information about centralized binary logging, including how to enable or configure this feature, see Analyzing Log Files.

# Scalability Features in Windows Server 2003

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This section describes features in Windows Server 2003 that can improve the scalability of your application server.

| **Important** |
| --- |
| Do not enable features described here on a production server before you establish a performance baseline in a test environment. If enabling any of these features degrades performance, continue testing or disable the feature and return your server to the pre-change configuration. |

**Kernel-mode driver**
Windows Server 2003 introduces a new kernel-mode driver, HTTP.sys, for HTTP parsing and caching. IIS 6.0 is built on top of HTTP.sys. HTTP.sys is specifically tuned to increase Web server throughput by directly processing requests in the kernel (in specific circumstances) or by efficiently routing requests to user-mode worker processes. The combination of kernel request processing and efficient user-mode routing have dramatically improved how IIS 6.0 scales and performs. For more information about HTTP.sys, see IIS 6.0 Architecture.

**64-bit support**
The complete Windows Server 2003 code base is compiled for both 32-bit and 64-bit platforms. Organizations that need highly scalable applications can take advantage of an operating system that runs — and is supported — on these two platforms.

**WSRM**
Windows System Resource Manager (WSRM) is a feature of Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition.

With WSRM, you can control how CPU and memory resources are allocated to applications, services, and processes. Managing resources in this way improves system performance and reduces the chance that applications, services, or processes will interfere with the rest of the system; it also creates a more consistent and predictable experience for users of applications and services running on the computer.

WSRM can be installed from the Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition operating system CD. For more information about WSRM, see Help in the WSRM snap-in.

**DFS**
Distributed File System (DFS) unifies files on different computers into a single namespace, making it easy to build a single, hierarchical view of multiple file servers and file server shares on a network. To use DFS as the file system for IIS, select the root for the Web site as a DFS root. You can then move resources within a DFS tree without affecting any HTML links. For more information about DFS, see Distributed File System and File Replication Services.

**FRS**
The File Replication service (FRS) provides multimaster file replication for designated directory trees between designated servers running Windows Server 2003. The designated directory trees must be on disk partitions formatted with the version of the NTFS file system used with Windows Server 2003. FRS must be used with DFS. DFS uses FRS to automatically synchronize content between assigned replicas. The combination of DFS and FRS can also work with the Active Directory® directory service to automatically synchronize the content of system volume information across domain controllers. For more information about FRS, see Distributed File System and File Replication Services.

# Improving IIS 6.0 Scalability and Availability with Network Load Balancing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The best way to guarantee the scalability and availability of your Internet services is to host your site with more than one computer. Microsoft Windows Server 2003 includes the Network Load Balancing service. Network Load Balancing enhances the availability and scalability of Internet server applications such as those used on Web, File Transfer Protocol (FTP), firewall, proxy, and virtual private network (VPN) servers, in addition to other mission-critical servers. A single computer running Windows can provide a limited level of server reliability and scalable performance. However, by combining the resources of two or more computers running Windows Server 2003 into a single cluster, Network Load Balancing can deliver the reliability and performance that Web servers and other mission-critical servers need. Figure 7.1 shows two connected Network Load Balancing clusters. The first cluster consists of two hosts and the second cluster consists of four hosts.

Each host runs separate copies of the server applications, such as those for a Web, FTP, or Telnet server. Network Load Balancing distributes incoming client requests across the hosts in the cluster. The load weight to be handled by each host can be configured as necessary. You can also dynamically add hosts to the cluster to handle the increased load. In addition, Network Load Balancing can direct all traffic to a designated single host, called the default host.

Network Load Balancing allows all of the computers in the cluster to be addressed by the same cluster IP address (but also maintains their existing unique, dedicated IP addresses). For more information about Network Load Balancing, see Help and Support Center for Windows Server 2003.

| **Note** |
| --- |
| FrontPage® Server Extensions from Microsoft do not work in a Network Load Balancing environment. Also, FrontPage Server Extensions do not work side-by-side with SharePoint™ Team Services from Microsoft on the same virtual server or Web site. |

**Related Topics**

For more information about upgrading your FrontPage-extended Web sites, see SharePoint Team Services.

# IIS Responses to Load-Balanced Application Pool Behaviors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 is designed to work with a variety of hardware and software network load balancers. However, the introduction of application pools and health-monitoring features such as rapid-fail protection in IIS 6.0 has the potential to confuse load balancers when an application pool fails to respond to a request, or when IIS health-monitoring features act on a faulty application pool. This section describes how HTTP.sys and IIS respond to load balancers for various application pool failures or problems.

For Layer 3 and Layer 4 load balancers (that is, basic load balancers such as Network Load Balancing), when an application pool fails, IIS causes the load balancer to run a TCP reset command. For Layer 7 load balancers (more advanced load balancers that balance the load based on higher-level application data, such as URLs, session data, and cookies) HTTP.sys sends a 503 error and attempts to connect to the application pool again after a specified period of time. IIS can also be configured to shut down the faulty application pool altogether. These responses can remedy application failures at the application pool level instead of forcing the load balancer to fail over the entire server. These responses also allow healthy application pools to continue processing requests without forcing the load balancer to fail over the entire server.

Table 7.1 summarizes how HTTP.sys and IIS respond to load balancers for various application pool failures.

**Table 7.1 IIS Responses to Load-Balanced Application Pool Behaviors**

| Condition | Auto-Shutdown of Application Pool? | Layer 7 Load Balancer Behavior | Layer 3 and Layer 4 Load Balancer Behavior |
|---|---|---|---|
| The application pool entered rapid-fail protection. | Yes | HTTP 503 error | IIS resets the TCP connection. |
| The application pool CPU threshold was exceeded. | Yes | HTTP 503 error | IIS resets the TCP connection. |
| An administrator disabled the application pool or shut down the WWW service. | No | HTTP 503 error | IIS resets the TCP connection. |
| The kernel-mode request queue is full. | No | HTTP 503 error | IIS resets the TCP connection. |

By default, the IIS metabase property **LoadBalancerCapabilities** is configured for Layer 7 responses (**LoadBalancerCapabilities** = 2). If your organization uses Layer 3 or Layer 4 load balancers, you will need to change this property in the IIS metabase to a value of 1.

| **Important** |
|---|
| It is recommended that you back up the IIS metabase before you change the metabase. For additional information, see Working with the Metabase. |

For more information about configuring load balancing, see the LoadBalancerCapabilities Metabase Property. For more information about the IIS 6.0 metabase, including how to change a metabase property, see Working with the Metabase.

**IIS Response When a Load-Balanced Application Pool Enters Rapid-Fail Protection**

When an application pool enters the rapid-fail protection state, HTTP.sys responds to requests with a 503 error. If IIS is configured to shut down the application pool when the application pool enters the rapid-fail protection state, IIS executes the auto-shutdown application pool command. For more information about rapid-fail protection, see Running IIS 6.0 as an Application Server. For load-balanced applications, HTTP.sys responds to requests in one of the following ways:

- Layer 7 response. When HTTP.sys receives requests for an application pool that is in the rapid-fail protection state, HTTP.sys sends a 503 error. If IIS is configured to shut down the application pool when it enters the rapid-fail protection state, IIS executes the auto-shutdown application pool command. When the error has been resolved, the administrator must restart the application pool.

- Layer 3 and Layer 4 response. When HTTP.sys receives requests for an application pool that is in the rapid-fail protection

state, HTTP.sys resets the TCP connection that carried the request. If IIS is configured to shut down the application pool when it enters the rapid-fail protection state, IIS executes the auto-shutdown application pool command. When the error has been resolved, the administrator must restart the application pool.

For information about rapid-fail protection, see Running IIS 6.0 as an Application Server.

**IIS Response When a Load-Balanced Application Pool Exceeds a Configured CPU Threshold**
The IIS CPU monitoring feature allows you to configure a CPU threshold for a specific application pool. The IIS CPU monitoring feature includes the option to shut down an application pool if the CPU exceeds a configured maximum. For load-balanced applications, HTTP.sys responds to requests in one of the following ways:

- Layer 7 response. When HTTP.sys receives subsequent requests for an application pool that has exceeded the configured CPU maximum, HTTP.sys sends a 503 error. If IIS is configured to shut down the application pool when it exceeds its CPU threshold, IIS executes the auto-shutdown application pool command. When the error has been resolved, the administrator must restart the application pool.

- Layer 3 and Layer 4 response. When HTTP.sys receives requests for an application pool that has exceeded the configured CPU maximum, HTTP.sys resets the TCP connection that carried the request. If IIS is configured to shut down the application pool when it exceeds its CPU threshold, IIS executes the auto-shutdown application pool command. When the error has been resolved, the administrator must restart the application pool.

For information about CPU monitoring, see Running IIS 6.0 as an Application Server.

**IIS Response When a Load-Balanced Application Pool Is Disabled by an Administrator or an Administrator Shuts Down the WWW Service**
When an application pool is shut down, the requests that have already been queued in kernel mode are lost. A shutdown of this nature indicates serious application failure and presents a potential threat to the rest of the system if the application continues processing. Such an application failure can affect the integrity of data in custom applications. For this reason, all requests to that application pool should be stopped.

- Layer 7 response. When HTTP.sys receives requests for a disabled application pool, or if the administrator shuts down the WWW service, HTTP.sys sends a 503 error. When the error has been resolved, the administrator must restart the application pool.

- Layer 3 and Layer 4 response. When HTTP.sys receives requests for a disabled application pool, or if the administrator shuts down the WWW service, HTTP.sys resets the TCP connection that carried the request.

**IIS Response When the Kernel-Mode Request Queue Is Full**
A full kernel-mode request queue is a temporary state. After application queues finish processing other requests, the kernel-mode request queue will begin accepting new requests.

- Layer 7 response. When HTTP.sys receives requests for an application pool but the request queue is full, HTTP.sys sends a 503 error.

- Layer 3 and Layer 4 response. When HTTP.sys receives requests for an application pool but the request queue is full, HTTP.sys resets the TCP connection that carried the request.

# Preserving Session State in Network Load Balancing Web Server Clusters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS enables a Web application to maintain user session data (also called *session state*) across multiple requests. For example, an online ordering application might maintain the user's shopping cart as part of the user's session. IIS uses *session cookies*, which are text files supplied by the user's browser and stored on the user's computer for each request to keep track of which session belongs to which user.

| **Note** |
| --- |
| Worker processes lose session state if the worker process is recycled. The ideal configuration for storing session state with IIS 6.0 is to store user session data in a back-end database. |

Ideally, Network Load Balancing always routes connections from a user who has an active session to the server where that session is stored. However, Network Load Balancing and other Layer 4 network load balancers do not use sessions or cookies to decide which Web server should handle an incoming request. For this reason, sessions can be lost between requests in a Network Load Balancing server cluster.

There are several ways to avoid losing sessions:

- Design the Web site application to store session state on the client. For more information, see Preserving Session State with ASP Web Applications in Network Load Balancing and Preserving Session State with ASP.NET Web Applications in Network Load Balancing.

- Store session state on a central server-side store, such as a database.

- Use the client affinity feature. When client affinity is enabled, Network Load Balancing directs all TCP connections to the same cluster host. This allows session state to be maintained in host memory. You can enable client affinity in the **Add/Edit Port Rules** dialog box in Network Load Balancing Manager. Choose either **Single** or **Class C** affinity to ensure that only one cluster host will handle all connections that are part of the same client session. This is important if the server application running on the cluster host maintains session state (such as server cookies) between connections. For more information about Network Load Balancing affinity, see Help in the Network Load Balancing snap-in.

# Preserving Session State with ASP Web Applications in Network Load Balancing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can enable session state persistence for Active Server Pages (ASP) applications. If you enable session state, the server creates a new Session object for each connection, session state is accessible, session storage is allowed, **Session_OnStart**and **Session_OnEnd**occurs, and the **ASPSessionID** cookie is sent to the client. If you do not enable session state, state access and storage are not allowed, events are not processed, and no cookie is sent. By default, session state is enabled with the session timeout set to 20 minutes. The corresponding metabase property is **AspAllowSessionState**.

- For information about enabling session state for an ASP application, see Enabling Session State Persistence.

# Preserving Session State with ASP.NET Web Applications in Network Load Balancing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you use **SqlServer** or **StateServer** session state mode, session state might be lost when you run an ASP.NET Web application in a Network Load Balancing server cluster. To maintain session state across different Web servers in the cluster, the application path of the Web site (for example, \LM\W3SVC\2) in the IIS metabase must be the same for all of the Web servers in the cluster.

On one Web server, the instance ID of the Web site where the ASP.NET application is hosted might be 1 (where the application path is \LM\W3SVC\1). On another Web server, the instance ID of the Web site might be 5 (where the application path is \LM\W3SVC\5).

| **Note** |
| --- |
| Web sites created on a clean installation of IIS 6.0 will maintain their individual site numbers, as determined by the **ServerComment** metabase property, across the load-balanced installation. For more information about the **ServerComment** metabase property, see the ServerComment Metabase Property.<br><br>For information about changing the application path of a Web site, see Synchronizing the Application Path of a Web Site. |

# Improving Scalability by Optimizing IIS 6.0 Queues

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A request queue holds a collection of one or more requests waiting to be executed. Request queues can develop when your site experiences high traffic volumes, or if your site blocks to wait for database processing. Large queues, or queues that are not cleared quickly, impact scalability by limiting the number of requests the server can process and by reducing throughput. More importantly, if users are forced to wait for a response from your server, they might perceive that the site is not available and click the **Stop** button on their Web browser. In this situation, the queuing problem grows because clicking the **Stop** button can fill a queue with requests that are no longer connected to a client's browser. If your site routinely develops queues, you might dramatically improve scalability and availability by adjusting the number of requests that can wait in a queue. You can set limits for the following request queues:

- TCP/IP queue
- Kernel request queue
- ASP request queue
- ASP.NET request queues

# TCP/IP Queue

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

At the TCP/IP layer, high-priority threads respond to client requests by validating that the server is or is not accepting and processing requests. If the server is accepting requests, the thread maintains the customer connection and attempts to hand off the request to HTTP.sys. The only reason you might need to adjust the TCP/IP queue is if users cannot connect to your site on the Web. Monitor the TCPv4\Connection Failures and TCPv4\Connections Reset counters (for TCPv6, use the same counters for the TCPv6 object). If the Connection Failures and Connections Reset counters increase steadily, examine your TCP/IP settings. For more information about TCP/IP, see Help and Support Center for Windows Server 2003.

# Kernel Request Queue

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After HTTP.sys detects the TCP/IP thread, it either begins serving the request with content stored in the HTTP.sys cache, if available (this is called a *cache hit*), or puts the request in a kernel request queue for the designated application pool. Because the request is still in the kernel, but is waiting in a queue for a specific application pool, this queue is sometimes called the *application pool queue*. In IIS Manager, this queue is called the *kernel request queue*.

When IIS 6.0 runs in worker process isolation mode, by default HTTP.sys checks the number of requests for a designated application pool queue before it adds a new request to the queue. If adding the new request to the queue exceeds the queue limit, the server rejects the request, logs a QueueFull error in the HTTP error log, and sends a 503 error (Service Unavailable) to the client. This 503 error response cannot be customized. During times of high traffic, if you experience this 503 error, try adjusting the number of requests that wait in the queue. Increase the number to a large value such as 16,000 and test to see if the 503 errors persist.

Requests in the application pool queue remain in the queue if you lower the queue maximum to a number less than 1,000 by using the following procedure. For information about adjusting the number of requests allowed in the kernel request queue, see Configuring Application Pool Queue-Length Limits.

# ASP Request Queue

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For requests to ASP pages, after the worker process picks up the request in the application pool queue, the request is sent to the Internet Server API (ISAPI) handler, which passes the request along to Asp.dll. If a thread is available, the ASP request is processed. If a thread is not available, the request waits in the ASP request queue. Requests are processed in the order in which they are received. If the ASP request queue fills to 3,000 requests (the default metabase value of **AspRequestQueueMax**) the server rejects the request, logs the error in the IIS log, and sends a 500 error (Server Too Busy) to the client.

If the number of queued requests is under 3,000, users with the last requests are forced to wait (called queue latency) as other requests are pulled from the queue and executed. This is an acceptable condition if the queue is cleared within a few seconds. After a few seconds, most users believe the server is not responding and click the **Stop** button on their Web browser. High queue latency results in poor performance for all ASP requests for the entire time the queue is saturated, because all ASP requests in a worker process share the same queue. Additionally, CPU utilization tends to spike when the queue is saturated, which results in slower response times.

You can improve ASP queuing by adjusting the default values for the **AspProcessorThreadMax** and **AspRequestQueueMax** metabase properties. **AspProcessorThreadMax** represents the maximum number of threads per processor, and **AspRequestQueueMax** represents the maximum size of the request queue. For more information about these metabase properties, see the AspProcessorThreadMax Metabase Property and AspRequestQueueMax Metabase Property.

Table 7.2 describes performance counters and their ideal values for ASP queuing. Monitor these counters in System Monitor by using a chart with one-second intervals before you change any metabase properties on your server. For more information about IIS 6.0 counters, see Performance Counters Reference.

**Table 7.2 Preferred Values for Active Server Pages Queuing Performance Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Active Server Pages\Request Wait Time | As low as possible. This counter determines how long clients connecting to your site must wait before the page starts executing. If this number is high, users connected to your site might be frustrated by slow response times. |
| Active Server Pages\Requests Queued | As low as possible. If large queues develop, or if this number fluctuates, you might need to adjust the metabase properties that affect ASP queuing, as described in Tuning AspRequestQueueMax. This counter is not as important as the Request Wait Time counter. Queues can clear quickly, but long wait times can frustrate users connected to your site. |
| Active Server Pages\Requests Rejected | As low as possible. If this number is high and Requests Queued is high, you might be reaching the ASP request queue default maximum of 3,000. You might need to adjust the metabase properties that affect ASP queuing, as described later in Tuning AspRequestQueueMax. |
| Active Server Pages\Requests/second | Application-specific. You want this number to be as high as possible. If Requests Queued is high, this number will typically be lower. Adjusting the metabase properties that affect ASP queuing can increase it. |
| Processor\% Processor Time (for each processor) | Application-specific. If Requests Queued never increases and % Processor Time is low, it is likely that ASP queuing is not affecting the performance of your site. |

# Tuning AspProcessorThreadMax

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the number of requests in the ASP queue is fluctuating and your CPUs are running below 50 percent, your requests might be blocking. *Blocking* occurs when a request that is being processed is forced to wait for an available thread to perform component processing or back-end processing. For example, an ASP page using ActiveX® Data Objects (ADO) to access a computer running Microsoft® SQL Server™ located on a separate computer will typically be blocked. If the SQL request executes a query that takes five seconds, and if dozens of requests arrive every second to execute this same query, soon all available threads will be allocated and each thread will wait five seconds for the query to be completed. You can reduce blocking by increasing the number of ASP threads.

| **Important** |
| --- |
| It is recommended that you back up the IIS metabase before you change the metabase. For additional information, see Working with the Metabase. |

Increasing the number of threads increases concurrency, which means that the server has more threads available to process requests (especially nonblocking requests). This might reduce queuing and improve response times. On a site with minor blocking (that is, the queue only occasionally reaches the value of the AspRequestQueueMax Metabase Property), increasing the threads can have a dramatic effect; in fact, it might eliminate all ASP queuing, because there are always enough threads to handle the blocking and nonblocking requests.

Typically, you can reduce blocking by increasing the number of threads in the AspProcessorThreadMax Metabase Property from 25 (the default) to 50 threads.

| **Note** |
| --- |
| After changing the value of **ASPProcessorThreadMax**, you will need to restart the WWW service. |

After increasing the number of ASP threads, you should expect to see a slight increase in CPU utilization, and the queue should fluctuate more quickly. If, after increasing the number of threads, Requests Queued increases and stays high and % Processor Time decreases, a significant percentage of your requests are being blocked. You might want to reexamine your application code and determine whether the source of the blocking can be mitigated or worked around. Or you might want to simply add more servers to your Web farm to reduce contention.

If your queue decreases and CPU utilization increases, continue increasing **AspProcessorThreadMax** until you hit your target CPU utilization (do not exceed 70 percent, and keep **AspProcessorThreadMax** below 100). Ultimately, you might discover that the network input/output (I/O) or another factor is placing a limit on your server's performance. You might not be able to improve this limit.

For more information about the IIS Metabase, see Working with the Metabase. For more information about ASPProcessorThreadMax and ASPRequestQueueMax, see the Metabase Property Reference.

# Tuning AspRequestQueueMax

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The goal of tuning the AspRequestQueueMax Metabase Property is to ensure good response time while minimizing how often the server sends the HTTP 503 error (Server Too Busy) to clients when the ASP request queue is full. If the value of **AspRequestQueueMax** is too low, the server will send the HTTP 503 error too often. If the value of **AspRequestQueueMax** is too large, users might perceive that the server is not responding when in fact their request is waiting in the queue. By watching the queue during periods of high traffic, you should see a pattern of ups and downs. Make note of the peak value, and set the value of **AspRequestQueueMax** just above the peak value. Use the queue to handle short-term spikes, ensure response time, and throttle the system to avoid overload when sustained, unexpected spikes occur. If you do not have data for adjusting **AspRequestQueueMax**, a good initial setting seems to be a one-to-one ratio of queue to total threads. For example, if the AspProcessorThreadMax Metabase Propertyy is set to 25 and you have four processors (4  25 = 100 threads), set **AspRequestQueueMax** to 100 and tune from there.

| **Note** |
| --- |
| After changing the value of **AspRequestQueueMax**, you will need to restart the WWW service.<br><br>For more information about the IIS Metabase, see Working with the Metabase. |

# Additional Metabase Properties

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following metabase properties also affect queuing.

**AspQueueTimeout**
The AspQueueTimeout Metabase Property specifies the amount of time (in seconds) that an ASP script request is allowed to wait in the queue. When requests are pulled from the queue, they are checked to see if they have expired (that is, they have waited longer than the value of this property). Expired requests are rejected with a 503 error (Service Unavailable). By default, ASP does not reject requests from valid connections, no matter how long they have been in the queue.

**AppPoolQueueLength**
The AppPoolQueueLength Metabase Property indicates to HTTP.sys how many requests to queue up for an application pool before it rejects future requests. When the limit for this property is exceeded, IIS rejects the additional requests with a 503 error. Setting the **AppPoolQueueLength** value to 0 means there is no maximum request queue length. This is not recommended.

For more information about these properties, see the Metabase Property Reference.

# ASP.NET Request Queues

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP.NET uses two request queues:

- The *global queue*, which is managed by the process that runs ASP.NET (Aspnet_wp). The global queue is configured in the Machine.config file by the **<processModel requestQueueLimit>** property.

- The *application queue*, or *virtual directory queue*, which is managed by the HttpRuntime class. The HttpRuntime class provides run-time services for ASP.NET applications. There is one queue for each virtual directory. The application queue is configured in Machine.config by the **<httpRuntime appRequestQueueLimit>** property.

When either queue exceeds its default limit, the request is rejected with a 503 error (Service Unavailable).

Worker processes that handle ASP.NET requests might run more threads than needed for ASP requests. Also, ASP.NET might queue requests more readily than ASP queues requests, but this should not be regarded as a scalability or performance issue. ASP.NET requests are executed more quickly than ASP requests. This means that with ASP.NET it is actually better to have fewer concurrent requests and more serial requests. Because ASP.NET maximizes the overall work on the CPU, this leads to fewer context switches.

Overall, ASP.NET is very self-tuning. For the global queue (Aspnet_wp process), the default ASP.NET thread numbers on four-processor and eight-processor servers should not require additional tuning. For servers with more than eight processors, you might want to decrease the default thread numbers by modifying the values of the **<processModel maxworkerthreads>** and **<processModel maxiothreads>** properties in Machine.config.

# ASP.NET Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the following counters to monitor queuing for all ASP.NET applications on your server.

**Request Execution Time**
The value of this counter is the number of milliseconds taken to execute the latest request. In the Microsoft .NET Framework version 1.0, request execution time begins when the worker process receives the request and stops when the ASP.NET ISAPI sends HSE_REQ_DONE_WITH_SESSION to IIS. This counter includes the time taken to write the response to the client for IIS 5.0, but not for IIS 6.0. Consequently, for IIS 5.0, a client with a slow network connection increases the value of this counter considerably.

In .NET Framework version 1.1, request execution time begins when the HttpContext for the request is created and stops before the response is sent to IIS. Assuming that user code does not call HttpResponse.Flush, this means that request execution time stops before any bytes are sent to IIS or to the client.

There is no threshold for this counter. The value of this counter should be stable. Experience will help you set a threshold for a particular site.

**Requests Queued**
The value of this counter is the number of requests currently in the queue. It includes requests in all ASP.NET queues. The Aspnet_wp process queue is a named pipe through which the request is sent from one process to the other. The number of requests in this queue increases if there is a shortage of available I/O threads in the Aspnet_wp process. When the limit specified by **<processModel requestQueueLimit=/>** is exceeded, requests will be rejected with a 503 error (Service Unavailable). Note that if a request is rejected for this reason, it will never reach managed code, and error handlers will not be notified. Normally this only occurs when the server is under a very heavy load.

Virtual directory queues maintain the availability of worker and I/O threads. The number of requests in these queues increases if the number of available worker threads or available I/O threads falls below the limit specified by **<httpRuntime minFreeThreads=/>**. When the limit specified by **<httpRuntime appRequestQueueLimit=/>** is exceeded, the request is rejected with a 503 error and the client is sent an HttpException with the message Service Unavailable.

**Requests Rejected**
The value of this counter is the number of rejected requests. Requests are rejected when one of the queue limits is exceeded. Back-end latency, such as that caused by a slow computer running SQL Server, is often preceded by a sudden increase in the number of pipeline instances and a decrease in % Processor Time and Requests/second. A server might be overwhelmed during times of heavy load due to processor or memory constraints that ultimately result in the rejection of requests.

The value of this counter should be 0. Values greater than 0 should be investigated.

**Request Wait Time**
The value of this counter is the number of milliseconds that the most recent request spent waiting in the global queue. This does not include any time the request spent waiting in the application queues.

The threshold for this counter is 1,000. The average request should spend 0 milliseconds waiting in the queue.

# ASP.NET Application Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the following counters to monitor queuing for individual ASP.NET applications.

**Requests Executing**
The number of requests currently being executed. This counter is incremented when the ASP.NET request pipeline begins to process the request and is decremented after the ASP.NET request pipeline finishes the request.

**Requests In Application Queue**
The number of requests in the application request queue. In addition to Requests Executing, Requests In Application Queue provides a warning when requests will be rejected. If there are only a few virtual directories, increasing the default value of the **appRequestQueueLimit** property in the Machine.config file to 200 or 300 might be suitable, especially for slow applications under heavy load.

**Pipeline Instance Count**
The number of active pipeline instances. Only one thread of execution can run within a pipeline instance, so this number gives the maximum number of concurrent requests that are being processed for a given application. The number of pipeline instances should not fluctuate. Sudden increases are indicative of back-end latency.

# Registry Entries for Thread Pool Queuing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following entries in the Windows registry determine the number of threads in the IIS thread pool. Tuning thread pools can produce dramatic improvement in IIS performance and scalability.

**MaxPoolThreads**
Specifies the maximum number of pool threads per processor. This is not an absolute limit; that is, IIS can increase the number of threads if the current load would benefit from having more threads available. Pool threads monitor the network for requests and process incoming requests. The value of **MaxPoolThreads** does not include threads that are consumed by ISAPI applications.

**PoolThreadLimit**
Specifies the maximum number of pool threads that can be created in the system. Pool threads monitor the network for requests and process incoming requests. **PoolThreadLimit** is an absolute limit that includes all core Web service threads. It is always greater than or equal to the value of **MaxPoolThreads**.

For more information about these registry entries, see the Global Registry Entries reference, and Optimizing IIS 6.0 Performance.

# Improving Scalability by Optimizing IIS 6.0 Caches

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A cache is a special subsystem that stores frequently requested data. Without caches or caching, IIS can potentially impose three time-consuming processes on each request, which can cause poor response times. These processes include:

- Reading metadata for each request, which generates a time-consuming remote procedure call (RPC) to the IIS Admin service.
- Retrieving the authentication token for the IUSR_*computername* account with a time-consuming RPC to Lsass.exe.
- Opening and reading the file.

To mitigate these time-consuming processes, HTTP.sys and IIS use caches. These caches are all enabled by default and should not require much tuning by administrators. If, while monitoring Web Service Cache counters in System Monitor, you begin to see rising numbers of cache misses or very low cache hit rates, you can adjust settings for the following:

- URI cache (user-mode URI cache)
- Token cache
- File cache
- HTTP.sys response cache (kernel URI cache)
- ASP caches, including the ASP template cache and the ASP script engine cache
- Global cache registry entries

For information about Universal Naming Convention (UNC) caching, see, Caching UNC-Based Files. For information about IIS cache counters, see the Performance Counters Reference.

# URI Cache

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The user-mode URI cache is known as the URI cache. The URI cache stores metadata about a URL. Metadata can include a variety of configuration data, including data about headers and authentication. This configuration data is stored in the IIS Admin service. The URI cache stores the metadata as an object. For each request that reaches IIS user mode, the worker process checks the URI cache to see if the object for the requested URL has been cached. If the object has not been cached, the worker process must call the IIS Admin service for the appropriate metadata. This call is expensive from a performance and scalability standpoint. If the URI cache has a stored object for the URL, the request pulls in the object and continues processing.

The IIS Admin service is responsible for URI cache change notification. If, for example, Default.htm changes, the IIS Admin service tells the worker process to flush the URI cache for that specific URL. Subsequent requests for that URL are cached in the URI cache. Table 7.3 describes the preferred or ideal values for URI cache counters. For more information about IIS 6.0 counters, see the Performance Counters Reference.

**Table 7.3 Preferred Values for URI Cache Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Web Service Cache\URI Cache Hits | Depends on content. If content cannot be cached in the HTTP.sys response cache, the value of this counter should be as high as possible. If your content can be stored in the HTTP.sys response cache, the value of this counter should be low. |
| Web Service Cache\URI Cache Hits% | Depends on content. If content cannot be cached in the HTTP.sys response cache, the value of this counter should be as high as possible. If your content can be stored in the HTTP.sys response cache, the value of this counter should be low. |
| Web Service Cache\URI Cache Misses | Low is better. The value of this counter increases when IIS cannot locate requested content in either the HTTP.sys response cache or the IIS file cache, and must locate the requested content on the hard disk. If the value of this counter is low, responses are being sent from either the IIS file cache or the HTTP.sys response cache. |

# Token Cache

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When a request is made to the server, the security credentials for the request (or the configured anonymous user) are used to create a user token on the server. The server impersonates this user token when accessing files or other system resources. The token is cached in what is commonly called the *token cache*, so that the Windows logon only takes place the first time the user accesses the system or after the user's token has been flushed from the cache. If a token does not exist in the cache for an incoming request, IIS must call the Lsass.exe process to get the token. This call is expensive from a performance and scalability standpoint.

| **Note** |
| --- |
| Integrated Windows authentication tokens are not cached. |

The IIS worker process is responsible for flushing the token cache. The worker process monitors the **UserTokenTTL** registry entry for change notification (*TTL* stands for time to live). If the token has expired (the default time to live is 15 minutes) or if the token has changed in any way, IIS flushes the token cache. Currently, there are no performance counters that monitor the token cache.

# File Cache

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS file cache stores file contents in memory. If the file is larger than the 256 KB default maximum file size, IIS creates a file handle, passes the handle to HTTP.sys, and then closes the handle. The maximum file size is controlled by the MaxCachedFileSize registry key. For more information about the MaxCachedFileSize registry key, see Global Registry Entries.

The IIS 6.0 file cache uses an algorithm that attempts to cache only frequently requested files. The algorithm requires that a file be requested at least twice in a 10-second activity period, or the file will not be cached. In the case of a request for a Default.htm file, the activity-period algorithm works in this way:

1. The worker process receives the request for Default.htm.
2. The worker process checks to see if the file is in the IIS file cache table. At this point, the file has not been cached yet (that is, no cache entry is found).
3. The IIS file cache checks the activity table to see if Default.htm has been requested within the last 10 seconds. Because the file has not been requested, the file cache enters Default.htm in the activity table and serves out the file handle.
4. Three seconds later, the worker process receives another request for Default.htm.
5. The file cache does not find the cache entry in the cache table, but the activity table contains an entry that is within the 10-second activity period.
6. The file cache again serves out the file handle, but this time the file cache gets the cache entry from the worker process and stores the cache entry in the cache table (the cache table flushes all unused entries every 30 seconds).
7. A third request for Default.htm is served directly from the file cache.

You can configure the activity period (which is 10 seconds by default) by modifying the **ActivityPeriod** registry entry. If you set the value of **ActivityPeriod** to 0, IIS always caches files. The **ActivityPeriod** registry entry is located in the following subkey:

HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Inetinfo\Parameters

| **Caution** |
|---|
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference. |

Windows provides file cache change notification at the directory level. This means Windows monitors the parent file directory and informs IIS when a file in the directory or any subdirectory has changed. When IIS gets the change notification, the worker process flushes the file from the IIS file cache.

Table 7.4 describes the preferred or ideal values for file cache counters. For more information about IIS 6.0 counters, see the Performance Counters Reference.

**Table 7.4 Preferred Values for File Cache Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Web Service Cache\Current Files Cached | Depends on content. A low value can indicate that HTTP.sys is caching a majority of static files, which is ideal. If the content files cannot be cached by HTTP.sys, a high value is good. |

| | |
|---|---|
| Web Service Cache\File Cache Flushes | Note that this counter value represents the number of times the cache was flushed, and not the number of files flushed. This value will continue to increase over time. If you edit files or change files often, this value will increase more rapidly. |
| Web Service Cache\File Cache Hits | Depends on content. If the content files cannot be cached by HTTP.sys, a high value is good. |
| Web Service Cache\File Cache Hits% | If the Kernel: Cache Hits % counter is low, this value should be high. If Kernel: Cache Hits % is low and this value is low, examine your file set and determine why your files are not being cached. Note that this counter does not include dynamic content, only static files. If your static files are not being cached, you might want to lengthen the activity period for this cache. |
| Web Service Cache\File Cache Misses | A *file cache miss* means the request for the file must go to the hard disk. File cache misses negatively impact performance and scalability. This value should be as low as possible. Also note that kernel cache hits will cause this value to be low. |
| Web Service Cache\Total Flushed Files | As low as possible. This value will increase if you edit or change content files, which results in a cache flush. |
| Web Service Cache\Maximum File Cache Memory Usage | The value of this counter and the value of Web Service Cache\Current File Cache Memory Usage should be the same. If the numbers are different, the cache was flushed. If this counter is significantly higher than Web Service Cache\Current File Cache Memory Usage, you might consider recycling the worker process because the application might have a memory leak. |
| Web Service Cache\Total Files Cached | Ideally, this value will be the same as Web Service Cache\Current Files Cached. If you edit or change your content files and subsequently flush the file cache, this value will decrease. |

# Http.sys Response Cache

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Kernel caching with the Http.sys response cache can be one of the most effective means of scaling and improving Web server performance. Cached responses are served from the kernel, which greatly improves response times and increases the number of requests per second that IIS can serve because requests for cached content never enter IIS user mode.

| **Note** |
| --- |
| The HTTP response cache is known as the kernel URI cache in System Monitor. |

For each request, the IIS worker process tells Http.sys whether or not to cache a response based on the activity-period cache algorithm. If a file is requested twice within 10 seconds (the default value for the **ActivityPeriod** registry entry) the IIS worker process tells Http.sys to cache the full response by URI. All subsequent requests for the cached response will be served from the cache. For more information about the activity-period cache algorithm, see File Cache.

Every 120 seconds, the Http.sys response cache runs a flush algorithm, which flushes cached files that have not been requested within the 120-second interval. The flush algorithm is also called when IIS receives change notification for a file — that is, when the file has been edited or changed in some way.

# HTTP.sys Cache Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table 7.5 describes the preferred or ideal values for HTTP.sys response cache counters. For more information about IIS 6.0 counters, see the Performance Counters Reference.

**Table 7.5 Preferred Values for HTTP.sys Response Cache Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Web Service Cache\Kernel: Current URIs Cached | The value of this counter should nearly equal the total number of cacheable responses on the server (presuming that all cacheable responses have been cached). If this value is considerably lower than the total number of cacheable responses on the server, make sure the corresponding files are not larger than the default size, 256 KB. For information about the criteria that determine which files cannot be cached in the HTTP.sys response cache, see Events and Conditions That Disable HTTP.sys Response Caching. |
| Web Service Cache\Kernel: Total Flushed URIs | As low as possible. The value of this counter represents the number of times a response was flushed. Note that responses are flushed from the cache if the associated file is edited or changed in any way, or if the file is not requested within 120 seconds. |
| Web Service Cache\Kernel: Total URIs Cached | Depends on content, but the value of this counter should nearly equal the total number of cacheable responses on the server (presuming all cacheable responses have been cached). If this value is significantly larger than the total number of cacheable responses on the server, the HTTP.sys response cache is caching responses, flushing responses, and then caching responses again, which can impact performance and scalability. Investigate why responses are being flushed from the cache. If the value of this counter is significantly lower than the total number of cacheable responses on your sites, determine why some of the corresponding content files are not being cached. |
| Web Service Cache\Kernel: URI Cache Flushes | As low as possible. This counter denotes the number of times the flush algorithm has been called. Note that a response will be flushed from the cache if the corresponding file is edited or changed in any way, or if the file was not requested within 120 seconds. |
| Web Service Cache\Kernel: Cache Hits | As high as possible. This counter is incremented continually. If the value of this counter is very low, investigate why requests are not finding the cached response. |
| Web Service Cache\Kernel: Cache Hits % | Depends on content. The value of this counter should reflect the ratio of requests for cacheable content to requests for content that is not cacheable. If, for example, roughly half the requests to your sites are for cacheable content, the value of this counter should be close to 50 percent. |
| Web Service Cache\Kernel: URI Cache Hits/sec | As high as possible. |
| Web Service Cache\Kernel: URI Cache Misses | Depends on content. All requests for content that cannot be cached result in a cache miss. If the value of this counter is high and the value of Cache Hits is low, investigate why your responses are not being cached. |

# Events and Conditions That Disable HTTP.sys Response Caching

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

The HTTP.sys response cache will cache any response that has the appropriate flag in the request header; however, HTTP.sys will not cache the response if one of the following criteria applies:

| **Note** |
| --- |
| This cache is disabled on a per-request basis. |

- The request is not an anonymous request.
- The request required authentication (that is, there was an "Authorization:" header present in the request).
- The site is configured to use a footer.
- Dynamic compression is enabled and is used for the response. (Static compression can be used for HTTP.sys caching.)
- There is a query string in the request.
- The request verb was not GET.
- The cache is disabled (the **MD_VR_NO_CACHE** metabase property equals 1).
- The request has an entity body.
- Certificate mapping is enabled for the URL in question.
- Custom logging is enabled for the site in question.
- The request HTTP version was neither 1.1 nor 1.0.
- There was a "Translate: f" header in the request (that is, it was a Web Distributed Authoring and Versioning [WebDAV] request).
- There was an "Expect:" header that did not contain exactly "100 continue."
- There was either an "If-Range" or "Range" header in the request. HTTP.sys processes only whole responses; it does not attempt to send ranged responses.
- The response spanned multiple SendResponse/SendResponseEntityBody calls. A cacheable response must come down in a single, vectored SendResponse call.
- The total response size was greater than the per-response maximum size, which is set by using the **UriMaxUriBytes** registry key. The default value is 256 KB.
- The size of the response header was greater than the per-response maximum header size. The default maximum value is 1024 bytes.
- The cache is already full. The default size of the cache is proportional to the physical memory in the computer.
- The response is zero length.

- There is an ISAPI filter installed that is not cache-aware. By default, ISAPI filters are not cache-aware, but you can set the **FilterEnableCache** metabase property for the filter to make it cache-aware. All filters that are included with IIS 6.0, including FrontPage and ASP.NET filters, are cache-aware.

- A static file is accessed as a default document. For example, Default.htm exists in the root directory. Accessing the specific file by name (Default.htm) causes HTTP.sys to cache the file. Accessing the site by requesting the root folder (/), for example http://contoso.com/ with no file specified results in an uncached response. Note, however, that a request to a URL such as http://contoso.com/ will be cached by user-mode file caching in the worker process, as usual.

- The Web site has an IP Restriction list (applies only to Windows 2003 Server Service Pack 1 (SP1)).

# ASP Caching

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The process of creating compiled ASP script files (called *templates*) and script engines each time an ASP page is requested can consume memory and CPU resources, which in turn can impact performance and scalability. The following section describes how you can improve ASP performance and scalability by caching ASP templates and ASP script engines.

# ASP Template Caching

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP processes the templates or template files that contain ASP scripts. ASP stores these templates in a template cache and then serves the cached templates for subsequent client requests. Caching ASP templates enhances performance and scalability, because cached templates are not compiled each time they are called.

The ASP template cache uses a least-recently-used algorithm for determining which templates are cached. This means that if the cache is full, the template that has been in the cache and has not been requested for the longest amount of time is replaced by the next template to enter the cache. Every time a new template is added to the cache, the template goes to the beginning of the cache. The ASP template cache stores up to 500 templates by default (as determined by the **AspScriptFileCacheSize** metabase property). Templates are moved to the beginning of the cache when they are requested. In the case where the 501st template is bumped from the cache, the template is written to disk. By default, the ASP disk cache can hold 2,000 templates (as determined by the **AspMaxDiskTemplateCacheFiles** metabase property). If a template in the disk cache is referenced, the template is moved back to the ASP template cache.

In worker process isolation mode, **AspScriptFileCacheSize** and **AspMaxDiskTemplateCacheFiles** are global settings, which means they apply to all ASP pages on the Web server. (They are process-level settings in IIS 5.0 isolation mode.) ASP pages can contain #include files and these #includefiles can make the ASP files very large. The default 500-file limit established by the ASP template cache applies only to ASP pages and not #include files. However, ASP files that contain #include files can grow large enough to cause memory shortages and errors. ASP will flush the ASP template cache if IIS runs out of memory. If the ASP template cache is flushed, each subsequent request to an ASP page will need to be recompiled before it is cached again. In these situations, you might see ASP queuing. If you display the Active Server Pages\In Memory Templates Cached counter in System Monitor and see spikes followed by a severe reduction in the number of cached templates, your ASP pages might be too big. This could cause your system to run out of memory, flush the cache, recompile, and then run out of memory again. To remedy this situation, reduce the size of the ASP template cache to a number less than 500. Table 7.6 lists the preferred or ideal values for ASP template cache counters. For more information about IIS 6.0 counters, see the Performance Counters Reference.

**Table 7.6 Preferred Values for ASP Template Cache Counters**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Active Server Pages\In Memory Templates Cached | The value of this counter should reflect the number of frequently requested ASP files on your site (also known as your *hot set*). |
| Active Server Pages\In Memory Template Cache Hit Rate | As high as possible. |
| Active Server Pages\Templates Cached | The value of this counter should be close to the value of the **AspMaxDiskTemplateCacheFiles** metabase property; however, this value represents the total number of templates cached in memory and cached to disk, so this value could be higher than **AspMaxDiskTemplateCacheFiles**. |
| Active Server Pages\Template Cache Hits | As high as possible. |
| Active Server Pages\Template Cache Hit Rate | If this value is low and the Active Server Pages\In Memory Template Cache Hit Rate is high, a majority of user requests are being served from the memory cache. Performance and scalability should show a positive impact by not having to read the template from disk. If the value of Active Server Pages\Templates Cached equals the value of the **AspMaxDiskTemplateCacheFiles** metabase property, the cache has reached its maximum value. When the cache has reached its maximum value, this value should be high, otherwise the cache is being flushed. |

The ASP disk cache begins caching files into a directory when the ASP memory cache is full. Furthermore, a file has to be requested at least twice before it becomes a candidate for the ASP disk cache. The corresponding metabase property, **AspMaxDiskTemplateCacheFiles**, specifies the maximum number of compiled ASP templates that can be stored. **AspDiskTemplateCacheDirectory** contains the name of the directory that ASP uses to store compiled ASP templates to disk after overflow of the in-memory cache.

| **Important** |
| --- |
| In order for disk caching to work, ASP needs a properly configured disk cache directory in which to store the compiled ASP files. This means that the Administrators and IIS_WPG groups have Read/Write and Delete permission on the disk cache directory, and the disk cache directory is a local directory on the Web server. |

The default location of the disk cache is *systemroot*\System32\inetsrv\ASP Compiled Templates. In worker process isolation mode, subdirectories under the disk cache directory are created for each application pool. In IIS 5.0 isolation mode, the default disk cache directory is *windir*\system32\inetsrv\ASP Compiled Templates.

For information about changing the settings for caching ASP templates and creating an ASP disk cache directory, see Configuring ASP Template Caching.

# Script Engine Caching

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP code is compiled and executed by Microsoft® Visual Basic® Scripting Edition (VBScript) by default. To improve performance and scalability of ASP code, ASP creates script engines. ASP script engines contain the object and marshalling data that VBScript.dll needs to execute the request. Each entry in the ASP script file cache can point to one or more entries in the ASP script engine cache.

Table 7.7 describes the preferred or ideal values for the ASP Script Engine Cache counter. For more information about IIS 6.0 counters, see the Performance Counters Reference. For information about changing the settings for caching ASP script engines, see Configuring ASP Script Engine Caching.

**Table 7.7 Preferred Value for ASP Script Engine Cache Counter**

| Object\Counter | Preferred or Ideal Value |
|---|---|
| Active Server Pages\Script Engines Cached | The value of this counter should be greater than or equal to the value of Active Server Pages\Requests Executing. If this number is low, the server might not have enough memory to store the script engines in the cache. Performance and scalability will suffer because the server must create script engines often. |

# Setting the ASP Cache Metabase Property and Registry Entry

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following metabase property and Windows registry entry affect ASP caching on your server. In most cases, these settings should not require tuning or adjusting. If you adjust these settings, you should monitor performance and scalability after making changes.

**AspScriptFileCacheSize**
The AspScriptFileCacheSize Metabase Property specifies the number of precompiled script files to cache. If set to 0, no script files are cached. If set to 4,294,967,295, all script files requested are cached. This property is used to tune performance, depending on the amount of available memory and the number of script file cache hits.

The metabase represents unlimited as the DWORD value of 4,294,967,295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Earlier versions of IIS represented unlimited as -1.

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference. |

**DisableLazyContentPropagation**
Windows registry path: HKLM\SYSTEM\CurrentControlSet\Services\ASP\Parameters

Data type: REG_DWORD

Default value: 0 (lazy propagation enabled)

Range: 0 - 1

*Lazy propagation* refers to the action that IIS takes when a large amount of content is updated at one time. IIS has an internal limit on the amount of content that can be updated in the in-memory template cache. If the size of the updated content exceeds that limit, IIS marks each of the files in the in-memory template cache as invalid. When it receives the first request to an invalid file, IIS begins to compile a new template, but it serves the expired template until the new template is compiled.

If you set the value of the registry entry DisableLazyContentPropagation to 1, IIS behaves as it does for IIS 5.0 and IIS 5.1 when a large amount of content is updated at one time. IIS flushes the in-memory template cache, and performance can slow to a standstill as each new request to the server forces IIS to compile new templates.

If you are developing Web pages and making changes to a few files at a time, you do not have to refresh your pages twice to see new changes because lazy propagation only applies when a large amount of content is updated at one time.

For information about the DisableLazyContentPropagation registry entry, see ASP Registry Entries.

**Related Topics**
For more information about editing the registry, see the Registry Reference.

# Global IIS Caching Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following registry entries affect caching on your server. In most cases, these settings should not require tuning or adjusting. If you find it necessary to adjust these settings, use caution and monitor performance and scalability after making changes.

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference. |

**DisableMemoryCache**
Windows registry path: HKLM\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters

Data type: REG_DWORD

Default value: 0 (disabled)

Range: 0 - 1

Disables server static file caching, which negatively impacts performance and scalability. It is not recommended that you disable caching unless you are troubleshooting an issue or debugging application code.

**MemCacheSize**
Windows registry path: HKLM\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters

Data type: REG_DWORD

Default value: approximately one-half of available physical memory, in megabytes (MB)

Range: 0 - 2500 MB

Controls the size of the static file cache. The default value is dynamically adjusted every 60 seconds.

**ObjectCacheTTL**
Windows registry path: HKLM\CurrentControlSet\Services\InetInfo\Parameters

Data type: REG_DWORD

Default value: 30 (seconds)

Range: 0 - 4,294,967,295 (unlimited)

Controls the TTL setting, which defines the length of time that objects are held in the cache. If an object in the memory cache has not been referenced for the specified period, that object will be phased out of the cache. If system memory is limited, or the contents of the server are dynamic, you can use a lower TTL to prevent system memory from being used to cache a large number of volatile objects. Setting **ObjectCacheTTL** to 0xFFFFFFFF disables the *object-cache scavenger* (the process that routinely reads the items in the cache to determine which items should stay in the cache and which items should be flushed) and allows cached objects to remain in the cache until they are overwritten. Disabling the cache scavenger is useful if your server has ample system memory and your data is relatively static.

**Related Topics**
For more information about these registry entries, see Global Registry Entries.

For more information about editing the registry, see the Registry Reference.

# ISP Scaling -- Strategies for Hosting Thousands of Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The ability for IIS to scale up to thousands of sites on one server depends on the type of content the site hosts and the number of application pools on the server. Your business model and service agreements with customers will also determine how many sites you can put on one server. There are three common Internet service provider (ISP) installation strategies you can use when IIS is running in worker process isolation mode:

- Shared static hosting
- Shared static and dynamic hosting
- Dedicated hosting

# Shared Static Hosting

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The *shared static hosting* strategy involves collecting large numbers of static sites together on one server. These static sites are typically personal home pages or business pages that experience very low traffic volumes on a daily basis, so performance and scalability issues are rarely an issue. Before provisioning your server, consider the following guidelines.

**Administer IIS by using command-line administration scripts or batch files**
Using IIS Manager to perform tasks such as provisioning thousands of new sites or configuring sites is extremely inefficient. If your server hosts a few thousand sites, IIS Manager can take several minutes to refresh as it reads configuration data from the metabase. In this case, it is more efficient to administer IIS by using command-line tools. For information about command-line administration tools in IIS 6.0, see IIS 6.0 Administration Scripts, Tips, and Tricks, or see Using Command-Line Administration Scripts. For general information about Web site and virtual directory configuration, see Configuring Internet Sites and Services.

**Create a logical folder structure**
A logical folder structure, for example Domain/username, will alleviate some of the administration overhead in locating sites when they require configuration changes.

**Use host header names to create multiple sites on one server**
Static IP addresses are in limited supply, and obtaining thousands of static IP addresses can be problematic. Static IP addresses are only necessary when a site requires Secure Sockets Layer (SSL). Also, static IP addresses have performance overhead costs. The WWW service must manage an endpoint for every site identified by a unique IP address, and this consumes memory from the nonpaged pool.

**Put all static sites in one application pool**
Static sites, if they are truly static, pose little or no crash risk for an application pool because static sites do not execute code. By putting the sites in one application pool, you limit the resource overhead that multiple application pools impose. You also limit the administrative overhead that comes with multiple application pools.

**Run all static sites with the same anonymous user account**
For static, public Web sites, the anonymous user account provides ample security. Before returning a page to the client, IIS checks NTFS file and directory permissions to see whether the IUSR_*computername* account is allowed access to the file. If access is not allowed, IIS attempts to use another authentication method. If none is selected, IIS returns an HTTP 403 error (Access Denied) to the browser.

**Recycle the application pool worker process (optional)**
You will need to monitor site traffic to determine a regular recycle schedule, if a regular recycle is needed. Ideally, you should recycle the worker process during low-traffic times, for example 3:00 A.M. local time. For more information about worker process recycling, see Running IIS 6.0 as an Application Server.

**Monitor startup times**
Although you should not need to restart your server very often, monitor startup times when you do restart the server. When an IIS server hosts thousands of Web sites, the size of the metabase grows significantly and the task of reading configuration data from the metabase while IIS is starting can strain your CPU resources. Your startup times might be a determining factor for when you need to add a new server to your installation.

**Monitor performance**
As you provision sites, regularly monitor site traffic and resource consumption. In this way, you will be able to see how the system scales and proactively determine when it is time to add a new server to your installation.

**Enable centralized binary logging**
Centralized binary logging writes all log file data in binary format to one centralized file, and preserves memory and CPU resources by not creating and writing to thousands of individual log files. For more information about centralized binary log files, see Analyzing Log Files.

**Partition log files on multiple disks**
If you choose not to use centralized binary logging, partition log files on multiple disks to minimize I/O. With multiple disk controllers writing log data to different disks, you will minimize I/O and preserve memory resources for other needs.

# Shared Static and Dynamic Hosting

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The *shared static and dynamic hosting* strategy mixes static and dynamic sites on the same server. If your customer base requires you to host a mix of static and dynamic sites on the same server, the following guidelines can help you maximize the number of sites and application pools you can host on one server. Most of the guidelines in Shared Static Hosting apply to this strategy as well.

**Separate static and dynamic content sites in different application pools**
If you need to host static and dynamic sites on the same server, put the static sites in one or more application pools and the dynamic sites in one or more different application pools. By isolating the static sites from the dynamic sites, you mitigate the possibility of a poorly developed application crashing the static content application pool.

**Set content quotas for sites**
Your business model and customer service agreement should define content quotas, for example 200 MB for each site. Set disk quotas in the properties of each physical hard disk by using the Quota service available in Windows Server 2003.

**Consider enabling Quality of Service (QoS) features for sites that are resource-intensive**
Features such as CPU monitoring, bandwidth throttling, and idle timeout will ensure that one site does not consume a majority of the resources and cause errors for other sites on the same server. For more information about these features, including how to enable them, see Optimizing IIS 6.0 Performance.

**Configure one unique anonymous user per site**
Configuring one unique anonymous user per site adds a security layer by ensuring that users cannot access content on sites to which they are not permitted access.

**Develop processes for handling service packs, security updates, and hotfixes**
If your customers will be using IIS 6.0 to administer their own dynamic sites, set up a process for handling service packs, security updates, and hotfixes to minimize downtime for your customers and to help ensure the security of your installation. Windows Server 2003 has improved management of updates with Auto Update version 1.0, which provides you with three options:

- Notify you the moment an update is available.
- Download the update and notify you of its availability.
- Scheduled installation (this option enables the update to be downloaded and automatically installed at a time you choose).

**For ASP content, allow ASP pages to run on MTA instead of STA**
Because of the overhead memory and CPU cost of running dynamic applications, your server will reach a limit in the number of application pools it can host. With ASP content, you can mitigate this limitation on application pools by enabling ASP pages to run on multithreaded apartment (MTA) threads instead of single-threaded apartment (STA) threads. ASP is capable of running all of its threads in an MTA. If your COM components are primarily free-threaded or both-threaded, running the ASP threads as MTA can improve performance significantly. By default, the **AspExecuteInMTA** metabase property is set to 0, which means that ASP does not execute in MTA. Set this property to 1 at the application level to enable ASP to run in MTA.

| **Note** |
| --- |
| MTA has some limitations with respect to components that can be instantiated. Objects that are strictly Apartment might show a performance regression because marshalling will occur and the potential for STA thread contention will increase. |

**If you need to set up more than 60 application pools where each pool is running as a unique identity on a server, change the UseSharedWPDesktop registry key**
If you are setting up your application pools with unique identities, depending on the applications and memory resources on your server, you will reach a limit of about 60 application pools. There are finite limits to some system resources that get allocated with each new logon session. This means that 60 processes can run concurrently as distinct accounts. IIS 6.0 supports

running these processes in a single shared workstation and desktop, at a cost of sharing a single encapsulation of a user session among all parties.

| ⚠Caution |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference. |

To scale beyond 60 application pools and to share a single desktop, change the value of the registry entry UseSharedWPDesktop, of data type DWORD, to 1. The registry entry is located in the subkey HKLM\System\CurrentControlSet\Services\W3SVC\Parameters\UseSharedWPDesktop. After changing this registry entry, you should be able to scale to hundreds of application pools and hundreds of concurrently running worker processes.

**If IIS is starting too many worker processes and your server is running out of resources, set a maximum number of concurrent worker processes**

With the IIS 6.0/HTTP.sys architecture and with a request load distributed across many application pools, IIS might attempt to start more worker processes than the server can sustain without running out of memory or CPU resources. The DemandStartThreshold Metabase Property (also called *concurrent process gating*), when set to a value less than the default, applies a hard limit to the number of IIS worker processes that can run concurrently. If the hard limit is exceeded, HTTP.sys returns an HTTP 503 error (Service Unavailable).

**Locate misbehaving applications and isolate them in their own application pool**

You can use Event Viewer and IIS logs to locate misbehaving applications, or you can use Log Manager and Trace Report, which are general-purpose tools supplied with Windows Server 2003. Log Manager creates trace data, which is then processed by the Windows Trace Report utility. The Trace Report utility creates a formatted, detailed report that is useful in assessing IIS and IIS-related activity in the operating system. Once you have located a misbehaving application, isolate the application in its own application pool so it doesn't affect other applications. Recycle the application pool regularly.

For more information about editing the registry, see the Registry Reference.

For more information about Log Manager and Trace Report, see The IIS Request-Based Tracing Process.

For more information about viewing and interpreting log files, see Analyzing Log Files.

# Dedicated Hosting

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Dedicated hosting is typically reserved for those customers who have the greatest availability, security, and performance requirements for their dynamic Web sites. In some cases, you might put only one or two sites on an IIS server to ensure there are enough memory and CPU resources to meet customer requirements. In other cases, dedicated hosting means the customer pays to have their own server or servers. Dedicated hosting can be configured in the following ways.

**Configure one unique application pool per Web site**
Process boundaries separate each worker process so that problems in one application pool do not affect other application pools on the server. By configuring each Web site in a different application pool, you ensure greater reliability, availability, and security. For information about how to configure application pools, see Running IIS 6.0 as an Application Server.

**Configure one unique anonymous user per site**
Configuring one unique anonymous user per site adds a security layer by ensuring that users cannot access content on sites to which they are not permitted access.

**Configure one unique user to run as the process identity of the application pool**
Configuring one unique user to run as the process identity of the application pool adds an additional layer of security by ensuring that one site cannot access content on another site. If you specify a unique user account, be sure to add that account to the IIS_WPG group. When you use a built-in account, try to use Network Service because it offers the best balance between security and functionality.

If you experience scalability issues on a dedicated hosting computer, see Shared Static and Dynamic Hosting.

# Improving Scalability Through UNC-Based Centralized Content Storage

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 delivers several technical changes that make it easier for ISPs or other organizations to create UNC-based centralized storage solutions. Centralized content storage can make it much easier to scale your installation to thousands of Web sites. Centralized storage can also help minimize time commitments for server management and administration. This section describes the following:

- Caching Changes. For UNC content, IIS 6.0 provides the new last-modified caching algorithm for both static and ASP files. In addition, IIS 6.0 improves the performance of change-notification-based caching for ASP files.

- UNC Authentication. IIS 6.0 now performs UNC authentication, formerly called Passthrough authentication, by default.

- Constrained Delegation. With constrained delegation, you can allow delegation only to certain services, so you can control the specific network resources that a service or computer can use.

# Caching UNC-based Files

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you can create UNC-based virtual directories, the IIS caches must treat each UNC path as a separate directory structure, and therefore ASP and static file caches must monitor each directory individually. In a centralized-content architecture with many different UNC shares, this has the potential to exhaust system resources.

The Web server and the file server are connected with a Server Message Block (SMB) connection. Only one SMB connection is created between a Web server and a file server; however, within that SMB connection, there are a finite number of work items. Work items can be consumed in a variety of ways and for varying amounts of time. For example, performing an operation — such as a **CreateFile** or **GetFileAttributes** command — on a file consumes an I/O work item for a short amount of time, but asking for a change notification on a directory structure consumes a work item for as long as the connection is intact. Each change-notification instance uses a work item until the connection is lost, and each request from a Web server to the file server uses a work item only temporarily. However, the scalability impact of the SMB connection is reduced by using last-modified caching.

IIS 6.0 has two methods for caching static and ASP files, called last-modified caching and change-notification caching. For information about configuring change-notification tracking or the time to live (TTL) for static and ASP files, see Configuring Last-Modified Caching and Configuring ASP Change-Notification Caching.

# UNC-based Caching Considerations

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You should decide which caching method to use based on your network architecture and your scalability and performance requirements. In general, last-modified caching is the most reliable method. It is recommended that you use this caching method when you require scalability for a system with a Web server that points to different file structures. You can also experience performance gains by using change-notification caching if your system uses a file server that reliably reports change notifications and you have only a few sites or virtual directories. For example, if you have a single Web site with one or two applications, and all of your content is stored on a Windows Server 2003–based file server, use change-notification caching.

To configure caching for optimum scalability and performance, you must edit the registry entries **MaxMpxCt**, **MaxWorkItems**, and **MaxCmds**. On the server running IIS, these entries are stored in the subkey HKLM\System\CurrentControlSet\Services\LanmanWorkstation\Parameters. On the remote file server running Windows Server 2003, these entries are stored in the subkey HKLM\System\CurrentControlSet\Services\LanmanServer\Parameters.

**MaxMpxCt**

The **MaxMpxCt** registry entry permits a server to provide a specified maximum number of simultaneous client requests to itself, and then enforces that limit. Because each client connection generates multiple instances (for example, Windows shell and Explorer.exe), with multiple clients connecting to the server, the number of client requests can be greater than the default **MaxMpxCt** value of 50. As soon as this limit is reached for that server, additional requests are refused until the number of requests drops below the limit again.

**MaxWorkItems**

The value of the registry entry **MaxWorkItems** should be at least four times as large as that for **MaxMpxCt**. For example, if **MaxMpxCt** has a value of 1,024, **MaxWorkItems** should have a value of at least 4,096.

Some resources, including Microsoft Knowledge Base articles, recommend setting the value of **MaxWorkItems** to 16,000. However, this could consume up to 250 MB of nonpaged pool memory, which could starve the system. To increase your systems reliability, it is recommended that you set the value of **MaxWorkItems** lower than 16,000.

To determine the number to set for the value of **MaxWorkItems**, monitor the Server object performance counters. The Work Item Shortages counter will indicate whether you need to make these values larger or increase the load capability of your file server by adding memory or clustering the file server. You must allow enough work items for two activities: change notifications and normal I/O requests.

**MaxCmds**

The **MaxCmds** registry entry sets the limit for the number of concurrent outstanding network requests between the SMB client and server that the client can support. The general formula for calculating the value of **MaxCmds** is as follows:

(number of distinct physical directories that IIS needs to monitor for change notifications) (1 (if static files exist) + 1 (if ASP content exists) + 1 (if ASP.NET content exists) + 50 (for concurrent default/regular file I/O)

This formula is merely a starting point for tuning your servers. You might need to increase your settings depending on concurrent traffic. For better scaling, you typically need to modify the values of the **MaxCmds**, **MaxMpxCt**, and **MaxWorkItems** registry entries on both the server running IIS and the remote file server. Before you modify the entries, however, watch the Server object performance counters while you stress-test your system. Carefully monitor the Work Item Shortages counter to see if you need to increase the values of the entries or increase the load capability of your file server by adding memory or clustering the file server. If you are using the non-default change-notification option for caching, you must allow enough work items for two activities: change notifications and normal I/O requests for the file.

# UNC-based Caching Scenarios

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following three scenarios illustrate the different UNC–based caching options in more detail and provide recommendations for setting maximum values:

- Wide content, low traffic. This scenario is an example of a typical low-end shared hosting server.
- Wide content, high traffic. This scenario represents an enterprise Web site that hosts hundreds of small applications and receives a high volume of traffic consisting mainly of anonymous users.
- Narrow content, high traffic. This scenario represents a dedicated hosted Web site with fewer than 10 applications, but with a very high volume of traffic consisting only of anonymous users.

When evaluating the settings in the tables in the following sections, consider the number of simultaneous work items that are opened from the server running IIS to the remote file server, but reflected (inversely) by the value of the **MaxCmds** entry. You should calculate all other remote file server settings based on that result.

| **Important** |
| --- |
| The settings in the following scenarios are intended as guidelines only. Changing the registry settings listed here will produce different results, depending on your specific system configuration. You should test your application with the default settings, and then increase the maximum settings accordingly. |

# Scenario 1: Wide Content, Low Traffic

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In this scenario, each site has its own directory structure, and there are no virtual directories below each site. Each server running IIS might have up to 20,000 sites, but only approximately 1,000 sites are active at any given time. Each site runs in its own process. Users are authenticated if they are publishing on the Web; otherwise, they are anonymous. The content is primarily ASP and static files, with a few ASP.NET applications.

If you enable file caching with the change-notification algorithm, you might use the following equation to calculate **MaxCmds**:

20,000 physical directories (1(static) + 1(ASP) +1(ASP.NET) + 50 = approximately 60,000 for **MaxCmds**

However, this setting would jeopardize server performance and scalability because it would consume hundreds of megabytes of nonpaged pool memory.

If you use caching with the default last-modified algorithm, no work items are used for change notification. Depending on active traffic for file I/O and your analysis of the performance counters, you might still need to increase the values of **MaxCmds**, **MaxWorkItems**, and **MaxMpxCt** from their default values. Table 7.8 lists the recommended settings for the wide-content, low-traffic scenario that uses the default last-modified caching algorithm.

**Table 7.8 Recommended Registry Settings for Wide Content, Low Traffic**

| Registry Entry | Server Running IIS | Remote File Server |
|---|---|---|
| MaxCmds | 3,072 (0xC00). This is the maximum number of work items allowed by this computer. | Default setting. |
| MaxMpxCt | Default setting. | 3,072 (0xC00). This is the maximum number of work items allowed per client computer. The client computer in this case is the server running IIS. |
| MaxWorkItems | Default setting. | 12,288 (0x3000). This value must be four times MaxMpxCt. |

# Scenario 2: Wide Content, High Traffic

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In this scenario, a large Web site has 300 applications. The site contains static files, ASP content and ASP.NET content. Most users access the site anonymously.

If you enable file caching with the change-notification algorithm, this site will consume approximately three work items per cache, per application, for a total of 900 work items.

If you enable file caching with the last-modified algorithm, the site will not consume any work items that would be consumed for long periods, but there will be temporary work items and heavy traffic between the Web server and the file server. The caches are all frequently used.

Because there are a manageable number of applications in this scenario that use less than 1,000 work items per client, you might attempt to use the change-notification caching algorithm. This would reduce the back-end network traffic.

Table 7.9 lists the recommended settings for the wide-content, high-traffic scenario that uses the change-notification algorithm.

**Table 7.9 Recommended Registry Settings for Wide Content, High Traffic**

| Registry Entry | Server Running IIS | Remote File Server |
|---|---|---|
| MaxCmds | 2,048 (0x800). This is the maximum number of work items allowed by this computer. | Default setting. |
| MaxMpxCt | Default setting. | 2,048 (0x800). This is the maximum number of work items allowed per client computer. The client computer in this case is the server running IIS. |
| MaxWorkItems | Default setting. | 8,192 (0x2000). This value must be four times MaxMpxCt. |

**Note**

The value listed in Table 7.9 for MaxCmds is higher than the value that results when you use the general formula for calculating MaxCmds because the value in the table was rounded.

If you have too many applications to use the change-notification algorithm, you can use the last-modified algorithm. You should extend the cache TTL value to approximately 30 seconds to reduce the traffic between the Web server and the file server. This scenario is the most difficult to tune properly.

# Scenario 3: Narrow Content, High Traffic

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In this scenario, a small site contains 10 applications and static, ASP, and ASP.NET files that receive a very high number of hits.

If you enable file caching with the change-notification algorithm, this site will consume approximately three work items per cache, per application, for a total of 30 work items.

If you enable file caching with the last-modified algorithm, the site will not consume any work items, but there will be heavy traffic between the Web server and the file server. The caches are all frequently used.

Because this scenario requires only a few work items to cache the content reliably, change notification is the recommended caching algorithm. You do not need to increase the default maximum settings by very much. Table 7.10 lists the recommended settings for the narrow-content, high-traffic scenario that uses the change-notification algorithm.

**Table 7.10 Recommended Registry Settings for Narrow Content, High Traffic**

| Registry Entry | Server Running IIS | Remote File Server |
|---|---|---|
| MaxCmds | 512 (0x200). This is the maximum number of work items allowed by this computer. | Default setting. |
| MaxMpxCt | Default setting. | 512 (0x200). This is the maximum number of work items allowed per client computer. The client computer in this case is the server running IIS. |
| MaxWorkItems | Default setting. | 2,048 (0x800). This value must be four times MaxMpxCt. |

**Note**

The value listed in Table 7.10 for MaxCmds is higher than the value that results when you use the general formula for calculating MaxCmds because the value in the table was rounded.

# Authentication for UNC Shares

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The UNC authentication method, also called UNC Passthrough authentication, determines the credentials to be used for gaining access to a UNC share on a remote computer. In IIS 6.0, UNC authentication works by looking at the request user and the credentials stored in the UNCUserName Metabase Property and UNCPassword Metabase Property to determine the credentials to pass through to the computer with the UNC share.

If you use IIS Manager to create a Web site or virtual directory and specify a UNC path for the content, IIS Manager prompts you to type a user name and password for the network resource. If you specify a user name and password, the **UNCUserName** and **UNCPassword**metabase properties are set.

If **UNCUserName** is specified (not empty) and **UNCPassword** is valid, the metabase user credentials are sent as the user identity for access to the remote share. If **UNCUserName** is specified (not empty) and **UNCPassword** is not valid, a 500.13 error (Internal Server Error: Invalid Username or Password) is sent to the client.

If **UNCUserName** is empty, the credentials of the request user — which can be either an authenticated set of credentials for authenticated requests or IUSR_*computername* credentials for anonymous requests — are sent as the user identity for access to the remote share. In other words, by default in IIS 6.0, you do not need to specify user name and password credentials.

| **Note** |
| --- |
| The **UNCAuthenticationPassthrough** metabase property is no longer used for UNC authentication. |

For more information about enabling UNC authentication, see Securing Virtual Directories.

# Constrained Delegation for UNC File Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Delegation* is the act of allowing a service to impersonate a user account or computer account in order to access resources throughout the network. When a service is trusted for delegation, that service can impersonate a user to use other network services. *Constrained delegation* is a new option for Windows Server 2003, and it is recommended that you use it with a Windows Server 2003 domain. With this option, you can specify the Service Principal Names (SPNs) to which an account can delegate. With this option, a service can be trusted for delegation, but the domain administrator can limit that trust to a select group of explicitly specified services. By only allowing delegation to specific services, you can control the specific network resources the service or computer can use.

Constrained delegation is particularly useful in scenarios where a site that requires authentication — that is, a site that does not allow anonymous access — contains content that is housed on a remote UNC file server. With constrained delegation, you can enable Windows Integrated authentication, which can use NTLM authentication or send credentials across the network as a Kerberos-based token.

If you do not use constrained delegation, but you enable Windows Integrated authentication and NTLM, the token that the Web server obtains from the Windows security infrastructure does not have sufficient permissions to access another computer, such as your file server. However, with constrained delegation and Windows Integrated authentication, the token received by the Web server from the Windows security infrastructure is a Kerberos-based token with permission to access other computers, including the file server. Essentially, constrained delegation allows an NTLM-based token to be upgraded to a Kerberos-based token. Be aware, however, that Kerberos-based authentication can degrade performance because each access check occurs on the file server.

For more information about constrained delegation, see Managing a Secure IIS 6.0 Solution.

When you set up a UNC-based virtual directory and specify a user name and password for that directory, you might receive an error message when you attempt to access the directory by using IIS Manager. This error occurs because IIS Manager sends the current Windows user credentials when it accesses the virtual directory. The credentials of the current Windows user might not be the same as those you specified for the UNC-based virtual directory. However, if you access your Web server over the Internet by using IIS Manager on a remote computer, the contents of the virtual directory will be displayed without error. Because using IIS Manager is not a reliable method of verifying whether your customers can access the content stored on the remote computer, you should test your virtual directories by making requests with a Web browser.

# Case Study: Scaling an ASP.NET Web Application on IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following case study illustrates how to monitor and tune IIS 6.0 for improved performance and scalability. In this study, network administrators in a fictional company, Contoso, were getting ready to roll out a new Web application for the purpose of selling books online. The application code had been extensively tested, but performance and scalability statistics were still unknown. To gather performance and scalability metrics, the administrators used the Microsoft Web Capacity Analysis Tool (WCAT) to stress-test the site.

Stress testing helps administrators locate performance and scalability bottlenecks in their Web application installation. By using a tool such as WCAT or the Microsoft Application Center Test (ACT) in a test environment to simulate the server load they can expect in a production environment, administrators can isolate and fix potential bottlenecks that might undermine the customer experience. Administrators can also plan the installation capacity.

The administrators in this study were preparing to roll out the Duwamish 7.0 ASP.NET application, a fictitious online bookseller application. Their rollout consisted of the following phases:

- Capacity planning
- Tuning production servers
- Scaling up
- Scaling out

| **Note** |
| --- |
| This case study does not provide information about how to create a WCAT script or how to perform stress testing by using WCAT. See the WCAT documentation (Wcatguide.doc) for information about how to create a WCAT script and how to use WCAT for stress testing. |

Related Topics

For more information about WCAT, see the IIS 6.0 Resource Kit Tools.

# Capacity Planning_IIS_SP1_TechRef

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

The administrators initially wanted to see how their application scaled on a server with four 500-MHz processors running IIS 6.0 in worker process isolation mode. Their goal was to stress the site to see how many requests per second the installation processed at (or close to) 100 percent CPU saturation. By understanding how the application performed when the CPU was saturated, they could begin to understand how the site would scale under a heavy load, and they could begin to plan the capacity of the installation based on traffic estimates. Table 7.11 describes the software and hardware used for this case study.

**Table 7.11 Case Study Software and Hardware**

| Software | Hardware |
|---|---|
| Web Servers:<br>Windows Server 2003 (RC1)<br>Default installation of IIS 6.0 (running in worker process isolation mode)<br>ASP.NET<br>Duwamish.NET 7.0 Web application | Web Servers:<br>Four 550-MHz Intel Pentium 3 processors<br>Compaq Proliant 6400R<br>512 MB RAM<br>Single 3COM Gigabyte Ethernet Server network adapter<br>Eight 900-MHz Pentium 3 processors<br>Compaq Proliant 6400R<br>8 GB RAM<br>Intel Pro Gigabit Optic Fiber Server network adapter |
| Database:<br>SQL Server 2000 | Database:<br>Two 1000-MHz Pentium 3 processors<br>Compaq DL360<br>264 MB RAM |

# Preparing to Test

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The administrators set up their WCAT configuration file to run 40 virtual clients (four client computers running 10 threads each). They set up their WCAT distribution file to imitate real-world customer use of their site. Table 7.12 shows the breakdown of the WCAT distribution file.

**Table 7.12 Description of WCAT Distribution File Classes for Contoso Stress Tests**

| Class Number | Percentage of Requests | Class Description |
|---|---|---|
| <class> 1 | 60 | User browses for books. The administrators assigned the highest percentage of requests to this action to reflect what they expect to be the highest percentage of real-world traffic to their site. |
| <class> 2 | 10 | User creates an account and buys a book. |
| <class> 3 | 20 | User logs on to an existing account, puts five books in the shopping cart, takes two books out of the shopping cart, and then completes the purchase. |
| <class> 4 | 10 | Invalid searches and other user mistakes. |

The administrators ran the stress test for 10 minutes. If they had wanted to locate bugs or bottlenecks in their Web application, they would have run the test for much longer; however, because they were not concerned about bugs in the application, the 10-minute test run was sufficient.

While the test ran, the administrators monitored the network to make sure the connection (with a capacity of 1 GB) was not saturated. In Windows Task Manager, on the **Networking** tab, the administrators noted that network traffic was steady at about 4 percent, which meant that the network was not a bottleneck.

The administrators then opened System Monitor and monitored the Processor(_Total)\% Processor Time counter. The counter showed that the CPU was saturated at 100 percent. The administrators ran the test several more times with fewer virtual clients and the CPU did not reach 100 percent saturation, so they concluded that the data from the test that ran 40 virtual clients would suit their needs for capacity planning, provided the WCAT log did not reveal test errors.

The log revealed no errors, so the administrators concluded the bottleneck is the CPU. The server installation could not scale beyond the 40 virtual clients because the server did not have sufficient processing power. If the administrators had failed to saturate the CPU, they would have looked elsewhere in the installation for the bottleneck — for example, disk I/O (reading and writing from disk) or database activity. Also, a badly written application can be the source of a bottleneck in cases where the CPU is not saturated during stress testing.

# Interpreting Test Data

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In a situation where the CPU constrains maximum performance, the WCAT results can be used to perform a cycles-per-request calculation for capacity planning. The WCAT log showed 893 requests per second on a server with four 550-MHz processors. Test results can be summarized as follows:

- 4 x 550 megacycles/second = 2,200 megacycles/second.
- 2,200,000,000 cycles/second divided by 893 requests/second = 2,463,606 cycles/request (on average). Rounded up, the server used 2.5 million cycles/request while the CPU was at 100 percent saturation.
- At this point, the administrators spoke with the business managers and marketing managers to learn about expected traffic loads per day. The managers explained that after extensive research, they expected 200,000 customers per day. Each customer will send roughly 60 requests per session, so the total requests/day is 60 200,000, or 12,000,000 total requests/day (estimated).
- 12,000,000 divided by 24 60 minutes 60 seconds = 139 anticipated requests per second.
- Rounding to 150 requests/second 2.5 megacycles per request = 375 MHz needed to process the expected traffic at any given time (on average).

The administrators did not want their Web server to run at 100 percent CPU utilization. Furthermore, the administrators knew from experience that all Web sites have a pattern to their traffic. In order to accurately assess their capacity needs, they would need to know how much CPU power would be needed to handle traffic spikes. After researching other online booksellers, the administrators determined that their site would be busiest in the evening hours from 6 P.M. to midnight (local time) and that their peaks would be around 300 requests per second. The administrators also knew that according to their company's policy, maximum CPU utilization during peak loads should rarely exceed 30 percent. This maximum helps to assure quality of service during times of heavy traffic.

With a goal of 300 requests per second and a maximum CPU utilization of 30 percent, the administrators adjusted their WCAT distribution and configuration files and then ran the stress test again. The tests showed that at 275 requests per second, CPU utilization approached 30 percent. In this way, the administrators determined that their current capacity on the server with four 550-MHz processors is sufficient for expected regular traffic and peak loads. In other words, the installation scales well for their current needs, and the installation should have sufficient resources available to handle peak loads.

# Tuning Production Servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Contoso best practices mandate that each server be configured for optimum performance and scalability before the server is put into production. These best practices specifically target disk setup, services running on the server by default, network setup, and caches.

**Use RAID**

To begin with, the administrators set up the site content on a redundant array of independent disks (RAID). RAID is a data storage method in which data — along with information used for error correction, such as parity bits — is distributed among two or more hard disk drives to improve performance and reliability. For information about setting up RAID, see Help and Support Center for Windows Server 2003.

If using RAID is not an option, consider moving the site content to a disk other than the system disk (that is, the disk on which the operating system is installed). By storing your site content on a disk other than the system disk, you reduce contention for disk access between the operating system and the Web sites. This further increases performance.

**Delete unused default documents**

The administrators knew that if a user tried to access the Web site by using a trailing slash — for example, http://www.contoso.com/website/ — the server would read each item listed in the default document list (such as Default.htm, Default.asp, and Index.htm) and perform a search to see if each document existed. As a best practice, the administrators deleted all the documents in the default document list that do not exist. They left only the default document that does exist — for Contoso, this is Default.aspx. You can delete unnecessary default documents by using IIS Manager to modify the **Documents** tab on the **Web Sites** property pages.

**Shut down unused services**

To conserve memory and CPU resources for the Web service, the administrators shut down unnecessary services. The server will host only the Contoso Web application, so the administrators stopped other IIS services such as the FTP, Simple Mail Transfer Protocol (SMTP), and Network News Transfer Protocol (NNTP) services. Using the Services snap-in, the administrators stopped the Automatic Updates, Task Scheduler, Wireless Configuration, and Print Spooler services (because they would not be printing from that server).

| **Important** |
| --- |
| Refer to Help and Support Center for Windows Server2003 to ensure that you understand the role of each service before you stop it. Monitor performance after stopping each service to ensure that the change does not negatively affect performance. |

**Change file and printer sharing defaults**

The administrators changed the default File and Printer Sharing for Network properties from **Maximize data throughput for file sharing** to **Maximize data throughput for network applications**. This small change resulted in a 10 percent increase in throughput. For information about how to change these properties, see To configure File and Printer Sharing for Microsoft Networks.

For more information about performance tuning, see Optimizing IIS 6.0 Performance.

# Scaling Up

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Scaling up* means adding hardware, such as RAM or CPUs, to a Web server to increase the number of sites a server can host. Scaling up can be an inexpensive way to boost performance, especially if you host static-content Web sites.

Shortly after moving the server with four 550-MHz processors into production, the Contoso Marketing department finalized plans for a major television advertisement campaign. The marketing director informed the administrators that site traffic would likely double in the next few weeks. The administrators needed to determine whether the server with four 550-MHz processors could handle sustained traffic loads of 600 requests per second while staying within the 30 percent CPU restriction. The cycles-per-request analysis is as follows:

- 4 x 550 megacycles/second = 2,200 megacycles/second.
- 2,200,000,000 cycles/second divided by 893 requests/second = 2,463,606 cycles/request (on average). Rounded up, the server performed 2.5 million cycles/request while the CPU was at 100 percent saturation.
- 600 requests/second 2.5 million cycles/request = 1500 MHz.
- 1500 MHz divided by 30 percent CPU saturation maximum (1500/.3) = 5000 megacycles/second.

As a result of this analysis, the administrators realized they needed a server that could perform 5,000 megacycles/second in order to use 1,500 megacycles/second at 30 percent CPU. The server with four 550-MHz processors could only achieve 2,200 megacycles/second. Consequently, they would need to scale up, scale out, or both.

To determine the results of scaling up, the administrators tested a server with eight 900-MHz processors. This new server was capable of 7,200 megacycles/second, which covered their current needs.

The administrators migrated the application and performed their WCAT stress test again. In an effort to saturate the CPU at 100 percent, the administrators ran the test with 48, then 72, and finally 120 virtual clients. CPU utilization never exceeded 70 percent. The administrators checked Task Manager and found that the network hovered around 11 percent. The administrators determined at this point that they had a bottleneck somewhere in the system, but for the purpose of their tests, the result of 1,904 requests/second with an average response time of 630 milliseconds was sufficient test data.

The server with four 550-MHz processors performed 893 requests/second. The server with eight 900-MHz processors performed 1,900 requests/second. The installation scaled at a ratio of 1 to 1.6 [(7200/1900)/(2200/893)] when moving from four to eight processors. The administrators understood this to be an acceptable scaling ratio. Realistically, the overhead in system resources and issues such as lock contention do not allow a system to scale linearly; and so they did not expect to see a scale ratio of 1 to 2 when moving from four to eight processors. According to their calculations, the administrators determined that the server with eight 900-MHz processors, barring any unforeseen problems, should scale and perform satisfactorily for their application.

# Scaling Out

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Scaling out* is the process of adding servers to an existing server environment to improve performance and to increase the number of Web sites that the system can host or publish. Scaling out reduces bottlenecks and lock contention because requests coming into the system do not share resources. The request load is balanced among servers.

The Contoso administrators understood that although scaling up to an eight-processor server would meet their performance and scalability needs, they would potentially gain more throughput and increased reliability by hosting their Web application on multiple servers. They decided to use two four-processor servers (one with four 550-MHz processors and one with four 900-MHz processors) with Network Load Balancing for load balancing and failover. After installing and configuring Network Load Balancing on both servers, the administrators ran their WCAT stress test using 500 virtual clients (five client computers running 100 threads each).

As one Network Load Balancing node, the two servers processed (on average) 1,900 requests per second when the Processor(_Total)\% Processor Time counter approached 100 percent. The administrators were initially concerned that the requests per second had not increased beyond the results of the eight-processor server by itself. After looking at the actual megacycles per request, as shown in Table 7.13, the administrators realized they actually had an 18 percent increase in throughput, because the number of megacycles per request had decreased in the Network Load Balancing test.

**Table 7.13 Megacycles/Request Calculations**

| Server | Megacycles/Second (# of Processors/MHz) | Requests/Second | Megacycles/Request |
|---|---|---|---|
| 4 x 550 MHz | 2,200 | 900 | 2.45 |
| 8 x 900 MHz | 7,200 | 1,900 | 3.8 |
| 4 x 550 MHz + 4 x 900 MHz | 5,800 | 1,900 | 3.1 |

With the 18 percent increase in throughput and the added reliability of hosting the Web application on two servers, the administrators asked themselves, Are we done? Is this good enough? Have we scaled this installation as much as we can scale it? They realized that the only truly accurate benchmark they could use for their application was the application itself. In other words, they had scaled the installation out to the point where they could readily process the expected traffic loads while staying within the 30 percent CPU utilization guideline. They had increased reliability by hosting the site on two servers, and they had executed their stress testing with no errors. Unless they began to experience errors from clients, or they noticed — during regular performance monitoring — that traffic loads were increasing and CPU usage was surpassing the 30 percent restriction, they had achieved their objective.

# Additional Resources for IIS 6.0 Scalability

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to IIS scalability.

**Related Information**

- IIS 6.0 Administration Scripts, Tips, and Tricks for information about command-line administration tools in IIS 6.0.
- IIS 6.0 Architecture for information about IIS 6.0 request processing modes.
- Optimizing IIS 6.0 Performance for information about performance tuning.
- Running IIS 6.0 as an Application Server for information about IIS 6.0 application isolation modes, including how to enable and configure worker process isolation mode.
- Working with the Metabase for information about the IIS 6.0 metabase, including how to change a metabase property.
- *Performance Testing Microsoft .NET Web Applications* by Microsoft Application Consulting and Engineering (ACE) Team, 2003, Redmond: Microsoft Press.

**Related IIS 6.0 Operations Guide Topics**

- Performance Counters Reference for information about IIS cache counters.
- Metabase Property Reference for information about specific IIS 6.0 properties.
- Using Command-Line Administration Scripts for information about administering IIS 6.0 programmatically.
- Performance Counters Reference for information about IIS 6.0 counters.

**Related Tools**

- WCAT

  The Microsoft Web Capacity Analysis Tool (WCAT) runs simulated workloads on client/server configurations. Using WCAT, you can test how IIS and network configurations respond to a variety of different client requests for content or data. The results of these tests can be used to determine the optimal server and network configuration for your server. WCAT and its documentation (Wcatguide.doc) are available in the IIS 6.0 Resource Kit Tools.

# Configuring Internet Sites and Services

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) provides four Internet services: the World Wide Web Publishing Service (WWW service) for hosting Internet and intranet content, the File Transfer Protocol (FTP) service for hosting sites from which users can upload and download files, the Network News Transfer Protocol (NNTP) service for hosting discussion groups, and the Simple Mail Transfer Protocol (SMTP) service for sending and receiving e-mail messages. The WWW service is installed by default. Otherwise, install only the services that you need. After you install IIS–based Internet services, you can create sites or virtual servers, configure properties and security settings, and set up components to further customize your server.

**In This Section**

# DNS Overview_IIS_SP1_TechRef

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

The Internet employs Transmission Control Protocol/Internet Protocol (TCP/IP) to locate and connect to network hosts, which are computers or other network devices. Each network host is identified by a unique IP address. For users to reach your IIS-based Internet site or service, you must have a unique IP address.

IP addresses are expressed in dotted-decimal notation and segmented into four 8-bit octets, for example, 192.168.1.42. It is difficult to remember and use numeric IP addresses, and many people prefer to use alphanumeric names. To address this issue, Domain Name System (DNS) provides a standard naming convention for locating IP-based computers. When you use DNS, clients can connect to an Internet site or service by typing a DNS domain name (such as www.microsoft.com) in their browsers, rather than an IP address (such as 192.168.1.42). A DNS domain name such as www.microsoft.com is easier to remember and type correctly.

The process of mapping a DNS domain name to an IP address is called *name resolution*. DNS name resolution is performed by a DNS service, such as the DNS service provided with the Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; and Windows® Server 2003, Datacenter Edition, operating systems. For more information about Windows Server 2003 DNS, see DNS in Help and Support Center for Windows Server 2003.

Before you can set up an IIS-based Internet site or service, you must obtain an IP address, and if you want users to be able to use a DNS domain name to connect to your Internet site or service, you must also register a unique DNS domain name. Before you request a DNS domain name to register, decide on a plan for your DNS namespace.

**Namespace Planning for DNS**

DNS uses a namespace that is hierarchically structured and based on the concept of a tree of named domains. The tree has multiple levels:

- The root domain. The root domain is the top-level organizational domain. Root domain names include com, org, and gov.
- Second-level domains. Second-level domains provide an identifying name. For example, if your company is named Contoso Pharmaceuticals, then the second-level domain can be *contoso* in contoso.com.
- Subdomains. Subdomains are arranged according to departments, geography, or other logical divisions to help users find information as quickly as possible. For example, you can create a subdomain of research.contoso.com.

The DNS namespace includes globally unique identifiers — Internet domain names, IP address numbers, protocol parameter and port numbers, and others — that are assigned to the organizations that request them. These identifiers must be unique for the Internet to function.

To effectively plan your DNS namespace, consider the long-term organization of your network architecture, as well as how users might look for information. For more information about namespace planning, see Namespace planning for DNS in Help and Support Center for Windows Server 2003.

**Registering a DNS Domain Name**

Your Internet service provider (ISP) should assign you an IP address for your server that you will use when you configure IIS to host your Internet site or sites. To register a DNS domain name, you can work directly with a naming authority. Many ISPs can register a DNS domain name for you. The InterNIC Web site maintains a list of registrars that are currently taking registrations for all available top-level domains. The InterNIC Web site organizes and lists these registrars alphabetically, by name, by location, and by supported languages. After you register your DNS domain name, your ISP or registrar can host the domain, or you can host the domain yourself (if you are a more advanced user). For more information about domain name registration services, see the InterNIC Web site.

# Configuring Web Sites in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS WWW service allows you to publish content on the Internet or an intranet. You can publish a static Web site or a dynamic application. The primary function of the WWW service is to connect client Hypertext Transfer Protocol (HTTP) requests to your Web site or sites. The WWW service is installed at *SystemDrive*:\Windows\System32by default when you start IIS.

| **Note** |
| --- |
| If you want to install the WWW service somewhere other than at the default location, you must use an unattended installation answer file and specify the alternative path using the **PathWWWRoot** parameter. For more information, see Appendix E: Unattended Setup. |

Related Information

For more information about the WWW service and IIS core components, see IIS 6.0 Architecture.

# Creating and Setting Up Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you use the Manage Your Server Wizard to install the application server role, the default Web site is created automatically. You can use this Web site as it is, change it, or create and use new Web sites. For step-by-step instructions for creating your first Web site, see Common Administrative Tasks or see Creating Web or FTP Sites.

Whether you plan to publish your site on an intranet or the Internet, the principles of providing content are the same. You place your Web files in directories on your server and configure IIS to serve those directories. Then users establish an HTTP connection and view the files with a browser. The first step in creating a Web site, therefore, is to design your server, directory, and file structure.

The two main types of directories in IIS are physical directories and virtual directories. Each Web site must have one home directory, which is the central location for the published pages of the site. In addition, you can create Web Distributed Authoring and Versioning (WebDAV) publishing directories, where users can publish, lock, and manage resources.

# Home Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The *home directory* is the central location for your published pages. It contains the pages or applications that you will publish. When you install the application server role, IIS creates a default home directory for the default Web site. The home directory for the default Web site is *SystemDrive*:\Inetpub\Wwwroot. You can change the home directory to another local directory or a shared directory on another computer, or you can redirect requests to a URL if your content is located on a different server on the Internet. For step-by-step instructions for setting the home directory, see Setting Home Directories.

If you set your home directory as a shared directory on another computer, then users might need to enter a user name and password to access the resource. If you set the home directory as a shared directory on another computer, it is important to use an account that has only the minimum credentials that are required to run the application. If you use an account with administrative credentials when you create this directory, then clients can gain access to server operations, which seriously jeopardizes the security of your network. For more information about security credentials, see Managing a Secure IIS 6.0 Solution.

If you have a simple Web site, you can set up subdirectories under the home directory. You can create subdirectories for the different elements used on your Web site, such as images, scripts, and server-side includes. Alternatively, in a simple Web site setting, you can set up virtual directories instead.

# Virtual Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To publish from any directory not contained within your home directory, you must create a *virtual directory*. A *virtual directory* is an *alias*, either for a physical directory on your server hard disk that does not reside in the home directory or for the home directory on another computer. An *alias* is a name that Web browsers use to access the virtual directory. Because an alias is usually shorter than the path name of the directory, it is more convenient for users to type. A client simply adds the alias to the URL of the Web site to browse the Web content in that virtual directory.

Using virtual directories offers several benefits. Not only is an alias usually easier for users to type and remember, but also it is a good security practice to use virtual directories because an alias hides the physical location of your files from unauthorized users. In addition, virtual directories make it easier for you to change and manage the directories on your site. If you change the name or location of a directory, you can simply change the mapping between the alias and the physical directory, rather than change the URL of the Web site.

In addition, virtual directories allow administrators to store content in different locations. Users can access the directories using simple URLs. For example, if a default Web site is located at C:\Inetpub\WWWRoot, an administrator can create a virtual directory as a subdirectory of the default Web site, but the virtual directory can have a physical directory in a different location, such as D:\Data. If the virtual directory has an alias of *Data*, and the server name is *MyWeb*, users can access the default Web site and the virtual directory by typing **http://MyWeb** and **http://MyWeb/Data**, respectively.

If you have a simple Web site housed on one directory, using virtual directories is an optional, although recommended, practice. However, if you have a complex site that spans multiple directories, drives, or computers, or if you want to specify different URLs for different parts of the site, you must use virtual directories. To set up a virtual directory that maps to a directory on another computer, you must specify the Universal Naming Convention (UNC) name of the directory and provide a user name and password.

For step-by-step instructions for creating and deleting virtual directories, see Using Virtual Directories.

# WebDAV Publishing Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

WebDAV is an industry-standard set of extensions to HTTP 1.1. WebDAV is a good alternative to FTP if you need a secure solution for publishing resources because it enables the same strong authentication, encryption, proxy support, and caching capabilities as any other HTTP-based Web site. In addition, with WebDAV, you can send multiple file transfers through a single TCP connection, whereas FTP requires a new connection for each file transferred. For more information about the WebDAV standard, see WebDAV Resources.

WebDAV is integrated into IIS, but it is disabled by default. For step-by-step instructions for enabling WebDAV in IIS, see Web Authoring with WebDAV. For information about securing WebDAV, see Securing WebDAV Publishing Directories later in this section.

With WebDAV, you can create Web publishing directories where users can publish, lock, and manage resources. To set up a WebDAV publishing directory, enable WebDAV, and then set up a virtual directory using IIS Manager in the same way that you set up a virtual directory for a standard Web site. For security purposes and to configure DAV custom properties, which are special properties that users can search on, a WebDAV publishing directory must reside on an NTFS file system partition. For step-by-step instructions for setting up a WebDAV publishing directory, see Creating Publishing Directories.

**Making the WebDAV Publishing Directory Available to Users**

After you enable WebDAV and set up a publishing directory, users can use the directory on your server as a collaborative work environment. Users with the correct permissions can copy and move files, and they can search for and modify the content and the properties of files. Multiple users can read a file concurrently, but the WebDAV lock and unlock capabilities allow only one person to modify the file at a time.

Users can access a WebDAV publishing directory through clients running Microsoft® Windows® 2000 or Microsoft® Windows® XP Professional operating systems, Microsoft® Internet Explorer 5 and 6, Microsoft® Office 2000 or Office XP products, and through any other client that supports the industry-standard WebDAV protocol.

For more information about WebDAV clients, including how they can access your WebDAV publishing directory, see About WebDAV.

**Enabling WebDAV Redirector**

WebDAV Redirector is a remote file system that allows clients running Windows XP Professional or Windows Server 2003 to connect to your WebDAV publishing directory through the command line. Once the client is connected, a user can create, modify, and save files on the WebDAV publishing directory using any existing applications that are written for a Windows 32-bit operating system. WebDAV Redirector enables users to access files on the Web as though they are on a mapped network drive. When enabling the WebDAV Redirector, you must ensure that the WebClient service is started.

For the WebDAV Redirector to work, the site that contains the virtual directory that is mapped to your WebDAV publishing directory must be set up exclusively as a WebDAV site. Therefore, you must delete all custom headers on that site, including custom headers for the Microsoft® FrontPage® 2002 Server Extensions. If your WebDAV Web site is set up as both a WebDAV site and a site running FrontPage 2002 Server Extensions, IIS will send the FrontPage custom header and the WebDAV Redirector will assume that the server is not a proper WebDAV site.

# Configuring Web Site Properties in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Every Web site is configured with default properties. You can change the default properties at the WWW service level (which affects all the Web sites on a server), the site level, the directory level, or the file level. IIS employs property inheritance to reduce Web site administration tasks. Lower-level properties are automatically inherited from higher-level properties. For example, the default **Connection Timeout** property is 900, which means that every file on every Web site on the server will time out after 900 seconds. If you want to reduce the time-out period for a certain Web site, you can change the setting at the site level and the change will be replicated to all the files and directories on that site. You can edit settings at lower levels individually to override inherited settings from the next level up. If you change a setting at a lower level, and then you later change a setting at a higher level that conflicts with the lower-level setting, you will be prompted to choose whether you want to change the lower-level setting to match the new higher-level setting. For step-by-step instructions for changing default settings using IIS Manager, see Changing Default Web Site Settings.

# Modifying the Default Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you install IIS, it creates the default Web site automatically. This Web site is configured with default settings that are not optimal for every environment. You can do one of three things with the default Web site:

- **Use it as is, without changing any of the settings**. This practice is not recommended for a production Internet or intranet site. It is recommended that you use the default Web site only in test or demonstration situations.

- **Delete the default Web site, and create new sites**. Many ISPs will delete the default Web site and then use custom scripts to create new Web sites as needed. For more information about creating Web sites programmatically, see IIS 6.0 Administration Scripts, Tips, and Tricks.

- **Modify the default Web site to work in your environment**. If you choose to modify the default Web site, then, as a best practice, change the properties immediately, before you create any directories or virtual directories. Directories and virtual directories inherit the properties of the default Web site.

  You can modify properties of the default Web site as appropriate for your environment.

**Modifying Default Web Site Identity Settings**
You can use the Web Site tab of the **Web Site Properties** dialog box to configure several key Web site identity settings.

**Description**
Change the description of the Web site, using a name that is appropriate for your environment. This name will appear only in IIS Manager.

**IP address**
Enter an IP address if you are creating a Web site bound to a specific IP address on the computer and you do not want to use the All Unassigned default setting, or if you recently changed the IP address of the server.

**TCP and SSL port**
Change the value for TCP, User Datagram Protocol (UDP), or both TCP and UDP ports only if you have special requirements. It is recommended that you leave the default TCP and SSL (Secure Sockets Layer) port settings (80 and 443, respectively) for production servers.

**Host header**
Enter a host header value if you plan to host multiple Web sites on the same server, or if you plan to publish the site so that users can access it by using a DNS name rather than the computer name. To create a host-header value, click **Advanced**, and then in the **Advanced Web Site Configuration** dialog box, click **Add to type in a host header value**. Any subsequent Web sites that you create cannot use the host header value that you enter for the default Web site. For more information about using host headers to host multiple Web sites, see Hosting Multiple Web Sites on the Same Server.

**Modifying the Default Authentication Method**
You can use the **Directory Security** tab of the **Web Site Properties** dialog box to change the authentication method. The authentication method determines whether users are identified, and how users must be identified to access your site. The authentication method you select varies, depending on the kind of site you are creating and the purpose of the site. For a complete discussion of authentication, see Managing a Secure IIS 6.0 Solution.

**Modifying the Default Physical File Location**
You can use the **Home Directory** tab of the **Web Site Properties** dialog box to specify the path to the home directory for your Web site and whether the home directory resides on the local computer or on a network computer. The default Web site home directory is *SystemDrive*:\Inetpub\Wwwroot.

**Enabling and Configuring Log File Formats**
You can use the **Web Site** tab of the **Web Site Properties** dialog box to enable logging and to specify the log format that you want to use. For more information about IIS logs, see Analyzing Log Files.

**Specifying the Application Pool**
You can use the **Home Directory** tab of the **Web Site Properties** dialog box to specify the application pool. For more

information about application pools, see IIS 6.0 Architecture and Running IIS 6.0 as an Application Server.

**Extending Web Sites with FrontPage 2002 Server Extensions**

You can install and enable FrontPage 2002 Server Extensions for Web sites. FrontPage 2002 Server Extensions provide Web-based and command-line administration that allow you to *extend* your virtual servers, which means that the site owner can author the site in FrontPage and delegate site ownership and administrative credentials for Web sites. FrontPage 2002 Server Extensions are not installed by default. For more information about FrontPage 2002 Server Extensions, including information about installing and enabling, see Using FrontPage 2002 Server Extensions with IIS 6.0.

# Redirecting Requests

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Redirecting* refers to the process of configuring the Web server to issue an HTTP 302 redirect message to the client, which instructs the client to resubmit the request for a new location. This process helps ensure that users always receive the Web page that they want, even if you changed the location of the page and did not update all of the links.

It is useful to redirect requests when the content is not hosted on the Web server or when you are updating your Web site and want to make a portion of the site temporarily unavailable. In addition, you can use a redirect when you have changed the name of a virtual directory and you want users to be able to access files using the old URL.

You can use redirect wildcards to perform basic rewriting operations for the redirected URL. For example, to redirect all requests for /Scripts/Filename.stm to a single file named Default.stm, and to redirect all requests for /Scripts/Filename.htm to a single file named Default.htm, you would type the following in the **Redirect to** box for the /Scripts virtual directory: ***;Filename.stm;/Default.stm;Filename.htm;/Default.htm**

| **Important** |
| --- |
| You must be a member of the Administrators group on the local computer to perform the following procedure or procedures. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **Run as** command to run IIS Manager as an administrator. At a command prompt, type **runas /***User***:***Administrative_AccountName* **mmc %systemroot%\system32\inetsrv\iis.msc**. |

**To use redirect wildcards**

1. In IIS Manager, click the local computer, right-click the Web site or directory that you want to redirect, and then click **Properties**.
2. In the **Web Site Properties** dialog box, click the **Home Directory** tab, the **Virtual Directory** tab,or the **Directory** tab.
3. In **The content for this resource should come from**, click **A redirection to a URL**.
4. In the **Redirect to** box, type the wildcard character (*), a semicolon (;), and then the URL. Separate pairs of wildcard characters and destination URLs with a semicolon.
5. In **The client will be sent to**, select the **The exact URL entered above** check box.

**Redirecting to Dynamic Content**

You can also redirect requests to dynamic content, which is useful for sending users to Common Gateway Interface (CGI) scripts, Active Server Pages (ASP), and .aspx pages. If you want to redirect to dynamic content, make sure that dynamic content is enabled on your server running IIS. To redirect to dynamic content, use redirect variables to pass parameters to the page. For example, to redirect all requests for scripts in the Scripts folder to a logging program named Logger.exe that records the requested URL and any parameters that are passed with the URL, type: **/Scripts/Logger.exe?URL=$V+PARAMS=$P**. In this example, $V and $P are redirect variables. For more complete information about redirect variables, see Redirect Reference.

Redirecting Requests to Files, Directories, or Programs

# Securing Web Sites in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To secure your Web sites, implement a defense-in-depth strategy that combines many different security measures. Use appropriate settings for authentication methods, Web site access control, IP address and domain name restrictions, and secure communications, including certificates and encryption. In addition, implement tools such as firewalls, and lock the rooms that contain hardware. You can use the **Directory Security** tab in the **Web Site Properties** dialog box to configure authentication, Web site access control, and IP address and domain name restrictions, and to enable secure communications. For a thorough discussion of IIS security, including how to configure security settings, see Managing a Secure IIS 6.0 Solution.

There are a number of considerations for configuring authentication and access-control settings for WebDAV-based remote publishing. These considerations are outlined in this section.

# Securing WebDAV Publishing Directories in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Just as with a standard Web site, you can use the **Directory Security** tab in the **Web Site Properties** dialog box to configure WebDAV authentication, Web site access control, and IP address and domain name restrictions, and to enable secure communications. Furthermore, for security reasons and to enable WebDAV custom search properties, your WebDAV publishing directory must reside on an NTFS file system partition. For more information about NTFS partitions, see Choosing a file system: NTFS, FAT, or FAT32 in Help and Support Center for Windows Server 2003.

Setting the Client Authentication Method

Because WebDAV is an HTTP-based protocol, the same authentication methods are available for your WebDAV publishing directory as for your Web sites. When you create a WebDAV virtual directory, the authentication settings will be set by default to Anonymous authentication and Integrated Windows authentication.

| **Important** |
| --- |
| Change the default authentication settings for your WebDAV site. Anonymous authentication and Integrated Windows authentication are appropriate for Web sites, but not for resources on a WebDAV publishing directory. |

Use the following best practices as guidelines when configuring client authentication for WebDAV. For more information about authentication, see Setting Web Site Authentication.

**Anonymous authentication**

Turn off Anonymous authentication to your WebDAV publishing directory. Without controlling access, your directory might be vandalized by unknown clients.

**Basic authentication**

Turn on Basic authentication only if you encrypt passwords through SSL. Basic authentication sends passwords over the connection in plaintext, so passwords can be intercepted and read. For more information about SSL, see Configuring SSL on a Web Server or Web Site.

**Digest authentication**

Turn on Digest authentication if users access your WebDAV publishing directory over the Internet and through firewalls because Digest authentication sends the passwords over the network as an MD5 hash. However, passwords are stored as plaintext in the Active Directory® directory service.

**Advanced Digest authentication**

Turn on Advanced Digest authentication if users access your WebDAV publishing directory over the Internet and through firewalls. Advanced Digest authentication is the best choice because, in addition to sending passwords over the network as an MD5 hash, the passwords are also stored in Active Directory as an MD5 hash rather than as plaintext.

**Integrated Windows authentication**

Turn off Integrated Windows authentication unless users access your WebDAV publishing directory only from an intranet.

**.NET Passport authentication**

Turn off .NET Passport authentication. Microsoft® .NET Passport authentication uses cookies to validate user credentials against a central .NET Passport server. However, the central .NET Passport server does not authorize or deny the access of a specific user to individual .NET Passport–enabled sites.

Configuring Access Control

You can control access to your WebDAV publishing directory by coordinating permissions in IIS and Windows Server 2003. The following information can help you set the correct permissions depending on what kind of content your WebDAV publishing directory contains and what you want to allow users to do with that content. For step-by-step instructions for setting permissions, see Securing Sites with Web Site Permissions.

**Read, Write, Directory browsing enabled**

Set these permissions if you want clients to see a list of resources, modify them (except for resources that do not have Write

permission), publish their own resources, or manipulate files.

**Write enabled; Read and Directory browsing disabled**

Set these permissions if you want clients to publish private information on the directory, but you do not want others to see what has been published. This configuration works well if clients are submitting ballots or performance reviews.

**Read and Write enabled; Directory browsing disabled**

Set these permissions only if you want to obscure file names as a security method. However, be aware that security by obscurity is a low-level security precaution because an attacker or a malicious user can guess file names by trial and error.

**Index this resource enabled**

Enable Indexing Service if you plan to let clients search directory resources.

You can also control access to your WebDAV publishing directory through discretionary access control lists (DACLs). When you set up a WebDAV publishing directory on an NTFS file system disk, the server running Windows Server 2003 is configured with a secure set of defaults that can be too restrictive for Web publishing. If you change the defaults, assign Write permission only to the specific users or groups that absolutely need Write permission. (Whenever possible, assign permissions to groups rather than users.) By default, the Users group is assigned only Read permission for most portions of the file system.

If you have script files in your WebDAV publishing directory that you do not want users to access, you can deny access to these files by verifying that the Script Source Access permission is not assigned. The extensions of your script files are listed in the Applications Mapping list. All other executable files, including files with .exe extensions, are treated as static HTML files unless the Scripts and Executables permission is assigned to the directory.

You can prevent users from downloading and viewing .exe files as HTML files but still allow clients to run them by assigning the Scripts and Executables permission. To do so, on the **Virtual Directory** tab of the publishing directory, on the **Execute permissions** list, click **Scripts and Executables**. When you assign the Scripts and Executables permission to the directory, all of the executable files are subject to the Script Source Access permission setting. You can assign the Script Source Access permission on the **Home Directory** tab of the **Web Site Properties** dialog box of the Web site that you are configuring. When the Script Source Access permission is assigned, clients with Read permission can see all the executables, and clients with Write permission can edit and run all the executables.

If you want clients to be able to write to an executable file that does not appear in the Application Mapping list, assign the Write permission and the Scripts Only Execute permission to the directory.

If you want clients to be able to write to any executable file, regardless of whether it appears in the Application Mapping list, assign the Script Source Access permission and the Scripts and Executables Execute permission to the directory.

# Hosting Multiple Web Sites on the Same Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can host and manage multiple Web sites on one server running Windows Server 2003 and IIS 6.0. To host multiple Web sites on a single Web server, you must configure a unique identity for each Web site by using one of three methods:

- Port-Based Routing
- IP-Based Routing
- Host-Header Routing

By using one of these three methods, you can create unique identities for multiple Web sites without installing a dedicated Web server for each site. You can also create a unique home directory for each site and store the content on the local server or on remote network shares. By doing so, you configure each Web site as a separate entity or virtual server.

For each server hosting multiple Web sites, choose one of the three routing methods listed earlier. When you use one method per server, performance improves because cache and routing lookups are optimized. Conversely, when you use a combination of nonstandard port numbers, unique IP addresses, and host headers to identify multiple Web sites on the same server, performance is degraded for all of the Web sites on the server. For more information about Web site performance, see Optimizing IIS 6.0 Performance.

You can add Web sites to a server by using IIS Manager or by using the lisweb.vbs command-line script. For step-by-step instructions for adding Web sites, see Adding Web Sites to an IIS 6.0 Server.

# Port-Based Routing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can use a nonstandard TCP port number for each Web site. Some administrators use ports other than port 80 for development and testing purposes or for running other server applications that require exclusive access to port 80.

When using port-based routing to host multiple Web sites on the same server, consider the following:

- A server can listen on a maximum of 64 ports at one time. The actual number of ports a server can listen on varies depending on the available RAM on the computer. Therefore, you cannot use port-based routing to route a large number of sites.
- Port-based routing consumes a vast amount of kernel resources and can degrade server performance.
- If you use a nonstandard TCP port number to identify a Web site, users cannot reach the site by using a standard name or URL. Instead, users must know the nonstandard TCP port number assigned to the Web site and add it to the name or IP address of the Web site in their browser. For example, to reach a private Web site named Contoso with an IP address of 10.0.0.02 and HTTP assigned to the nonstandard TCP port 8080, users would have to type **http://contoso:8080** or **http://10.0.0.02:8080** in their browser to reach the site.

If you choose to use a nonstandard port for a nonproduction server, use a port number higher than 1023 so that it does not conflict with the well-known port numbers that the Internet Assigned Numbers Authority (IANA) assigns.

# IP-Based Routing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

With IIS 6.0, you can configure Web sites to listen on all available IP addresses or on an individual IP address. If you use multiple IP addresses to distinguish between different Web sites on the same server, you must configure IIS to assign each site a unique, static IP address.

Although it is simple to configure IP–based routing, this strategy typically is viable only for large corporations and ISPs. Unique IP addresses are in short supply, so it can be difficult and expensive to obtain a block of static IP addresses.

One advantage of IP–based routing is that it enables you to host multiple Web sites that require SSL on the same server. However, hosting a large number of sites that require SSL on the same server can degrade performance because so many requests have to be encrypted and decrypted.

# Host-Header Routing

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

You can use one IP address (or the **All Unassigned** setting) for multiple Web sites and distinguish the Web sites with unique host-header names. This option is easy to configure by using IIS Manager. To use host-header names, your computer or network must be using a name resolution system such as DNS.

When a client sends a request for an HTTP connection to the server running IIS, the client request includes a field in the HTTP header called HOST. This field contains the host name of the requested Web server. For example, when you type **http://www.microsoft.com** into your browser, your browser sends a packet with an HTTP header that includes the following field: HOST: www.microsoft.com. Because the name of the field is *HOST* and it is in the HTTP header of the client, it is referred to as the *host header*. For more information on the HTTP 1.1 standard, see the RFC 2616, Hypertext Transfer Protocol -- HTTP/1.1 on the Internet Engineering Tasks Force Web site.

With host-header routing, when a client request reaches the server, IIS uses the host name, rather than only the IP address as it does with IP–based routing, to determine which Web site the client is requesting. To set up multiple Web sites on the same server to take advantage of host-header routing, the host-header names must be DNS domain names that are publicly available and registered with an authorized Internet naming authority. For more information about obtaining a DNS name, see DNS Overview_IIS_SP1_TechRef.

| **Note** |
| --- |
| To set up an intranet site for host-header routing, the host-header name can be an intranet site name. |

**Host-Header Routing and SSL**

Beginning with Windows Server 2003 Service Pack 1 (SP1), IIS supports the use of SSL with host header routing. For more information about setting up host headers for an SSL-enabled Web site, see Configuring SSL Host Headers.

# Configuring FTP Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS includes the FTP service for publishing and managing files. FTP uses TCP at the transport layer, so all the data that is exchanged between the server and the client is guaranteed not only to be delivered but also to be delivered intact, as originally sent.

The IIS Admin service, which is physically part of the Inetinfo.exe process, manages the protocols in IIS that are not related to the Web, including FTP. By default, the FTP service is not installed on a server running Windows Server 2003. Once it is installed, the FTP sites start automatically the next time you restart the IIS services.

# Installing the FTP Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you can set up an FTP site, you must install the FTP service from Add or Remove Programs in Control Panel. For information about how to install the FTP service, see FTP Site Setup.

When you install the FTP service, a default FTP site directory is created with the home directory *SystemDrive*:\Inetpub\Ftproot.

There are two kinds of directories for FTP site content: user home directories and shared virtual directories. Each FTP site, except for those in Active Directory Isolation mode, must have a home directory that serves as the initial directory for users connecting to the site. In most configurations, each user has an individual directory under this site home directory. Create a virtual directory to hold additional content that is accessible to every user that logs on to the site, or if you want to use different URLs for different parts of the site. This virtual directory is different than the anonymous user home directory that is accessible to all anonymous users. Home and virtual directories for FTP sites function similarly to Web site directories. For more information about directories, see Creating and Setting Up Web Sites.

| **Note** |
| --- |
| Virtual directory names do not show up when listing the home directory of a user. Instead, virtual directories are used as if they were subdirectories of the user's home directory. A site administrator can publish these virtual directories in the site welcome message. |

# Configuring FTP Site Properties

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The FTP service uses inherited default property settings, much like the WWW service does. Settings on lower levels automatically inherit higher-level settings, and you can edit lower-level settings individually to override inherited settings from the next level up. If you use IIS Manager to change a setting at a lower level and then later change a setting at a higher level that conflicts with the lower-level setting, you are prompted to choose whether you want to change the lower-level setting to match the new higher-level setting. For step-by-step instructions for changing settings, see Changing Default FTP Site Settings.

**Configuring Site Messages**

When you set up an FTP site, you can configure IIS to send messages when a user accesses the FTP site. You can create the following messages:

- **Banner**. This message is sent to users as they connect but before they log on to an FTP site. A banner message usually informs users about what kind of information is available on the FTP site.
- **Welcome**.This message welcomes users to an FTP site after they have logged on.
- **Exit**. This message appears when users log off from an FTP site.
- **Maximum connections**. This message is sent to users when the maximum number of connections for the FTP site has been reached.

**Setting the Directory Output Style**

You can set the directory output style of your FTP site. The directory output style can be either Microsoft® MS-DOS® operating system-based or UNIX-based, and the output style defines the format that is used when an FTP client sends a **list** command.

By default, the MS-DOS directory output style displays the year in a two-digit format, for example, 03. You can change this setting to display the year in a four-digit format, for example, 2003, by enabling the **FtpDirBrowseShowLongDate** metabase property. For more information, see FtpDirBrowseShowLongDate Metabase Property.

The UNIX directory output style displays the year in a four-digit format when the date of the file is different from the year of the FTP server. The year is not returned in cases where the file date is the same as the year of the FTP server.

**Setting the Authentication Method**

Two types of users can connect to an FTP site: anonymous users and authenticated users. Set the authentication method to allow only anonymous users, authenticated users, or both anonymous users and authenticated users. If you want to allow only anonymous users, in the **FTP Sites Properties** dialog box, on the**Security Accounts** tab, select the **Allow anonymous connections** check box and the **Allow only anonymous connections** check box. If you want to allow only authenticated users, clear the **Allow anonymous connections** check box. If you want to allow anonymous users and authenticated users, select only the **Allow anonymous connections** check box. Anonymous access to FTP resources works similarly to anonymous access to Web sites. If anonymous access is allowed, all client connections with the user name *anonymous* or *ftp* are accepted and authenticated as the anonymous user. By default, the user account that is configured as the anonymous user is IUSR_*ComputerName*. As an Internet convention for anonymous FTP user identification, the anonymous user is prompted for a password, which is used as a user name.

If a site uses FTP User Isolation and a user connects with a user name and password, then the user is authenticated with his or her Windows account and mapped to individual home directories. This practice is not secure because credentials are transmitted over the network in plaintext and can therefore be intercepted and read. For step-by-step instructions for setting the FTP authentication method, see FTP Site Authentication in IIS 6.0.

| **Note** |
| --- |
| You cannot set the authentication method and the anonymous user properties using IIS Manager for FTP sites that are configured for the **Isolate users using Active Directory** mode. The **Isolate users using Active Directory**mode is explained in more detail later in this section. |

**Setting the Passive Connection Port Range**

FTP clients connect to FTP servers through a well-known service port, TCP port 21, and establish a control channel for sending requests and receiving replies. For actual file data transfers, a second connection is established: a *data channel*. By default, the server connects back to the client to establish the data connection, which is an active-mode connection. However, to support clients that are behind firewalls and cannot accept incoming connections, the FTP protocol allows the client to connect to the server to establish the data channel, which is a passive-mode connection. Passive-mode connections are established through the following process: the client requests a passive mode (PASV), the server replies with a unique port number, and the client connects to that port.

By default, the FTP server allocates ports for passive-mode connections from the WinSock dynamic range, 1024 to 5000. If the server itself is behind a firewall, the 1024 to 5000 port range must be open for incoming connections at the firewall. This requirement can expose the server to potential attack because many applications share the WinSock dynamic port range. To reduce the attack surface, you can configure the FTP service to allocate ports for passive-mode connections from a port range above 5000, which allows you to assign a port range to be used exclusively by FTP passive-mode connections and to create firewall and router policies that open that range for incoming TCP connections.

To set the port range for passive-mode connections, edit the **PassivePortRange**property in the metabase. When you set the port range, consider the number of anticipated concurrent file transfers because each client might need a distinct port. For performance reasons, the port range should be at least two times the number of anticipated concurrent file transfers.

For more information about setting the port range used for FTP passive-mode connections, see PassivePortRange Metabase Property.

# Securing FTP Sites in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FTP is not a secure means of transferring data. Although you can configure the FTP service to require a valid user name and password combination, neither the credentials that are specified at log on nor the data itself is encrypted or encoded in any way. The credentials are sent across the network in plaintext and can be intercepted and analyzed by any station on any network between the FTP client and the FTP server. If your plaintext credentials are intercepted and analyzed by a malicious user, then someone other than the intended user can log on to your FTP site and download the files that you placed there or gain access to other network resources, even network resources that require Windows account authentication. For more information about setting the authentication method for your FTP site, see Configuring FTP Site Properties.

If you intend to place sensitive data on your FTP site or if secure communication between clients and your FTP server is important, consider using FTP over an encrypted channel, such as a virtual private network (VPN) secured with Point-to-Point Tunneling Protocol (PPTP) or Internet Protocol security (IPsec). To learn how to set up a private network over the Internet using PPTP or how to set up secure IP communications with a VPN and IPsec, see the PPTP, VPN, and IPsec topics in Help and Support Center for Windows Server 2003. For more information about IPsec and IIS, see Managing a Secure IIS 6.0 Solution.

If you need to authorize users or host sensitive content, then WebDAV is a good alternative to FTP because WebDAV can take advantage of SSL for secure communications. For more information about WebDAV, see WebDAV Publishing Directories.

# Creating Additional FTP Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you install the FTP service, the default FTP site is created with a default directory that is located at *SystemDrive*:\Inetpub\Ftproot. If you want to add additional FTP sites, then you can use the FTP Site Creation Wizard or the Iisftp.vbs command-line script, which is stored in the *SystemDrive*:\Windows\System32 directory. Iisftp.vbs sets up the home directory and configuration in the metabase for the new FTP site. For step-by-step instructions for creating new FTP sites with the wizard or the command-line script, see Adding FTP Sites to Your Server.

Each FTP site must have a unique IP and port number combination, so each site must have a unique IP address or a unique TCP port number (other than 21, which is the default port number for FTP connections). It is recommended that you create multiple sites with unique IP addresses instead of multiple sites with unique port numbers because when you use a port other than the default port 21, users must type the port number, in addition to the computer name, to locate the site.

If you use a name resolution system, such as Windows Server 2003 DNS, and you use port 21 for FTP, then visitors can type **ftp://** followed by your computer name in their browsers to reach your site. If you use a port other than port 21, then users have to type **ftp://**followed by the port number and the name of your computer. If you have multiple sites with multiple IP addresses, then each address needs to have a corresponding registered domain name, which users must type instead of your computer name. For more information about registering a domain name, see DNS Overview_IIS_SP1_TechRef.

# Hosting Multiple FTP Sites with FTP User Isolation

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can host multiple FTP sites on the same server running IIS. If you are an ISP or an application service provider in a multi-site Internet hosting scenario and you want to ensure that your customers cannot access the FTP directories of one another, then you can enable FTP User Isolation. When you enable FTP User Isolation, the user's top-level directory appears as the root of the FTP site, so other users cannot view or overwrite content. Within the user's specific site, the user can create, modify, or delete files and folders.

FTP User Isolation supports three isolation modes: **Do not isolate users**, **Isolate users**, and **Isolate users using Active Directory**. You can select the isolation mode during FTP site setup using the FTP Site Creation Wizard. You can use lisftp.vbs to configure FTP User Isolation, using the */isolation*parameter. When you use the */isolation* parameter, specify either **AD**, for Active Directory isolation, or **Local**, for local isolation. If you do not include the */isolation* parameter, the site will not isolate users.

You can select a different isolation mode for each FTP site.

| **Important** |
| --- |
| After you set the FTP User Isolation mode and finish the FTP Site Creation Wizard or create the site using lisftp.vbs, do not change the isolation setting manually. |

#### Do Not Isolate Users Mode

The **Do not isolate users** mode does not enforce FTP User Isolation and is designed to work like earlier versions of the FTP service in IIS. Because isolation is not enforced among the different users that log on to your FTP server, this mode is ideal for a site that offers only download capabilities for shared content or for sites that do not require protection of data between users.

In this mode, all user directories are in one level as a subdirectory of the FTP site directory. The site directory can reside either on the local computer or on a network share. When a user accesses the FTP site, the home directory is determined as follows:

- By default, the initial user directory is set to the physical path configured as the FTP site directory. If this directory does not exist, the user connection is denied.
- If a user name is supplied, the home directory is derived from the user name. For anonymous users, the derived name is *anonymous*. For local computer users, the derived name is the user name. For domain users, the derived name is the user name without the domain name.
- If a directory with the derived name exists in the site directory, then that directory becomes the initial log-on directory for the user.

| **Important** |
| --- |
| The user is not restricted to this subdirectory and can navigate up to the site directory and into other subdirectories unless you have set ACLs to prevent users from accessing them. |

#### Isolate Users Mode

The **Isolate users**mode determines a unique home directory for each user derived from the user name. The home directory of the user is treated as a root directory for the user, and the user cannot navigate or access the physical file system outside of the root directory. If users need access to dedicated shared folders, then you can establish a virtual directory.

User home directories are located in a two-level directory structure under the FTP site directory. The site directory can reside either on the local computer or on a network share. When a user accesses the FTP site, the home directory is determined in one of three ways:

- For anonymous users, the home directory is **LocalUser\Public** under the FTP root directory.
- For local users, the home directory is **LocalUser***UserName* under the FTP root directory.

- For users that log on with *Domain\UserName*, the home directory is *Domain\UserName* under the FTP root directory.

The user home directory must be created before the user logs on. If the directory does not exist when the user attempts to connect, the connection is denied.

For information about creating a new FTP site or converting an existing FTP site to Isolate users mode, see Creating a New FTP Site with Isolate Users Mode and Converting an Existing FTP Site to Isolate Users Mode.

**Isolate Users Using Active Directory Mode**

In the **Isolate users using Active Directory** mode, the FTP service is integrated with Active Directory to retrieve home directory information for users. To accomplish this integration, the Active Directory user object is extended with two properties: **msIIS-FTPRoot** and **msIIS-FTPDir.** The **msIIS-FTPRoot** property stores the file server share, and the **msIIS-FTPDir** property stores the relative physical path to the home directory for each user. You can use Iisftp.vbs to get and set these properties.

Information that is frequently retrieved from Active Directory is cached by the FTP service. The default caching interval is 10 minutes. You can adjust the caching interval by editing the registry entry DsCacheRefreshSecs.

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference on the Microsoft® Windows® Server 2003 Resource Kit companion CD or at the Windows Server 2003 Resource Kit web site. |

If the FTP service successfully accesses the path, it becomes the home directory for the user. The user cannot access the file system outside this directory. The user is denied access if either the **msIIS-FTPRoot** or **msIIS-FTPDir** property does not exist, or if the resulting home directory cannot be accessed.

This configuration option provides maximum flexibility and control over user home directories in an ISP environment. For example, John Doe connects to his FTP site at ftp.example.com. The example.com network load-balancing server (NLBS) resolves this request to the server FTPS3. John Doe enters the user name JohnDoe. FTPS3 is configured with the default domain name Domain4, so the user Domain4\JohnDoe is authenticated and the home directory information for John Doe is retrieved from Active Directory as \\FS1\Share2\Users\u2\johndoe_dir. From now on, FTPS3 will access the data under this home directory for all the FTP requests from John Doe. This example is illustrated in Figure 8.1.

**User Home Directories**

In the **Isolate users using Active Directory** mode, each user's home directory resides on an arbitrary network path, which provides you with the flexibility to distribute user home directories across multiple servers, volumes, and directories. In addition, you can move user's home directories transparently from one location to another, which affects the service for the users only during the duration of the move. You can also set the **msIIS-FTPRoot** and **msIIS-FTPDir** properties so that the users home directory maps to a local folder on the FTP server; for example, **msIIS-FTPRoot** is set to **E:\FTPUsers**.

**Configuring Isolate Users Using Active Directory Mode**

There are three main steps to configuring the **Isolate users using Active Directory** mode:

- Configure the file servers.
- Configure Active Directory.
- Create and configure the FTP sites to be isolated.

When you configure the file servers, you must create the shares and user directories for all the users that are permitted to connect to the FTP service, including the user configured to impersonate anonymous users. Before you complete this step, consider factors such as expected disk space usage, storage management, and network traffic.

To configure Active Directory, you need a server running Windows Server 2003, Standard Edition, and Active Directory. Configure the user object in Active Directory for each user, including the user configured to impersonate the anonymous user, by setting the **msIIS-FTPRoot** and **msIIS-FTPDir** properties to point to the home directories that you previously created. You can do this by using the lisftp.vbs command-line utility with the **/SetADProp**command. To learn more about setting up Active Directory, see Active Directory in Help and Support Center for Windows Server 2003.

For information about working with FTP sites with **Isolate users using Active Directory** mode, see Creating a New FTP Site with Isolate Users Using Active Directory Mode, Enabling Anonymous Access for an FTP Site Configured with Isolate Users Using Active Directory Mode, and Converting an Existing FTP Site to Isolate Users Using Active Directory Mode.

# Configuring the NNTP Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS NNTP service enables you to create a news server to host discussion groups. NNTP is the protocol for distributing, posting, and retrieving news items between a news server and client.

You can use the NNTP service to host local discussion groups, called *newsgroups*, on a single computer. For example, you can create departmental newsgroups where company department members can discuss projects and issues. Or you can create a newsgroup and allow customers to access it over the Internet for technical or customer support. Because the NNTP service is in complete compliance with the NNTP protocol, users can use any newsreader client, such as the Microsoft® Outlook® Express messaging and collaboration client, to participate in newsgroup discussions.

You can also configure the NNTP service for *newsfeeds*. Newsfeeds enable users of different newsgroups to read and post articles to other newsgroups, as if the users were using a single group. An article that is posted to one newsgroup gets sent to other newsgroups, where it can be read.

The NNTP service is hosted by Inetinfo.exe. Clients connect to the NNTP service through TCP port 119 by default. If you enable encrypted SSL connections, the default port is 563.

# Installing the NNTP Service and Setting Up NNTP Virtual Servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The NNTP service is not installed by default. You must install the NNTP service using Control Panel, which creates a default NNTP configuration that you can customize using IIS Manager. For step-by-step instructions for installing the NNTP service, see NNTP Server Setup.

The NNTP service stores newsgroup articles on virtual servers with one or more directory hierarchies. Each virtual server has its own virtual directory or directories, which contain newsgroup articles, or messages, stored as files. In addition, the NNTP service involves other file types, which include internal files as well as the public newsgroup message files. When you install the NNTP service, a default NNTP virtual server configuration is created with a message store in *SystemDrive*:\Inetpub\Nntpfile\Root.

**Virtual Servers**
You can have multiple NNTP virtual servers running on IIS. Each virtual server has its own properties, expiration policies, and virtual directories. Create as many NNTP virtual servers as you need. Consider creating multiple virtual servers to host different types of newsgroups on the same server. For example, you might want to host internal departmental newsgroups on the same server with Internet-based customer service newsgroups. Because those newsgroups will have different settings, it is easiest to set them up on different virtual servers. However, if you have many different departmental newsgroups that have the same property settings, consider hosting all of them on the same virtual server.

Each virtual server should have a unique IP address/TCP port combination. Although it is possible to host multiple NNTP virtual servers on a single IP address by using a different TCP port for each one, this configuration is not recommended because users will have to configure their client software specifically to use the nonstandard TCP port.

**File and Message Types**
The NNTP service involves several file and message types, including:

- **Message files**. Message files are messages that are posted to newsgroups, receive an .nws extension, and are stored in the directory that the NNTP service creates for them.

- **Internal files**. Users never see or use internal files, which are files that the NNTP service creates that list the subjects of the stored articles. These internal files have an .xix extension, and the NNTP service creates one subject file for every 128 articles in a newsgroup. The NNTP service also uses .tag files to mark folders as newsgroups or virtual roots. In addition, the NNTP service maintains a number of internal data structure files with .hsh, .hdr, .lst, and .txt extensions. These files are essential for the NNTP service; do not delete them. If you accidentally delete the internal files or if they become corrupted, you can restore them by rebuilding the NNTP service. For more information about rebuilding the NNTP service, see Rebuilding the NNTP Service.

- **Control messages**. Control messages are specially formatted messages that direct the NNTP service to delete a specific article from a newsgroup or to add or delete an entire newsgroup. Control messages are stored in directories that the NNTP service creates. For more information about control messages, see Using Control Messages.

When you create an NNTP virtual server, you are prompted to enter two directory paths: a path for internal files and a path for newsgroup message files. If possible, put these two paths on different disk partitions because the internal files can be corrupted if the disk partition runs out of disk space. Also, if you expect a high volume of traffic on your NNTP virtual server, you can place the files on a drive in a redundant array of independent disks (RAID) to improve performance.

**Virtual Directories**
A virtual directory is a directory on a local or remote disk drive that acts as the root of a part of the newsgroup hierarchy. Virtual directories enable you to store newsgroup files on multiple disk drives. Using more than one disk drive can improve the performance of a heavily used disk drive and can provide more storage. Virtual directories also enable you to change the physical location of the directory without changing the name of the newsgroup.

Virtual directories can be located on a local disk drive or on a network drive. However, if you store content in a remote location, then you must configure the remote computer with at least Read and Write permissions for the user name that you provide. Make sure that the remote location is secure and maintained by a trusted administrator. There is no advantage to creating a virtual directory on the same physical drive as the home directory. For step-by-step instructions for creating virtual directories, see Creating Virtual Directories in IIS 6.0.

# Configuring NNTP Virtual Server Properties

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NNTP virtual server properties** dialog box in IIS Manager allows you to configure many different settings for your virtual server, including access control, logging, newsgroup limits, and security. Use the **General** tab to set the IP address and, optionally, the port number for the NNTP virtual server. You can also set connection limits and time-outs, specify a path header, and enable logging. Auditing server activity with log files is a good way to detect if unauthorized external users are attempting to access your virtual server or if internal users are trying to access resources that they do not have authority to access. Use the **Settings** tab for management tasks, such as enabling moderated newsgroups and control messages. For more information, see Creating and Managing Newsgroups. Use the **Access**, **Settings**, and **Security** tabs to configure security-related settings. For more information about setting properties that affect security, see Securing NNTP Virtual Servers.

For a detailed description of each property on every **Properties** tab and for more information about logging, see Configuring NNTP Virtual Servers.

# Securing NNTP Virtual Servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By configuring the properties of your NNTP virtual server correctly, you can increase the security of your NNTP server and your network. The **Access**, **Settings**, and **Security** tabs each have security-related properties that you can use to configure access-related settings, set post and connection limits, and assign administrative credentials. You can also increase security through the use of access control lists (ACLs).

**Configuring Access-Related Settings**
The **Access** tab has three important security-related settings: Authentication, Certificate, and Connection.

**Authentication**
The Authentication option allows you to select from the following authentication methods for newsgroup users:

**Anonymous access**. Anonymous access is enabled by default. If you do not disable Anonymous access, everyone is able to access all of the newsgroups on this virtual server.

- **Basic authentication**. If you enable Basic authentication and you disable anonymous access, users must enter a valid Windows user name and an authorized password to access the newsgroup. However, those credentials are not encrypted when they are sent across the network (credentials are sent in plaintext). Basic authentication leaves your server vulnerable to a dictionary attack. Use this option only if your newsgroups are internal.

- **Integrated Windows authentication**. If you enable Integrated Windows authentication and you disable anonymous access, users must enter a valid Windows user name and an authorized password to access the newsgroup, and those credentials are encrypted when they are sent over the network. Integrated Windows authentication can also leave your Web server vulnerable to a dictionary attack. Outlook Express supports this protocol.

- **SSL client authentication**. SSL provides a secure, encrypted connection between the NNTP service and the client. SSL support requires that an SSL certificate is installed on the computer running Windows Server 2003 and that the client software supports SSL. (Outlook Express supports SSL.) If a server certificate is installed, then the NNTP service uses SSL whenever a client requests it. You have the option to require SSL for all newsgroups or for newsgroups located in a virtual directory.

**Certificate**
The Certificate option starts the Web Server Certificate Wizard, which you can use to create and administer server certificates used in secure Web communications, such as those that require SSL.

**Connection**
The Connection option allows you to restrict access to the virtual server based on the IP address of the client. By default, all IP addresses have access to the NNTP service. You can either allow or deny access to a specific list of IP addresses, and you can specify the IP addresses individually or as a group using a subnet mask. You can also specify IP addresses using a domain name, but doing so adds the overhead of a DNS lookup for each connection. For more information about domain names and DNS, see DNS Overview.

**Setting Post and Connection Limits**
There are several options on the **Settings** tab that affect the security of your NNTP virtual server. You can set the post size, in kilobytes, of the largest single article a user can post. You can also set the connection size, in megabytes, of the maximum amount of data that a user can post to a newsgroup during a connection. When you set limits on the size of posts and connections, you help prevent a malicious individual from trying to overload your server resources by posting extremely large articles.

**Assigning Administrative Credentials**
You can use the **Security** tab to grant administrative credentials to Windows user accounts. By default, the Windows Administrator account is granted administrative credentials. For more information about security and access control, see Managing a Secure IIS 6.0 Solution.

**Creating ACLs**
After you set the authentication requirements for your virtual server, you can further restrict access to newsgroups with ACLs. For example, in the case of departmental newsgroups, ACLs can prevent non-executives from reading the executive

newsgroup. You can control access to individual newsgroups or sets of newsgroups by assigning permissions on your computer running Windows Server 2003 for the directories that contain those newsgroups. You can set permissions for an individual directory or for a set of directories. For more information about ACLs, see Access control in Help and Support Center for Windows Server 2003.

# Creating and Managing Newsgroups

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A *newsgroup* is the organizational structure for a group of related news articles. For example, if you are creating departmental newsgroups, then you can create the accounting, human resources, and executive newsgroups. If you expect a lot of newsgroup activity, then you can break down the newsgroups into narrower categories. However, because articles within each newsgroup are organized by subject, you do not need to create a separate newsgroup for each subject.

# Creating Newsgroups

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

There are three ways to create a newsgroup:

- Use the New Newsgroup Wizard in IIS Manager. For step-by-step instructions for creating a newsgroup with the wizard, see Creating Newsgroups in IIS 6.0.
- Use the Rgroup.vbs command-line script.
- Use a control message. For more information about using control messages, see Using Control Messages.

When you create a newsgroup, the NNTP service creates the directory for the newsgroup automatically.

**Creating Newsgroups Using Rgroup.vbs**

You can use Rgroup.vbs to create newsgroups. You can also use Rgroup.vbs to delete and modify newsgroups. Table 8.1 lists and describes the parameters that you can use with Rgroup.vbs.

| **Important** |
|---|
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **Run as** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /User:***MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

**Table 8.1 Rgroup.vbs Parameters**

| Parameter | Description |
|---|---|
| -t *Operation*, where *Operation* is one of the following arguments:<br>• **f**<br>• **a**<br>• **d**<br>• **g**<br>• **l** | Finds a group.<br>Adds a group.<br>Deletes a group.<br>Gets the properties of a newsgroup.<br>Loads newsgroups from an active file. |
| **-s** *Server* | Specifies the name of the server that is affected by this change. |
| **-v** *VirtualServerID* | Specifies the ID of the virtual server. |
| **-c** *CreationDate* | Specifies the date on which the newsgroup is created. |
| **-g** *Group* | Specifies the group to be modified or deleted. The wildcard character (*) can be used during searches (**Rgroup.vbs –t f**). |
| **-n** *NumberOfResults* | Specifies the maximum number of newsgroups to return for a search (required with **Rgroup.vbs –t f**). |

| | |
|---|---|
| **-m** *Moderator* | Specifies the full e-mail address of the moderator. |
| **-d** *Description* | Provides a description of the newsgroup. |
| **-p** *Description* | Specifies the response to the**List PrettyName**s command. |
| **-r true** \| **false** | Indicates whether the newsgroup is read-only. |
| **-u true** \| **false** | Indicates whether the group is moderated by the default moderator. |
| **-a** *FileName* | Specifies the names of the active file. |

Table 8.2 lists examples of how to use Rgroup.vbs.

**Table 8.2 Rgroup.vbs Script Examples**

| Command-line Script | Function |
|---|---|
| **Rgroup.vbs -t f -g alt.*** | Finds all newsgroups beginning with *alt*. |
| **Rgroup.vbs -t d -g my.old.group** | Deletes the newsgroup my.old.group. |
| **Rgroup.vbs -t a -g my.new.group** | Adds the newsgroup my.new.group. |

# Moderating Newsgroups

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you want to control which articles are posted to a newsgroup or if you want to designate someone to control the articles, then create a moderated newsgroup. Articles submitted to a moderated newsgroup are not posted until they are approved by the moderator that you choose for that newsgroup. The moderator can filter inappropriate material and can detect if someone is trying to compromise information on the server or the server itself. To use moderated newsgroups, you must specify either an SMTP mail server to send articles directly to the moderator or a directory where the articles are stored for the moderator.

When a user submits an article to a moderated newsgroup, the NNTP service sends the article to the newsgroup moderator. The moderator can either approve the article and send it back to the NNTP service to be posted, or discard the article. For discarded articles, the moderator can send a message to the author of the article to explain why the article was rejected. Any NNTP client can be used to post messages to a moderated newsgroup. However, the moderator needs to use an NNTP client that supports moderating functions.

Alternatively, you can specify a default moderator domain. If you choose to use the default moderator for a newsgroup, articles are sent to *Newsgroup_Name@DefaultDomain*, where *Newsgroup_Name* is the name of the newsgroup. (The periods are replaced by underscores.) For example, articles posted to the newsgroup rec.sports.tennis, with a default domain of contoso.com, are sent to rec_sports_tennis@contoso.com.

Use the **Settings** tab in the **NNTP virtual server properties** dialog box to enable moderated newsgroups. For step-by-step instructions for enabling and setting up moderated newsgroups, see Moderating Newsgroups in IIS 6.0.

# Managing Newsgroup Messages

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can set expiration policies to delete newsgroup messages automatically after a certain period of time. You can also delete messages that are no longer needed.

#### Setting Expiration Policies

You can specify how long articles are kept in an NNTP service newsgroup by defining expiration policies. An expiration policy can apply to a single newsgroup or to any number of newsgroups. You can define as many policies as you need. In each case, the oldest articles are deleted first.

If you are hosting a newsgroup that is intended for internal project tracking or to record organizational information, then do not set an expiration policy. Manually delete and save articles. If you are hosting a busy newsgroup that receives many articles, set a short expiration policy to avoid overloading your server resources.

If you do not specify an expiration policy for a newsgroup, then delete articles manually when they are no longer needed. You can set and modify expiration policies using IIS Manager, or you can use Rexpire.vbs. To set expiration policies in IIS Manager, right-click **Expiration Policies**, point to **New**, and click **Expiration Policy**.

#### Setting Expiration Policies Using Rexpire.vbs

You can use Rexpire.vbs to set expiration policies. You can also use this command to delete and modify expiration policies. Table 8.3 lists and describes the parameters you can use with Rexpire.vbs.

**Table 8.3 Rexpire.vbs Parameters**

| Parameter | Description |
|---|---|
| -t *Operation*, where *Operation* is one of the following arguments:<br>• **a**<br>• **d**<br>• **g**<br>• **s**<br>• **e** | Adds the expiration policy.<br>Deletes the expiration policy.<br>Gets the expiration policy.<br>Sets the expiration policy.<br>Enumerates the expiration policies. |
| **-s** *Server* | Specifies the name of the server to be configured. |
| **-v** *VirtualServerID* | Specifies the ID of the virtual server. |
| **-I** *ExpireID* | Specifies the ID of the expiration policy. |
| **-h** *ExpireTime* | Specifies the number of hours until articles are discarded. |
| **-d** *MegabytesExpireSize* | Specifies the limit, in megabytes, of the size of the data in the virtual directory at which articles begin to be deleted. The default is 500 MB. |
| **-n** *Newsgroups* | Specifies the newsgroups to which the command is applied. NOTE: You can use strings that contain the wildcard character (*). |
| **-p** *PolicyName* | Specifies the name of the expiration policy. |
| **o- true** \| **false** | Indicates whether this is a one-time expiration policy. |

Table 8.4 lists examples of how you can use Rexpire.vbs.

**Table 8.4 Rexpire.vbs Script Examples**

| Command Script | Function |
|---|---|
| **Rexpire.vbs -t e -v 1** | Enumerates the expiration policies for NNTP site 1. |
| **Rexpire.vbs -t a -n alt.binaries.* -h 24** | Creates an expiration policy that expires articles on alt.binaries that are older than 24 hours. |
| **Rexpire.vbs -t s -i 1 -h 24** | Sets policy 1, which expires any articles older than 24 hours. |
| **Rexpire.vbs -t d -i 1** | Deletes expiration policy 1. |

**Deleting Messages Using Rcancel.vbs**

You cannot delete messages in IIS Manager, but you can delete messages using Rcancel.vbs or control messages. For more information about control messages, see Using Control Messages.

Table 8.5 lists and describes the parameters you can use with Rcancel.vbs. You must supply the message ID to cancel the message.

**Table 8.5 Rcancel.vbs Parameters**

| Parameter | Description |
|---|---|
| **-m** *MessageID* | Specifies the ID of message to cancel. |
| **-s** *Server* | Specifies the computer to configure. |
| **-I** *VirtualServerID* | Specifies the ID of the virtual server. |

The following example shows how you would use Rcancel.vbs:

```
Rcancel.vbs -m "<ugjWStxCBHA.1240@example.microsoft.com>"
```

# Limiting Newsgroup Enumeration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you host many newsgroups on one server, then you might want to limit or filter the newsgroups that are displayed in IIS Manager. You can specify how many newsgroups to display or you can filter the display to show only newsgroups of a certain type. For example, if you have many different departmental newsgroups that are broken down into subgroups, then you might want to filter the display to show only the top-level departmental newsgroups. To limit or filter newsgroup enumeration, in IIS Manager, right-click **Newsgroups**, and then click **Limit groups enumeration**. For more information, see Limiting Newsgroup Enumeration in IIS 6.0.

# Managing Sessions_IIS_SP1_TechRef

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

There might be times when you need to manage or monitor sessions as an administrator. You can terminate a session or all current sessions, or you can enumerate users. For example, if a specific user is posting inappropriate messages to an unmoderated newsgroup, you can terminate the session for that user.

You can manage sessions in IIS Manager or by using the Rsess.vbs command-line script. To manage sessions in IIS Manager, right-click the session, and then click the appropriate action.

**Managing Sessions Using Rsess.vbs**

Table 8.6 lists and describes the parameters that you can use with Rsess.vbs.

**Table 8.6 Rsess.vbs Parameters**

| Parameter | Description |
|---|---|
| **-t** *operation*, where *Operation* is one of the following arguments:<br>• **e**<br>• **d**<br>• **a** | Enumerates current sessions.<br>Deletes the session. (You must also specify **-u** *UserName*or **-I** *IPAddress*.)<br>Deletes all sessions and terminates the client connection. |
| **-u** *UserName* | Specifies the user name to delete. |
| **-I** *IPAddress* | Specifies the IP or host name to delete. |
| **-s** *Server* | Specifies the name of the server to configure. |
| **-v** *VirtualServerID* | Specifies the ID of the virtual server (an integer). |

Table 8.7 lists examples of how you can use Rsess.vbs.

**Table 8.7 Rsess.vbs Script Examples**

| Command Script | Function |
|---|---|
| `Rsess.vbs -t e -v 1` | Lists the current sessions for NNTP site 1. |
| `Rsess.vbs -t d -u john_doe` | Terminates the session for the user john_doe. |
| `Rsess.vbs -t a` | Terminates all sessions. |

| Note |
|---|
| **Rsess.vbs -t e** returns a list of the local feed (that is, the inbound push feed) as an anonymous connection. |

# Using Control Messages

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*Control messages* are specially formatted newsgroup messages that can create newsgroups, delete newsgroups, and delete posts. You can enable or disable control messages for newsgroups and for newsfeeds. If you enable control messages, then they are enabled for every user. If you want to restrict access to control messages to administrators only, then set appropriate ACLs for the control groups and enable either Basic authentication or Integrated Windows authentication.

In IIS Manager, use the **Settings** tab in the **NNTP virtual server properties** dialog box to enable or disable control messages for newsgroups. Use the Rfeed.vbs command-line script to enable or disable control messages for newsfeeds. Control messages are disabled by default in IIS 6.0. However, if you have upgraded from the Microsoft® Windows® 2000 operating system and you enabled control messages in that operating system, control messages are enabled in IIS 6.0.

#### Generating Control Messages

Control messages are generated automatically by NNTP client software, NNTP servers, and special utility programs. You can also generate control messages manually by connecting to the NNTP server using Telnet and entering the control messages directly.

The NNTP service accepts the following basic control messages:

**Cancel**: Deletes a specified article.

**Newgroup**: Creates a newsgroup.

**Rmgroup**: Deletes an existing newsgroup.

The Cancel control message is generated by client programs. The Newgroup and Rmgroup messages are typically generated by NNTP servers.

Control messages look like other newsgroup messages, but control messages have the following headers:

**From**: The name of the user or service from which this message originated.

**Subject**: A description of the subject.

**Newsgroups**: The name of the newsgroup affected by the control message, such as control.cancel|newgroup|rmgroup or any other valid newsgroup.

**Approved**: The user or administrator who created the message. If the newsgroup is moderated, the name of the moderator must appear. If the group is not moderated, any name can be used.

**Control**: The control header. Control messages must contain one of the following control headers:

- **Newgroup** <*name of new group*>. Creates a new group, for example, `newgroup Test.One`.
- **Rmgroup** <*name of group to delete*>. Deletes an existing newsgroup, for example, `rmgroup Test.One`.
- **cancel** <*MessageID*>. Deletes the message that is referenced by the message ID, for example, `cancel <BMO2mVOECHA.2772@server.domain.microsoft.com>`.

A blank line separates the headers from the message body. The message body can contain any text, or it can be blank. The following appears at the end of the control message:

```
{CRLF}.{CRLF}
```

#### Restricting Access to Control Messages

When the NNTP service receives Cancel, Newgroup, and Rmgroup control messages, it posts them into the following newsgroups, respectively: control.cancel, control.newgroup, and control.rmgroup. These newsgroups are created automatically. Control messages are sent to the control newsgroups regardless of where they were originally posted. The NNTP service also automatically creates a control virtual directory.

Restrict access to control messages to prevent unauthorized users from changing your newsgroups or deleting messages. You can restrict access by configuring the control newsgroups as moderated newsgroups or by restricting access to a limited group of users. For more information about moderating and restricting access, see Moderating Newsgroups and Configuring NNTP Virtual Server Properties.

In addition, any ACLs that you have in place for your existing newsgroups apply to control messages. For example, if you have a newsgroup named Microsoft.Software and you have secured the \Inetpub\Nntpfile\Root\Microsoft\Software directory with ACLs that restrict anonymous users from creating subfolders, then when an anonymous user posts a newsgroup control message in Microsoft.Software, the control message is not processed.

# Rebuilding the NNTP Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can fix several common problems with the NNTP service by rebuilding it. Rebuild the NNTP service when:

- The virtual server does not start.
- You delete internal newsgroup files accidentally.
- You recover the system after a disk failure occurs.
- Users cannot gain access to articles that they are authorized to read.
- An error message that is written to the Event Viewer system log tells you to rebuild the server.

For more information about rebuilding the NNTP service, see Rebuilding the IIS NNTP Service.

# Backing Up and Restoring an NNTP Virtual Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can back up your locally hosted NNTP virtual servers so that you can restore them in case of a serious system failure.

To back up an NNTP virtual server, use the **ntbackup** command or the Backup or Restore wizard to back up everything under *LocalDrive*:\Inetpub\Nntpfile. For more information about backing up and restoring Windows Server 2003–based files and directories, see Backing up and restoring data in Help and Support Center for Windows Server 2003.

# Managing Newsfeeds

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Newsfeeds send articles between the IIS NNTP service and other NNTP servers. With newsfeeds, the articles that are posted to one server can be read by users of the other servers. There are several different kinds of newsfeeds:

- Usenet: You can create an external newsfeed to Usenet to enable users of your news site to access the articles that are posted to any Usenet news site. A Usenet provider uses one or more NNTP servers to push new articles to the NNTP service. The NNTP service pushes the articles that are posted by your users to your Usenet provider.

- Peer newsfeed: If your organization has more than one news site, you can share articles between the sites. A peer newsfeed is ideal for private newsgroups that are not appropriate for public distribution on Usenet.

- Master/slave newsfeed: If the volume of traffic on your news site exceeds the capacity of a single computer, you can use multiple computers and share articles among them. A single master news site pushes articles to and from multiple subordinate sites. All clients connect to the subordinate sites.

  The master site controls the article numbers and keeps all the subordinate sites synchronized. Because all the subordinate sites have the same data, a master/slave newsfeed also provides a backup in case one of the computers fails.

Newsfeeds are not enabled by default. For information about enabling newsfeeds, see Enabling Newsfeeds.

**Adding, Deleting, and Modifying Newsfeeds**

Use Rfeed.vbs to add, delete, and modify newsfeeds. Table 8.8 lists and describes the parameters that you can use with Rfeed.vbs.

**Table 8.8 Rfeed.vbs Parameters**

| Parameter | Description |
|---|---|
| **-t** *Operation*, where *Operation* is one of the following:<br>• **a**<br>• **d**<br>• **g**<br>• **s**<br>• **e** | Adds a feed.<br>Deletes a feed.<br>Gets information about a feed.<br>Sets feed information.<br>Enumerates feeds. |
| **-s***Serve* | Specifies the computer name of the server to configure. |
| **-v***VirtualServerID* | Specifies the ID of the virtual server. |
| **-fpeer \|master\| slave** | Indicates the feed type. |
| **-r** *FeedServer* | Specifies the server that you push newsfeeds to or pull newsfeeds from. |
| **-u***UucpName* | Specifies the name that you put in the path header. (The default is the host name of the server.) |
| **-a** *AuthInfoAccount* | Specifies the user name to use when you connect. |
| **-b** *AuthInfoPassword* | Specifies the password to use when you connect. |

| | |
|---|---|
| **-I***FeedID* | Specifies the ID of the specified feed. |
| Parameters for inbound feed settings:<br>• **-ia pull** \| **accept**\|**none**<br>• **-in NewsgroupPatterns**<br>• **-ix***#Minute*<br>• **-iz true**\| **false**<br>• **-im** *#Connection*<br>• **-io** *Date*<br>• **-ic true** \|**false**<br>• **-ip** *PortNumber*<br>• **-it***Directory* | Indicates whether to enable or disable pull feeds.<br>Specifies newsgroup patterns.<br>Specifies the amount of time (in minutes) between feed runs.<br>Indicates whether to process control messages.<br>Specifies the maximum number of connection attempts that are allowed.<br>Gets articles after this date (pull feed only).<br>Indicates whether to create newsgroups automatically during pull feeds.<br>Specifies the outbound IP port for pull feeds.<br>Specifies the temporary files directory. |
| Parameters for outbound feed settings:<br>• **-oa push** \| **none**<br>• **-on Patterns**<br>• **-ox** *#Minutes*<br>• **-oz true**\| **false**<br>• **-om** *#Connections*<br>• **-op***PortNumber*<br>• **-ot***Directory* | Indicates whether to enable a push feed.<br>Specifies newsgroup patterns.<br>Specifies the amount of time (in minutes) between feed runs.<br>Indicates whether to process control messages.<br>Specifies the maximum number of connection attempts allowed.<br>Specifies the outbound IP port for push feeds.<br>Specifies the temporary files directory. |

Table 8.9 lists examples of how you can use Rfeed.vbs.

**Table 8.9 Rfeed.vbs Script Examples**

| Command Script | Function |
|---|---|
| **Rfeed.vbs -t e** | Enumerates feeds. |
| **Rfeed.vbs -t a -r FeedServer.microsoft.com -f peer -ia pull -in *** | Adds a pull feed from peer server FeedServer.microsoft.com, from which the articles from all the newsgroups are to be pulled. |
| **Rfeed.vbs -t d -i 1** | Deletes feed 1. |
| **Rfeed.vbs -t -s -i 1 -ix 120** | Sets the wait time between feed runs to 120 minutes. |

# Configuring the SMTP Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS SMTP service is a simple component for delivering and receiving e-mail messages. A message is transferred to a designated SMTP server to initiate the delivery. The originating SMTP server initiates communications with a DNS server, based on the domain name of the recipient e-mail address. The DNS server looks up and then returns the host name of the destination SMTP server for that domain.

Next, the originating SMTP server communicates with the destination SMTP server directly through TCP/IP port 25. If the user name of the recipient e-mail address matches one of the authorized user accounts on the destination SMTP server, the message is transferred to the destination SMTP sever, where it waits for the recipient to pick up the message through a client program.

The SMTP service also can transfer messages through one or more intermediate relay SMTP servers. A *relay SMTP server* receives the original message and then delivers it to the destination SMTP server or redirects it to another relay server. This process is repeated until the message is delivered or a designated time-out period passes.

The IIS SMTP service is commonly used to create a *smart host*, which is an SMTP server through which all outgoing messages are routed. For example, you can set up a smart host as a stand-alone SMTP server that sits between the Microsoft® Exchange server at your organization and the Internet. In this scenario, the smart host routes all e-mail from the Exchange server to the Internet and provides an added layer of protection between the Internet and the internal network. A smart host can also operate within a network.

Another common use for the SMTP service is to enable e-mail messages to be delivered from a Web site. For example, a company can provide an e-mail link for sending feedback messages or for requesting information. The SMTP service receives and routes those messages to the appropriate mailbox or to another SMTP server. Collaboration Data Objects (CDO) provides a simple object model that applications can leverage to submit mail to the SMTP server. For more information about CDO, see Overview of CDO on MSDN.

# Installing the SMTP Service and Creating an SMTP Virtual Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS SMTP service is not installed by default. Use Control Panel to install the SMTP service, and use IIS Manager to change the default SMTP configuration. For step-by-step instructions for installing the SMTP service, see SMTP Server Setup.

When you install the SMTP service, IIS creates the default SMTP virtual server automatically. In most cases, you need only one SMTP virtual server so that you can modify the default SMTP virtual server to work in your environment. However, if you are hosting multiple domains and want to have more than one default domain, for example, then you can create multiple SMTP virtual servers. To an end user, each SMTP virtual server appears as a separate server with a unique IP address/TCP port combination. To create a new virtual server, right-click **Default SMTP Virtual Server**, point to **New**, and click **Virtual Server.**

**Default Settings**

The default SMTP virtual server has the following default settings.

**Name**: The name of the virtual server that appears in IIS Manager. You can change the name of the virtual server to anything that you want by right-clicking the virtual server in IIS Manager and then clicking Rename.

**IP address/TCP port**: All unassigned/25. You can use the **General** tab in the **SMTP virtual server properties** dialog box to change this setting. If you change this setting, you must specify an IP address/TCP port combination that is not being used by another SMTP virtual server. TCP port 25 is both the default TCP port and the recommended TCP port. More than one virtual server can use the same TCP port, provided that they are configured with different IP addresses. If you do not set a unique IP address/TCP port combination, the SMTP virtual server will not start.

**Default domain**: The domain name that is listed on the **Computer Name** tab in **System Properties**. The default domain is used to stamp messages from addresses that do not have a domain. An SMTP virtual server can have only one default domain, and it cannot be deleted. To change the name of the default domain, double-click the virtual server, and double-click **Domains**. Right-click the local (default) domain, and click **Rename**. For more information about domains, see Organizing Messages Using SMTP Domains.

**Home directory**: *LocalDrive*:\Inetpub\Mailroot. The home directory is the root of your SMTP content directories, and it must be local to the computer on which the SMTP service runs.

If you create a new virtual server, you can configure default settings using the New Virtual Server Wizard.

# Configuring an SMTP Virtual Server as a Smart Host

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This section provides information about configuring an SMTP virtual server as a smart host. Only the properties for which there are special considerations for the smart host scenario are covered. For more complete information about configuring every virtual server property, see SMTP Administration.

**Setting Delivery Properties**

Delivery properties govern how the SMTP service handles outbound e-mail messages and are especially important when you configure a smart host.

To designate a smart host for delivering messages, in the **SMTP virtual server properties** dialog box, click the **Delivery** tab, and then click **Advanced**. In the **Advanced Delivery** dialog box, type the name of the virtual server that will act as the smart host. If the server you are currently configuring will be the smart host, then type its name.

You can also designate a *masquerade domain* in the **Advanced Delivery** dialog box. In a masquerade domain, e-mail that is sent from one domain looks as though it were sent from another. For example, if you have one SMTP virtual server named mail.contoso.com and you want all e-mail to look as though it were sent from contoso.com, then configure a masquerade domain.

If you configure a smart host that sits outside your firewall, click **Outbound Connections** to set the authentication type and provide the necessary credentials for the SMTP server to which your smart host will connect. For more information about authentication methods, see Securing SMTP Virtual Servers.

# Securing SMTP Virtual Servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

There are many steps you can take to make your SMTP virtual server more secure, including configuring access-related settings such as the authentication method, limiting administrative access, and setting connection limits.

**Configuring Access-Related Settings**
You can restrict access to your SMTP server by requiring authentication, limiting access according to IP address, or both. Restrict access by using the **Access** tab of the **SMTP virtual server properties** dialog box. The **Access** tab has five important security-related settings: Authentication, Certificate, Communication, Connection, and Relay.

**Authentication**
The Authentication option allows you to select from the following methods for authenticating users who attempt to connect to your SMTP server:

- **Anonymous access**. Anonymous access does not require users to enter a user name and password. This option is intended for servers that accept mail from outside the network.

  For example, if you are creating a stand-alone smart host that sits outside of your firewall and in front of your Exchange server, then you might select Anonymous access. Or, if you are creating a server to receive e-mail from a public Web site, then you might select Anonymous access.

- **Basic authentication**. Basic authentication requires users to enter a valid user name and password; however, the credentials are sent across the network unencrypted. If you select Basic authentication, then select **Requires TLS encryption**, which encrypts the user credentials. To require TLS encryption, you must have a valid SSL certificate installed on the server.

- **Integrated Windows authentication**. Integrated Windows authentication requires users to enter a valid Windows user name and password to connect to your SMTP server. Credentials are sent across the network encrypted. You can select Integrated Windows authentication if you are setting up a smart host to relay messages within your network or if you are setting up a server to receive e-mail from internal sites, such as a company intranet.

**Certificate and Communication**
The Certificate and Communication options allow you to secure communication by installing security certificates and requiring encryption. To install a certificate, click **Certificate** to start the New Certificate Wizard. Then, if you want to require the SMTP service to use SSL to encrypt every message, click **Communication**.

**Connection**
The Connection option allows you to restrict access to your server based on IP address. For example, if you are setting up a smart host that works inside your network, then you can use the **Only the list below** option to restrict access to the range of IP addresses for your network. If you are setting up a smart host that relays external e-mail or if you are setting up a server to accept e-mail from a public Web site, then connection control can be an effective way to restrict unsolicited commercial e-mail. After you identify the IP address or addresses of computers that send bulk e-mail, you can use the **All except the list below**option to prevent computers with specific IP addresses from connecting to your server. Although you can restrict access based solely on the domain name, this practice is not recommended because of the resources required to perform a reverse DNS lookup to identify the IP address of the computer attempting to connect.

**Relay**
The Relay option allows you to send e-mail to an SMTP server, which then sends it to the destination server or to another SMTP relay server. By default, the SMTP service blocks all computers from relaying unwanted mail through the virtual server, except those that meet the authentication requirements you designated in the **Authentication** dialog box. If you are setting up a smart host, enable only authenticated users to relay messages. If you are setting up a server to receive e-mail from the Internet, do not allow relaying, which can make you vulnerable to outside users who attempt to send unsolicited commercial e-mail through your SMTP server.

**Limiting Administrative Access**
You can restrict access to your server to only trusted administrators and make sure that administrators are granted only the access that they need to accomplish their work. Limit administrator access by using the **Security** tab of the **SMTP virtual**

**server properties** dialog box.

**Setting Messages Limits**

You can set message limits to prevent large, incoming messages from affecting the performance of your server. Set message limits by using the **Messages** tab of the **SMTP virtual server properties** dialog box.

There are two message limit settings. The first limits the message size. If a mail client sends a message that exceeds the limit, then the mail client receives an error. The second limits the session size, the maximum amount of data that is accepted during the total connection. This setting applies to the sum of all the messages that are sent during the connection and to only the message body.

To help protect against users who send unsolicited, commercial e-mail to your SMTP server, you can limit the maximum number of recipients for a single message sent in one connection. For more information about setting message and recipient limits, see Managing Messages_IIS_SP1_Ops.

# Organizing Messages Using SMTP Domains

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

SMTP domains are used for organizing messages for delivery. There are two main types of domains: local and remote.

**Organizing Messages Using Local Domains**
A *local domain* is a DNS domain that is serviced by the local SMTP server. Any message with a local domain name that arrives at an SMTP server must be delivered to a local mailbox or drop directory, forwarded to another local address, or returned to the sender with a nondelivery report.

You can specify local domains to be either default or alias. The SMTP service uses the default domain to stamp message headers that lack a domain specification. An alias domain is an alias for the default domain. For example, if Contoso Pharmaceuticals merges with Contoso Corporate, then customers might not know which domain to use. If ContosoPharmaceuticals.com is the default domain, then you can set ContosoCorporate.com as an alias domain, which allows users to send mail to either the ContosoPharmaceuticals.com domain or the ContosoCorporate.com domain so that the mail is still delivered to the correct recipient.

**Organizing Messages Using Remote Domains**
A *remote domain* is a domain that is not served by the local SMTP server. When mail is routed to a remote domain and the address is found, the SMTP service sends the mail to another server. Therefore, if you are setting up a smart host as a stand-alone server in front of your Exchange server, then you need to create a remote domain using the domain of your Exchange server.

**Related Information**

- For information about creating alias and remote domains, see Creating SMTP Domains.

# Additional Resources for Configuring Sites and Services in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to this section.

**Related Information**

- Analyzing Log Files for information about IIS logs.
- Common IIS 6.0 Administrative Tasks for information about creating a Web site.
- IIS 6.0 Administration Scripts, Tips, and Tricks for information about creating Web sites programmatically.
- IIS 6.0 Architecture for information about the WWW service and IIS core components.
- Managing a Secure IIS 6.0 Solution for information about IIS security.
- Running IIS 6.0 as an Application Server for information about application pools.
- Appendix E: Unattended Setup for information about unattended installation.
- Working with the Metabase for information about the IIS metabase.

**Related Windows Server 2003 Help Topics**
For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the **Search in title only** checkbox.

- Access control in Help and Support Center for Windows Server 2003.
- Active Directory in Help and Support Center for Windows Server 2003 for information about using Active Directory.
- Backing up and restoring data in Help and Support Center for Windows Server 2003 for information about how to back up servers running Windows Server 2003.
- Choosing a file system: NTFS, FAT, or FAT32 in Help and Support Center for Windows Server 2003 for information to help you decide which file system is the best solution for your server.
- DNS in Help and Support Center for Windows Server 2003 for information about the Windows Server 2003 DNS feature.
- Namespace planning for DNS in Help and Support Center for Windows Server 2003 for information about planning namespaces for DNS.

# IIS 6.0 Administration Scripts, Tips, and Tricks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Day-to-day administration of Internet Information Services (IIS) 6.0 includes tasks such as creating and configuring Web and File Transfer Protocol (FTP) sites, managing server certificates, and backing up IIS–based content and configuration. To work more efficiently, you can perform most of these administration tasks programmatically and remotely, whether you are administering IIS in a single-site or multi-site environment.

**In This Section**

Creating and Configuring a Site Programmatically

Creating a Web Site from a Template

Comparing Programmatic Administration Methods for IIS 6.0

Managing Server Certificates Programmatically

Managing IIS 6.0 Remotely

Scheduling IIS 6.0 Backups

Restarting and Alternatives to Restarting IIS 6.0

**Related Sections**

- For information about specific commands, including command syntax, see Command-line reference A-Z in Help and Support Center for Microsoft® Windows® Server 2003.
- For information about configuring Web sites as well as the File Transfer Protocol (FTP), Network News Transfer Protocol (NNTP), and Simple Mail Transfer Protocol (SMTP) services, see Configuring Internet Sites and Services.
- For information about installing and using FrontPage® 2002 Server Extensions from Microsoft, see Using FrontPage 2002 Server Extensions with IIS 6.0.

# Creating and Configuring a Site Programmatically

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

One of the most common tasks for Internet service providers (ISPs) and administrators who manage complex intranet sites hosted on servers running Internet Information Services (IIS) 6.0 is creating and configuring new Web sites and File Transfer Protocol (FTP) sites. Although you can create these sites by using IIS Manager, if you create sites often or create many sites at once, it can be faster and easier to create sites programmatically. For more information about creating Web sites and FTP sites by using IIS Manager, see Configuring Internet Sites and Services.

You can use a combination of scripts and tools to create a batch file that will automate all of the creating and configuring tasks. The steps for creating the batch file are as follows:

- Set up and configure DNS.
- Create directories.
- Add temporary content.
- Create Web sites.
- Set up FrontPage® 2002 Server Extensions from Microsoft.
- Create FTP sites.
- Set access control lists (ACLs).
- Include verification and error checking.

The following sections provide details, including sample scripts, for each step of the process for creating a batch file. In the final section, a complete batch file that you can customize for your environment is provided.

**Variables**
Some of the sample scripts in the following sections contain one or more of the following variables:

**%1** =User

**%2** = Domain

**%3** = .com (extension)

**%4** = y or n (indicates whether FrontPage 2002 Server Extensions should be installed)

If you type **newsite.bat user domain.com y** at a command prompt, after you save the complete batch file in a text editor, each entry becomes a variable in the script. The variable **%1** represents User; the variable **%2%3** represents Domain.com; and the variable **%2** represents Domain.

# Setting Up and Configuring DNS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Domain Name System (DNS) is an important part of creating new sites, especially if you host many sites on a single server with one Internet Protocol (IP) address. For more information about DNS and IP addresses, see Configuring Internet Sites and Services.

One tool that can be helpful in managing DNS is the **Dnscmd.exe** command-line tool that is provided with the Support Tools for Microsoft® Windows® Server 2003, Standard Edition; Microsoft® Windows® Server 2003, Enterprise Edition; and Microsoft® Windows® Server 2003, Datacenter Edition operating systems. You can use **Dnscmd.exe** to view, manage, and update existing DNS server configurations or to set up and configure new DNS servers on your network. Before you use Dnscmd.exe, decide how best to configure DNS zones for your network, or, if you have a designated DNS administrator for the network, ask him or her which parameters to use. For more information about using Dnscmd.exe, see Server administration using Dnscmd in Help and Support Center for Microsoft® Windows® Server 2003.

Listing 9.1 shows how you can use Dnscmd.exe to set up a DNS zone for contoso.com, create entries for contoso.com and www.contoso.com that point to IP address 10.1.1.1, and then set up a canonical name (CNAME) for www.contoso.com that instructs the DNS server to use the same IP address that is configured for contoso.com.

| **Important** |
| --- |
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /User:***MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

**Listing 9.1 Sample Script for Setting Up and Configuring DNS**

```
dnscmd PRIMARY /zoneadd contoso.COM /primary /file contoso.COM.dns
//sets up the overall zone contoso.COM on the primary name server

dnscmd SECONDARY /zoneadd contoso.COM /secondary /file contoso.COM.dns
//sets up the zone on the secondary

dnscmd PRIMARY /recordadd contoso.COM @ A 1.1.1.1
//sets up the record on the primary server for contoso.COM pointing to the IP 10.1.1.1

dnscmd PRIMARY /recordadd contoso.COM www CNAME contoso.COM
//sets up a CNAME record for WWW.contoso.com to point to the same IP as
// contoso.COM
```

# Creating Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you set up and configure DNS, you should create the physical directory for your sites. You can use the **mkdir** command to create a directory programmatically. For more information about **mkdir**, including command syntax, see Mkdir in the command-line reference section of Help and Support Center for Windows Server 2003.

Although it is simple to create a directory, the task requires advanced planning to create logical structures. Listing 9.2 uses C:\Web\UserName\Domain, where a users content is in a directory that has the same name as the user name. Each users domain is a subdirectory of the user name directory. This structure allows users to use FTP to download files to their folders and access other directories as necessary.

**Listing 9.2 Sample Script for Setting Up Directories**

```
mkdir C:\WEB\USERNAME\
mkdir C:\WEB\USERNAME\DOMAIN\
```

To prevent mistakes, such as unintentionally overwriting an existing directory, include error handling in your script. You can use the **if [not] exist** command in batch programs to check for and respond to certain conditions, as seen in Listing 9.3. For more information about the **if** commands, including command syntax, see If in the command-line reference section of Help and Support Center for Windows Server 2003.

**Listing 9.3 Sample Script for Error Handling**

```
If NOT exist C:\WEB\USERNAME\ goto errornofolder1
If NOT exist C:\WEB\USERNAME\DOMAIN\ goto errornofolder2
```

**Creating Directories Remotely**

| **Important** |
| --- |
| As a best security practice, use the **net use** command to authenticate with the remote computer before you use **mkdir** remotely. For more information about the **net use**command, including command syntax, see Net services commands in the command-line reference section of Help and Support Center for Windows Server 2003. |

To create directories on a remote computer, use the following command-line syntax:

```
\\Server\c$\Web\UserName\
```

# Adding Temporary Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you create sites, you can add temporary content files that users can replace with their own content when they are ready. An example of a temporary content file is a home page that says Coming Soon or Under Construction. Use the Adsutil.vbs command-line script to add temporary content files.

Adsutil.vbs is a flexible tool that uses the Microsoft® Visual Basic® development system, Scripting Edition (VBScript), with Microsoft® Active Directory® Service Interfaces (ADSI) to manipulate the IIS configuration. Note that Adsutil.vbs is not a Microsoft-supported product. The documentation for, and the format of, Adsutil.vbs can change at any time. For more information about Adsutil.vbs, including syntax and parameters, see Using the Adsutil.vbs Administration Script.

You must use the CScript.exe command-line tool, which is installed with Windows Script Host, to run Adsutil.vbs. You can set CScript.exe as the default run-time program by typing **CScript //h:cscript //nologo //s** at the command prompt.The optional **//nologo** parameter disables the display of the CScript copyright banner. Alternatively, you can type **Cscript.exe** at the beginning of the Adsutil.vbs script. For more information about using Adsutil.vbs, including commands and parameters, see Using the Adsutil.vbs Administration Script.

Listing 9.4 uses Adsutil.vbs to add a file named temp.htm to the list of default documents. Although you do not have to use the name temp.htm, do not name the file default.htm because default.htm would take precedence if the user added only index.htm as the home page. The sample script adds the temp.htm file as the last file on the **Documents** tab in the Web site properties so that temp.htm can never override a users home page, even if the user never deletes temp.htm. You must type the complete Adsutil.vbs script on one line.

**Listing 9.4 Sample Script for Setting Up Temporary Files**

```
Adsutil.vbs set w3svc/defaultdoc
"default.htm,default.html,default.asp,default.aspx,index.htm,index.html,index.
asp,index.aspx,temp.htm"
```

After you add a temporary file, use the **copy** command to copy the file to the users directory. For example, to copy temp.htm to the users directory, at the command prompt, type **copy temp.htm C:***web******username******domain***\temp.htm**.

**Adding Temporary Content Remotely**

You can run any of the Adsutil.vbs commands remotely. To add temporary content to a remote computer, add **-s:***Server* to the end of the command, where *Server* is the name of the target server.

# Creating Web Sites in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you configure DNS, create the directories, and populate the directories with temporary content, you need to create the Web sites. You can use IIS Manager to create Web sites, or you can use the Iisweb.vbs command-line script, which is stored in the *systemroot*\System32 folder.

When you use Iisweb.vbs to create a Web site, you specify only the basic properties that are needed to create the site and identify its contents. Iisweb.vbs uses the same default properties that IIS Manager uses when creating new Web sites, and it adheres to the same rules for inheriting properties. For more information about default Web site properties, see Configuring Internet Sites and Services. For more information about Iisweb.vbs, including command syntax, see Creating Web Sites Using Iisweb.vbs. For example, to create a Web site on the local computer using the directory specified in the preceding sample scripts, at a command prompt, type **iisweb /create** *c:\web\user\domain contoso.com* **/d** *www.contoso.com*.

**Creating Web Sites Remotely**

To create a Web site on a remote computer, type **/s** *Server*after the **/create** parameter, where *Server* is the name of the target computer. To specify the IP address of the target computer, type **/i** *IPAddress* after the **/s** parameter, where*IPAddress* is the IP address.

# Providing Additional Host Headers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Many users request additional host headers, such as contoso.com, without the www prefix. You can use Adsutil.vbs to set host headers, but you need to specify the site identification (ID). Although you can find out the site ID by parsing it from Adsutil.vbs output, an easier way is to integrate the Translate.js command-line script, which uses the IIS Windows Management Instrumentation (WMI) provider, into your Adsutil.vbs command. For more information about the IIS WMI provider, see IIS WMI Provider on MSDN.

The Translate.js script appears below. Copy it exactly as it is shown, and then save it in the same location as your other scripts. If you do not specify a location, it will be saved to C:\Windows\System32 by default. You need to use CScript.exe to run Translate.js. For information about using CScript.exe, see Adding Temporary Content.

```
TRANSLATE.JS
var serverComment = WScript.Arguments(0);
var query = "SELECT Name, ServerComment FROM IIsWebServerSetting WHERE ServerComment='"
+ serverComment + "'";
var providerObj = GetObject("winmgmts:/root/MicrosoftIISv2");
var sites = providerObj.ExecQuery(query);

if (sites.Count != 0)
{
   for(e = new Enumerator(sites); ! e.atEnd(); e.moveNext())
   {
      var item = e.item();
      // Print the site ID only by leaving the "W3SVC/" prefix out.
      WScript.Echo(item.Name.substr(6));
   }
}
else
{
   WScript.Echo("No sites found.");
}
```

After you save Translate.js, you can integrate it with Adsutil.vbs to provide additional host headers. Listing 9.5 uses 80:contoso.com to designate the site IP binding as All Unassigned. If you want to designate a specific IP address, type the IP address followed by a colon (:) in front of this string, as in **IPAddress:80:contoso.com**.

**Listing 9.5 Sample Script for Setting Up Host Headers**

```
cscript //nologo translate.js "CONTOSO.COM" > siteid.txt

for /f %%I in (siteid.txt) do SET SITEID=%%I

Adsutil set w3svc/%SITEID%/serverbindings ":80:WWW.CONTOSO.COM" ":80:CONTOSO.COM"

Del siteid.txt
```

**Providing Additional Host Headers Remotely**

| **Important** |
| --- |
| To provide additional host headers remotely while logged in with a domain account, you must have administrative credentials on both computers. When logged in with a local user account, you must have an account with the same user name and password on the remote computer, as well as administrative credentials on both computers. |

To modify Translate.js to access a remote server, add the server name when you get the object by changing **GetObject(winmgmts:/root/MicrosoftIISv2);** to **GetObject(winmgmts://***Server***/root/MicrosoftIISv2);**, where *Server*is the name of the remote server.

# Installing and Setting Up FrontPage 2002 Server Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions provide Web-based and command-line administration for extending virtual servers. *Extending*a virtual server means enabling various FrontPage 2002 Server Extensions features to improve the way that you manage the content development and security of your site. Extending virtual servers with FrontPage 2002 Server Extensions enables the site owner to author the site in FrontPage and delegate site ownership and administration credentials.

FrontPage 2002 Server Extensions include new security features, such as roles and rights, and new features for monitoring server health and Web site use. For more information about improvements in FrontPage 2002 Server Extensions, see Using FrontPage 2002 Server Extensions with IIS 6.0.

Listing 9.6 enables both FrontPage 2002 Server Extensions and FTP on the same site. The sample script sets up FTP by default and checks the *%4*variable. If the *%4* variable is **y**, the script goes to the FrontPage 2002 Server Extensions setup section. Otherwise, FrontPage 2002 Server Extensions setup is skipped.

**Listing 9.6 Sample Script for Setting up FTP and FrontPage 2002 Server Extensions**

```
:iffp
if "%4"=="y" goto fpse
goto skipfp
```

There are two options for setting up FrontPage 2002 Server Extensions. You can add the full FrontPage 2002 Server Extensions path to System Properties, or you can include the path in the batch file each time you run it. The locations are as follows:

- For FrontPage 2002 Server Extensions: *Drive*:\Program Files\Common Files\Microsoft Shared\Web Server Extensions\50\Bin

- For FrontPage 2000 Server Extensions: *Drive*:\Program Files\Common Files\Microsoft Shared\Web Server Extensions\40\Bin

**To add the FrontPage 2002 Server Extensions path to System Properties**

1. From the **Start**menu, right-click **My Computer**, and then click **Properties**.
2. In the **System Properties**dialog box, click the **Advanced** tab, and then click **Environment Variables**.
3. In the **Environment Variables**dialog box, in **System variables**, click the path, and then click **Edit**.
4. In the **Edit System Variable** dialog box, in the **Variable value** box, type a semicolon (**;**) at the end of the path, and then do one of the following:
   - For FrontPage 2002 Server Extensions, type: *Drive***:\Program Files\Common Files\Microsoft Shared\Web Server Extensions\50\bin**
   - For FrontPage 2000 Server Extensions, type: *Drive***:\Program Files\Common Files\Microsoft Shared\Web Server Extensions\40\bin**

To include the FrontPage 2002 Server Extensions path in the batch file each time you run it, run a script like Listing 9.7. This sample script does not add the path to System Properties.

**Listing 9.7 Sample Script for Installing FrontPage 2002 Server Extensions Batch Files**

```
@set path=%path%;%SYSTEMDRIVE%\inetpub\adminscripts;%SystemDrive%\Program Files\Common
Files\Microsoft Shared\Web Server Extensions\50\bin
```

After you set up FrontPage 2002 Server Extensions, you can use SharePoint™ Team Services from Microsoft command-line tools to install and administer FrontPage 2002 Server Extensions from the local server or from a remote computer. The Owsadm.exe command-line tool runs on only the server, and the Owsrmadm.exe command-line tool can be run from a remote

computer. These tools are available at *systemroot*\Program Files\Common Files\Microsoft Shared\Web Server Extensions\50\Bin.

**Installing FrontPage 2002 Server Extensions Locally**

To view the command-line options for Owsadm.exe, at the command prompt, change the directory to the *systemroot*\Program Files\Common Files\Microsoft Shared\Web Server Extensions\50\Bin folder, and then type **owsadm.exe -h**.

| **Note** |
| --- |
| In the following sample scripts, CONTOSO.COM is case sensitive. |

Listing 9.8 uses Owsadm.exe to install FrontPage 2002 Server Extensions on the local server.

**Listing 9.8 Sample Script for Installing FrontPage 2002 Extensions System Properties**

```
:fpse
owsadm -o install -p 80 -m www.CONTOSO.COM -t msiis -u USER
```

To install FrontPage 2000 Server Extensions, use Listing 9.9.

**Listing 9.9 Sample Script for Installing FrontPage 2000 Extensions System Properties**

```
:fpse
fpsrvadm -o install -p 80 -m www.CONTOSO.COM -t msiis -u USER
```

**Security Considerations for Installing FrontPage 2002 Server Extensions Remotely**

Be aware of security considerations when using Owsrmadm.exe. When you administer a server remotely, a wider community of users is given greater access to the Web server from the Internet, which can create a security risk. During remote administration of Windows SharePoint Team Services and FrontPage 2002 Server Extensions, an unauthorized person can gain access to Web sites, based on the Windows SharePoint Team Services or FrontPage 2002 Server Extensions on your server, and modify Web site settings, and even delete Web sites. To increase security when administering FrontPage 2002 Server Extensions remotely, you should use a Secure Sockets Layer (SSL) connection, and you should use a nonstandard administration port to access Fpadmdll.dll.

To require SSL security for authoring and site administration tasks, use the **Require SSL for authoring and administration** option on the **Set Installation Defaults** tab in **Server Administration**, or set the **RequireSSL** property by using the **setproperty** command.

When you install FrontPage 2002 Server Extensions, a nonstandard administration port is created. Use this administration port to access Fpadmdll.dll, which, on the Web server, acts as the form handler for any of the FrontPage 2002 Server Extensions HTML–based administration pages.

For more information about using Owsrmadm.exe, see Using the Administration Tools Remotely in the SharePoint Team Services Administrator's Guide.

# Creating FTP Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The directory structures for the sample scripts in this section include an overall user folder that contains a folder for each of the user's domains. For example, if the user has two domains, the structure would be *C:\Web\User\Domain1* and *C:\Web\User\Domain2*. For the purposes of uploading content through FTP, you need to set up an FTP virtual directory that points to C:\Web\User so that the user can upload to either domain easily. Instructions for setting up a virtual directory are provided later in this section.

You can have only one FTP site per IP address on TCP port 21, so you need to use virtual directories and ACLs to ensure that users are sent to the correct directory. You can create and host multiple FTP sites with the same IP address, as long as they have different ports. This configuration can be difficult to manage. It requires making sure that the port number is explicitly defined in the URL, and you might also need to open the port at the firewall.

If you want to configure multiple users to a single FTP site but also ensure that users cannot access and download from the directories of other users, you can create FTP sites by using FTP isolation. Some of the benefits of FTP isolation include added security and easier migration of users to different servers.

FTP user isolation supports two isolation modes: Isolate users and Isolate users using Active Directory. You can also create FTP sites with no isolation. You can configure FTP user isolation with the Iisftp.vbs command-line script by using the **/isolation** parameter with either the **AD** argument for Active Directory isolation, or the **Local** argument, for local isolation. If you do not include the **/isolation** parameter, the site will not isolate users. For more detailed information about creating multiple FTP sites and setting up FTP user isolation, see Configuring Internet Sites and Services.

# Setting Up FTP Virtual Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can set up an FTP virtual directory by using lisftpdr.vbs. The directory structure in these sample scripts has a domain beneath each user folder. If you set up your directory this way, when your users upload content they can change directories into any domain they own. For more information about lisftpdr.vbs, including command syntax, see Creating FTP Virtual Directories Using lisftpdr.vbs.

For example, to use one FTP site that points to the same IP address as the Web sites and creates a virtual directory for a user named USER, at the command prompt, type **iisftpdr /create** *ftpsitename* **USER** *c:\web\user*. In Listing 9.10, Translateftp.js gets the site ID and uses an Adsutil.vbs command to assign write permissions for the user on the new virtual directory. The sample script creates Translateftp.js by copying Translate.js, renaming it Translateftp.js, and changing two elements.

The first element that is changed is the IISWebServerSetting class. Translate.js queries the IISWebServerSetting class by using WMI. For FTP, you must switch to the IISFtpServerSetting class. This class corresponds to the IIsFtpServer IIS Admin object, and it contains the read/write properties for the object. For more information about the IISWebServerSetting element, see see the IIS Programmatic Administration Reference ion MSDN.

The second element that is changed is the JavaScript *item.Name***.substr()** call. The **substr()** method returns a specified part of a string. By changing the setting from six (6) to nine (9) for Translateftp.js, the script will return the FTP site ID as a return string.

**Listing 9.10 Sample Script for Setting UP FTP Virtual Directories**

```
TRANSLATEFTP.JS
var serverComment = WScript.Arguments(0);
var query = "SELECT Name, ServerComment FROM IIsFTPServerSetting WHERE ServerComment='"
+ serverComment + "'";
var providerObj = GetObject("winmgmts:/root/MicrosoftIISv2");
var sites = providerObj.ExecQuery(query);

if (sites.Count != 0)
{
   for(e = new Enumerator(sites); ! e.atEnd(); e.moveNext())
   {
      var item = e.item();
      //Print the site ID only by leaving the "MSFTPSVC/" prefix out.
      WScript.Echo(item.Name.substr(9));
   }
}
else
{
   WScript.Echo("No sites found.");
}

The ADSUTIL command and integration with translateftp.js.

cscript //nologo translate.js "FTPSITEID" > ftpsiteid.txt

for /f %%I in (ftpsiteid.txt) do SET FTPSITEID=%%I

adsutil.vbs set msftpsvc/%FTPSITEID%/root/USER/accesswrite "true"

del ftpsiteid.txt
```

**Setting Up FTP Remotely**

| **Important** |
| --- |
| To set up FTP remotely while logged in with a domain account, you must have administrative credentials on both computers. When logged in with a local user account, you must have an account with the same user name and password on the remote computer, as well as administrative credentials on both computers. |

To modify Translateftp.js to access a remote server, add the server name when you get the object by changing **GetObject(winmgmts:/root/MicrosoftIISv2);** to **GetObject(winmgmts://***Server***/root/MicrosoftIISv2);**, where *Server* is

the name of the remote server.

# Setting ACLs

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Depending on the requirements of your Web sites and services, you might want to explicitly set ACLs for groups and accounts in IIS. For example, you might need to ensure that ASP.NET can run on a Web site. You can use one of several tools to programmatically display and modify ACLs for your physical folders. For a list of the default IIS ACLs, and a list of popular ACL tools, see Managing a Secure IIS 6.0 Solution.

| **Important** |
|---|
| If you use FrontPage2002 Server Extensions and FTP on the same site (which is not recommended), you should set ACLs after you install FrontPage2002 Server Extensions to prevent FrontPage2002 Server Extensions from changing the permissions. |

For example, to edit the ACLs instead of replacing them, so that the defaults will be inherited from c:\web, and the FrontPage 2002 Server Extensions permissions will be left intact, at the command prompt, type **cacls** *c:\web\user* **/t /e /g user:c networkservice:r <***y.txt*.

You will need to use a text file to simulate pressing ENTER+Y+ENTER, which confirms the operation. To do so, create a .text file named Y.txt, type the following, and save the file:

**<enter>**

**Y**

**<enter>**

Because this sample script uses cacls, the account name is specified as networkservice instead of Network Service, but both names refer to the same account.

#### Recommended and Inherited ACLs

Table 9.1 lists several accounts or groups with ACLs that you might need to change, as well as an explanation for the recommendation.

**Table 9.1 Recommended ACLs**

| Account or Group Name | Recommended ACL | Explanation |
|---|---|---|
| IUSR_*ComputerName* | Read | Anonymous browsing account (used by default). |
| Network Service | Read | ASP.NET requires read access on the Network Service account.<br>**Note**<br>IIS 6.0 runs under this account by default when IIS is running in worker process isolation mode. In IIS 5 compatibility mode, the default account is ASPNET. |
| USER | Change | Account for the site administrator. |

Table 9.2 lists the ACLs that are inherited from the folder structure, but that can be added in the script.

**Table 9.2 Inherited ACLs**

| Account or Group Name | Inherited ACL | Explanation |
|---|---|---|
| Administrators | Full | Account for users in the Administrators group. |
| System | Full | Account for users who need system access. |

#### Setting ACLs Remotely

To run cacls remotely, use the following command-line syntax, where *Server* is the name of the target server, and *c$\web* is the path:

**cacls ** *Server\c$\web*

# Including Verification and Error Checking

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

As a best practice, you should place error-checking and verification code at the start of and throughout your batch file. If you plan to be present while you run the batch file, you do not need extensive verification.

One way to have your batch file check for errors is to include a **net user** command that verifies that the user name is in the domain and then parses the command output for any text that says the user does not exist. For example, use the following command-line syntax to verify that the user name is in the domain:

**net user** *user/domain* **>** *user.txt*

Then, parse the command output for the text string The user name could not be found, which would indicate that the user is not in the domain. You can use the **findstr** command to parse a file for a text string.

Another way to have your batch file check for errors is to include the **if not exist** command and other commands that ensure that the previous portion of the script succeeded. Ideally, you should run this script after each series of commands to check, for example, that the DNS entries were created, and then to check that the directories were created, and so on. You should also include error-handling code after the error-checking code, such as a loop that waits a few minutes to attempt to complete a series of commands again, or a more complex series of commands, while the batch file parses a specific error.

Listing 9.11 provides simple error checking for the existence of all variables. In addition, this sample script allows another administrator, who might not be familiar with your script, to use the **/?** parameter to get information on how to use the script.

**Listing 9.11 Sample Script for Error Checking**

```
if "%1" == "?" goto usage
if "%1" == "/?" goto usage
if "%1" == "-?" goto usage

if "%1" == "" goto errormissingvariable
if "%2" == "" goto errormissingvariable
if "%3" == "" goto errormissingvariable
if "%4" == "" goto errormissingvariable
```

# The Complete Batch File

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Listing 9.12 provides the complete batch file named Newsite.bat. The complete batch file includes the series of commands that are documented in the preceding sections, variables for elements such as the server IP address and DNS servers, and the @ symbol in front of certain lines to hide them from the console window.

After you save Newsite.bat, type the following at the command prompt to run it:

**newsite.bat user domain.com n**

**%1 = user**

**%2 = domain**

**%3 = .com** (extension)

**%4 = y|n** (to indicate whether to install FrontPage 2002 Server Extensions)

**Listing 9.12 NEWSITE.BAT: Sample Batch File**

```
@SET PRIMARYNS=dns.contoso.com
@SET SECONDARYNS=dns1.contoso.com

FrontPage 2002 Server Extensions, n  for none.)
@echo EXAMPLE myusername mydomain .com y
@goto end

:end
```

# Comparing Programmatic Administration Methods for IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 can be configured programmatically from standalone scripts or applications. Table 9.3 describes these methods of configuring IIS, and lists some of the advantages and disadvantages of using each method.

**Table 9.3 Comparison of Programmatic Administration Methods for IIS 6.0**

| Configuration Method | Advantages | Disadvantages |
|---|---|---|
| Command-line tools included with IIS | • Provides solutions to the most common administration tasks. | • Some tools are not available on earlier versions of IIS. |
| Active Directory Service Interfaces (ADSI) | • Can configure large sites and multiple servers.<br>• Supports scripting.<br>• Applies changes immediately without restarting the server.<br>• Supports IIS 4.0 through IIS 6.0. | • Requires knowledge of which supporting properties need to be created and set.<br>• Some functionality is missing when using the IIS ADSI provider from System.DirectoryServices. |
| Windows Management Instrumentation (WMI) | • Can configure large sites and multiple servers<br>• Supports scripting.<br>• Applies changes immediately without restarting the server. | • Requires knowledge of which supporting properties need to be created and set.<br>• Cannot be used when you are configuring a server running IIS 5.1 or earlier. |
| Admin Base Objects (ABO) | • Provides a faster method of configuring IIS than ADSI or WMI. | • Requires knowledge of which supporting properties need to be created and set.<br>• Does not support scripting.<br>• Only supports applications written in C++ or Visual Basic 6.0.<br>• Is more difficult to use than ADSI or WMI.<br>• Provides no safeguards to prevent configuration of invalid settings. |

For more detailed information about the programmatic administration methods described in Table 9.3, see the IIS Software Development Kit on MSDN.

# Managing Server Certificates Programmatically

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

There are many ways to manage server certificates programmatically. This section provides a description of two different methods, including sample scripts for performing management tasks related to server certificates. One method uses the **IISCertObj** COM object, and the other method uses a *CAPICOM*-based script. CAPICOM is a Cryptographic interface (CryptoAPI).

# Managing Server Certificates by Using IISCertObj

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can use **IISCertObj** to perform the following tasks:

- Import copies of a server certificate from a .pfx file (a file containing a PFX-encrypted server certificate and a private key) from a server to multiple servers.
- Save backup copies of server certificates on a central site.
- Copy a server certificate from one server to multiple servers.

When using **IISCertObj**, you must set properties for the methods that you call. The following sections outline the necessary properties and the methods that you need to manage server certificates.

**Setting IISCertObj Properties**

Because a method will return an error message if the required properties for that method are not available when the method is called, you should set properties before you call methods. Table 9.4 lists the **IISCertObj** properties that you need to generate server certificate requests.

**Table 9.4 Required IISCertObj Properties**

| Property Attribute | Name Attribute | Value | Description |
|---|---|---|---|
| `ServerName` | Data Type | String, write only | Contains the name of the computer on which server certificate operations are executed. |
| `UserName` | Data Type | String, write only | Specifies the user name that is used to log on to the remote computer. If UserName is empty, the credentials of the user that is currently logged on are used. |
| `UserPassword` | Data Type | String, write only | Specifies the password that is used for logging onto the remote computer. |
| `InstanceName` | Data Type | String, write only | Identifies the targeted metabase instance. W3svc/1 is an example. |

**Applying IISCertObj Methods**

You can apply the following methods to the **IISCertObj** object: **Copy**, **Export**, **GetCertInfo**, **Import**, **ImportToCertStore**, **IsExportable**, **IsInstalled**, **Move**, and **RemoveCert**.

**Copy**

The **Copy** method allows you to copy a server certificate from one instance of IIS to another and from one computer to another. Use the following syntax with the Copy method:

```
            bAllowExport, bOverwriteExisting, DestinationServerName,
DestinationServerInstance, DestinationServerUserName, DestinationServerPassword
```

Table 9.5 lists the parameters that the Copy method uses.

**Table 9.5 Copy Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|

| | | |
|---|---|---|
| `bAllowExport` | Boolean | Indicates whether the imported server certificate will be exportable (true) or not exportable (false). |
| `bOverwriteExisting` | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (true) or not overwritten (false). |
| `DestinationServerName` | String | Specifies the computer name of the server to which the server certificate will be moved. |
| `DestinationServerInstance` | String | Specifies the IIS metabase instance at which the server certificate will be pointed. For example, w3svc/1. |
| `DestinationServerUserName` | String | Specifies the user name for the destination server. If empty, the user name of the user who is currently logged on will be used. |
| `DestinationServerPassword` | String | Specifies the password for the destination server when the *DestinationServerUserName* parameter is used. |

**Export**

The **Export** method exports a copy of a server certificate to a file. The target file can be on a local or remote computer. Use the following syntax with the Export method:

```
Export FileName Password bPrivateKey bCertChain bRemoveCert
```

Table 9.6 lists the parameters that the Export method uses.

**Table 9.6 Export Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| `FileName` | String | Specifies the name of the targeted file. For example, C:\Mydir\Mycert.pfx. |
| `Password` | String | Specifies the password that is used to secure the file specified as *FileName*. |
| `bPrivateKey` | Boolean | Indicates whether the private key is exported (true) or not exported (false). |
| `bCertChain` | Boolean | Indicates whether the certificate trust chain is exported (true) or not exported (false). |
| `bRemoveCert` | Boolean | Indicates whether the binding of a server certificate is removed (true) or not removed (false). |

**GetCertInfo**

The **GetCertInfo** method allows you to acquire information on a server certificate that is installed on the computer specified by the **IISCertObj** properties, **ServerName** and **InstanceName**.

The GetCertInfo method uses no parameters.

**Import**

The **Import** method imports a copy of a server certificate from a file to a local or remote computer. Use the following syntax with the Import method:

```
FileName Password bAllowExport bOverWriteExisting
```

Table 9.7 lists the parameters that the Import method uses.

**Table 9.7 Import Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| `FileName` | String | Specifies the name of the server certificate file to import. |
| `Password` | String | Specifies the password that is used to secure the file specified as *FileName*. |
| `bAllowExport` | Boolean | Indicates whether the imported server certificate is exportable (true) or not exportable (false). |
| `bOverwriteExisting` | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (true) or not overwritten (false). |

**ImportToCertStore**

The **ImportToCertStore** method imports a copy of a server certificate from a file to the certificate store on a local or remote computer. Use the following syntax with the ImportToCertStore method:

```
ImportToCertStore FileName Password bAllowExport bOverwriteExisting
```

Table 9.8 lists the parameters that the ImportToCertStore method uses.

**Table 9.8 ImportToCertStore Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| `FileName` | String | Specifies the name of the server certificate file to import. |
| `Password` | String | Specifies the password that is used to secure the file specified as *FileName*. |
| `bAllowExport` | Boolean | Indicates whether the imported server certificate is exportable (true) or not exportable (false). |
| `bOverwriteExisting` | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (true) or not overwritten (false). |

**IsExportable**

The **IsExportable** method allows you to determine whether a server certificate is exportable from a computer that is specified by the IIS **ServerName** and **InstanceName** properties.

The IsExportable method uses no parameters.

**IsInstalled**

The **IsInstalled** method allows you to determine whether a server certificate is installed on a computer that is specified by the IIS **ServerName** and **InstanceName** properties.

The IsInstalled method uses no parameters.

**Move**

The **Move** method allows you to move a server certificate from one instance of IIS to another, and from one computer to another. Use the following syntax with the Move method:

```
Move bAllowExport bOverwriteExisting DestinationServerName DestinationServerInstance
DestinationServerUserName DestinationServerPassword
```

Table 9.9 lists the parameters that the Move method uses.

**Table 9.9 Move Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| bAllowExport | Boolean | Indicates whether the imported server certificate is exportable (true) or not exportable (false). |
| bOverWriteExisting | Boolean | Indicates whether, if an identical server certificate already exists, it is overwritten (true) or not overwritten (false). |
| DestinationServerName | String | Specifies the computer name of the server to which the server certificate will be moved. |
| DestinationServerInstance | String | Specifies the IIS metabase instance at which the server certificate will be pointed. For example, w3svc/1. |
| DestinationServerUserName | String | Specifies the user name for the destination server. If no user name is entered, the user name of the user that is currently logged on will be used. |
| DestinationServerPassword | String | Specifies the password for the destination server when the *DestinationServerUserName* parameter is used. |

**RemoveCert**

The **RemoveCert** method allows you to delete a server certificate from a certificate store. Use the following syntax with the RemoveCert method:

```
RemoveCert bRemoveFromCertStore bPrivateKey
```

Table 9.10 lists the parameters that the RemoveCert method uses.

**Table 9.10 RemoveCert Method Parameters**

| Parameter | Data Type | Description |
|---|---|---|
| bRemoveFromCertStore | Boolean | Indicates whether the server certificate is removed (true) or not removed (false). |
| bPrivateKey | Boolean | Indicates whether the private key of the server certificate is removed (true) or not removed (false). |

**Sample Server Certificate Management Scripts**

In IIS, if you use Windows Script Host or ASP, you can execute scripts that communicate with **IISCertObj** programmatically to import, archive, or export server certificates.

**Importing server certificates to multiple servers**

Large sites often need to use one server certificate for secure user logon to multiple servers. It would be time-consuming to use the Microsoft Management Console (MMC) to add copies of the server certificate to each server. By using the **Import** method, you can install copies of the same server certificate on all of the targeted servers.

To import a server certificate from a certificate store on one server to other servers, first save the following script in your text editor as CertImport.vbs.

| **Important** |
|---|
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /***User:MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

```
Option Explicit
```

```
Dim iiscertobj, pfxfile, pfxfilepassword, InstanceName, WebFarmServers, IISServer
Set iiscertobj = WScript.CreateObject("IIS.CertObj")
pfxfile = WScript.Arguments(0)
pfxfilepassword = WScript.Arguments(1)
InstanceName = WScript.Arguments(2)
WebFarmServers = split(WScript.Arguments(3), ",")
iiscertobj.UserName = WScript.Arguments(4)
iiscertobj.UserPassword = WScript.Arguments(5)
For Each IISServer in WebFarmServers
  iiscertobj.ServerName = IISServer
  iiscertobj.InstanceName = InstanceName
  iiscertobj.Import pfxfile, pfxfilepassword, true, true
Next
```

After you save the script as CertImport.vbs, run this command:

**Certimport.vbs cert.pfx pfxPassword w3svc/1 iisserver1,iisserver2,iisserver3 Administrator aal34290**

**Saving backup copies of server certificates in a central archive**

Using the **Export** method, you can archive a backup of each server certificate on your server farm to a central site.

To export copies of server certificates to the central site, first save the following script in your text editor as Save_all_certs.vbs.

```
Option Explicit
Dim iiscertobj, targetServer, targetServers, pfxbasename, pfxpassword, InstanceName
Set iiscertobj = WScript.CreateObject("IIS.CertObj")
pfxbasename = WScript.Arguments(0)
pfxpassword = WScript.Arguments(1)
InstanceName = WScript.Arguments(2)
targetServers = split(WScript.Arguments(3), ",")
iiscertobj.UserName = WScript.Arguments(4)
iiscertobj.UserPassword = WScript.Arguments(5)
iiscertobj.InstanceName = InstanceName
For Each targetServer in targetServers
  iiscertobj.ServerName = targetServer
  iiscertobj.Export pfxbasename + targetServer + ".pfx", pfxpassword, true, false,
false
Next
```

After you save the script as Save_all_certs.vbs, run this command:

**Save_all_certs.vbs C:\certbackup\ pfxpassword w3svc/1 iisserver1,iisserver2,iisserver3 Administrator aal34290**

**Copying a server certificate from an existing server to a new server**

Using the **Copy** method, you can copy a server certificate to a new server after you add the server to a server farm.

To copy a server certificate from an existing server to a new server, first save the following script in your text editor as Certcopy.vbs.

```
Option Explicit
Dim iiscertobj, targetServer, targetServers, targetInstance
Set iiscertobj = WScript.CreateObject("IIS.CertObj")
iiscertobj.ServerName = WScript.Arguments(0)
iiscertobj.Instancename = WScript.Arguments(1)
targetServers = split(WScript.Arguments(2), ",")
targetInstance = WScript.Arguments(3)
iiscertobj.UserName = WScript.Arguments(4)
iiscertobj.UserPassword = WScript.Arguments(5)
For Each targetServer in targetServers
  iiscertobj.Copy true, true, targetServer, targetInstance
Next
```

After you save this script as Certcopy.vbs, run this command:

**Certcopy.vbs iisServer1 w3svc/1 iisServer2 w3svc/1 Administrator asdf-0324**

# Extracting Server Certificate Information with a CAPICOM-Based Script

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

CAPICOM is an easy-to-use interface into CryptoAPI. CAPICOM allows you to incorporate Public Key Infrastructure (PKI) functionality into your applications by providing a simple interface for searching the certificate store and using server certificates to sign or encrypt data. Applications using CAPICOM objects call interfaces into CAPICOM.dll. CAPICOM.dll must be present and registered at run time to use CAPICOM objects. If you use CAPICOM objects in a Visual Basic project, you should add CAPICOM.dll to the project references. CAPICOM.dll is available with the Platform SDK. For more information about CAPICOM, see the CAPICOM Reference on MSDN.

**Registering CAPICOM.dll**
To register CAPICOM.dll, at the command prompt, change directories to the directory where CAPICOM.dll is stored, and then type **regsvr32 capicom.dll**.

You can use CAPICOM to create any number of server certificate–related management scripts. Listing 9.15 uses CAPICOM to extract SSL script information from IIS.

**Listing 9.15 Sample Script for Extracting CAPICOM SSL Script Information**

```

# Managing IIS 6.0 Remotely

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can remotely administer your server running IIS on an intranet or the Internet by using WMI or ADSI scripts, or you can use one of the following tools to manage IIS remotely:

- IIS Manager. You can use IIS Manager on your server to remotely connect to and administer an intranet server running IIS 5.0, IIS 5.1, and IIS 6.0. (IIS 3.0 and IIS 4.0 are not supported.)

- Terminal Services. Terminal Services does not require you to install IIS Manager on the remote client computer because once you are connected to the server running IIS, you use IIS Manager on the Web server as if you are logged on locally.

- Remote Administration (HTML) tool. You can use the Remote Administration (HTML) tool to administer your Web server from any Web browser on your intranet. This version of the Remote Administration (HTML) tool runs only on servers running IIS 6.0.

- For more information about using these tools to manage IIS remotely, see Administering Servers Remotely in IIS 6.0.

# Scheduling IIS 6.0 Backups

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Using available tools, you can create a simple script to back up your IIS content and configuration as often as is required in your environment. After you create this script, you can type one additional command to schedule the backup to occur regularly.

**Backing Up IIS Content**

You can include the **xcopy** command in a simple script for copying IIS and backing up content. **Xcopy** offers useful parameters for copying permissions, auditing settings, and copying hidden files.

| **Important** |
|---|
| You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /***User:MyMachine******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any parameters). |

To back up content with **xcopy**, use the following command-line syntax:

**xcopy** *Source Destination* **[/o] [/x] [/e] [/h] [/y] [c]**

Table 9.11 lists relevant **xcopy** parameters.

**Table 9.11 Xcopy Parameters**

| Parameter | Description |
|---|---|
| *Source* | Specifies the name of the source server. |
| *Destination* | Specifies the name of the destination server. |
| **o** | Copies ACLs. |
| **x** | Copies auditing settings (used with /**o**). |
| **e** | Copies the empty directories. |
| **h** | Copies the hidden directories. |
| **y** | Overwrites without prompting. |
| **c** | Continues to copy even if errors occur. |

**Backing Up IIS Configuration**

To back up the metabase, you can run the Iisback.vbs command-line script with the **/backup** parameter, which places a backup file in *systemroot*\System32\Inetsrv\Metaback. After you run Iisback.vbs, you should copy the backup file to your main backup location. These examples use the backup location \\Mybackupserver\Share$.

If you want to create a batch file, you can set the name with dynamic variables, such as **%date%**, and static, user-defined variables, such as **%server%**.

Next, copy the backup files that are created in the *systemroot*\System32\Inetsrv\Metaback folder. The files that are created are named *Name*.MD# and *Name*.SC#, where *Name* is the name you specify and # is the version number of the backup set, starting with zero (0). If you use the same name for subsequent backups, the version number will be incremented by 1 for each backup set that uses the same name. For more information about backing up the metabase, see Working with the Metabase.

Listing 9.16 is an example of a backup batch file that copies both content and configuration.

**Listing 9.16 Backup.bat: Sample Backup Batch File**

```
set server=myserver
```

```
set name=%date%-%server%
iisback /backup /b %name% /e %password%
xcopy %windir%\system32\inetsrv\metaback\%name%.* \\mybackupserver\share$\%server%
xcopy /o /x /e /h /y /c c:\web \\mybackupserver\share$\%server%
```

This batch file copies the backup files and all of the Web content — one or more Web sites that are subfolders of C:\WEB\ — to the backup location that is a subfolder of the folder that has the same name as the server. The defined variables **%server%** and **%name%** allow you to change the server name quickly without having to go through the batch file.

To schedule this backup process as a nightly task at 9 pm, type **at 9:00p /every:m,t,w,th,f,s,su c:\backup.bat** at the command prompt.

For more information about backing up a computer running Windows Server 2003, see How to Back up Data on the Windows Server System 2003 Web site.

# Restarting and Alternatives to Restarting IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In earlier versions of IIS, if an application became unavailable, restarting IIS by using the IISReset.exe command-line tool was a common recovery practice. However, restarting or stopping IIS, or rebooting your Web server is a severe action. When you restart IIS, all of the sessions that are connected to your Web server, including the World Wide Web Publishing service (WWW service), FTP, Simple Mail Transfer Protocol (SMTP), and Network News Transfer Protocol (NNTP), are dropped. Any data held in Web applications is lost, and all of the Internet sites are unavailable until the Internet services are restarted. To avoid this, IIS 6.0 requires fewer restarts than earlier versions of IIS.

For more information about restarting IIS and alternatives to restarting IIS, see Restarting IIS.

| **Important** |
| --- |
| Although using IISReset.exe is not recommended, if you do use IISReset.exe, always use the **/noforce** parameter. The **/noforce** parameter is recommended as a safeguard against data loss in case the IIS services cannot all be stopped within the one-minute time-out period. |

**Automatic Restart**

In IIS 6.0, the WWW service is hosted by the service host, Svchost.exe. The FTP, NNTP, and SMTP services and the IIS metabase, known as the IIS Admin service (IISAdmin.dll), live in Inetinfo.exe. If the IIS Admin service terminates abnormally, IIS restarts automatically. This feature is known as Automatic Restart.

In IIS 5.0, if the IIS Admin service terminated abnormally, both the WWW service and the IIS Admin service had to be restarted because they shared the same application space. In IIS 6.0, if the IIS Admin service terminates abnormally, the WWW service does not go down because the IIS Admin service and the WWW service run in separate process spaces. In this case, the WWW service acknowledges that the metabase has terminated abnormally and checks to see whether IISReset.exe is configured on the IIS Admin service. If IISReset.exe is configured on the IIS Admin service, IIS waits for the IIS Admin service to start again and then reconnects the WWW service.

**Worker Process Isolation Mode**

Worker process isolation mode is the default service mode in IIS; it is designed to ensure that your applications do not interfere with other services and cause the need to restart IIS. If you are running IIS in worker process isolation mode, you can configure it to periodically restart worker processes in the application pool. You can also recycle application pools manually. In addition, you can configure worker process isolation mode so that if a particular application pool experiences consecutive multiple failures, the application can be automatically disabled, allowing for rapid-fail protection. Finally, in worker process isolation mode you can use CPU monitoring, which is a tool for monitoring and automatically shutting down worker processes that consume large amounts of CPU time.

# Additional Resources for IIS 6.0 Administration

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

# Analyzing Log Files

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) 6.0 offers a number of ways to record the activity of your Web sites, File Transfer Protocol (FTP) sites, Network News Transfer Protocol (NNTP) service, and Simple Mail Transfer Protocol (SMTP) service and allows you to choose the log file format that works best for your environment. IIS logging is designed to be more detailed than the event logging or performance monitoring features of the Microsoft® Windows® Server 2003, Standard Edition, Windows® Server 2003, Enterprise Edition, and Windows® Server 2003, Datacenter Edition, operating systems. IIS log files can include information such as who has visited your site, what was viewed, and when the information was last viewed. You can monitor attempts to access your sites, virtual folders, or files and determine whether attempts were made to read or write to your files. IIS log file formats allow you to record events independently for any site, virtual folder, or file.

# What's New in Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Logging in IIS 6.0 differs from logging in previous versions of IIS in several ways. The redesigned IIS architecture, which allows for multiple worker processes, affects how the IIS core components handle logging. In addition, IIS 6.0 provides new logging features and log file formats.

**Events Are Logged by HTTP.sys**
In IIS 5.0, all logging is done by the Inetinfo.exe component and is accomplished using Component Object Model (COM) modules that are written for logging. This system is effective in IIS 5.0 because there is only one server process model, Inetinfo.exe. However, in IIS 6.0, logging is done by the HTTP protocol stack (HTTP.sys). IIS 6.0 passes user-mode events to HTTP.sys through application programming interfaces (APIs), and then the user-mode events are logged by HTTP.sys.

HTTP.sys handles logging for two main reasons. When IIS 6.0 is running in worker process isolation mode, each worker process can perform its own logging and a sites applications can spread across multiple application pools. If Inetinfo.exe performed logging in this environment, multi-instance or synchronization problems could occur. Such problems can be avoided because HTTP.sys performs logging. In addition, in IIS 6.0, requests can be served completely from the HTTP.sys kernel-mode cache without ever passing through Inetinfo.exe, so logging from HTTP.sys ensures that cached responses are recorded.

The log file format for which HTTP.sys does not perform logging is only Open Database Connectivity (ODBC) logging. For more information about how ODBC logging is handled, see ODBC Logging. For more information about the IIS 6.0 architecture and core components, see IIS 6.0 Architecture.

**W3C Centralized Logging**
W3C centralized logging is a global configuration on the server where all Web sites write data to a single log file. This single log file uses the W3C Extended log file format and can be viewed in a text editor, unlike centralized binary logging, which writes data in a binary format and requires a parsing tool to view the data. W3C centralized logging is available in Windows Server 2003 Service Pack 1 or later. For more information about this logging option, see W3C Centralized Logging.

**Substatus Error Code Logging**
To reduce the possibility that a malicious user might use the information provided by substatus error codes to attack the Web server, substatus error codes are not returned to the client in IIS 6.0. Instead, administrators using the World Wide Web Consortium (W3C) Extended log file format can record substatus error codes when requests fail. Substatus error code logging is turned on by default for the W3C Extended log file format. For more information about substatus error code logging, see Substatus Error Codes.

**IIS Centralized Binary Logging**
Centralized binary logging is a process in which IIS creates a single log file that contains binary, unformatted log data for all of the Web sites hosted on a server. In contrast, the other available IIS logging methods create one formatted, human-readable log file per Web site. Centralized binary logging provides organizations with a way to record detailed information about all of their Web sites, using a minimum of system resources. For more information about centralized binary logging, see IIS Centralized Binary Logging.

**HTTP.sys Error Logging**
HTTP.sys sometimes generates its own errors that, because of the IIS 6.0 architecture, are not recorded with the worker-process-driven events. To account for these errors, IIS 6.0 supports HTTP.sys error log files. One example of an event that would trigger a log file entry in the HTTP.sys error log file is a connection time-out. For more information about HTTP.sys error log files, see HTTP.sys Error Log Files.

**Remote Logging**
You can write log data to a remote share over a network using a full, Universal Naming Convention (UNC) path. For example, you can specify *Servername**LogFiles* as the storage directory for your log files, where *Servername*represents the name of the remote server, and *LogFiles* represents the name of the directory where the log files are stored.

For more information about remote logging, see Remote Logging.

# Log File Formats in IIS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS provides six different log file formats that you can use to track and analyze information about your IIS-based sites and services. In addition to the six available formats, you can create your own custom log file format. For more information about custom logging, see Custom Logging Modules.

The following log file formats and logging options are available in IIS:

- W3C Extended Log File Format Text-based, customizable format for a single site. This is the default format.
- W3C Centralized Logging All data from all Web sites is recorded in a single log file in the W3C log file format.
- NCSA Common Log File Format Text-based, fixed format for a single site.
- IIS Log File Format Text-based, fixed format for a single site.
- ODBC Logging Fixed format for a single site. Data is recorded in an ODBC-compliant database.
- Centralized Binary Logging Binary-based, unformatted data that is not customizable. Data is recorded from multiple Web sites and sent to a single log file. To interpret the data, you need a special parser.
- HTTP.sys Error Log Files Fixed format for HTTP.sys-generated errors.

You can read text-based log files using a text editor such as Notepad, which is included with Windows, but administrators often import the files into a report-generating software tool for further analysis.

For step-by-step instructions on how to enable logging, see Enabling Logging.

**UTF-8 Format for Non-English Languages and Security**
*UTF-8* is a method of character encoding that allows for both single and multibyte characters in one string. If you want to read text-based (W3C Extended, IIS, and NCSA Common) log files in a language other than English, you can enable the UTF-8 format. You also need the UTF-8 format if you serve URLs in a language other than the native server code page, for example, if you serve Chinese URLs on a Japanese system. In addition, because IIS 6.0 tries to serve URLs in code pages other than the server default code page by default, you might want to enable the UTF-8 format for security reasons. It is a good security practice to enable the UTF-8 format in case of an attack based on URLs in UTF-8 that might not translate correctly to the default code page.

| **Note** |
| --- |
| IIS does not support the UTF-8 format for FTP site log files. |

For information about enabling UTF-8, see Enabling UTF-8 Format for Non-English Languages and Security.

**Log File Locations and ACLs**
If you create a log file directory of C:\LogFilesfor HTTP.sys-generated logging (W3C Extended log file format, NCSA Common log file format, IIS log file format, centralized binary logging, or HTTP.sys error logging), then HTTP.sys generates the following subdirectories, and the log files are created under these subdirectories:

- For the W3C Extended, NCSA Common, and IIS log file formats, HTTP.sys generates the subdirectory C:\LogFiles\W3SVC#, where # is the site ID.
- For centralized binary logging, HTTP.sys generates the subdirectory C:\LogFiles\W3SVC.
- For HTTP.sys error logging, HTTP.sys generates the subdirectory C:\WINDOWS\System32\LogFiles\HTTPErr.

By default, the log file directory has the following access control lists (ACLs):

- NT Authority\System: Full access
- Built-in\Administrators: Full access
- Everyone: No access (Although the No access permission is the effective permission, this setting is not explicitly set by HTTP.sys.)

Individual log files in the log file directory have the following controls:

- NT Authority\System: Full access
- Built-in\Administrators: Read and delete access
- Everyone: No access (Although the No access permission is the effective permission, this setting is not explicitly set by HTTP.sys.)

| **Important** |
| --- |
| The default log file directory ACLs (DACLs) are set for optimum security. If you choose to create log file directories with less restrictive ACLs, your system might be more vulnerable to attack. |

If you are using the W3C Extended, NCSA Common, or IIS log file formats and it is necessary to do so, you can create a subdirectory called W3SVC# of the C:\LogFiles directory and set ACLs for that directory that are different from the defaults. For example, if you need to allow a site administrator to read the log files, create a W3SVC# subdirectory of the C:\LogFiles directory and set Read ACLs for the site's administrator.

| **Important** |
| --- |
| The owner of the W3SVC# subdirectory must be a member of the Local Administrators group. If not, HTTP.sys writes an error to the NT Event log and disables logging. |

For more information about file and directory security and access control, see Managing a Secure IIS 6.0 Solution.

# W3C Extended Log File Format

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The W3C Extended log file format is the default log file format for IIS. It is a customizable ASCII text-based format. You can use IIS Manager to select which fields to include in the log file, which enables you to keep log files as small as possible. Because HTTP.sys handles the W3C Extended log file format, this format records HTTP.sys kernel-mode cache hits.

Table 10.1 lists and describes the available fields. Default fields are noted.

**Table 10.1 W3C Extended Log File Fields**

| Field | Appears As | Description | Default Y/N |
|---|---|---|---|
| Date | date | The date on which the activity occurred. | Y |
| Time | time | The time, in coordinated universal time (UTC), at which the activity occurred. | Y |
| Client IP Address | c-ip | The IP address of the client that made the request. | Y |
| User Name | cs-username | The name of the authenticated user who accessed your server. Anonymous users are indicated by a hyphen. | Y |
| Service Name and Instance Number | s-sitename | The Internet service name and instance number that was running on the client. | N |
| Server Name | s-computername | The name of the server on which the log file entry was generated. | N |
| Server IP Address | s-ip | The IP address of the server on which the log file entry was generated. | Y |
| Server Port | s-port | The server port number that is configured for the service. | Y |
| Method | cs-method | The requested action, for example, a GET method. | Y |
| URI Stem | cs-uri-stem | The target of the action, for example, Default.htm. | Y |
| URI Query | cs-uri-query | The query, if any, that the client was trying to perform. A Universal Resource Identifier (URI) query is necessary only for dynamic pages. | Y |
| HTTP Status | sc-status | The HTTP status code. | Y |
| Win32 Status | sc-win32-status | The Windows status code. | N |
| Bytes Sent | sc-bytes | The number of bytes that the server sent. | N |
| Bytes Received | cs-bytes | The number of bytes that the server received. | N |
| Time Taken | time-taken | The length of time that the action took, in milliseconds. | N |
| Protocol Version | cs-version | The protocol version see commentHTTP or FTP see commentthat the client used. | N |
| Host | cs-host | The host header name, if any. | N |

| | | | |
|---|---|---|---|
| User Agent | cs(User-Agent) | The browser type that the client used. | Y |
| Cookie | cs(Cookie) | The content of the cookie sent or received, if any. | N |
| Referrer | cs(Referrer) | The site that the user last visited. This site provided a link to the current site. | N |
| Protocol Substatus | sc-substatus | The substatus error code. | Y |

You can select as many of the W3C Extended log file fields as you want. Some fields may not contain information. When a select field does not contain information, a hyphen (-) appears as a placeholder. If a field contains a nonprintable character, HTTP.sys replaces it with a plus sign (+) to preserve the log file format. Nonprintable characters can appear as a result of virus attacks such as when a malicious user sends carriage returns and line feeds that could break the log file format. You can avoid this problem if you replace nonprintable characters with the plus sign (+).

Fields are separated by spaces. Field prefixes have the following meanings:

- s- Server actions
- c- Client actions
- cs- Client-to-server actions
- sc- Server-to-client actions

**Note**

FTP log files do not record the following fields:

- cs-uri-query
- cs-host
- cs(User-Agent)
- cs(Cookie)
- cs(Referrer)
- sc-substatus

**Note**

For the **Time Taken** field, the client-request time stamp is initialized when HTTP.sys starts parsing the request. If the response size is less than or equal to 2 kilobytes and from memory, or the **force buffer** flag is set, the **Time Taken** value usually does not include network time. Otherwise, the **TimeTaken** value generally includes network time. For more information about the **Time Taken** field in IIS, see Description of the time-taken field in IIS 6.0 and IIS 7.0 HTTP logging.

For information about status codes, see IIS Status Codes.

For more information about the W3C Extended log file format, see Extended Log File Format.

For information about HTTP request buffering that uses the HTTP Server API Version 1, see HttpSendHttpResponse Function.

# W3C Extended Log File Examples

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

**Example of an Intranet Site**

The following example shows a W3C Extended log file entry from an intranet site, as viewed in a text editor. The log file includes only the default fields.

```
#Software: Microsoft Internet Information Services 6.0
#Version: 1.0
#Date: 2002-05-02 17:42:15
#Fields: date time c-ip cs-username s-ip s-port cs-method cs-uri-stem cs-uri-query sc-status cs(User-Agent)
2002-05-02 17:42:15 172.22.255.255 - 172.30.255.255 80 GET /images/picture.jpg - 200 Mozilla/4.0+(compatible;MSIE+5.5;+Windows+2000+Server)
```

You can interpret the preceding log file entry as follows:

#Software: Microsoft Internet Information Services 6.0

This indicates the version of IIS that is running.

#Version: 1.0

This indicates the log file format.

#Date: 2002-05-02 17:42:15

This indicates when the first log file entry was recorded, which is when the entire log file was created.

#Fields: date time c-ip cs-username s-ip s-port cs-method cs-uri-stem ...

This indicates the fields that are recorded in the log file entry and the order in which they are recorded

Table 10.2 lists and describes the fields that are recorded in this example.

| **Note** |
|---|
| Use the order shown in the Fields log file entry to parse all entries until the next log file entry begins. The field order is subject to change and is different in IIS 6.0 than it was in IIS 5.0. |

**Table 10.2 Example of a W3C Extended Log File Entry from an Intranet Site**

| Field | Appears As | Description |
|---|---|---|
| date | 2002-05-02 | This log file entry was recorded on May 2, 2002. |
| time | 17:42:15 | This log file entry was recorded at 5:42 P.M. UTC. Entries are recorded to the log file when the send completion for the last IIS send occurs. |
| c-ip | 172.22.255.255 | The IP address of the client. |
| cs-username | - | The user was anonymous. |
| s-ip | 172.30.255.255 | The IP address of the server. |
| s-port | 80 | The server port. |
| cs-method | GET | The user issued a **GET**, or download, command. |

| | | |
|---|---|---|
| cs-uri-stem | /images/picture.jpg | The user wanted to download the picture.jpg file from the Images folder. |
| cs-uri-query | - | The URI query did not occur. (URI queries are necessary only for dynamic pages, such as ASP pages, so this field usually contains a hyphen for static pages.) |
| sc-status | 200 | The request was fulfilled with no errors. |
| cs(User-Agent) | Mozilla/4.0+ (compatible;MSIE+5.5;+Windows+2000+Server) | The type of browser that the client used, as represented by the browser. |

**Example of an Internet Site**

The following example shows a W3C Extended log file entry from an Internet site, as viewed in a text editor. The log file contains several fields in addition to the default fields and is typical of the kind of log file you would run to monitor an Internet site.

```
#Software: Microsoft Internet Information Services 6.0
#Version: 1.0
#Date: 2002-05-24 20:18:01
#Fields: date time c-ip cs-username s-ip s-port cs-method cs-uri-stem cs-uri-query sc-
status sc-bytes cs-bytes time-taken cs(User-Agent) cs(Referrer)
2002-05-24 20:18:01 172.224.24.114 - 206.73.118.24 80 GET /Default.htm - 200 7930 248
31 Mozilla/4.0+(compatible;+MSIE+5.01;+Windows+2000+Server) http://64.224.24.114/
```

You can interpret the preceding log file entry as follows:

#Software: Microsoft Internet Information Services 6.0

This indicates the version of IIS that is running.

#Version: 1.0

This indicates the log file format.

#Date: 2002-05-24 20:18:01

This indicates when the first log file entry was recorded, which is when the entire log file was created.

#Fields: date time c-ip cs-username s-ip s-port cs-method cs-uri-stem ...

This indicates the fields that are recorded in the log file entry and the order in which they are recorded. Table 10.3 lists and describes the fields recorded in this example.

**Table 10.3 Example of a W3C Extended Log File Entry from an Internet Site**

| Field | Appears As | Description |
|---|---|---|
| date | 2002-05-24 | This log file entry was recorded on May 24, 2002. |
| time | 20:18:01 | This log file entry was recorded at 8:18 P.M. UTC. |
| c-ip | 172.224.24.114 | The IP address of the client. |
| cs-username | - | The user was anonymous. |
| s-ip | 206.73.118.24 | The IP address of the server. |
| s-port | 80 | The server port. |
| cs-method | GET | The user issued a **GET**, or download, command. |
| cs-uri-stem | /Default.htm | The user wanted to download the contents of Default.htm. |
| cs-uri-query | - | The URI query did not occur. |

| | | |
|---|---|---|
| sc-status | 200 | The request was fulfilled without error. |
| sc-bytes | 7930 | The number of bytes that the server sent to the client. |
| cs-bytes | 248 | The number of bytes that the client sent to the server. |
| time-taken | 31 | The action was completed in 31 milliseconds. |
| cs(User-Agent) | Mozilla/4.0+ (compatible;+MSIE+5.01;+Windows+2000+Server) | The type of browser that the client used, as represented by the browser. |
| cs(Referrer) | http://62.224.24.114/ | The Web page that provided the link to the Web site. |

**Example of an FTP Site**

The following example shows a W3C Extended log file entry from an Internet FTP site, as viewed in a text editor. The example does not include all of the default fields and is typical of the kind of log file that you would run to monitor an FTP site.

```
#Software: Microsoft Internet Information Services 6.0
#Version: 1.0
#Date: 2002-06-04 16:40:23
#Fields: time c-ip cs-method cs-uri-stem sc-status
16:40:23 10.152.10.200 [6994]USER anonymous 331
16:40:25 10.152.10.200 [6994]PASS anonymous@example.net 530
```

You can interpret the preceding log file example as follows:

#Software: Microsoft Internet Information Services 6.0

This indicates the version of IIS that is running.

#Version: 1.0

This indicates the log file format.

#Date: 2002-06-04 16:40:23

This indicates when the first log file entry was recorded, which is when the log was created.

#Fields: time c-ip cs-method cs-uri-stem sc-status

This indicates the fields that are recorded in the log file entry and the order in which they are recorded. Table 10.4 lists and describes the fields recorded in this example.

**Table 10.4 Example of a W3C Extended Log File Entry from an FTP Site**

| Field | Appears As | Description |
|---|---|---|
| time | 16:40:23 | This log file entry was recorded at 4:40 P.M. UTC. |
| c-ip | 10.152.10.200 | The IP address of the client. |
| cs-method | [6994]USER | The **USER FTP** command was used, which requests a user name and is always followed by a **PASS FTP** command. 6994 is the connection number corresponding to an anonymous user. |
| cs-uri-stem | anonymous | The user (the target of the **USER** command) was anonymous. |
| sc-status | 331 | The user name was accepted. |
| time | 16:40:25 | The next recorded action occurred at 4:40 P.M. UTC. |
| c-ip | 10.152.10.200 | The IP address of the client. |
| cs-method | [6994]PASS | The **PASS FTP** command was used, which supplies a password for the user name and is always preceded by a **USER** command. |

| | | |
|---|---|---|
| cs-uri-stem | anonymous@example.net | The password (the target of the **PASS** command) supplied. |
| sc-status | 530 | The user was not logged on. |

# Substatus Error Codes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In an effort to reduce the attack surface of IIS, in IIS 6.0, error messages do not return specific error message content, including the substatus error code, to clients. However, to allow administrators to track errors and debug failed requests, IIS provides the ability to record substatus error codes in the W3C Extended log file format. Substatus error code logging is enabled by default. For more information about enabling and disabling substatus error code logging, see Substatus Error Codes in Log Files.

If an error message contains too much information about the server and an explanation of why a particular request failed to execute, malicious users can use the information from the error message to attack the server. For example, an error code such as 404.2 indicates that a file or directory is not returned because the server lockdown policy restricts it. In IIS 6.0, a 404.2 error is returned to the client as a 404 error message. The simple 404 error message does not provide a malicious user with any details about the configuration of the server.

When substatus error code logging is enabled by default, only members of the Administrators group and users with LocalSystem user accounts can access log files that contain substatus error codes. To analyze an error, the administrator locates the error and substatus error code in the log file and checks the code against the IIS 6.0 HTTP.sys error code list. For example, if a client request to an Active Server Pages (ASP) page returned a 403 error, the administrator can determine that the actual error was 403.9 by viewing the log file. The administrator checks the IIS 6.0 HTTP.sys error code list and learns that, in this situation, the file or directory was not found because too many clients were trying to connect to the server at once. The administrator can remedy the situation quickly and easily by changing the maximum number of connections setting to unlimited. To see the IIS 6.0 HTTP.sys error code list, see HTTP Status Codes in IIS 6.0.

# W3C Centralized Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

W3C centralized logging is a global configuration on the server where all Web sites write data to a single log file. Data is stored in the log file using the W3C Extended log file format. The log file can be viewed in a text editor, unlike IIS Centralized Binary Logging which writes data in binary format and requires a parsing tool to view the data. W3C centralized logging is available in Windows Server 2003 Service Pack 1 or later.

| **Important** |
| --- |
| FTP, NNTP, and SMTP do not support W3C centralized logging. |

By default, IIS Web sites write data to individual log files (one log file per Web site). On servers hosting large numbers of sites (hundreds or thousands), the process of maintaining large numbers of open file handles to log files can negatively impact how the server scales. W3C centralized logging improves server scalability on servers hosting large numbers of sites because IIS requires only one open file handle for logging.

W3C centralized logging is a server property, not a site property, so when you enable this feature all Web sites on that server are configured to write log data to the central log file.

| **Note** |
| --- |
| W3C centralized logging uses the W3C Extended log format, which includes the following four fields: **HostHeader**, **Cookie**, **UserAgent**, and **Referrer**. These fields are not available with centralized binary logging. |

For the procedure to enable W3C centralized logging, see Enabling W3C Centralized Logging.

# NCSA Common Log File Format

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The NCSA Common log file format is a fixed ASCII text-based format, so you cannot customize it. The NCSA Common log file format is available for Web sites and for SMTP and NNTP services, but it is not available for FTP sites. Because HTTP.sys handles the NCSA Common log file format, this format records HTTP.sys kernel-mode cache hits.

The NCSA Common log file format records the following data:

- Remote host address
- Remote log name (This value is always a hyphen.)
- User name
- Date, time, and Greenwich mean time (GMT) offset
- Request and protocol version
- Service status code (A value of 200 indicates that the request was fulfilled successfully.)
- Bytes sent

Not all fields will contain information. For fields for which there is no information, a hyphen (-) appears as a placeholder. If a field contains a nonprintable character, HTTP.sys replaces it with a plus sign (+) to preserve the log file format. This typically occurs with virus attacks, when, for example, a malicious user sends carriage returns and line feeds that, if not replaced with the plus sign (+), would break the log file format.

Fields are separated by spaces, and time is recorded as local time with the GMT offset.

# NCSA Common Log File Example

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following example shows an NCSA Common log file entry, as viewed in a text editor.

```
172.21.13.45 - Microsoft\JohnDoe [08/Apr/2001:17:39:04 -0800] "GET
/scripts/iisadmin/ism.dll?http/serv HTTP/1.0" 200 3401
```

Table 10.5 lists and describes the fields recorded in this example.

**Table 10.5 Example of an NCSA Common Log File Entry**

| Field | Appears As | Description |
|---|---|---|
| Remote host address | 172.21.13.45 | The IP address of the client. |
| Remote log name | - | The name is unavailable. |
| User name | Microsoft\JohnDoe | The name of the user is JohnDoe. |
| Date, time, and GMT offset | [08/Apr/2001:17:39:04 -0800] | The log file entry was created on April 8, 2001 at 5:39 P.M. The difference between the local time and the GMT is eight hours. |
| Request and protocol version | GET /scripts/iisadmin/ism.dll?http/serv HTTP/1.0 | The client issued a **GET** command for the Ism.dll file using HTTP version 1.0. |
| Service status code | 200 | The request was fulfilled successfully. |
| Bytes sent | 3401 | The number of bytes sent. |

# IIS Log File Format

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS log file format is a fixed ASCII text-based format, so you cannot customize it. Because HTTP.sys handles the IIS log file format, this format records HTTP.sys kernel-mode cache hits.

The IIS log file format records the following data:

- Client IP address
- User name
- Date
- Time
- Service and instance
- Server name
- Server IP address
- Time taken
- Client bytes sent
- Server bytes sent
- Service status code (A value of 200 indicates that the request was fulfilled successfully.)
- Windows status code (A value of 0 indicates that the request was fulfilled successfully.)
- Request type
- Target of operation
- Parameters (the parameters that are passed to a script)

Not all fields will contain information. For fields for which there is no information, a hyphen (-) appears as a placeholder. If a field contains a nonprintable character, HTTP.sys replaces it with a plus sign (+) to preserve the log file format. This typically occurs with virus attacks, when, for example, a malicious user sends carriage returns and line feeds that, if not replaced with the plus sign (+), would break the log file format.

Fields are separated by commas, making the format easier to read than the other ASCII formats, which use spaces for separators. The time is recorded as local time. A Web site instance is displayed as W3SVC#, and an FTP site instance is displayed as MSFTPSVC#, where # is the instance of the site. Time taken is recorded in milliseconds. For more information about the time taken field, see W3C Extended Log File Format.

# IIS Log File Example

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following example shows an IIS log file entry, as viewed in a text editor:

```
192.168.114.201, -, 03/20/01, 7:55:20, W3SVC2, SERVER, 172.21.13.45, 4502, 163, 3223,
200, 0, GET, /DeptLogo.gif, -,
```

Table 10.6 lists and describes the fields recorded in this example.

**Table 10.6 Example of an IIS Log File Entry**

| Field | Appears As | Description |
|---|---|---|
| Client IP address | 192.168.114.201 | The IP address of the client. |
| User name | - | The user is anonymous. |
| Date | 03/20/01 | This log file entry was made on March 20, 2001. |
| Time | 7:55:20 | This log file entry was recorded at 7:55 A.M. |
| Service and instance | W3SVC2 | This is a Web site, and the site instance is 2. |
| Server name | SERVER | The name of the server. |
| Server IP | 172.21.13.45 | The IP address of the server. |
| Time taken | 4502 | This action took 4,502 milliseconds. |
| Client bytes sent | 163 | The number of bytes sent from the client to the server. |
| Server bytes sent | 3223 | The number of bytes sent from the server to the client. |
| Service status code | 200 | The request was fulfilled successfully. |
| Windows status code | 0 | The request was fulfilled successfully. |
| Request type | GET | The user issued a **GET**, or download, command. |
| Target of operation | /DeptLogo.gif | The user wanted to download the DeptLogo.gif file. |
| Parameters | - | There were no parameters passed. |

# ODBC Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ODBC logging records a fixed set of data fields in an ODBC-compliant database, such as Microsoft® Access or Microsoft® SQL Server™. With ODBC logging, you must set up a database to receive the data, and then specify this database as the database to which log files should be recorded.

When ODBC logging is enabled, IIS disables the HTTP.sys kernel-mode cache. For this reason, implementing ODBC logging will degrade overall server performance. ODBC logging is not recommended unless your database limits you to this option.

IIS includes a Structured Query Language (SQL) template file that you can run in a SQL database to create a table that accepts log file entries from IIS. The file is named Logtemp.sql, and it is located in the *systemroot*\System32\Inetsrv directory by default.

**Important**

For security reasons, do not use the well-known SQL Server administrator account name SA for ODBC logging. If a malicious user accessed the worker process, that user could use the SA account to access the SQL Server. Remove the SA account, and create a new account with the least necessary rights. For more information, see SQL Server 2000 Operations Guide: Security Administration.

Table 10.7 lists the fields, data types, and descriptions of the fields recorded in the ODBC logging format.

**Table 10.7 ODBC Logging Fields**

| Field | Data Type | Description |
|---|---|---|
| ClientHost | varchar(255) | The IP address of the client. |
| UserName | varchar(255) | The domain name of the client. |
| LogTime | datetime | The connection date and time. |
| Service | varchar(255) | The IIS service. |
| Machine | varchar(255) | The name of the computer. |
| ServerIP | varchar(50) | The IP address of the server. |
| ProcessingTime | integer | The processing time, in milliseconds. |
| BytesRecvd | integer | The number of bytes that the server received. |
| BytesSent | integer | The number of bytes that the server sent. |
| ServiceStatus | integer | The service status or reply code. A value of 200 indicates that the request was fulfilled successfully. |
| Win32Status | integer | The Windows status or error code. A value of 0 indicates that the request was fulfilled successfully. |
| Operation | varchar(255) | The command that the user requested. |
| Target | varchar(255) | The recipient. |
| Parameters | varchar(255) | The request parameters that the client sent. |

# IIS Centralized Binary Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Centralized binary logging is a process where multiple Web sites send binary, unformatted log data to a single log file. In contrast, the other IIS logging methods create one log file per Web site.

| **Important** |
| --- |
| FTP, NNTP, and SMTP do not support centralized binary logging. |

When a server running IIS hosts many Web sites, the process of creating hundreds or thousands of formatted log files and writing the log data to a disk can quickly consume valuable CPU and memory resources, thereby creating performance and scalability problems. Centralized binary logging minimizes the amount of system resources that are used for logging, while at the same time providing detailed log data for organizations that require it.

Centralized binary logging is a server property, not a site property, so when you enable centralized binary logging on a server, all of the Web sites on that server are configured to write log data to the central log file. When you enable centralized binary logging, you cannot record data from individual Web sites in a different format. The centralized binary logging log file has an Internet binary log (.ibl) file name extension. This file name extension ensures that text utilities do not try to open and read the central binary logging log file.

When to Use Centralized Binary Logging

Centralized binary logging is particularly useful when many Web sites are hosted on the same server or where server resources are at a premium. With centralized binary logging, an administrator can maximize the number of Web sites that a server can host and record activity for because centralized binary logging reduces the amount of system resources that are consumed during logging and decreases code paths in IIS, thus increasing performance and scalability.

Centralized binary logging can also reduce administration burdens for Internet service providers (ISPs) for whom collecting and storing logged data is imperative. For example, if an ISP has six servers with 10,000 Web sites per server, the ISP would have to manage 10,000 log files per day per server running IIS. With centralized binary logging, the ISP would have to manage and store only one file per server, per day.

Log files can be vital to troubleshooting applications. However, an organization might not want to take up system resources for log files that are used only in debugging situations. For example, a Web application team at an enterprise organization uses ASP and Microsoft® Visual Basic® development system to develop COM components that access a SQL database. The application team needs to maximize the response time of individual requests and maximize the amount of concurrent work that a group of servers can handle. Central binary logging can help the team achieve these goals.

For information about enabling centralized binary logging for all Web sites hosted on a server running IIS 6.0, see Centralized Binary Logging in IIS 6.0.

When you are ready to extract data from a raw log file, you can do one of the following:

- Create a tool that locates and extracts the data that you want from the raw file and converts the data into formatted text. You can view a header file and log file format descriptions in the IIS 6.0 Software Development Kit on MSDN.

- Use the Log Parser tool to extract data from the raw file. The Log Parser tool and its accompanying user documentation are included in the IIS 6.0 Resource Kit Tools.

Centralized Binary Logging File Format

The raw centralized binary logging log file is made up of fixed-length records or index records that contain string identifiers. The index records appear because, in an effort to record as much information as possible, variable-length string fields are replaced by numeric identifiers — indexes — that map the variable-length string to the logged identifier.

The raw log file is not human-readable, and it cannot be read using most available log analyzers. To extract data from a raw log file, you can create a tool that locates and extracts the data and then converts it into formatted text. For more information about the header file and log file format descriptions that you need to create such a tool, see Centralized Binary Log File Format.

Centralized binary logging records the following information, which is similar, but not identical, to the W3C Extended log file

format:

- Date
- Time
- Client IP address
- User name
- Site ID
- Server name
- Server IP address
- Server port
- Method
- URI stem
- URI query
- Protocol status
- Windows status
- Bytes sent
- Bytes received
- Time taken
- Protocol version
- Protocol substatus

For information about the **Time Taken** field, see W3C Extended Log File Format.

| **Note** |
| --- |
| The following fields are reported in W3C Extended log files, but they are not recorded in centralized binary logging log files: |

- Host. The host header.
- User agent. The browser type of the client; this string is too large to be practical for the binary format.
- Cookie. The content of the cookie that was sent.
- Referrer. The site that the user last visited.

# Centralized Binary Log File Format

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Centralized binary log files require a specialized parser to interpret the log data. You can use the file format provided in this appendix to create a custom parser.

See Also

**Concepts**

Analyzing Log Files

# Centralized Binary Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Centralized binary logging was designed to log as much information as possible while using the least amount of system resources. Therefore, numeric identifiers, which are called *indexes*, are substituted for variable-length strings in key fields. The indexes map the variable-length string to the logged identifier. When centralized binary logging is enabled, every site hosted on a server running Internet Information Services (IIS) sends raw log data to a single file.

# IIS Binary Log File Names

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The binary log file has an Internet binary log, or .ibl, file name extension. This file name extension was created so that text utilities that recognize the .log format would not attempt to open the binary log file.

Depending on the recycling option you choose, the binary log file will be named as follows:

- **Date-based recycling**: rayymmddhh.ibl. The time in the name is expressed in Universal Coordinated Time (UTC).
- **Size recycling**: raw#.ibl. IIS assigns a number to each log file, in increments of one. The # represents the number of the log file.

# Record Order

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The typical central binary log file has the records shown in Figure F.1, and they appear in the order shown. However, the exact order depends on the arrival order of cache-hit requests and cache-miss requests.

# Record Types

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

All binary log record files have a two-byte **RecordType** field defined as the first element. Parsers should read the **USHORT** field first to determine the record type before parsing the whole record. Table F.1 lists the numbers that represent the binary log file record types.

Table F.1 Record Types

| Record Type | Number |
|---|---|
| #define HTTP_RAW_RECORD_HEADER_TYPE | (0) |
| #define HTTP_RAW_RECORD_INDEX_DATA_TYPE | (2) |
| #define HTTP_RAW_RECORD_HIT_LOG_DATA_TYPE | (3) |
| #define HTTP_RAW_RECORD_MISS_LOG_DATA_TYPE | (4) |
| #define HTTP_RAW_RECORD_CACHE_NOTIFICATION_DATA_TYPE | (5) |

Basic data types, such as **ULONG**, shown in the records in the rest of this appendix are written to the binary log file in host order, unless otherwise specified.

| **Note** |
|---|
| You must use the Windows.H header file to make most of the following data types available. For more information about the Windows.H header file, search for Windows.H on MSDN. |

Header Record

The header record is the first log file record. It contains fields that identify which server generated the log file, and the date and time that the file was created. This information enables you to validate the file, see the statement of capabilities, and move the logs from one computer to another for post-processing, all without losing the source of the information.

A header record is always included at the beginning of each log file, and if the server is restarted during the logging period, header records are also written into the middle of each log file. For example, if the server is configured to start a new log file every day and the server is then restarted in the middle of the day, a second header is placed in the middle of that days log file.

Example F.1 contains a description of the header record with inline comments.

Example F.1 Header Record

| **Note** |
|---|
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
#define MAX_COMPUTER_NAME_LEN           (256)

typedef struct _RAW_FILE_HEADER
{
    // Must be RAW_RECORD_HEADER_TYPE, i.e. value is 0
    //
    USHORT          RecordType;

    // Identifies the version of the Internet Binary Log File.
    //
    union {
```

```
        struct {
            UCHAR MajorVersion; // MAJOR_RAW_LOG_FILE_VERSION == 1
            UCHAR MinorVersion; // MINOR_RAW_LOG_FILE_VERSION == 0
        };
        USHORT Version;
    };

    // Shows the alignment padding size. sizeof(PVOID). Important for    // parsers to
be able to determine the padding size (depending on    // the processor architecture of
the computer that generated the    // log field). ie. X86 == 4 bytes ia64 == 8 bytes.
    //
    ULONG           AlignmentSize;

// UTC based system timestamp for the raw file creation/opening. (Can// be used  to
populate a FILETIME structure.)
//
    LARGE_INTEGER   DateTime;

    // Name of the server which created/opened the raw file. Maximum    // computer
name length is set to 256, and it is null-terminated if    // the length is not exactly
256 characters. This is important to    // identify the source computer for the log. In
either case, the    // parser should skip the remaining bytes to reach the next record.
    //
    WCHAR           ComputerName[MAX_COMPUTER_NAME_LEN];

} RAW_FILE_HEADER, *PRAW_FILE_HEADER;
```

File Footers

The binary log file format does not write a footer. You can detect the next file based on the timestamps in the header and the log file records written in the previous log file.

Inline Records

Each request record contains the following inline records:

- The RAWLOGID, which is a unique identifier for URLs.
- An IP address type flag, which tells you whether the IP address is IPv4 or IPv6.

**Unique identifier for URLs**

Centralized binary logging contains a 64-bit URL identifier. To conserve space, frequent URLs are written once and then given a random identifier called the RAWLOGID. Example F.2 lists a RAWLOGID.

Example F.2 URL Identifier

| **Note** |
| --- |
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
typedef struct _RAWLOGID
{
    //
    // The identifier is a 64-bit field and is a random number.
    //

    ULONG   UIDLowPart;
    ULONG   UIDHighPart;

} RAWLOGID, *PRAWLOGID;
```

**IP address type**

Each request record has either an IPv4 or IPv6 address encoded within it. Additionally, a flag in the first part of the log entry

indicates the IP version of the address field. Example F.3 lists an IPv4 address, and Example F.4 lists an IPv6 address.

Example F.3 IPv4 Address

| **Note** |
| --- |
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
typedef struct _RAWLOG_IPV4_ADDRESSES {

    // The IPV4 client address or source of the request
    ULONG client;

    // The IPV4 server address or address of the server that received    // the request
ULONG server;

} RAWLOG_IPV4_ADDRESSES, *PRAWLOG_IPV4_ADDRESSES;
```

Example F.4 IPv6 Address

| **Note** |
| --- |
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
typedef struct _RAWLOG_IPV6_ADDRESSES {

    // The IPV6 client address or source of the request
   USHORT client[8];

    // The IPV6 server address or address of the server that received    // the request
   USHORT server[8];

} RAWLOG_IPV6_ADDRESSES, *PRAWLOG_IPV6_ADDRESSES;
```

Cache or User-Mode Request

For every HTTP request sent to IIS 6.0, the HTTP protocol stack (HTTP.sys) checks the cache entry for a response that matches the incoming request. If the request matches, then HTTP.sys fulfills the request from the cache. If the request does not match, then requests are sent to the user-mode IIS worker process for further processing. The binary log file contains one record type for cache hits and a different record type for cache misses, which are requests sent to the user-mode IIS worker process.

Centralized binary logging records data for all of the fields that are recorded by default in W3C Extended logging format, except for the User-Agent field. This field is too large to record because the string comes from the client browser, and if an index is used, then it would imply the comparison and hashing of this field for every record that is logged.

Cache-Hit Record

Example F.5 applies to requests that are served directly from the HTTP.sys cache. There is one record per request.

Example F.5 Cache-Hit Record

| **Note** |
| --- |
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
typedef struct _RAW_FILE_HIT_LOG_DATA
{
    // Type must be RAW_RECORD_HIT_LOG_DATA_TYPE i.e. value is 3.
```

```
    //
    USHORT          RecordType;

    // Optional flags.
    //
    union
    {
        struct
        {
            USHORT IPv6:1;              // Are IPs for this request IPv6 or not?
            USHORT ProtocolVersion:3;   // See protocol version table below.
            USHORT Method:6;            // See HTTP Verb Table below.
            USHORT Reserved:6;
        };
        USHORT Value;
    } Flags;

    // Site ID. Represents which site owns this log record as per the
    // metabase numeric metabase SiteID.
    //
    ULONG           SiteID;

    // UTC Timestamp for the Log Hit.
    //
    LARGE_INTEGER   DateTime;

    // The IP Port the request came in on
    //
    USHORT          ServerPort;

    // ProtocolStatus - 200, 404, 503 etc - value should never be
    // greater than 999
    //
    USHORT          ProtocolStatus;

    // Other fields of the response
    //
    ULONG           Win32Status;
    ULONGLONG       TimeTaken;      // in milliseconds
    ULONGLONG       BytesSent;   // in bytes
    ULONGLONG       BytesReceived; // in bytes

    // For cache hits, there will always be at least one Uri Index    // record written
prior to this record. (see _RAW_INDEX_FIELD_DATA    // record)
    //
    RAWLOGID   UriId;

    // Either IPv4 or IPv6 address structure will follow.
    //
    // _RAWLOG_IPV4_ADDRESSES or
    // _RAWLOG_IPV6_ADDRESSES

} RAW_FILE_HIT_LOG_DATA, *PRAW_FILE_HIT_LOG_DATA;
```

Table F.2 lists the values that correspond to each protocol version.

Table F.2 Protocol Versions

| Value | Protocol Version |
|---|---|
| 0 | Unknown |
| 1 | HTTP 0.9 |
| 2 | HTTP 1.0 |
| 3 | HTTP 1.1 |

Table F.3 lists the HTTP methods used for the binary log file format. The mapping of the method field is essentially the same as the HTTP_VERB type definition in the Http.h HTTP API header file in the Microsoft Platform SDK. For more information about the Http.h header file, see HTTP API.

**Table F.3 HTTP Methods**

| Value | HTTP Method |
|---|---|
| 0 | Unparsed |
| 1 | Unknown (for new verbs) |
| 2 | Invalid |
| 3 | OPTIONS |
| 4 | GET |
| 5 | HEAD |
| 6 | POST |
| 7 | PUT |
| 8 | DELETE |
| 9 | TRACE |
| 10 | CONNECT |
| 11 | TRACK |
| 12 | MOVE |
| 13 | COPY |
| 14 | PROPFIND |
| 15 | PROPPATCH |
| 16 | MKCOL |
| 17 | LOCK |
| 18 | UNLOCK |
| 19 | SEARCH |

Cache-Miss Record

Example F.6 applies to requests that are served from the user-mode worker process. There is one record per request.

**Example F.6 Cache-Miss Record**

| **Note** |
|---|
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
typedef struct _RAW_FILE_MISS_LOG_DATA
{
    // Type must be RAW_RECORD_MISS_LOG_DATA_TYPE i.e. value is 4
    //
    USHORT          RecordType;

    // Optional flags.
    //
    union
    {
        struct
        {
            USHORT IPv6:1;              // Are IPs for this request IPv6 or not?
            USHORT ProtocolVersion:3;   // See protocol version table above.
            USHORT Method:6;            // See HTTP Verb Table above.
            USHORT Reserved:6;
        };
        USHORT Value;
    } Flags;

    // Site ID. Represents which site owns this log record as per the
    // metabase numeric metabase SiteID.
    //
    ULONG           SiteID;

    // UTC Timestamp for the Log Hit.
    //
    LARGE_INTEGER   DateTime;

    // The IP Port the request came in on.
    //
    USHORT          ServerPort;

    // ProtocolStatus - 200, 404, 503 etc - value should never be
    // greater than 999
    //
    USHORT          ProtocolStatus;

    // Other fields of the response
    //
    ULONG           Win32Status;
    ULONGLONG       TimeTaken;         // in milliseconds
    ULONGLONG       BytesSent;      // in bytes
    ULONGLONG       BytesReceived;      // in bytes

    // Substatus is only relevant for requests served from user mode.
    // All cache-hit responses will have an implied Substatus of 0.
    //
    USHORT          SubStatus;

    // Variable-length fields follow the structure.
    //
    USHORT          UriStemSize;
    USHORT          UriQuerySize;
    USHORT          UserNameSize;

    // Either IPv4 or IPv6 address structure will follow. The client    // address
appears first, followed by the server address.
    //
    // _RAWLOG_IPV4_ADDRESSES or
    // _RAWLOG_IPV6_ADDRESSES

    // Then the URIStem - UriStemSize bytes
    // Then the URIQuery - UriQuerySize bytes
    // Then the UserName - Align the UserNameSize bytes up to the size of
    // AlignmentSize (in the header record) multiple

} RAW_FILE_MISS_LOG_DATA, *PRAW_FILE_MISS_LOG_DATA;
```

After writing the RAW_FILE_MISS_LOG_DATA record to the file that is already aligned, HTTP.sys appends the variable size strings to the end of the structures. However, if the total length of the bytes written after the structure is not aligned, HTTP.sys

provides padding to ensure proper alignment of the next record.

Parsers should be aware of this padding and must skip it after reading the last variable size string that follows the RAW_FILE_MISS_LOG_DATA record.

For example, if a cache-miss record has a URIStem of 8 bytes, URIQuery of 0 bytes, and UserName of 4 bytes, then HTTP.sys adds the following padding:

ALIGN_UP ((8 + 0 + 4), AlignmentSize) - (8 + 0 + 4). This would be 4 bytes for a binary log file generated on an IA64, and 0 bytes for a binary log file generated for I386.

After reading the last variable size string, the parser should skip the padding bytes.

Log File Index Mapping Record

A log file index mapping record maps a specific URL to a RAWLOGID. This record always appears before the RAWLOGID is referenced in a cache-hit record. If a subsequent record for the same URL appears in a log file, then it receives a new RAWLOGID and subsequent cache-hit records refer to the new ID. This occurs because HTTP.sys periodically flushes cached items and recaches after a period of time, and a new RAWLOGID is generated for the recached item. Example F.7 lists the log file index mapping record.

**Example F.7 Log File Index Mapping Record**

| **Note** |
| --- |
| Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs). |

```
#define URI_BYTES_INLINED       (4)
#define URI_WCHARS_INLINED      (URI_BYTES_INLINED/sizeof(WCHAR))

typedef struct _RAW_INDEX_FIELD_DATA
{
    // RAW_RECORD_INDEX_DATA_TYPE == i.e. 2
    //
    USHORT          RecordType;

    // Size of the variable size string (in bytes).
    // When reading and writing need to align the DIFF(Size - 4)
    // up to AlignmentSize.
    //
    USHORT          Size;

    // Unique ID for the URI.
    //
    RAWLOGID   Id;

    // Variable size string follows immediately after the structure.
    // Array of 4 bytes is defined to be able to make it PVOID aligned
    // on ia64. Typically URIs will be bigger than 4 bytes.
    //
    WCHAR           Str[URI_WCHARS_INLINED];

} RAW_INDEX_FIELD_DATA, *PRAW_INDEX_FIELD_DATA;
```

Cache Flushes

The HTTP.sys kernel-mode cache sometimes flushes completely. Significant configuration changes, such as changes to bandwidth throttling settings, can trigger a full cache flush. In the rare event that the cache flushes, the binary log file writes a record that indicates that you should dump all unique identifiers in memory and restart the process of recording the URL to new and unique ID mappings.

These records are rare and typically occur on servers that are reconfigured frequently. Example F.8 lists a cache flush record.

**Example F.8 Cache Flush Record**

| **Note** |
| --- |

Please be aware that Microsoft might change this data format at any time and is likely to do so in future Windows releases. Developers who use this data structure definition will need to alter program logic, recompile, and then re-release their applications for future releases of Windows (or service packs).

```
typedef struct _RAW_FILE_CACHE_NOTIFICATION
{
    // Must be RAW_RECORD_CACHE_NOTIFICATION_DATA_TYPE i.e. 5
    //
    USHORT          RecordType;

    // Reserved for alignment
    //
    USHORT          Reserved[3];

} RAW_FILE_CACHE_NOTIFICATION, *PRAW_FILE_CACHE_NOTIFICATION;
```

# HTTP.sys Error Log Files

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For the W3C Extended, IIS, and NCSA Common log file formats and for centralized binary logging, the log data is generated from the worker processes, passed to HTTP.sys through APIs, and then recorded in log files. However, because of the separation of the HTTP protocol stack in kernel mode and the worker processes in user mode, HTTP.sys-initiated error responses are not recognized by the user mode and are, therefore, not passed back to HTTP.sys for logging. To record these error responses, HTTP.sys needs its own error logging scheme that comes directly from the kernel mode. This is accomplished with HTTP.sys error logging. By default, HTTP.sys error logging is turned on.

**Common HTTP.sys Error Log File Entries**

There are a number of cases where HTTP.sys will generate its own errors. For example, when HTTP.sys sends an error response back to a client and a site is not yet associated with the request, an error is recorded in the HTTP.sys error log files. This error usually happens when there is a parse error in the request that was last received on the connection and HTTP.sys disconnects the connection after sending the response.

Another example of an HTTP.sys-generated error is a connection time-out. If a time-out occurs during a request, the request is recorded in the HTTP.sys error log file to provide more information about the connection.

Also, if a worker process in user mode unexpectedly terminates or closes its application pool handle while there are still outstanding requests that were queued and routed to this worker process, the outstanding requests are recorded in the HTTP.sys error log files. In this case, you can use the site ID field entry to identify the problematic site.

HTTP.sys error log files will sometimes contain connection errors that occur when IIS does not immediately destroy connections that the client terminates before a response for the last request on these connections is complete. HTTP.sys cannot resolve these connections (also known as *zombie* connections) until IIS completes its send or passes the last send call containing the logging information. Typically, unresolved connections are recorded in normal IIS log files. However, if IIS never sends the logging information back to HTTP.sys, unresolved connections are dropped after 30 seconds to one minute. HTTP.sys records these dropped connections in the HTTP.sys error log file to alert the administrator to their presence.

# Configuring HTTP.sys Error Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To change the configuration of HTTP.sys error logging, you must edit the registry. HTTP.sys reads the configuration only once during startup. If you change the configuration, HTTP.sys can pick up the change only at the next startup. The HTTP.sys error logging configuration is global.

You must have administrative credentials to edit the HTTP.sys configuration in the registry.

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Windows Server 2003 Resource Kit Registry Reference. |

**Registry Parameters**

Three parameters control HTTP.sys error logging. They are located under the following registry key: **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\HTTP\Parameters**.

There are three entries that can be set:

- **EnableErrorLogging (DWORD)**. The default value is TRUE.
- **ErrorLogFileTruncateSize (DWORD)**. The default value is 1 * 1024 * 1024 bytes. The value cannot be smaller than this, and it must be specified in bytes.
- **ErrorLoggingDir (String)**. The default value is *systemroot*\System32\LogFiles. When specified, this value must be a fully qualified directory string, but you can use *systemroot*. For example:

  C:\LogFiles

  — or —

  *systemroot*\LogFiles

Although you can specify the directory, HTTP.sys will create a subdirectory named HTTPERR under the given log directory and put the error log files in this subdirectory. By default, members of the Administrators group and users with a LocalSystem user account have full access to the log files and directories. No other users have access rights.

The log file naming convention for HTTP.sys error logging is Httperr.#, where # is a sequence number. HTTP.sys error log files have a .log extension. For example, Httperr1.log. The error log files are recycled, based on their sizes. The default recycle size for error log files is 1 megabyte (MB). You can configure the value in the registry, but it cannot be smaller than 1 MB.

When the following events occur, HTTP.sys records them in the Windows Event log:

- HTTP.sys cannot create an error log file.
- The administrator sets an unacceptable configuration in the registry.
- There is not enough disk space.
- There is any other write failure.

# Log File Format for HTTP.sys Error Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP.sys error log files contain a fixed set of fields. Table 10.8 lists the fields that are recorded in HTTP.sys error logging log files and describes them.

**Table 10.8 HTTP.sys Error Logging Fields**

| Field | Description |
|---|---|
| Date | The date, in UTC time. This entry is always 10 characters long, for example, `2000-01-31`. |
| Time | The time, in UTC time. This entry is always eight characters long, for example, `00:12:23`. |
| Client IP | The IP address of the client. The version of the IP address can be either IPv4 or IPv6. If it is IPv6, the Scope ID field also appears. |
| Client Port | The port number of the client. |
| Server IP | The IP address of the server. The server IP address can be either IPv4 or IPv6. If it is IPv6, the Scope ID field also appears. |
| Server Port | The port number of the server. |
| Protocol version | The protocol version, if the last request on the connection has been parsed enough to identify the protocol version. If either the major or the minor version is greater than or equal to 10, the driver records the version as HTTP/?.?. |
| Verb | The verb, if the last request that was parsed passed the verb state. Unknown verbs are also recorded. HTTP.sys enforces a length limit of 255 bytes for the verb; anything longer is truncated. |
| CookedURL and query | The URL and its query, if both exist. A question mark (?) separates the URL from the query. If the URL of the request is completely processed (also known as *cooked*), then the processed URL is recorded with a local code page conversion and is treated as a Unicode field.<br><br>If only the unprocessed (raw) URL was present at the time of logging, then it is recorded as is, without a local code page conversion. HTTP.sys enforces a length limit of 4096 bytes for the URL; anything longer is truncated. |
| Protocol status | The protocol status of the response for the request, if it is available. The value cannot be greater than 999. |
| Site ID | The site ID, as a numeric value. For example, instead of recording W3SVC1, the field contains 1. There is no maximum value for the site ID. (This value can be as large as a MAX_ULONG.) |
| Reason phrase | Detailed information about why the error occurred, depending on the error type. This field can never be empty. For more information about reason phrases, see HTTP.sys Reason Phrases later in this section. |

For fields for which information is unavailable, a hyphen (-) appears as a placeholder. Fields are separated by spaces. If a field contains a nonprintable character, HTTP.sys replaces it with a plus sign (+) to preserve the log file format.

# HTTP.sys Reason Phrases

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following reason phrases can appear in an HTTP.sys error log file to describe the error that caused the log file entry:

**Connection_Abandoned_By_AppPool**
This reason phrase indicates that the error was caused by a worker process stopping unexpectedly and orphaning requests.

**Connection_Dropped**
This reason phrase indicates that a *zombie* connection was dropped by IIS and not resolved correctly.

**Various connection time-out errors**
These reason phrases include the following various connection time-out errors:

- Timer_ConnectionIdle. There has been no new data sent over the connection since the last send from the client to server, and the connection timed out.
- Timer_HeaderWait. A connection was initiated with the server, but the headers for the request were not received in a timely manner.
- Timer_MinBytesPerSecond. The minimum throughput rate was not maintained.
- Timer_EntityBody. The connection expired while waiting for the entity body to arrive.
- Timer_AppPool. The connection expired because the request waited too long in an application pool queue.

**Various errors**
These reason phrases include the following errors, most of which are parse errors:

- BadRequest
- Verb
- URL
- Header
- Hostname
- Invalid_CR/LF
- Number
- FieldLength
- RequestLength
- Forbidden
- LengthRequired
- Precondition
- EntityTooLarge

- URL_Length
- Internal
- N/I

**Internal**
This reason phrase indicates that an HTTP Error 500, internal server error, occurred.

**N/I**
This reason phrase indicates that an HTTP Error 501, not implemented, occurred.

**All 503 errors**
The 503 errors are service unavailable errors. These reason phrases include the following 503 errors:

- N/A. The service is unavailable.
- ConnLimit. The site connection limit has been reached.
- AppOffline. Because of rapid fail protection, the application was taken offline by IIS.
- QueueFull. The application request queue is full.
- Disabled. The administrator has taken the application offline.
- AppShutdown. The application was automatically shut down because of an administrator policy.
- AppPoolTimer. The application pool process is too busy to handle the request.

**Version_N/S**
This reason phrase indicates that an HTTP error 505, HTTP version not supported, occurred.

# HTTP.sys Error Log File Examples

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following example shows an HTTP.sys error log file entry, as viewed in a text editor:

```
2002-07-05 18:45:09 172.31.77.6 2094 172.31.77.6 80 HTTP/1.1 GET /qos/1kbfile.txt 503 -
ConnLimit
```

Table 10.9 lists and describes the fields that are recorded in this example.

**Table 10.9 Example of an HTTP.sys Error Log File Entry**

| Field | Appears As | Description |
|---|---|---|
| Date | 2002-07-05 | This log file entry was recorded on July 5, 2002. |
| Time | 18:45:09 | This log file entry was recorded at 6:45 P.M. |
| Client IP | 172.31.77.6 | The IP address of the client. |
| Client port | 2094 | The client port number. |
| Server IP | 172.31.77.6 | The IP address of the server. |
| Server port | 80 | The server port number. |
| Protocol version | HTTP/1.1 | The protocol version. |
| Verb | GET | The user requested a **GET**, which requests a file. |
| Cooked URL and query | /qos/1kbfile.txt | The query was unavailable, and the URL of the request was completely processed (also known as cooked), so /qos/1kbfile.txt is the local code page conversion. |
| Protocol status | 503 | The service was unavailable. |
| Site ID | – | The site ID was unavailable. |
| Reason Phrase | ConnLimit | The connection limit was reached. |

# Custom Logging Modules

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS supports custom logging modules that are COM objects that must expose a base set of methods for IIS to use. These methods are defined in the ILogPlugin, ILogPluginEx, and ILogUIPlugin interfaces. You can implement custom logging modules when you create your own log file formats or when you manipulate log data. For more information about the methods for the ILogPlugin, ILogPluginEx, and ILogUIPlugin interfaces, see Custom Logging Module Interfaces on MSDN. For information about creating custom logging modules, see Creating a Custom Logging Module for IIS on MSDN.

**Custom Logging Considerations**

Before you create and use custom logging modules, it is important to consider the following:

- If you want to implement custom logging for a site, consider synchronization issues. For example, different instances of a logging module can record information for different applications within the same site — but from different worker processes. To avoid synchronization problems, you can write a per-application pool log instead of a per-site log or you can use Microsoft® Win32® application programming interface synchronization primitives. Alternatively, for existing custom logging modules that you cannot change, all of the site's applications must be assigned to the same application pool to avoid the possibility of multiple worker processes writing entries to the same log file. In addition, the application pool must have the following configuration:

    - **MaxProcesses** = 1

    - **DisallowOverlappingRotation** = True

- Because the worker process, not HTTP.sys, handles custom logging modules, the HTTP.sys kernel-mode cache is disabled for the site for which a custom logging module is specified.

- In IIS 6.0, HTTP.sys uses the LocalSystem user account when writing log data to the currently selected LogFiles directory. Custom logging modules, however, use the accounts of the application pool in which they are running. The default account for application pools is the Network Service user account. For this reason, custom logging modules can cause write problems or errors when writing to the default LogFiles folder. You can correct this problem by configuring your custom logging modules to write to a different folder.

- If you choose to have custom logging modules write to a different folder, be sure to set a proper ACL on the new folder. Consider giving write permissions to the IIS_WPG group, which is a built-in user group that has the minimum set of permissions that IIS requires. If the identity account is not in the IIS_WPG group and has not been assigned appropriate rights, then the worker process fails to start. For more information about ACLs, see Managing a Secure IIS 6.0 Solution.

| **Important** |
| --- |
| When a custom logging module is loaded, IIS disables the HTTP.sys kernel-mode cache. For this reason, implementing a custom logging module can degrade overall server performance. |

Once you have created a custom logging module, you can add your format to the Active Log Format list in IIS Manager. To add the custom format to the Active Log Format list, you must edit the metabase with the Adsutil.vbs command-line script.

# Additional Resources for IIS 6.0 Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to this section.

**Related Information**

- Centralized Binary Log File Format for information about centralized binary logging.
- IIS 6.0 Architecture for information about the IIS 6.0 architecture and core components.
- Managing a Secure IIS 6.0 Solution for information about file and directory security and access control.
- The W3C Extended Log File Format site for information about the W3C Extended log file format.

**Related Help Topics**

- Enabling Logging for information about how to enable logging.
- Substatus Error Codes in Log Files for information about enabling and disabling substatus error code logging.

**Related Tools**

- Log Parser tool (LogParser.exe)

  Use the Log Parser tool to extract data from the raw file. The Log Parser tool and its accompanying user documentation are included in the IIS 6.0 Resource Kit Tools.

# Troubleshooting IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When administering Web applications, you will have problems to solve — whether fixing a service interruption, analyzing a configuration problem, or working around system resource contention problems. Whether the application is an internal corporate Web-presence or a widely available, scaled-out, data-intensive Web application, any problems that you encounter can seem nearly impossible to resolve, and attempting to do so consumes valuable time and resources.

This section describes how to troubleshoot Web applications on production computers running the Microsoft® Windows® Server 2003 operating system and Internet Information Services (IIS) 6.0. It explains how to use troubleshooting tools to administer IIS and discusses in detail service and program areas that might require troubleshooting, such as security, service startup, the IIS metabase, HTTP, and ASP.

**In This Section**

Overview of Troubleshooting IIS 6.0

Tools for Troubleshooting IIS 6.0

IIS Fundamentals

Common IIS Troubleshooting Tasks

HTTP Status Codes in IIS 6.0

Troubleshooting IIS Configuration Problems

Troubleshooting HTTP.sys Problems

Troubleshooting Miscellaneous IIS Problems

Advanced IIS Troubleshooting with Tracing and Debugging

Additional Resources for Troubleshooting IIS 6.0

**Related Information**

# Overview of Troubleshooting IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Problems that occur when administering IIS 6.0 might be difficult to solve for any of the following reasons:

- Problem reports from end users might be vague or incomplete, lacking such information as the content of error messages, how frequently a problem occurs, or the specific conditions under which the problem occurred.
- Logs do not record information that reveals the cause of the problem.
- The problem occurs in a complex, widely distributed application, which is difficult to track comprehensively.

The goal of troubleshooting is to isolate and determine the causes of problems that interfere with normal operation. This section describes a troubleshooting methodology and some of the tools that you can use to troubleshoot a server running IIS 6.0 and the Web applications that it hosts.

# Troubleshooting Methodology

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To efficiently troubleshoot Web applications, you need to apply and consistently use a troubleshooting framework, or methodology. Doing so helps you to streamline your troubleshooting activities and approach problems with confidence.

The fundamental troubleshooting methodology has five phases:

- **Phase 1: Discovery.** Gather information about the problem.
- **Phase 2: Planning.** Create a plan of action.
- **Phase 3: Problem Reproduction.** Reproduce the problem, or determine that you cannot reproduce it. If you cannot reproduce the problem, then you might not have enough information to confirm that there is a problem.
- **Phase 4: Problem Isolation.** Isolate the variables that relate directly to the problem.
- **Phase 5: Analysis.** Analyze your findings to determine the cause of the problem.

**Phase 1: Discovery**

Most problems are discovered by the end user. Problems might also be revealed by the operating system or by application logging and event tracking utilities. When a problem is reported, begin the troubleshooting process by gathering information to confirm that a problem exists.

**Interview the user who reported the problem**

If an end user reported the problem, ask that user for detailed information about what occurred. If possible, get the exact text of any error messages. If the problem recurs, ask the user to provide screen shots for error-message information or other symptoms that appeared on a screen. If the problem is behavioral and does not generate an error message, ask very specific, closed-ended questions. For example, you might ask the following questions:

- What time did the problem occur? (You can use this information to locate proximate events a large log file or to correlate the problem with external causes.)
- Which button(s) or link(s) did you click just before the problem occurred?
- Did you refresh or re-request the Web page to recover from the problem?

**Examine the records**

The Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Web Edition; and Windows® Server 2003, Datacenter Edition operating systems provide logging and event tracking. Check the logs for entries around the time that the problem occurred. Additionally, the application itself might log events. For example, the IIS logs and the HTTP error log record this information. For more information, see Analyzing Log Files.

**Phase 2: Planning**

Creating a plan of action is quite possibly the most important phase in the troubleshooting process. In this phase, you list the steps that you will follow as you proceed through the other troubleshooting phases. Stick to this plan and refer to it often. When you are bogged down in the tasks of the problem isolation phase, referring to your plan will help you remember where you are in the troubleshooting process and avoid getting sidetracked. Revise the plan as you progress — in most cases one step will dictate later steps.

When troubleshooting IIS–related problems, your plan might consist of configuring IIS logging to log extra details and then setting up a Performance Monitor log to run during a specific period of time. Based on the results of these actions, the next step might involve making a configuration change.

**Phase 3: Problem Reproduction**

Determine whether the problem is readily reproducible. The ability to reproduce the problem on demand is fundamental to properly and efficiently troubleshooting the problem. Use the information that you gathered in Phase 1 to reproduce the

problem, most often by repeating the actions taken by the end user before the problem occurred. If you can readily reproduce the problem, the isolation phase is more manageable. When you have determined a set of steps or events that trigger the problem, move to the isolation phase.

If you cannot readily reproduce the problem, the problem isolation phase can be tedious or isolating the problem can be impossible. If you cannot reproduce the problem, prepare to gather the right kind of information the next time it happens. Consider doing any or all of the following:

- Enable more detailed event tracking.
- Ask users to watch for the problem and pay close attention to what they are doing if it occurs.
- Write additional code in the application that looks for and highlights the problem if it happens again.

For example, when dealing with a Web application problem, you might add extra tracing code to your ASP pages or you might configure Windows security auditing for specific failures. The goal is to gather enough information so that the next time the problem occurs, the information that you obtain will be sufficient to correctly diagnose the problem.

**Phase 4: Problem Isolation**
In the problem isolation phase, you reproduce the problem as efficiently as possible by using repetitive steps. In this phase, you eliminate variables — such as settings, file actions, component starts/stops, or any change in the execution — that do not cause the problem, narrowing the variables down to those that are responsible for the problem.

You have succeeded in isolating the problem when you achieve the following conditions:

- The problem can be reproduced consistently when you take a fixed series of actions.
- The problem cannot be reproduced when you omit any of those actions.

For example, when troubleshooting IIS–related problems, you might do the following:

- Configure a Web application to be hosted in its own worker process or configure a component to execute in an isolated host process like a COM+ Dllhost.exe in order to determine which part of an application is consuming CPU time or leaking memory.
- Configure security settings on a URL in varying degrees through repetitive tests to isolate authentication problems.
- Capture performance data to determine whether a problem lies in the core Web server or in a Web service extension–based application, such as ASP or ASP.NET.

**Phase 5: Analysis**
Depending on the nature of the problem, the analysis phase can be the most difficult phase of the troubleshooting process. In the analysis phase, you use everything that you learned in the previous phases to do the following:

- Determine the cause of the problem.
- Explore how the problem affects the application.
- Determine the best way to solve the problem.

  This step might be a simple formality if, after Phase 3 is complete, you know what the problem is and how to fix it. If not, you must perform additional analysis of the data you have gathered. You might find that you must spend more time in the isolation phase.

  You might find that there are several ways to fix the problem. Take what you have learned about the problem and decide which actions to take. Ask yourself these kinds of questions:

  - What is the impact of the problem?

    - Do the benefits of fixing the problem outweigh the costs of fixing it?
    - Is there an acceptable workaround?

- Record your progress and the data that you have gathered.

  As you obtain information about a problem, you will make decisions about the steps that you need to take that will often alter your plan of action. It is important to record the information that you collect so that you have a way to account for your decisions as you move through the process of troubleshooting. If you find yourself taking the wrong path, having this information will allow you to backtrack to the point where you made the wrong decision. In addition, your ability to explain the changes or improvements in the problem is often important to other stakeholders.

# Tools for Troubleshooting IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Good tools are an indispensable part of any troubleshooting effort. This section identifies tools that you can use to help troubleshoot problems that you encounter on applications running on IIS 6.0. It also provides tips for getting the most benefit from each tool. Specific tool usage scenarios are also discussed in this section.

The following tools are useful for troubleshooting problems that occur with IIS 6.0:

- **WFetch (WFetch.exe).** This tool allows you to generate customized HTTP requests and view request and response data.
- **File Monitor (FileMon.exe).** This tool allows you to view and capture real-time file system activity.
- **Registry Monitor (RegMon.exe).** This tool allows you to view and capture real-time system registry activity.
- **IIS Request Monitor.** This tool captures information about HTTP requests in IIS worker processes, which can help you isolate and understand problems when worker processes become slow or unresponsive.
- **Secure Socket Layer (SSL) Diagnostic Tool (SSLDiag).** This tool helps you identify configuration problems in the IIS metabase, certificates, or certificate stores when running Web sites that use SSL.
- **Authentication and Access Control Diagnostics (authdiag.exe).** This tool allows you to review, test, and correct problems with authentication and authorization.
- **IIS 6.0 Enterprise Tracing for Windows.** This tool allows you to trace HTTP requests as they move through various components in your server architecture. IIS components provide informational events and error events (if applicable) to the ETW architecture as requests enter and exit each component. You can view the event data to see exactly where in the IIS architecture a request failed or became unresponsive.
- **Network Monitor.** This network tracing utility allows you to view activity in the network stack. Network Monitor is included with Windows Server 2003.
- **System Monitor.** This tool allows you to view and collect system performance data. System Monitor is included with Windows Server 2003.
- **HRPlus.** This tool provides error lookup functionality.
- **Microsoft Debugging Tools for Windows.** This tool allows you to debug and diagnose application problems.

# WFetch

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A simple HTTP request that is issued by typing a URL in the address bar of a browser might produce multiple network requests to the target server running IIS. However, the user does not see all of the resulting response data because the browser does not display it. WFetch allows you to fully customize an HTTP request and send it to a Web server so that you can see the raw HTTP request and response data. WFetch is included in the Internet Information Services (IIS) 6.0 Resource Kit Tools in the Microsoft Download Center.

For more information about using WFetch in a testing environment, see Knowledge Base article 284285, How To: Wfetch.exe to Troubleshoot HTTP Connections.

# File Monitor and Registry Monitor

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When troubleshooting IIS 6.0, you can use File Monitor and Registry Monitor to obtain two specific types of information:

- Verification that a specific file (File Monitor) or registry key (Registry Monitor) is being accessed by a given process.
- Information about whether that access results in an Access Denied error.

Both File Monitor and Registry Monitor can be downloaded from the System Internals Web site.

To install File Monitor and Registry Monitor, unzip and copy each .exe file to a desired location. To use one of these tools, double-click the appropriate executable file (FileMon.exe or RegMon.exe). Both utilities start in capture mode, which means that they display all file system (File Monitor) or registry (Registry Monitor) activity from all processes as it happens. Before you begin troubleshooting a problem, stop the capture and clear the entries that have been written.

**To stop or start a capture in FileMon.exe or RegMon.exe**

- On the **Options** menu, click **Capture Events**.

**To clear the current capture in FileMon.exe or RegMon.exe**

- On the **Edit** menu, click **Clear Display**.

**Tips for Using File Monitor and Registry Monitor for Troubleshooting**

Use the following tips to streamline the troubleshooting process when using File Monitor and Registry Monitor:

- **Isolate your task as much as possible.** The output from a capture comes very quickly and at a high volume. The larger the capture, the harder it is to find the information that you want. When you are ready, perform only the tasks that will produce the file or registry access that you are trying to verify.
- **Avoid unnecessary clicking or activity.** Performing extraneous operations while File Monitor or Registry Monitor is running will produce unrelated and unnecessary data in the output.
- **Start a capture as closely as possible to when you perform the task.** Separate your utility window from the workspace that contains the process that you are using to troubleshoot so that you can easily switch between programs. If possible, press ALT+TAB to quickly switch programs.
- **Create a capture filter for the process name that you are working with.** Registry Monitor and File Monitor both have capture filter functionality, which you can use to remove extraneous activity from the capture. You can filter on any string in an entry. For example, a common filter is the IIS 6.0 worker process name, W3wp.exe.

**To set a capture filter for W3wp.exe**

1. On the **Edit** menu of the appropriate tool, click **Filter/Highlight**.
2. In the **Include** box, type **W3wp.exe** and then click **Apply**.

When you have finished the task, stop the capture and scan the results for specific output. Usually, your objective will be to verify whether the problem is being caused by or is related to an access denial. In either tool, you can see whether this is the case by looking for the text ACCESS DENIED in the Result column.

If you need to compare the time that an event occurred with some other activity on your network, change the time format of the capture from the elapsed time, which is the default, to the literal time of day.

# IIS Request Monitor

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS Request Monitor is a command-line tool that captures information about HTTP requests in IIS worker processes. Administrators and developers can use Request Monitor to understand which HTTP requests are executing in a worker process when the worker process has become unresponsive or very slow. Request Monitor works with IIS 6.0 running on Windows Server 2003, Service Pack 1 or later.

For more information about the IIS Request Monitor, see Currently Executing Requests Tracing.

# SSL Diagnostics Version 1.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

SSL Diagnostics Version 1.0 helps you identify configuration problems in the IIS metabase, certificates, or certificate stores when running Web sites that use SSL. This tool allows you to review SSL configuration information, simulate the SSL handshake to locate errors, or "hot swap" certificates for testing purposes.

For information about the x86 version of SSL Diagnostics Version 1.0, see SSL Diagnostics Version 1.0 (x86).

For information about the 64-bit version of SSL Diagnostics Version 1.0, see SSL Diagnostics Version 1.0 (ia64).

# Authentication and Access Control Diagnostics Version 1.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Authentication and Access Control Diagnostics (Authdiag.exe) Version 1.0 allows you to review, test, and correct problems with authentication and authorization. You can use Authdiag.exe to check settings on Web sites, FTP sites, virtual directories, Web directories, and files. Authdiag.exe can help you troubleshoot the following types of issues:

- ACCESS DENIED errors caused by the following situations:
    - NTFS authentication failures
    - Required privileges missing
    - Invalid permissions on registry keys
    - Incorrect configuration for IIS metabase properties.
- Authentication failures based on invalid configuration.
- UNC configuration issues.
- Failure of the system default permissions for IIS, based on incorrect permissions to directories such as *%windir%*\system32\inetsrv.
- Failure within an Active Server Page (ASP) based on failed permissions.
- Failure to access the Home Directory or FTP Root because the Anonymous User or Authenticated User does not have the appropriate permissions.

Authdiag.exe provides both user interface (UI) and command-line modes of operation. Use the UI mode for troubleshooting authentication and authorization problems on a local server. Use the command-line mode for troubleshooting on a local server.

# IIS 6.0 Enterprise Tracing for Windows

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003 includes Enterprise Tracing for Windows (ETW), a framework for implementing tracing providers that can be used for debugging and capacity planning. IIS 6.0 implements a number of providers to trace key transitions and the progress that an HTTP request makes as it moves through the IIS service framework. These providers include the following:

- IIS: WWW Server. This provider traces the transition of a request from HTTP.sys through various IIS subcomponents.
- IIS: SSL Filter. This provider traces calls into and out of the SSL Filter, which is used for SSL traffic.
- IIS: ISAPI Extension. This provider traces the transition of a request into and out of Internet Server API (ISAPI) extension processing.
- IIS: ASP. Traces the start and completion of the execution of an ASP request.
- IIS: IIS Admin Tracing. Traces the IIS Admin service during startup and shutdown.

For more detailed information about tracing IIS requests, including an introduction to tracing, an explanation of the different tracing providers in IIS, the different types of tracing, and how to troubleshoot IIS with trace data, see Troubleshooting IIS 6.0 with Tracing.

For the procedures to trace IIS requests and view trace data, see Advanced Troubleshooting with IIS Tracing.

For an explanation of the tracing events returned by IIS, see Tracing Events Reference.

# Network Monitor Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When troubleshooting IIS–related problems, you can use Network Monitor to start a capture, reproduce a problem, and view the capture. Network Monitor is included with Windows Server 2003.

**Procedures**

**To install Network Monitor**

1. From the **Start** menu, click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. In the left pane, click **Add/Remove Windows Components**.
4. Click **Management and Monitoring Tools** and then click **Details**.
5. Select the **Network Monitor Tools** check box and then click **OK**.
6. Click **Next**.
7. When installation is complete, click **Finish**.

   Network Monitor is now available on the Administrative Tools menu.

| **Note** |
| --- |
| Network Monitor, unlike WFetch, is a good tool for analyzing TCP connection management or three-way handshake information. For more information about using Network Monitor in this way, see Knowledge Base article 172983, Explanation of the Three-Way Handshake via TCP/IP. |

**Tips for Using Network Monitor for Troubleshooting**

Consider the following tips when using Network Monitor for troubleshooting:

- As with any utility that captures large volumes of data, it is important to plan your Network Monitor capture and to time the beginning and end of captures so that they minimize extraneous network traffic.
- Network Monitor, like File Monitor and Registry Monitor, can display the timestamp instead of the elapsed time in the capture. Displaying the timestamp along with synchronizing system clocks on participating computers can help you accurately isolate problems.
- Increase the capture buffer size from its default of 1 MB to 20 MB.

**To adjust Network Monitor capture settings**

1. On the **Capture** menu, click **Buffer Settings**.
2. In the **Buffer Size (MB)** box, type **20**.
3. Click **OK**.

Applying filters to captures allows you to record only relevant data. You can also apply a filter after the capture has completed to filter the data that is displayed. Filtering by protocol and by network addresses are the two most common ways to quickly filter Network Monitor capture data.

**To filter capture data by HTTP protocol**

1. While viewing a saved capture file, on the **Display** menu, click **Filter**.
2. In the **Display Filter** dialog box, click **Protocol == Any**, and then click **Edit Expression**.

3. In the **Expression** dialog box, click **Disable All**.
4. In the **Disabled Protocols** list box, click **HTTP**, and then click **Enable**.
5. Click **OK** twice.

   Network Monitor filters and then displays only HTTP traffic.

| To filter capture data by network addresses |
| --- |
| 1. While viewing a saved capture file, on the **Display** menu, click **Filter**.<br>2. In the **Display Filter** dialog box, click **ANY<-->ANY**, and then click **Edit Expression**.<br>3. In the **Expression** dialog box, choose the source and destination network. If you don't see the one you want, type the address that you want in the **Edit Addresses box**. |

By default, Network Monitor only parses traffic on port 80 as HTTP traffic. You can customize Network Monitor to parse traffic on other ports, for example, on port 8080, as HTTP traffic.

**To configure Network Monitor to parse traffic on non-standard HTTP ports**

1. Open Notepad.
2. Open the **Tcpip.ini file**, which is located in the **Parsers** folder under the Network Monitor installation point (by default, *systemroot*\System32\Netmon).
3. Locate the **[TCP_HandoffSet]** section.
4. Below the **80=HTTP** line, type the following new line: **8080=HTTP**
5. Save and then close the Tcpip.ini file.
6. Open the **Http.ini file**, which is located in the same folder as Tcpip.ini.
7. Locate the **[Ports]** section.
8. Immediately after the text **SrcPorts=80**, type the new port, preceded by a comma. The line now reads **SrcPorts=80,8080**.
9. Save and then close the Http.ini file.

To start any new parsing activity, close and reopen your captures.

For more information about HTTP traffic and Network Monitor, see Knowledge Base article 252876, How to View HTTP Data Frames Using Network Monitor. For more information about capturing network traffic, see Knowledge Base article 148942, How to Capture Network Traffic with Network Monitor.

# System Monitor Tool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

System Monitor is part of the Performance snap-in, which is accessible through Administrative Tools. When generating a performance log for troubleshooting, add, at a minimum, the following counter objects:

- .NET CLR (Common Language Runtime)
- Active Server Pages (ASP)
- ASP.NET
- Memory
- Process
- Processor
- Thread
- Web Service

Alternatively, you can observe real-time data on the display, if doing so meets your troubleshooting needs.

For information about starting System Monitor, and selecting performance objects and counters, see Viewing Counter Data in the Performance Console.

# HRPlus

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HRESULTS are a type of 32-bit error code returned from various parts of the Windows Server 2003 operating system and its components. HRPlus is a free tool that is used primarily for decoding HRESULT values returned by COM applications, but it also can be used to generate custom HRESULT values for use in your own applications. Additionally, you can use HRPlus to decode Win32 error codes.

To obtain a copy of HRPlus, search for "hrplus" on the Simtel Web site.

# Microsoft Debugging Tools for Windows

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Microsoft Debugging Tools for Windows toolkit provides a robust suite of utilities for troubleshooting and debugging software. For more information about Microsoft Debugging Tools for Windows, see Debugging Tools for Windows - Overview, and Advanced IIS Troubleshooting with Tracing and Debugging.

# IIS Fundamentals

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS is an HTTP protocol server, which means that it accepts and replies to HTTP requests. IIS processes three types of HTTP requests:

- Static content (like HTM document) requests
- CGI requests
- ISAPI requests

By understanding the fundamentals of IIS architecture and the related functionality, you can discover and isolate problems much more quickly. You will also be better equipped to differentiate between real problems and expected behavior.

This section explores the following functionality, which any IIS troubleshooter must understand:

- HTTP Protocol Basics: Explains the way Internet browsers and servers running IIS communicate with each other.
- IIS Service Startup: Sometimes problems arise even before IIS starts servicing requests. This section describes the startup process and typical startup behavior, which can help you determine the causes of problems.
- HTTP Request Walkthrough: Explains the various phases that a typical request passes through as it moves through the service.

# HTTP Protocol Basics

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Troubleshooting IIS often requires that you examine the communications between a Web client and the server running IIS. By understanding the fundamentals of this communication, you can easily interpret network monitor traces and similar records.

Hypertext Transfer Protocol (HTTP) is the communication protocol used to exchange information between a client system and a Web server across a TCP/IP connection. The interchange is generally referred to as an HTTP transaction. In an HTTP transaction, the client system opens a TCP connection with the Web server and submits an HTTP request. The Web server, in turn, issues an HTTP response, completing one HTTP transaction. HTTP is stateless, in that there is no provision in the protocols design for information about any single request persisting beyond one transaction.

The following code segment is an example of an HTTP GET request:

```
GET /default.htm HTTP/1.1\r\n
Host: rhynoruv\r\n
Accept: */*\r\n
\r\n
```

The request line contains an HTTP method, a Uniform Resource Identifier (URI), and the HTTP version number, followed by carriage return and line feed characters. Typically, the request line is followed by a series of HTTP headers. Depending on the type of request, an HTTP request can have a variety of headers. With HTTP 1.1, the simplest GET request consists of the request line and only one HTTP header — the Host header. Two carriage returns/line feeds designate the end of the HTTP request header. In a simple GET request, these indicate the end of the request. Some requests include data, which is called the *entity body,* in addition to the HTTP headers. In the HTTP request, the division between the headers and the entity body is designated by two carriage returns/line feeds.

The following code sample shows an HTTP response, which is similar to a request:

```
HTTP/1.1 200 OK\r\n
Content-Length: 50\r\n
Content-Type: text/html\r\n
Last-Modified: Sun, 20 Oct 2002 22:52:16 GMT\r\n
Accept-Ranges: bytes\r\n
ETag: "255591568b78c21:5cd"\r\n
Server: Microsoft-IIS/6.0\r\n
MicrosoftOfficeWebServer: 5.0_Pub\r\n
X-Powered-By: ASP.NET\r\n
Date: Sun, 20 Oct 2002 22:52:35 GMT\r\n
\r\n

<HTML>\r\n
<BODY>\r\n
\r\n
Hello World.\r\n
\r\n
</BODY>\r\n
</HTML>
```

The first line is the status line, which consists of the HTTP version, a numeric HTTP status code, and then a reason phrase that briefly explains the status code. The status code is often the first indicator of a problem. For information about status codes, see HTTP Status Codes in IIS 6.0.

There are two other important aspects of the HTTP protocol that you must understand before you attempt troubleshooting: the provisions for managing TCP connections and how credential management (authentication) occurs.

# HTTP Connection Management

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Because the TCP/IP protocol is so robust, establishing a new TCP connection for every HTTP request is relatively expensive in terms of network roundtrips. The two versions of HTTP (1.0 and 1.1) avoid incurring this overhead differently.

HTTP 1.0 transactions typically involved a client opening a TCP connection with the Web server and issuing an HTTP request. The server would then send its response and close the TCP connection. The client could optionally ask that the TCP connection remain open beyond the first transaction with the HTTP header **Connection: keep-alive**.

Starting with HTTP 1.1, persistent connections are implicit; in other words, the Web client and Web server keep the underlying TCP connection open until either sends an indication that the connection can be closed with the **Connection: close** header. Because the connection remains open, a way to designate the end of the entity-body is required. The **Content-Length** header performs this function by specifying the size of the entity-body, in bytes.

# HTTP Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP contains provisions for negotiating access to a secured resource, a process called *authentication*. Typically, an initial request from a client will not contain any authentication information; such a request is considered an *anonymous* request. If the requested resource is secured, the Web server can respond with a 401-Access Denied error and, optionally, can include one or more **WWW-Authenticate** HTTP headers. Each **WWW-Authenticate** header indicates a type of authentication scheme the server uses. The client can then choose to engage in one of these authentication schemes; doing so sometimes requires several more HTTP roundtrips.

For more information about authentication schemes, see 401.1 and 401.2-Authentication Problems. For more information about IIS authentication types, see Managing a Secure IIS 6.0 Solution.

For more detailed information about the HTTP protocol, see RFC 2616, Hypertext Transfer Protocol — HTTP/1.1 at the Internet Engineering Task Force Web site.

# IIS Service Startup

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

On rare occasions, you might encounter problems related to starting the IIS services infrastructure. The IIS services are generally robust enough to handle problems and recover from them gracefully. If a problem does occur and if it is appropriate, an event is logged to the application/system event log explaining the failure. Typically, the startup process never needs troubleshooting beyond examining messages written to the event log and taking the required corrective action. However, because it is helpful to understand the inner workings of an application in order to recognize problematic behavior, this section describes the major stages of the IIS services infrastructure startup process.

For information about the components of the services infrastructure, see IIS 6.0 Architecture.

The Windows Service Control Manager (SCM) performs Windows operating system service management operations. Among other things, SCM is responsible for signaling services to begin the startup process and for managing service dependencies. Some services are configured to *auto-start*, which means that SCM asks those services to start when the system is restarted. Other services are configured to manually start (or *demand-start*), which means that SCM starts those services only when prompted by an external request or when a service dependency demands it.

IIS services startup begins when the computer restarts. The IIS Admin service, which is hosted by Inetinfo.exe, is configured as an auto-start service. This is the first service in the IIS service infrastructure that is asked by SCM to start. The IIS Admin service depends upon the Remote Procedure Call (RPCSS) service and the Security Accounts Manager (SAMSS) service, which means that SCM guarantees that these are started before the IIS Admin service.

The next auto-start service in the IIS services infrastructure that starts is the World Wide Web Publishing Service (WWW service). It is hosted by Svchost.exe. In addition to the IIS Admin and RPCSS services, the WWW service has dependencies on the HTTP SSL (HTTPFilter) service. The IIS Admin service and RPCSS were started earlier, but before SCM starts the WWW service, it needs to demand-start the HTTPFilter service.

The HTTPFilter service has dependencies on the IIS Admin service and the HTTP service. It is this dependency on HTTP that causes SCM to start the HTTP.sys kernel-mode driver. Consequently, SCM starts the HTTPFilter service, which runs in Lsass.exe (or Inetinfo.exe if you are running in IIS 5.0 isolation mode), and then starts the WWW service.

The following sections describe what happens when these services start.

**HTTP.sys**

In IIS 6.0, unlike in earlier versions of IIS, the HTTP.sys kernel-mode device driver is not part of the core IIS services. In Windows Server 2003, the HTTP.sys driver actually exposes an API set that any application or service, not just IIS, can leverage. However, since IIS 6.0 is the major client, so to speak, of HTTP.sys, it is beneficial to understand how HTTP.sys relates to IIS 6.0.

The primary responsibility of HTTP.sys is to listen for and respond to HTTP requests on the network endpoints on which it is requested to do so. When HTTP.sys starts, by default it listens for HTTP requests on all IP addresses configured on the system. In some cases, though, it is beneficial for HTTP.sys to listen only on specific addresses — for example, if Windows Media Services needs to listen on port 80 of a specific IP address, outside of the HTTP.sys driver. To accommodate this need, HTTP.sys has an IP inclusion list. This list, when it contains entries, tells HTTP.sys which IP addresses to listen on, and, thereby, which IP addresses not to listen on. At startup, HTTP.sys examines this list and configures itself accordingly. As a result, changes to this list take effect only when the service is restarted.

| **Note** |
| --- |
| You can use the HttpCfg.exe utility to configure the IP inclusion list. For information about HttpCfg.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click **Windows Support Tools**. |

**IIS Admin Service**

The IIS Admin service primarily is responsible for managing the IIS metabase. During startup, it reads the MetaBase.xml file and creates its in-memory representation. Because the IIS Admin service creates this in-memory snapshot, if the metabase file is corrupt or if the XML code in the file is not syntactically well-formed, the IIS Admin service will fail to start. The IIS Admin service is responsible for synchronizing access to the metabase through the various control interfaces, even when manual updates are made directly to the MetaBase.xml file. During startup, the IIS Admin service sets up the control interfaces, like IMSAdmin, and registers for necessary file change notifications from the Windows Server 2003 operating system in order to monitor changes to the XML file.

**WWW Service**
The WWW service recognizes the following entities:

- URLs. The combined application and site binding information.
- Applications. Unique URLs that, when merged with a sites bindings and endpoints, provide full mapping information that enables HTTP.sys to determine which application pool requests that application should be directed to, and the metadata that should be used to support them.
- Sites. The specific bindings and endpoints that HTTP.sys should listen to. Sites contain one or more applications.
- Application pools. Sets of applications that are routed to the same set of worker processes. Application pools are also a common configuration for the worker processes that serve the applications in the pool.
- Application root. Also known as the Web application starting point, an application root is designated when you create and configure an application on a node in a Web site directory structure. You can have more than one application per Web site. The root of a newly created Web site, including the default Web site that is created when you install IIS, is an application starting point. Every file and directory beneath the starting-point directory in your Web site is considered part of the application until another starting-point directory is found. Thus, directory boundaries define the scope of an application.

When the WWW service starts, it performs the following operations:

1. Reads WWW Service configuration information from the IIS Admin service. This information includes global data, application pool data, Web site data, and application data.
2. Validates this data and logs any errors to the event log, choosing to ignore a record or to alter properties in the record to the defaults.
3. Configures HTTP.sys for all sites, applications, and application pools that are registered, and starts the ones that are set to start automatically.
4. Enables HTTP.sys configuration all at once, allowing IIS to accept requests.
5. If IIS 5.0 isolation mode is enabled, starts a worker process in Inetinfo.exe and waits for the worker process to start.

At this point, IIS can accept incoming HTTP requests. The first HTTP request to an application pool launches the worker process (W3wp.exe). In other words, an application pool can be started even though a worker process is not running.

**Worker Process Startup**
The fundamental aspects of a worker process startup routine are fairly straightforward. The worker process typically does the following:

1. Starts the metabase listener and listens for change notifications.
2. Initializes the IIS thread pool.
3. Obtains the application pool, which was specified in the command-line parameters, and then sets up the communication mechanism that it will use to receive requests from HTTP.sys.
4. Sets up communication with the WWW service to enable pinging and recycling.
5. Initializes other internal caches and structures that are used to process HTTP requests.
6. Initializes the Web service extension restriction list.
7. Begins accepting requests from HTTP.sys.

# HTTP Request Walkthrough

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

An HTTP request takes only one of three basic paths through the WWW service depending on whether the request is for a static file, an ISAPI extension, or for CGI processing. This section describes these paths. Understanding the request flow is invaluable during the problem isolation phase of the troubleshooting process.

# Common Request Operations

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

All HTTP requests arrive from the network and are passed up to the HTTP.sys listener from the TCP protocol stack. HTTP.sys parses the HTTP headers and makes sure that the request is well formed and valid. In most cases, HTTP.sys then determines into which application request queue to place the request.

Worker processes are signaled by the presence of requests in the HTTP request queue to start processing the requests. Using the HTTP headers, the worker process determines first which kind of authentication needs to be performed. It is here that the HTTP request goes through the process of getting a user context. All HTTP requests are authenticated (except in the case of anonymous requests served from the HTTP.sys kernel-mode cache) and have a Windows security context, which becomes the *user context of the request*. Even a request for content that has anonymous access enabled acquires the security context of the configured anonymous account; it is not anonymous in that there is no Windows user whatsoever. Through the authentication process, the worker process obtains a security token for the user by means of a Windows logon API. The user context and the associated Windows security token are fundamental and have a wide-reaching effect on how the rest of the request proceeds. Failures in this area and in areas related to security typically manifest themselves as HTTP 401 errors. For information about troubleshooting this type of error, see HTTP Status Codes in IIS 6.0.

After a user context has been obtained, the worker process determines from the HTTP headers the kind of content the request is requesting, and then chooses the appropriate handler. At this point, the three request types become relevant.

# Requests for Static Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A request for static content is the most basic kind of request that IIS handles. For this request type, IIS validates that the user has access to the file and then returns the file.

This request type also involves validation against the Multipurpose Internet Mail Exchange (MIME) type restriction feature. If the request is for a restricted file type, IIS returns a 404.3-MIME Map Policy Prevents This Request error. For more information, see Requests for static files return 404 error.

IIS can also cause a response to be cached in the HTTP.sys kernel-mode cache. For more information, see the Http.sys Response Cache.

# Requests Handled by ISAPI Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Active Server Pages (ASP) and ASP.NET requests are handled by ISAPI extensions. A request is designated an ISAPI request when it requests a file whose extension is mapped to an ISAPI extension DLL in the **ScriptMaps** metabase property. A request is also designated an ISAPI request when it requests an ISAPI DLL directly in the URL or when a wildcard **ScriptMaps** entry exists, whereby all requests go through the mapped ISAPI DLL. IIS calls a well-known entry point in the ISAPI DLL and passes a structure containing all of the information required about a request. When IIS is configured for IIS 5.0 isolation mode, ISAPI requests also can be passed *out-of-process* to a Dllhost.exe worker process. Before an ISAPI request is executed, IIS checks the **WebSvcExtRestrictionList** metabase property to ensure that the ISAPI is allowed. If the ISAPI is not allowed, IIS returns a 404.2 error.

In this kind of request, the ISAPI extension DLL is responsible for processing the HTTP request and then sending the response. When an ISAPI extension DLL processes a request, any number of things can happen. In the case of ASP and ASP.NET, the user context obtained during authentication is typically impersonated before the ScriptMap file is opened. These kinds of requests, where distributed and dynamic operations are performed, often involve custom-built components and backend data stores.

# CGI Requests

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

*CGI requests* directly request a CGI executable. They are similar to ISAPI requests in that the CGI performs all of the execution work and also has to be enabled in the **WebSvcExtRestrictionList** metabase property. Unlike ISAPI requests, CGI requests involve launching a new process for each request. However, this design does not perform or scale very well — especially not on heavily trafficked Web sites. Consequently, CGI requests are typically used less often than other kinds of requests.

# Common IIS Troubleshooting Tasks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Several basic IIS troubleshooting tasks are helpful in many different troubleshooting situations. These tasks include: disabling HTTP friendly error messages in Internet Explorer, generating a custom HTTP request, checking basic request functionality, browsing with different host name styles, using substatus and Win32 errors in W3C extended logging, configuring the WWW service to log worker process recycling events, checking Windows NT system and application event logs, checking the HTTP error and IIS logs, restarting the IIS service, and identifying the process ID of the worker process. Perform these tasks during the initial steps of the discovery phase, or when initially diagnosing a problem.

# Generating an HTTP Request

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To observe the raw HTTP traffic between a browser and IIS, use WFetch. Commonly, you might use WFetch when a user receives an HTTP 403-Forbidden error. In such a situation, you might begin troubleshooting by checking the access control list (ACL) configuration on the requested content. If that does not reveal the cause, you most likely would start troubleshooting the problem as an authentication problem. However, the 403 message indicates that these are the wrong actions to take. Disabling friendly HTTP error messages in Internet Explorer and re-trying the request with WFetch would have yielded a much more meaningful error: Directory Listing Denied. This virtual directory does not allow contents to be listed. You would then immediately realize that Directory Browsing is disallowed for that virtual directory and that either Default Documents is disabled or it is enabled, but none of the configured documents are present in that directory.

**To generate a simple HTTP request using WFetch**

1. Start WFetch.
2. From the **Verb** list box, click **GET**.
3. In the **Host** box, type a host name — for example, *www.contoso.com*.
4. In the **Path** box, type the following: **/**
5. In the **Auth** list box, click **Anonymous**.

   The **Port**, **Ver** (HTTP Version), and **Connect** settings can be left at their defaults.
6. Click **Go**.

WFetch sends an HTTP request to the local instance of IIS and then receives the response. In the Log Output window, you can view the HTTP request and response data. Notice the individual headers in both the request and response, and the entity body in the response. Figure 11.1 WFetch Startup Screen below shows WFetch in the default startup state.

# Checking Basic Functionality with Test Request Files

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Occasionally, you might need to assess the core functional health of the various request types in IIS. Determining which kinds of requests work and which do not is a fundamental step in the isolation phase. The easiest way to accomplish this is to create several test files that can be placed in various application roots in your various Web sites.

Making these test requests from different locations is as important as making requests of different types. Consider that a directory location determines which application, URL, and application pool a request will be routed through. These locations can indicate at which point a particular kind of request is failing. The following examples are test request files for static content, ASP ISAPI, and ASP.NET ISAPI requests, respectively.

**Static Content Test Request File**
To create a static content test request file, create an HTML file with the following HTML code:

```
<HTML>
<BODY>
<H3>Hello World</H3>
</BODY>
</HTML>
```

Save this code in a file called Simple_Request.htm and use it to troubleshoot static content problems.

**ASP Test Request File**
For an ASP test file, you need include only dynamic ASP code inside of <% %> delimiters. However, output that returns the current time, user, and application pool is useful, too. To create an ASP request file that returns this information, create an HTML file with the following code:

```
<%@ Language=VBScript %>
<html>
<body>
<%
Response.Write ("The time is now: " & Now() & "<p>")
Response.Write ("The authenticated user is (blank if anonymous) : " & _
         Request.ServerVariables("LOGON_USER") & _
         "<p>")
Response.Write ("The application pool that served this request is: " & _
         Request.ServerVariables("APP_POOL_ID") & _
         "<p>")
%>
</body>
</html>
```

Save this code in a file called Simple_Request.asp.

**ASP.NET Test Request File**
The code for an ASP.NET test request is similar to that of an ASP test request:

```
<%@ Page Language="VB" Debug="True" Trace="True" %>
<%@ Import Namespace=System.Web%>

<HTML>
   <script language="VB" runat="server">

      Sub Page_Load(Src As Object, E As EventArgs)

      dim ctx as HttpContext = HttpContext.Current

      lblTime.Text = Now()
        lblUserIdentity.Text = ctx.Request.ServerVariables("LOGON_USER")
        lblAppPool.Text = ctx.Request.ServerVariables("APP_POOL_ID")

     End Sub

   </script>
   <body style="FONT: 8pt verdana">
```

```
      <form runat="server">
       The time is now:
      <asp:Label id="lblTime" runat="server" /><p>
       The authenticated user is (blank if anonymous):
      <asp:Label id="lblUserIdentity" runat="server" /><p>
   The application pool that served this request is:
       <asp:Label id="lblAppPool" runat="server" /><p>
      </form>
   </body>
</HTML>
```

Save this code in a file called Simple_Request.aspx.

**Testing Simple Object Creation**

A simple COM or .NET object that returns a basic hello world string is a useful troubleshooting tool. Placing that object locally on the server running IIS or remotely on your application tier, and then testing from ASP or from a simple script file or compiled client can help you determine where problems exist in your distributed applications architecture.

**Testing Application Code Outside of IIS**

Another way to test basic functionality is to test your applications completely outside of IIS. For example, if you are testing COM object creation failures, you can create a simple Microsoft Visual Basic® Scripting Edition (VBScript) file that contains your object creation code and then run the script when you log on to the IIS Web server. Variations might involve creating other custom applications by using other development tools.

# Browsing with Different Host Name Styles

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Connectivity and authentication problems can be related to Domain Name System (DNS) issues, the configuration of host headers, and general network anomalies. To understand the nature of a problem, it is sometimes helpful to vary the way that you type the host name in the requested Uniform Resource Locator (URL). Use any of the following variations:

- Fully Qualified Domain Name (FQDN). A fully qualified DNS name that uniquely identifies the computer. This name is a combination of the DNS host name and the DNS domain name, in the format *Hostname,DomainName*. For example, if the DNS host name is host1 and the DNS domain name is example.contoso.com, the fully qualified DNS name is host1.example.contoso.com.

- Network BIOS (NetBIOS) name. The computer name recognized by Windows Internet Name Service (WINS) in the format *HostName*, which maps the name to an IP address. For example, the NetBIOS name for host1.example.contoso.com is host1.

- IP address. The address used to identify a unique node on an IP network. This address is typically represented with the decimal value of each octet, separated by a period (for example, 192.168.7.27).

| **Note** |
| --- |
| IIS6.0 also supports IPv6 addressing. For more information, see IPv6 and IIS 6.0. |

Browsing with different host name styles is useful for the following reasons:

- Certificate authentication requires matching the host name from the URL to the Common Name (CN) imprinted in the server certificate.

- In Kerberos authentication, the requested Kerberos service ticket is keyed off of the host name entered in the URL. If the wrong host name is used, a service ticket might not be obtainable.

- The host header configuration in the **ServerBindings** metabase property dictates how an HTTP request is routed into the service. This relies upon matching the requested host name with an appropriate host header configuration.

- The simple name resolution process can differ when you use a NetBIOS name instead of an FQDN. Using a NetBIOS name in the URL is similar to pinging to test name resolution of the NetBIOS name to the IP address.

- Internet Explorer can unexpectedly prompt for credentials during NTLM authentication (also referred to as Windows NT Challenge/Response authentication) when the host name portion of the requested URL contains a period. Using the NetBIOS name rather than an FQDN or IP address might indicate the cause. For more information, see Knowledge Base article 258063, Internet Explorer May Prompt You for a Password.

- Browsing by IP address is a foolproof way to rule out name resolution problems. However, the host header (set with the **ServerBindings** property) must be appropriately configured.

# Using Substatus and Win32 Errors in W3C Extended Logging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To reduce the attack surface of IIS 6.0, custom error messages do not return specific error message information, including the substatus code, to remote client computers. If a custom error message contains too much information about the core Web server and an explanation of why a particular request failed to execute, malicious users can use the information to attack the Web server. As an example, an error code such as 404.2-Web Service Extension Lockdown Policy Prevents This Request is returned to a Web client as 404-File or Directory Not Found, and, thereby, gives the Web client no indication of why the request failed.

Although this change to error message reporting reduces the possibility of an attack by a malicious user, it makes it difficult to debug a failed request. For this reason, you can enable substatus error codes logging to IIS log files when appropriate. Note that on clean installs, substatus code logging for W3C Extended format files is enabled by default. Doing so is particularly useful when the logging of Win32 error codes is enabled. Then, to obtain the information that you need, you simply locate the specific request in the log file and check the Win32 error code and substatus code. This feature is called W3C extended logging. Figure 11.2 Extended Logging Properties Sheet shows substatus codes as they appear on the extended logging properties sheet.

For more information about logging substatus error codes, see Substatus Error Codes in Log Files.

# Configuring the WWW Service to Log Worker Process Recycling Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Proper configuration of IIS is always essential to successful troubleshooting. By setting the **LogEventOnRecycle** metabase property, you can direct the WWW service to log worker process recycling events in the event log. To accomplish this, you can set the **LogEventOnRecycle** property directly as a bitmask or you can set individual **AppPoolRecycle** property settings to **true**. The **LogEventOnRecycle** property is set to **AppPoolRecycleMemory** by default.

This is important as there could be occasions when the problem reported happened at or near the same time as a worker process recycle for the application. Having this information makes it easier to troubleshoot exactly what happened at the time of the problem to the entire server.

Table 11.1 summarizes the event IDs that are logged, and the related metabase properties and their bitmasks.

**Table 11.1 LogEventOnRecycle Configuration**

| Recycle Condition | Event ID | Metabase Property | Bitmask |
|---|---|---|---|
| Elapsed time | 1074 | **AppPoolRecycleTime** | 1 (0x1) |
| Number of requests processed | 1075 | **AppPoolRecycleRequests** | 2 (0x2) |
| Scheduled recycle | 1076 | **AppPoolRecycleSchedule** | 4 (0x4) |
| Virtual memory consumed | 1077 | **AppPoolRecycleMemory** | 8 (0x8) |
| ISAPI reported itself unhealthy | 1078 | **AppPoolRecycleIsapiUnhealthy** | 16 (0x10) |
| Recycled on demand | 1079 | **AppPoolRecycleOnDemand** | 32 (0x20) |
| Recycled due to configuration change | 1080 | **AppPoolRecycleConfigChange** | 64 (0x40) |
| Private memory consumed | 1117 | **AppPoolRecyclePrivateMemory** | 128 (0x80) |

# Checking NT System and Application Event Logs

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When looking for information about a problem, always consult the event logs for the application. Logging begins automatically when Windows is started. There are three types of logs: system, security, and application. For each type of log, you can filter the events to be viewed, designate the number of entries to view, specify how long to save entries, and specify whether to automatically overwrite existing events when the log becomes full.

For information about opening Event Viewer to see the event logs, see About Events.

# Checking the HTTP Error Log

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In IIS 6.0, HTTP.sys logs errors in the HTTP error log. The HTTP error log is the first place you should look when IIS returns an HTTP 503–Service Unavailable error, for example. The HTTP error log is located in *systemroot*\System32\LogFiles\HTTPERR.

For information about HTTP errors, see HTTP Status Codes in IIS 6.0.

# Checking the IIS Logs

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The IIS logs provide a great deal of information about the activity of a Web application. You can find the IIS logs in *systemroot*\System32\LogFiles\W3SVC*number*, where *number* is the site ID for the Web site.

# Restarting IIS Services

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

During troubleshooting, you might need to restart the IIS services. You can use IIS Manager to start or to stop any Web site on your server running IIS, to stop or recycle an application pool, or to restart the WWW service, which restarts the complete IIS service base.

# Restarting a Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Stopping a Web site causes the WWW service to remove the URLs for that site from the HTTP.sys configuration. The WWW service then marks the Web site as stopped in the metabase and directs the Web site not to start again automatically when the WWW service is restarted. Stopping a Web site does not cause loaded segments of the applications to unload, nor does it affect the worker processes that might be running when you stop the site. Additionally, requests that are waiting in the application pool queue in HTTP.sys will still be processed. However, new requests will either generate HTTP 404-Not Found errors, or, if no other Web site is listening on the port, will send the client a socket connection error.

Web sites can be stopped and started by using either IIS Manager or the IisWeb.vbs command-line script. For information about stopping and restarting a Web site by using either IIS Manager or IisWeb.vbs, see Starting and Stopping Web Sites.

# Recycling an Application Pool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Application pools are made up of a listening and routing structure in HTTP.sys and one or more ready-to-start worker processes that are waiting to process incoming requests. In worker process isolation mode, you can configure IIS to periodically restart worker processes under certain conditions. This automatic restarting of worker processes is called *recycling*.

Recycling an application pool causes the WWW service to shut down all running worker processes that are serving the application pool, and then start new worker processes. Whether the WWW service starts the new worker processes before it stops the existing one depends on the **DisallowOverlappingRotation** property in the metabase. Recycling an application pool does not alter any state in HTTP.sys or change any configuration in the metabase.

| **Note** |
| --- |
| When an application pool is serviced by more than one worker process, the recycle operation is staggered in some scenarios. Only when a worker process is recycled on demand or when all of the worker processes hit their memory limits at the same time would they be restarted simultaneously.<br><br>For information about recycling an application pool on demand, see Configuring Worker Processes for Recycling. |

# Stopping an Application Pool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Stopping an application pool causes the WWW service to shut down all running worker processes serving that application pool. HTTP.sys is then directed to return HTTP 503-Service Unavailable errors for any requests currently queued for this pool, and to return HTTP 503 errors for all future requests. The application pool is marked as stopped in the metabase and is configured not to start automatically when the WWW service is restarted. You must manually start the application pool to cause it to serve requests again.

# Restarting the WWW Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Sometimes, as a last resort, you need to restart the WWW service. For information about restarting the WWW service, see Starting and Stopping Services.

# HTTP Status Codes in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP status codes provide the best information about what is happening with IIS. On an active Web server, HTTP status codes provide a continuous feed of up-to-the-moment information about the activity and health of the server.

Most HTTP status codes have three digits, for example, 401. Some status codes have three digits followed by a decimal point, and one or two more digits (for example, 300.12). In such a case, the number that follows the decimal point is called the substatus code.

Codes within each hundred-number range provide specific types of information, as summarized in Table 11.2 HTTP Status Codes.

**Table 11.2 HTTP Status Codes**

| Status Code Range | Type of Code |
|---|---|
| 100 | Informational |
| 200 | Successful |
| 300 | Redirection |
| 400 | Client Error |
| 500 | Server Error |

As an administrator, at some point you will inevitably need to determine which HTTP status codes are being returned by IIS. There are a number of ways to do this. Your choice of method depends on the amount of information that you need and the type of problem that you are troubleshooting. If you have a problem that is limited to one or a few clients, viewing the status codes from the clients Web browser or issuing a reproduced HTTP request with WFetch might best serve your needs. However, if you need to look for an individual request or for a collection of multiple requests over a period of time, you should examine the IIS logs. Viewing IIS logs allows you to see not only the main HTTP status code, but the Win32 error code and the HTTP substatus code (if logging is configured to do so). The Win32 error codes and the HTTP substatus codes often contain information that is critical to your troubleshooting effort.

The following sections describe the HTTP status codes and provide troubleshooting suggestions.

# HTTP 1xx-2xx -- Informational and Success Codes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP status codes in the 1*xx* are typically informational. Status codes in the 2*xx* range indicate that the transaction was successful. Because the codes in both ranges are self-explanatory, they do not require further discussion.

# HTTP 3xx -- Redirection Codes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP status codes in the 3*xx* range pertain to *redirection* (telling the browser to issue a new request at a different location). These codes do not indicate that a problem has occurred.

Table 11.3 HTTP 300-Class Error Codes Returned by IIS lists the HTTP redirection codes that IIS returns.

**Table 11.3 HTTP 300-Class Error Codes Returned by IIS**

| Status Code | Condition |
|---|---|
| 301 | Permanent Redirect. |
| 302 | Object Moved |
| 304 | Not Modified. |
| 307 | Temporary redirect. |

# 301-Permanent Redirect

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This redirection status code tells the Web client that the location for the requested resource has permanently changed. The new location is specified in the **Location** HTTP header. This is primarily useful for Web clients that keep record of HTTP URL links. Upon receiving this status code, the Web client can update the stored URL with the new location.

# 302-Object Moved

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This standard redirection status code tells the Web client to issue a new request to the location specified in the **Location** HTTP header.

# 304-Not Modified

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

RFC 2616, "Hypertext Transfer Protocol — HTTP/1.1", provides functionality for conditional GET requests. For example, an HTTP client can specify an **If-Modified-Since** HTTP header that consists of a time and date stamp, which tells the server that it has a cached copy of the content being requested. If the request meets the condition specified in the **If-Modified-Since** header, the server will not return a body, but will return the 304-Not Modified result.

For more information about RFC 2616, see the W3C World Wide Web Consortium Web site.

# 307-Temporary Redirect

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The temporary redirect option, which is new in IIS 6.0, is used to prevent a Web browser from losing data when the browser issues an HTTP POST request. Normally, when a Web browser issues a POST request and then receives a 302-Object Moved redirect message from the Web server, the browser issues a GET request for the new location and loses the data in the **POST** request. With a 307 redirect, the browser reissues the POST request with the original data to the new location.

For more information about temporary HTTP redirects, see the HttpRedirect Metabase Property.

# Courtesy Redirects

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When a browser makes an HTTP request, the request sometimes takes the form http://example.contoso.com/vdir1. Notice that there is no trailing / at the end of the URL. In this case, vdir1 is a directory, instead of a file. As a *courtesy* to the Web browser, IIS responds to this request with a 302-Object Moved redirect message with the HTTP header: **Location: /***vdir1***/**. This is known as a courtesy redirect.

Courtesy redirection can produce unexpected behavior when the Web server is behind a Network Address Translation (NAT) device —a proxy server, for example. Suppose, for example, that the Web site is configured to listen on port 8080 and the NAT device is configured to forward HTTP requests on port 80 to the Web server on port 8080. In this configuration, the NAT device accepts the Web browsers request, but when the courtesy redirect occurs, IIS appends the port number to the host name. The NAT device needs to be aware of this and alter the response appropriately before returning it to the client.

For more information, see Knowledge Base article 298408, IIS Generates Courtesy Redirect When Folder Without Trailing Slash Is Requested, and Knowledge Base article 313074, How To Redirect Browser Requests in Internet Information Services 5.0.

# HTTP 40x -- Client Error Codes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP status codes in the 4*xx* range indicate that a problem occurred with the request. Request problems can range from the request not meeting authentication requirements to the request being malformed. RFC 2616, "Hypertext Transfer Protocol — HTTP/1.1", refers to request problems as client errors because the requests originate from the client. For more information about RFC 2616, see the W3C World Wide Web Consortium Web site.

Table 11.4 HTTP 400-Class Client Error Codes Returned by IIS lists the client error codes that IIS returns. The descriptions for most codes are self-explanatory. When additional information about a code is required, it is provided in one of the following sections.

**Table 11.4 HTTP 400-Class Client Error Codes Returned by IIS**

| Status Code | Condition |
|---|---|
| 400 | Cannot resolve the request. |
| 401.*x* | Unauthorized. |
| 403.*x* | Forbidden. |
| 404.*x* | File or directory not found. |
| 405 | HTTP verb used to access this page is not allowed. |
| 406 | Client browser does not accept the MIME type of the requested page. |
| 407 | Initial proxy authentication required by the Web server. |
| 412 | Precondition set by the client failed when evaluated on the Web server. |
| 413 | Request entity too large. |
| 414 | Request URL is too large and therefore unacceptable on the Web server. |
| 415 | Unsupported media type. |
| 416 | Requested range not satisfiable. |
| 417 | Expectation failed. |
| 423 | Locked error. |

# HTTP 400-Cannot Resolve the Request

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS returns a 400 error code when the request is malformed. Though there are a variety causes for this error, the most common reason is that the request does not comply with RFC 2616. For example, if the request is made in HTTP 1.1, RFC 2616 requires that the request include a **Host** header. The simplest HTTP 1.1 request would look similar to the following:

```
GET / HTTP/1.1
Host: example.contoso.com
```

You can use WFetch to issue such a custom-built request. Most HTTP clients adhere to HTTP RFC 2616 and issue well-formed requests. However, if you are developing a custom HTTP client and are experiencing HTTP 400 problems, use WFetch to make test requests.

**To issue a simple HTTP 1.1 request using WFetch**

1. Start **WFetch**.
2. From the **Advanced Request** list box, click **Raw Request**.
3. In the box, type the following text, where *ComputerName* is the name of your server running IIS:

   ```
   GET / HTTP/1.1\r\n
   Host: ComputerName\r\n
   \r\n
   ```

4. Ensure that the **Host** box contains the same *ComputerName* as noted above.
5. Click **Go**.

This sends the most basic HTTP 1.1 GET request to the server.

HTTP.sys records some errors in its own log file. Table 11.5 HTTP.sys Logged Reason Codes for HTTP 400 Errors lists the HTTP.sys reason codes and explanations for each of the 400 errors. These errors are not recorded in the IIS logs.

**Table 11.5 HTTP.sys Logged Reason Codes for HTTP 400 Errors**

| Reason Code | Condition |
|---|---|

| | |
|---|---|
| BadRequest | The request could not be understood by the server because the syntax was incorrect.<br>In the following instances, HTTP.sys, the kernel-mode driver, will reject a request as a BadRequest. HTTP.sys returns an HTTP 400 error (Bad Request) to the client. This HTTP 400 error is not customizable:<br>• The verb used in the request is invalid.<br>• The requested URL is invalid.<br>• The requested header name is invalid.<br>• The requested hostname is invalid.<br>• The request contains an invalid carriage return and/or line feed as a terminator.<br>• The request contains an invalid content length header or invalid entity chunk length.<br>• The cumulative length of the headers in the request is longer than the maximum allowed.<br>• The header field in the request is too long.<br>• The request header is too long. |
| Verb | Invalid verb. |
| URL | Invalid URL. |
| Header | Invalid header name. |
| Hostname | Invalid hostname. |
| Invalid_CR/LF | Invalid carriage return or line feed. |
| Number | Invalid number. |
| FieldLength | A header field in the request was too long. |
| RequestLength | The request length was too long. |

# HTTP 401.x-Unauthorized

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Authentication is one of the first operations performed when an HTTP request is issued. *Authentication* is the process whereby IIS creates a user context for an HTTP request, typically by obtaining credentials from the HTTP client using a preconfigured authentication method, and then calling a Windows logon API using those credentials. The API then returns a security token for the request, which represents the user context.

After the authentication process concludes, IIS determines where the HTTP request goes next based on the resource that is being requested. Regardless of this choice, IIS issues an authorization check against the requested resource. IIS checks to ensure that the user context associated with this request is allowed to make the request. Usually, IIS performs a file ACL check to authenticate the request.

When IIS cannot authenticate a request, it returns a 401.*x*-Unauthorized code. The substatus codes provide detailed information about why the request failed, as shown in Table 11.1 LogEventOnRecycle Configuration. The descriptions for most substatus codes are self-explanatory. When additional information about a substatus code is required, it is provided in one of the following sections.

**Table 11.6 HTTP 401-Substatus Codes**

| 401 Substatus Code | Condition |
|---|---|
| 1 | Access is denied due to invalid credentials. |
| 2 | Access is denied due to server configuration favoring an alternate authentication method. |
| 3 | Access is denied due to an ACL set on the requested resource. |
| 4 | Authorization failed by a filter installed on the Web server. |
| 5 | Authorization failed by an ISAPI/CGI application. |
| 7 | Access denied by URL authorization policy on the Web server. |

# 401.1 and 401.2-Authentication Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Typically, HTTP 401.1 and 401.2 errors are encountered when the authentication process fails in some way — either because the mechanism that IIS used to obtain the credentials has failed or because the credentials themselves are invalid. This is an important distinction that is a critical to the problem isolation process. These errors tell you that, before performing any other function, IIS has failed to authenticate the user.

For a brief overview of the authentication options available in IIS, see Managing a Secure IIS 6.0 Solution.

**Initial Isolation**
When you know that authentication has failed, gather the following information:

- The URL that is being requested
- The authentication method that is configured for that node in the metabase

When you know the requested URL, you can use IIS Manager to verify the authentication methods that are enabled. Alternatively, you can use the Adsutil.vbs command-line script to check the **AuthFlags** metabase property. For information about the settings for this property, see AuthFlags Metabase Property.

**Multiple Authentication Methods**
Typically, initial HTTP requests to a server are anonymous. In most cases, a Web browser does not know to send authentication information, and, therefore, it issues a request without this information. If Anonymous authentication is enabled for the requested resource, IIS does not attempt to use other authentication protocols, but instead attempts to obtain a security token for the IUSR_*ComputerName* account by calling one of the Windows logon APIs. If this fails, then IIS looks to see if other authentication methods are enabled for the URL and sends back a 401.2 response to the browser that includes a list of **WWW-Authenticate** HTTP headers that specify the authentication schemes IIS is configured to accept for that URL.

At this stage, typically it is up to the HTTP client to choose to continue the HTTP transaction, to pick a protocol from the list, and to proceed to authenticate with that protocol. If this process is successful, IIS then calls a logon API and obtains a security token that it can use to associate a user context with the HTTP request.

**LogonMethod Default Has Changed**
The **LogonMethod** metabase property designates the kind of logon token that IIS asks for when calling the Windows logon APIs for Anonymous or Basic authentication. In earlier versions of IIS, the default was set to **0**, which caused IIS to request an INTERACTIVE token. This sometimes caused problems when the IUSR_*ComputerName*, or, in the case of Basic authentication, the user credentials did not have the **Log on locally** user right. In such a case, IIS returns a 401.1 error.

In IIS 6.0, the default value of **LogonMethod** has changed to **3**, which evaluates to a NETWORK_CLEARTEXT token. This token is very similar to an INTERACTIVE token; however, it does not allow the user to physically log on to the system console and does not require the Log on locally user right.

For more information, see Securing Sites with Web Site Permissions.

**No Authentication Methods Selected (AuthFlags=0)**
IIS returns a 401.2 error when no authentication methods are enabled. If you receive this error, ensure that an authentication method is enabled.

**Anonymous Accounts (IUSR_ComputerName) Attempting Sub-authentication Logon Receive the 401.1 Error: Logon Failed**
By default, the sub-authentication component, Iissuba.dll, is not enabled in IIS 6.0. In earlier versions, Iissuba.dll allowed IIS to manage passwords on anonymous accounts, which created a potential security risk. In IIS 6.0, you can use sub-authentication to manage passwords for anonymous accounts. To do so, your configuration must meet the following requirements:

- For applications for which you grant anonymous access, the worker process must run as LocalSystem.
- The sub-authentication component, Iissuba.dll, must be registered.
- The **AnonymousPasswordSync** metabase property must be enabled (set to **true**).

The actions taken to meet these requirements are different for clean installations of IIS 6.0 and upgrades to IIS 6.0 than they are for installations of IIS with sub-authentication configured. For more information about configuring sub-authentication, see Anonymous Authentication in IIS 6.0.

Additionally, when you encounter a 401.1 error, ensure that the account configured for anonymous authentication has not expired or is not locked out.

**Non-Anonymous authentication**
Initially, a Web browser issues an anonymous request. If Anonymous authentication is not enabled or if Anonymous authentication fails, IIS sends a list of supported authentication protocols as a group of **WWW-Authenticate** HTTP headers. At this point, the browser chooses the protocol to use, and then continues processing the request.

**Basic authentication**
Basic authentication is the simplest authentication protocol. Because of its simplicity, it is a good authentication method to enable temporarily when you are troubleshooting authentication problems. Use this authentication protocol if you want to quickly verify that a password is correct or that communication with a domain controller is working.

If the user name is a domain account, IIS contacts a domain controller to verify the credentials. If this fails, IIS returns a 401.2 error. If communication with the domain controller is successful, but the user name or password is invalid, IIS returns a 401.1 error.

Internet Explorer — not IIS — allows the user three connection attempts before rejecting the connection request and reporting an error to the user. When the Web server verifies that the user name and password correspond to a valid Windows Server 2003 user account, a connection is established.

**Integrated Windows authentication**
Integrated Windows authentication actually encompasses two different authentication protocols: Kerberos and Windows NT Challenge/Response, also known as NTLM. When this authentication protocol is enabled, IIS sends the following HTTP headers to the browser:

- **WWW-Authenticate: Negotiate**
- **WWW-Authenticate: NTLM**

The **Negotiate** header indicates that IIS can negotiate which of the two Windows authentication protocols to use. Internet Explorer 5, or later, recognizes this authentication header and determines which of the two authentication protocols to use. The **NTLM** authentication header is used as a fallback for browsers that do not support the **Negotiate** authentication header.

**Kerberos protocol authentication**
Authentication with the Kerberos protocol occurs as follows:

1. IIS requests authentication.
2. If the Windows user has not logged on to a domain, a dialog box requesting credentials appears in Internet Explorer, and then IIS contacts the Ticket Granting Server or Key Distribution Center (KDC) to request and receive a Ticket Granting Ticket. It then sends the Ticket Granting Ticket along with information about the server running IIS to the KDC.
    a. If the Windows user has already successfully logged on to the domain and received a Ticket Granting Ticket, IIS sends this ticket along with information about the IIS server to the KDC.
    b. The KDC issues the client a Resource Ticket.
    c. The client passes this ticket to the server running IIS.

    When troubleshooting Kerberos, ensure that the browser can make a trusted connection to the KDC by meeting the requirements listed in Microsoft Knowledge Base article 326985, How To: Troubleshoot Kerberos-related Issues in IIS.

Additionally, consider potential problems with the following:

- Service Principal Names. Kerberos uses a service for authentication. When the client passes the Ticket Granting Ticket and the information about IIS to the KDC, part of this information includes the server name from the URL that the browser is attempting to reach. By default, upon installation a systems NetBIOS name is registered in Active Directory® directory service. This is the name that a KDC uses to recognize IIS. It is called the Service Principal Name (SPN). If the browser is accessing the Web server by using some other host name — either the FQDN or another host header name — that name must be registered with Active Directory. You can do this by using the Setspn.exe command-line utility. For more information about Setspn.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click **Windows Support Tools**.

- Kerberos authentication. If you suspect that you are having a problem with the SPN, test Kerberos authentication by using the NetBIOS computer name. If the test is successful, you probably need to use the Setspn.exe command-line utility.

  To run Setspn.exe, at a command prompt, type the following:

  **Setspn -A HOST/***ServicePrincipalNameServiceAccount*

  In the above syntax, *ServicePrincipalName* is the new host name that you want to register and *ServiceAccount* is the identity under which the process that is hosting the service will be running. For computer accounts, like NetworkService or LocalSystem, use the NetBIOS name of the computer.

| **Note** |
| --- |
| The LocalService account, along with any other local accounts on an IIS server, cannot be authenticated by a KDC. Therefore, you cannot use the Kerberos protocol for authentication if the worker process identity is set to LocalService or to another account on the local computer. |

- Trust for delegation configuration. When troubleshooting Kerberos authentication, also ensure that the IIS computer is configured to be trusted for delegation in Active Directory. If the server running IIS is a member of the domain and is not a domain controller, then it must be trusted for delegation in order for Kerberos to work properly.

**To configure a computer to be trusted for delegation**

1. On the Domain controller, click **Start**, point to **Administrative Tools**, and click **Active Directory Users and Computers**.
2. Under the domain, double-click the **Computers** folder, right-click the server that is running IIS, and then click **Properties**.
3. Click the **General** tab.
4. Select the **Trusted for delegation** check box.
5. Click **OK**.

   The computer account is now trusted for delegation.

   - Security auditing. By enabling security auditing on the server running IIS, you can use the events that are logged to discover whether problems are occurring.

     For information about using the security log to troubleshoot Kerberos, see article 326985, How To: Troubleshoot Kerberos-related Issues in IIS.

**Windows NT Challenge/Response protocol**

Windows NT Challenge/Response (NTCR) protocol differs from Kerberos in that the server presents the HTTP client with a "challenge" and the client responds with its response. This way, the client's password is never sent over the network. Authentication with the NTCR protocol occurs as follows:

1. Typically, the client issues an initial anonymous request. When the anonymous request is rejected, IIS returns a 401.2

error and the **WWW-Authenticate** headers.

2. If the client fails or does not support Kerberos, the **Negotiate** and **NTLM** header values initiate an NTCR authentication exchange. The client closes the TCP connection, opens a new one, and sends a request that includes an **Authorization: NTLM** header. This header also includes encoded text that represents the users *UserName*, *ComputerName*, and *Domain*. This text is used by the Windows Security Support Provider Interface (SSPI) to generate the challenge. If the user account is not a local Windows account on the IIS server, the data is passed on to an appropriate domain controller, which then generates the challenge.

3. The challenge is sent to the client and IIS returns another 401.2 error.

4. The client uses its password and the challenge to create a mathematical hash. The client sends the hash back to the server in another **Authorization: NTLM** header.

5. The server accepts the response, and the local security provider or the appropriate domain controller recreates the same hash and compares the two. If they match, the user is successfully authenticated.

When troubleshooting NTCR authentication, note the following:

- Point-to-point connections. NTCR authentication requires point-to-point connection between the client and the server that is running IIS. Consequently, the NTRC protocol will not work with some European Organization for Nuclear Research (CERN) proxies and other Internet devices. As a result, NTCR is not suitable for use over the Internet. If a connection is broken during authentication, IIS returns a 401.2 error.

- HTTP keep-alives. A connection must be maintained through the entire authentication sequence. Therefore, HTTP keep-alives must be enabled on the server running IIS. If they are not enabled, IIS continues to return 401.2 errors until the browser fails the authentication sequence.

- Security privileges. The user account accessing the server must have the **Access this computer from the network** privilege. If this is not the case, IIS returns a 401.1 error.

- Domain controller communication. As with Basic authentication, if the credentials presented by the client are for a domain user account, the server running IIS needs to contact a domain controller.

**AuthPersistence Usage in IIS 6.0**

In earlier versions of IIS, the **AuthPersistence** metabase property had three possible settings. Two of the settings allowed administrators to enhance performance by specifying persistence based on the existence of a proxy server. Administrators could use either of those **AuthPersistence** settings to force IIS to negotiate one-time-per-client connections and then use those credentials for subsequent requests over the same connections. These two settings have been removed from IIS 6.0 for security reasons.

In IIS 6.0, the only valid setting for the **AuthPersistence** metabase property is **AuthPersistSingleRequest**, and NTLM is the only IIS 6.0 authentication protocol that honors this setting. The setting for **AuthPersistSingleRequest** is honored only in the following circumstances:

- Integrated Windows authentication is set to *NTLM*.

- Integrated Windows authentication is set to *Negotiate*, and NTLM authentication is used.

In either of these cases, **AuthPersistSingleRequest** is **False** — that is, not set — for backward compatibility with earlier versions of IIS. A value of **False** means that authentication persists for subsequent requests over the same connection.

In IIS 6.0, all other authentication protocols assume that the value of **AuthPersistSingleRequest** is **True** — that is, set — so authentication persists only for a single request over a connection. IIS 6.0 automatically resets authentication at the end of a request and forces each subsequent request over the same connection to authenticate.

**401.3-Unauthorized: Access Is Denied Due to an ACL Set on the Requested Resource**

A 401.3 error is a catchall "access denied" error. To troubleshoot this error, first check the authentication method that is

enabled on the requested URL. This will help you determine the security context under which the request is expected to execute: as an anonymous user or as an authenticated user. How you proceed depends on whether the user is authenticated or not.

Verify file and directory ACLs. When the requested URL is a directory, not a file, check the default document(s) that are configured for that URL. Sometimes, if the first document in the default document list is missing, the second document in the list might generate a 401.3 error.

After verifying the ACLs, you have a few options. You can enable security auditing for object access failures. This can be difficult, though, because you have to enable auditing on the individual objects (files, directories, and so on) that you want to monitor. Alternatively, you can use File Monitor and Registry Monitor to look for access denied problems in the registry or file system.

**Simplified UNC authentication model**

The Universal Naming Convention (UNC) authentication method, also called UNC Pass-through authentication, determines the credentials used for gaining access to a UNC share on a remote computer. Beginning with IIS 6.0, the UNC authentication method looks at the request user and the credentials stored in the **UNCUserName** and **UNCPassword** properties of the metabase to determine the credentials to pass through to the computer with the UNC share. This occurs in the following way:

1. If the **UNCUserName** is specified (not empty) and **UNCPassword** is valid, the requested user credentials are sent as the user identity for access to the remote share. If the **UNCUserName** is specified and the **UNCPassword** is not valid, a 500-Internal Server Error message is sent to the client. For information about troubleshooting this error, see HTTP 500.x -- Internal Server Error Codes.

2. If the **UNCUserName** is not specified, then the credentials of the request user (either an authenticated set of credentials for authenticated requests or IUSR_*ComputerName* credentials for anonymous requests) are sent as the user identity for access to the remote share.

| **Note** |
| --- |
| The **UNCAuthenticationPassthrough** metabase property is no longer used for UNC authentication. |

# HTTP 403.x-Forbidden

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Typically, 403 errors occur when an operation or request is disallowed because a requirement other than proper authentication credentials is not met. Commonly, this error occurs when a script request is made to a Web directory for which script access is not enabled. In such a case, first verify for which resource the request is being made. If the request is, indeed, for script code, such as ASP or ASP.NET, check the **execute permissions** for that directory in IIS Manager and ensure that at least **Script** is selected.

Table 11.7 HTTP 403 Substatus Codes lists the HTTP 403 error substatus codes.

**Table 11.7 HTTP 403 Substatus Codes**

| 403 Substatus Code | Description |
|---|---|
| None | Access is denied. |
| 1 | Execute access is denied. |
| 2 | Read access is denied. |
| 3 | Write access is denied. |
| 4 | SSL is required to view this resource. |
| 5 | SSL 128 is required to view this resource. |
| 6 | IP address of the client has been rejected. |
| 7 | SSL client certificate is required. |
| 8 | DNS name of the client is rejected. |
| 9 | Too many clients are trying to connect to the Web server. |
| 10 | Web server is configured to deny Execute access. |
| 11 | Password has been changed. |
| 12 | Client certificate is denied access by the server certificate mapper. |
| 13 | Client certificate has been revoked on the Web server. |
| 14 | Directory listing is denied on the Web server. |
| 15 | Client access licenses have exceeded limits on the Web server. |
| 16 | Client certificate is ill-formed or is not trusted by the Web server. |
| 17 | Client certificate has expired or is not yet valid. |
| 18 | Cannot execute requested URL in the current application pool. |
| 19 | Cannot execute CGIs for the client in this application pool. |

| | |
|---|---|
| 20 | Passport logon failed. |

# HTTP 404.x-File or Directory Not Found

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A HTTP 404 error indicates that the requested resource was not found. Table 11.8 HTTP 404 Substatus Codes lists the substatus codes for the 404 error. The descriptions for most substatus codes are self-explanatory. When additional information about a substatus code is required, it is provided in one of the following sections.

**Table 11.8 HTTP 404 Substatus Codes**

| 404 Substatus Code | Condition |
|---|---|
| None | File or directory not found. |
| 1 | Web site not accessible on the requested port. |
| 2 | Web service extension lockdown policy prevents this request. |
| 3 | MIME map policy prevents this request. |

Whether the requested resource is a file or a directory, begin by checking the following potential causes:

- Verify the file or directory. Examine the requested URL and check the physical path to which it maps.
- Check for unexpected host header routing. Problems with host headers occur when you have created more than one virtual Web server and rely on host header routing to serve content from the appropriate server. A 404 error results when you request a URL that exists on only one virtual server and, because of the configuration of the host header, the request is routed to the other virtual server.
- Verify that the request has been made on the correct port. The 404.1 error is returned when a request is made to a port on which the WWW service is not listening.
- Ensure that the requested file is not hidden. IIS sends a 404 error if the **Hidden** file attribute for a requested file is set.
- Validate (*ScriptMaps) Web service extension requests. 404 errors are sometimes returned when you have a *ScriptMap Web service extension and the Verify that file exists option is set to **true**. Because no file is actually associated with a *ScriptMap request, IIS cannot check for the file, so it returns a 404 error.

Both the Web service extension lockdown policy and **MimeMap** restriction features can cause a 404 error to be returned to the client making the request. If one of these features is the cause of an HTTP 404 error, do the following:

- Check the sc-substatus field for the request in the IIS W3C extended log. For information about enabling substatus logging, see Using Substatus and Win32 Errors in W3C Extended Logging.
- Check the Win32 error in the IIS W3C extended log. By default, IIS logs all Win32 errors associated with the request that are returned by the underlying operating system.
- Enable a modified custom error for the HTTP 404 error that you suspect. You can configure IIS to return a response to the client that contains the substatus code by editing the custom error page for the 404 error, and placing some custom text into the file. The custom error pages are located in *systemroot*\Help\IisHelp\Common.

| **Important** |
|---|
| Enabling a custom error that provides substatus information undermines the security strategy used by IIS and should be done temporarily and only for troubleshooting purposes. |

**404.1-Web Site Not Accessible on the Requested Port**
The 404.1 error can occur only on computers with multiple IP addresses. If a specific IP address/port combination receives a client request, and the IP address is not configured to listen on that particular port, IIS returns a 404.1 HTTP error.

For example, if a computer has two IP addresses and only one of those IP addresses is configured to listen on port 80, any requests received on the other IP address with port 80 causes IIS to return a 404.1 error. This error should be set only at the service level because it is returned to clients only when multiple IP addresses are used on the server.

**404.2-Lockdown Policy Prevents This Request**
If a request is denied because the associated ISAPI or CGI has not been unlocked, a 404.2 error is returned. When substatus logging is enabled, if you look at this request in the IIS logs, you will see an entry similar to the following:

```
2002-11-25 05:46:15 127.0.0.1 GET /default.asp - 80 - 127.0.0.1 - 404 2 1260
```

If IIS logging is not configured to log the substatus code, you can check the Win32 error to verify this condition. When a 404.2 error occurs, IIS logs the Win32 error 1260, which is an ERROR_ACCESS_DISABLED_BY_POLICY error.

**404.3-MIME Map Policy Prevents This Request**
If a request is denied because a MIME map restriction is in effect, a 404.3 error is returned. When substatus logging is enabled, if you look at this request in the IIS logs, you will see an entry similar to the following:

```
2002-11-25 05:46:27 127.0.0.1 GET /somefile.unkext - 80 - 127.0.0.1 - 404 3 50
```

As with a 404.2 error, a 404.3 error causes a Win32 error to be logged. In this case, the error is 50, which is an ERROR_NOT_SUPPORTED error.

Another quick way to verify that a MIME map restriction is in effect is to add a wildcard MIME type to the virtual directory in question. This enables all MIME types to be served without restriction. Then, repeat the failed HTTP request and verify that it is served successfully.

| **Note** |
| --- |
| Adding a wildcard MIME type to the virtual directory is a troubleshooting step, not a solution to the problem. Leaving the wildcard in place and allowing all MIME types to be served compromises the security of the server. |

For more information about adding a wildcard MIME type, see Working with MIME Types.

**405-HTTP Verb Used to Access This Page Is Not Allowed**
This HTTP code is returned when the client makes an HTTP request that contains a verb that is not allowed. This condition can occur when:

- A request for static content contains verbs other than GET or HEAD, and the request is made to a URL that did not end with a /. Instead performing a courtesy redirect, IIS sends the 405 error.
- An HTTP request for an ISAPI application contains a verb not listed in the **ScriptMaps**configuration for that ISAPI.

**407-Initial Proxy Authentication Required by the Web Server**
This error indicates that an intermediary proxy server between the HTTP client and the Web server requires some form of authentication. How you troubleshoot this kind of error depends upon the proxy server itself. Generally speaking, running a network trace with Network Monitor is helpful. If the Web client is a custom client, ask its developer to ensure that it is handling security appropriately.

**413-Request Entity Is Too Large**
For security reasons, you can limit the size of the *entity-body* of an HTTP request by modifying the **MaxRequestEntityAllowed** metabase property. When an entity-body of a client request exceeds the size that is specified in the **MaxRequestEntityAllowed** property, IIS returns a 413 error. If this error is logged for an individual request, an application on the Web server might have encountered an unexpected event and generated a request that is too large. If this error is logged for many requests, a malicious user might be attempting to compromise your Web server.

**414-Request URL Is Too Large and Therefore Unacceptable on the Web Server**
Just as the entity body of a request can be too large for IIS to process, a URL can be too long for IIS to process. IIS returns a 414 error if this occurs.

# HTTP 5xx Server Error Codes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Error codes in the 5*xx* range indicate server problems. Table 11.9 HTTP 500-Class Client Error Codes Returned by IIS lists the HTTP 5*xx*-class codes that IIS returns. The descriptions for most codes are self-explanatory. When additional information about a code is required, it is provided in one of the following sections.

**Table 11.9 HTTP 500-Class Client Error Codes Returned by IIS**

| Status Code | Condition |
|---|---|
| 500.*x* | Internal server error. |
| 501 | Header values specify a configuration that is not implemented. |
| 502 | Bad gateway. |
| 503 | Service unavailable. |
| 504 | Gateway timeout. |
| 505 | HTTP version not supported. |

# HTTP 500.x -- Internal Server Error Codes

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table 11.10 HTTP 500 Substatus Codes lists the most common 500 substatus codes returned by IIS. The descriptions for most substatus codes are self-explanatory. When additional information about a substatus code is required, it is provided in one of the following sections.

**Table 11.10 HTTP 500 Substatus Codes**

| 500 Substatus Code | Condition |
|---|---|
| 11 | Application is shutting down on the Web server. |
| 12 | Application is busy restarting on the Web server. |
| 13 | Web server is too busy. |
| 14 | Invalid application configuration on the server. |
| 15 | Direct requests for Global.asa are not allowed. |
| 16 | UNC authorization credentials are incorrect. |
| 17 | URL authorization store cannot be found. |
| 18 | URL authorization store cannot be opened. |
| 100 | Internal ASP error. |

**500.11 and 500.12-Application State Issues**

Users rarely encounter 500.11 and 500.12 errors in their browser. These errors indicate that the ASP application to which the requested ASP page belongs is in the process of shutting down, restarting, or both. Restarts and shutdowns can be triggered directly from code when the built-in APIs available to ASP developers are used. Occasionally, these errors occur when the Global.asa file for the application (if one exists) is updated or altered in such a way that a file change notification is issued. Because IIS monitors for file change notifications on ASP content, IIS receives this notification, and because the file is the Global.asa file, IIS restarts the application.

If users often encounter these errors in their browser and you are certain that the code in the Global.asa file is not being updated, virus scanning and backup software, which sometimes sweep the ASP content and trigger a notification, might be causing these errors. For more information, see Microsoft Knowledge Base article 248013, Err Msg: HTTP Error 500-12 Application Restarting.

**500.13-Web Server Too Busy**

ASP requests are executed by threads from a pool of threads whose size is limited to 25 threads per processor, by default. If more ASP requests arrive than there are threads available to execute them, ASP places the extra requests in a queue, where they wait until a thread becomes available. By default, this queue is limited to 3000 requests. If the queue becomes full, the next ASP request, instead of being queued, causes a 500.13-Web server too busy error. The number of requests that can wait in the queue is controlled by the **AspRequestQueueMax** metabase property. Change the **AspRequestQueueMax** property to produce the desired user experience — a smaller queue allows users to more quickly see the 500.13 error when ASP requests are backed up.

If users encounter this error, select the **Active Server Pages/Requests Queued** performance counter check box. If the queue fills up, but ultimately empties again, or if the queue remains partially filled but requests move through very quickly, there probably is not a problem, just a spike in traffic. However, if the queue remains partially or completely full for a sustained period and requests do not appear to be moving through quickly enough, there might be a problem.

Diagnosing a problem of this type can be a complex process. For information about diagnosing such problems, see Advanced IIS Troubleshooting with Tracing and Debugging.

**500.16-UNC Authorization Credentials Are Incorrect**

Problems with content stored on remote file servers can be more complex than problems with locally stored content. The 500.16 error indicates that there is a specific configuration problem with remotely stored content. When IIS is configured to use specific credentials to access the UNC path in the metabase, it uses those credentials to open the content on the remote file server. To do this, IIS uses a Windows logon API to obtain a security token that it can use to impersonate a security identity when accessing the remotely stored content. If the call to the Windows logon API fails, indicating that there is a problem with the user name or password, IIS returns an HTTP 500.16 error.

**500.17 and 500.18-IIS URL Authorization Issues**

IIS URL Authorization is a security feature that is new in IIS 6.0. Among other administrative tasks, IIS URL Authorization configures the Authorization Manager store by setting the **AzStoreName** metabase property. This store can be an XML file or an LDAP location. It is configured by setting the **AzStoreName** property to an appropriate string that represents the path to a store. For example: **msxml://c:\MyStore.xml** or **msldap://CN=MyAzStore, CN=Program Data, DC=MyDomain, DC=com**.

The 500.17 and 500.18 errors pertain to problems accessing the Authorization Manager store. A 500.17 error indicates that the store could not be found. To begin troubleshooting one of these errors, try to verify the path specified in the string by either opening the XML file or testing the LDAP path with a simple client, such as LDP.exe. For more information about LDP.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click **Windows Support Tools**.

A 500.18 error typically indicates that the store was found, but could not be opened. The error description might contain information such as an HRESULT and description. However, this error generally occurs because there is an ACL–related problem. The security context that is used to open the store is that of the worker process identity. To troubleshoot, verify that the configured worker process identity is a member of the built-in IIS_WPG group and that this group has access to the store. File Monitor is a good utility to use in such a case.

For more information about IIS URL Authorization, see URL Authorization in IIS 6.0.

# 503-Service Unavailable

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP 503 errors are returned more often in IIS 6.0 than in earlier versions of IIS. Typically, the HTTP 503-Service Unavailable error is returned directly from HTTP.sys when there is a problem with getting the request up to the worker process. However, this error can occur for a variety of reasons, as listed in Table 11.11 HTTP 503 Errors from HTTP.sys.

**Table 11.11 HTTP 503 Errors from HTTP.sys**

| Reason String | Text in HTTP.sys Error Log | Cause(s) of Error |
|---|---|---|
| Service unavailable. | N/A | • IIS cannot start any new worker processes because of limited system resources or because starting a new worker process would exceed the **DemandStartThreshold**property.<br>• Bandwidth throttling is enabled, but the filter addition fails.<br>• The control channel or internal configuration group for the URL is inactive.<br>• The send for a request that was serviced from the cache failed (typically under low memory conditions). |
| Too many users. | ConnLimit | The connection limit for the site or server as a whole has been reached. |
| Application taken offline. | AppOffline | The application pool has been put into Rapid Fail Protection and has been disabled automatically. |
| Application request queue full. | QueueFull | The application pools request queue has been exceeded and the request cannot be queued. |
| Administrator has taken application offline. | Disabled | The administrator has stopped the application pool. |
| Application automatically shut down due to administrator policy. | AppShutdown | The application pool has been shut down because it exceeded its CPU usage limit. |
| Request timed out in app pool queue. | AppPoolTimer | The application pool is too busy to handle the request. The request has, therefore, timed out in the queue and has been returned with a 503 error. |

For security purposes, the description that is sent back to the client (Service Unavailable) does not fully describe the error. HTTP.sys keeps its own error log. Requests that generate 503 errors never pass into user mode; therefore, the HTTP error log is the only place these problems are documented. To troubleshoot the cause of the 503 error, use the following procedure.

**To check for possible causes of HTTP 503 errors**

1. Check the HTTP.sys error log for information about the error being returned. See Table 11.11 HTTP 503 Errors from HTTP.sys for error descriptions.
2. Check the event logs. Typically, the event logs contain more detailed information about the cause of a 503 error.
3. Verify that health/recycling issues are not causing the error.
4. Check for server binding conflicts.
5. Check the IP inclusion list for errors.

# Other HTTP.sys Error Log Errors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In some cases, HTTP.sys generates entries in its error log that are not associated with a specific HTTP request and that do not have HTTP error codes. Table 11.12 Other HTTP.sys Errors lists these errors.

**Table 11.12 Other HTTP.sys Errors**

| Logged Reason Code | Condition |
|---|---|
| Timer_ConnectionIdle | The connection was reset as its idle time exceeded the **ConnectionTimeout** property. |
| Timer_HeaderWait | The headers for the request were not received within the time limit specified by the **HeaderWaitTimeout** property. |
| Timer_MinBytesPerSecond | The throughput rate of this connection has dropped below the limit specified in the **MinFileBytesPerSec** property. |
| Timer_EntityBody | The entity body was not received within the specified timeout. |
| Timer_Response | The connection was reset because the response was not processed within the specified time limit. |
| Timer_AppPool | The connection was reset because the request stayed in the request queue of the application pool longer than the specified time limit. |

For complete information about the errors logged in the HTTP error log, see Error Logging in the HTTP API. For more information about available configuration options in HTTP.sys, see Microsoft Knowledge Base article 820129, Inf: Http.sys Registry Settings for IIS.

# Troubleshooting IIS Configuration Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Configuration problems present their own unique troubleshooting challenges. This section provides information about troubleshooting common configuration problems that occur with the integrity of XML in the IIS metabase and with UNC content.

# Preserving the Integrity of XML in the IIS Metabase

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

With the introduction of the XML-based IIS configuration store, administrators now have the ability to directly edit XML in a text editor. This feature is called edit-while-running. Because XML has very strict rules about syntax, the XML store needs to be well-formed at all times. Manually editing the XML store with a text editor can introduce syntax errors in the MetaBase.xml file. Therefore, when manually editing the MetaBase.xml file with a text editor, observe the following guidelines:

- If a syntax error in the XML file creates a problem, use the metabase backup/restore feature to restore the metabase from the backup files.
- Open the MetaBase.xml file in Internet Explorer, which has a built-in XML parser. If a syntax error occurs, Internet Explorer displays it and notes its location.

For information about the metabase edit-while-running feature of IIS, see Enabling Edit-While-Running in IIS 6.0. For information about the metabase backup/restore feature, see Restoring the Metabase from Backup Files.

# Troubleshooting Problems with UNC Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Traditionally, situations that involve Universal Naming Convention (UNC) content have experienced configuration and performance problems related to security, user delegation, and file caching. Improvements in IIS 6.0 affect how these problems are resolved. Figure 11.3 IIS 6.0 UNC Authentication illustrates the logic IIS 6.0 uses to manage and serve content from a UNC file share.

# Accessing and Executing Remote Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When IIS accesses content stored on a remote file server, user delegation becomes a factor because IIS uses the clients credentials to access content on the file server. In effect, the Web client passes the users credentials to IIS, which then delegates them to the file server for the authorization check. In IIS 6.0, user delegation is easier because, by default, IIS uses the credentials of the request user (the anonymous user identity for anonymous requests and the authenticated users identity for authenticated requests) to access the content on the remote file server. So, by default, IIS does *pass-through authentication*, which means that IIS passes the user credentials through to the remote file server. If you want IIS to use a specific user when accessing remote content, set the **UNCUsername** and **UNCPassword** properties in the IIS metabase. For information about setting these properties, see the UNCUserName Metabase Property and the UNCPassword Metabase Property.

**Logging On**

In Figure 11.3 IIS 6.0 UNC Authentication, the request user is the identity of the request coming into the Web server, such as a GET request for http://www.contoso.com/staticfile.txt. If anonymous access is enabled, this request uses the identity of the anonymous user as specified in the metabase (typically, IUSR_*ComputerName*). If anonymous access is disabled and a valid authenticated request comes in, IIS uses that users account to log on. However, in the case of UNC content, at this stage, IIS checks if **UNCUserName** is specified in the metabase. If so, IIS logs on as that user. If **UNCUserName** is not specified in the metabase or if it is set to an empty string, then IIS logs on as the user who originally made the request (that is, as an anonymous user or as an authenticated user).

| **Note** |
| --- |
| The **UNCPassthroughAuthentication** metabase property has been removed from IIS 6.0. In IIS 6.0, pass-through authentication is enabled by default. To disable pass-through authentication, use the **UNCUserName** and **UNCPassword** properties. |

**Accessing the Remote Server**

After IIS has a user identity, it must access the remote file server. The type of authentication (Anonymous, Basic, NTLM, Kerberos) enabled on the server can significantly affect how successful this step is. In almost all cases, Basic authentication enables IIS to access a remote file server (although you must always use SSL with Basic authentication since user names and passwords are sent in plain text). Using Basic authentication can help you verify that everything else is working properly.

**Executing the Remote Content**

So far, we have discussed how remote content is *accessed*. Remote content must also be *executed* in the context of this user account. In other words, if **UNCUserName** and **UNCUserPassword** are set, then all remote content will be accessed and executed in the context of **UNCUserName**. This might not be desirable for most applications, because with this approach you lose the identity of the originating Internet/Intranet user. If pass-through authentication is being used, then the request is processed under the identity of the request user.

The process illustrated in Figure 11.3 IIS 6.0 UNC Authentication applies to all content that is executed or retrieved by the server. Consequently, static content, such as Graphics Interchange Format (GIF) and Hypertext Markup Language(HTML) pages, Script-Mapped files, CGI executables, and ISAPI Extension DLLs (like ASP, ASP.Net, and so on) runs under this user context. (ISAPI filters run under the context of the worker process identity. By default, the worker process runs as NetworkService, which is a local account.)

**Working in a Domain Environment**

In most cases, you will want to run your Web servers and file server in a domain environment because it is much simpler to use a domain environment in which you can control one set of users and groups from the domain controller. Furthermore, if you want to use Windows Integrated Authentication in this scenario, then you need to use a domain environment to take advantage of the new constrained delegation feature of Windows Server 2003. Instructions on setting up constrained delegation follow. For more information about constrained delegation, see Delegating authentication in Help and Support Center for Windows Server 2003.

**Working in a Workgroup Environment**

Web servers and a file server used in a workgroup environment are difficult to manage and maintain. In a workgroup environment, because one user account has access to another computer only if that computer has a user with the same user name and password, you have added administrative overhead. To add a new user to your environment, you have to add the

user to both servers and you need to ensure that both accounts have the same password.

For an detailed explanation of using remote content on a UNC share, see Deploying and Configuring Internet Information Services (IIS) 6.0 with Remotely Stored Content on UNC Servers and NAS Devices.

# Troubleshooting File Caching Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

There are two causes for problems with file caching of UNC content:

- Vendor's implementation and support for file change notifications. Usually non-Windows-powered Network Attached Storage (NAS) vendors provide fixes for known problems; however, as a workaround, caching is typically disabled to prevent those problems.

- The number of simultaneous distinct file structures that the ASP and static file caches can monitor for changes. Because each monitor takes up a work item indefinitely from the Server Message Block (SMB) connection with the file server, IIS can exhaust a system's SMB resources by trying to cache a wide and disparate set of directories.

To address these problems, several changes have been made to the way IIS caches content. These changes improve performance and reliability in most cases; however, these changes can have unexpected effects on UNC stored content.

**ASP and Static File Caching Changes**

IIS 6.0 has a new caching algorithm for the ASP script and static file cache when the content is being stored on a UNC share. In earlier versions, IIS registered for a file change notification from the operating system for each directory structure so that it would be notified when a file changed. In IIS 6.0, the Web server simply checks the Last-Modified date on the cached file instead of requesting these notifications. If the Last-Modified date has not changed, the cached version of the file is sent out. If the file is new, the cache is updated with the new version of the file and is sent to the client.

To further improve performance, the algorithm has a staleness aspect that causes IIS to check the Last-Modified date only if more than five seconds have passed since the last check. Otherwise, IIS assumes that the file has not changed, and serves the cached version. For more information about this algorithm, see Troubleshooting Performance Problems with UNC Content.

| **Note** |
| --- |
| The server-side includes file handler (ssinc.dll) makes use of the user-mode static-file cache, so the configuration you apply to the user-mode static-file cache also applies to .stm, .shtml, and any other files you have mapped to ssinc.dll. |

**Troubleshooting Problems with Stale Content**

When stale content is being served by the Web Server even though the content has been updated on the remote file server, disable the Web Server cache as the first step in isolating the problem.

| **Note** |
| --- |
| First ensure that your results are not being affected by the 5-second staleness factor. |

For information about disabling caching of ASP files and static files, see Configuring ASP Template Caching and Configuring Last-Modified Caching.

# Troubleshooting Performance Problems with UNC Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Using the Last-Modified time to check for changes (instead of monitoring each virtual directory for change notifications) permits greater scalability when many virtual directories are mapped to UNC shares. Checking the Last-Modified time on the remote file server every time IIS wants to send a file is relatively expensive in terms of processing overhead. IIS checks the Last-Modified time on a file every five seconds by default; otherwise, it assumes that nothing has changed and serves the content from the cache, even though it might be stale.

For some sites, a five-second window will be too large a window, and for others, too small. The sampling interval is configurable with the following registry keys, which are not present by default:

- **Static pages** Set the registry property, **FileAttributeCheckThreshold**, a DWORD value, located at **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Inetinfo\Parameters**.

- **ASP Scripts** Set the registry property, **FileMonitoringTimeoutSeconds**, a DWORD value, located at **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\ASP\Parameters**.

Using the last-modified cache update mechanism will result in more reliable and secure delivery of content. Additionally, it will scale well on a wide application structure (where your Web server has lots of applications pointing at thousands of different directories). There is, however, a performance penalty that might be noticeable in regards to static content.

Even with these new file-caching algorithms, overall performance of UNC-based content can still be slightly slower than that of local content. However, depending on the content size, the difference is usually negligible.

If you think that the performance of your server has diminished due to these changes, you can enable change notification–based caching by adding the following registry keys, which are not present by default:

- **Static Pages** Set the registry property, **DoDirMonitoringForUNC**, a DWORD value, located at **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Inetinfo\Parameters**.

- **ASP Scripts** Set the registry property, **EnableChangeNotificationForUNC**, a DWORD value, located at **HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\ASP\Parameters**.

These entries do not exist in the registry by default. To add it to the registry, use the registry editor, Regedit.exe.

However, note that this option is not always recommended because it can cause the operating system to suffer from the scalability problems that were present in earlier version of IIS. Additionally, share-level permissions will no longer be honored by the Web server (NTFS ACLs are always honored). Consider modifying this registry entry only if you have a small directory structure, are not concerned about share-level permissions, and consider performance the most important metric.

When deciding which caching mechanism to use, consider the following tradeoffs. The most reliable and secure method is using the default: Last-Modified-based caching. It is reliable because it does not rely on the change-notification functionality of the file server and it scales well on a wide application structure (where your Web server has lots of applications pointing at thousands of different directories). It is more secure because share-level permission changes are honored (the cache accesses the file often, which automatically triggers the authorization check against the current file system ACL and the current share ACL).

However, if you are using a file server that reliably reports change notifications *and* if you have few sites or virtual directories, using change-notification is significantly faster. For example, if you have a single Web site with a couple of applications and all of your content is stored on a Windows Server 2003 file server, it is recommended that you use the change-notification method of caching.

**Related Information**

- For more information about using remote content on a UNC share, see Deploying and Configuring Internet Information Services (IIS) 6.0 with Remotely Stored Content on UNC Servers and NAS Devices.

- For more information about the FileAttributeCheckThreshold registry key, see Global Registry Entries.

- For more information about the FileMonitoringTimeoutSeconds and EnableChangeNotificationForUNC registry keys, see ASP Registry Entries.

# Troubleshooting IIS Manager and UNC Content Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Because of the way that IIS Manager displays the virtual directory, managing Web content that is stored on remote UNC shares can be confusing. IIS Manager uses the credentials of the logged-in user (the user actually running IIS Manager), who might not necessarily have the right credentials to access the remote file share. In this case, IIS Manager displays a stop-sign icon for the virtual directory. If this occurs, test UNC access by making requests with a Web browser.

You might want to create virtual directories that reference UNC-mapped drives. IIS does not support mapped drives because they are user-specific. For more information, see Microsoft Knowledge Base article 257174, Using Mapped Drives with IIS.

# Troubleshooting Errors That Occur When UNC Content Is Under High Load

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the Web server and the remote file server are not configured properly for high stress conditions, errors might occur. The following configuration errors might be reported in the browser, in the event log on the IIS server or remote file server, or the IIS logs:

- `Windows cannot find the network path. Verify that the network path is correct and the destination computer is not busy or turned off. If Windows still cannot find the network path, contact your network administrator. Error code: 0x80070033`
- `The network location cannot be reached. For information about network troubleshooting, see Windows Help.Error code: 0x800704CF`
- `Not enough server storage is available to process this command. Error code: 0x8007046`

**Modifying the MaxUserPort Registry Entry**

The first two errors are returned when the server running IIS has a shortage of outbound TCP ports when it attempts to make the UNC connection. In this case, the Web server returns HTTP 500 errors for all requests until TCP ports are available again. To fix this problem, you can modify the MaxUserPort registry entry on the server running IIS to specify an increase in the number of available ports. This entry does not exist in the registry by default. To add it to the registry, use the registry editor, Regedit.exe.

| **Caution** |
| --- |
| Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference in the Microsoft Windows Server 2003 Deployment Kit. |

For example, if you have many concurrent authenticated users, a different SMB connection is opened from the computer running IIS to the remote file server for each individual user. These SMB connections use ports. By default, you are limited to ports from 1024 to 5000 for outbound TCP connections (slightly fewer than 4,000 ports are available), so you might need to increase this value to a higher number, such as 10000 or 20000, to provide additional ports for SMB connections. Be aware that this might cause problems with applications that create sockets on these higher ports. For more information, see Microsoft Windows 2000 TCP/IP Implementation Details.

**Checking the File Server Setting**

If you receive the `Not enough server storage is available to process this command. Error code: 0x8007046A` message, check your file server settings. This IIS error usually accompanies event log messages like the following:

- `The server was unable to allocate from the system nonpaged pool because the pool was empty.`
- `The server was unable to allocate a work item <n> times in the last 60 seconds.`

Normally, these messages indicate that your file server is set to use too much nonpaged system memory. This can be quickly verified by opening Task Manager, clicking the **Performance** tab and checking the **Nonpaged** value in the **Kernel Memory** frame. Limit the amount of kernel memory that the Server service can use by configuring the SMB settings as discussed later in this section.

When troubleshooting this kind of error, check the following performance counters on the computer running the Web server:

- Server\Files Open
- Server\Server Sessions

- Server\Work Item Shortages

**Modifying the Work Item Configuration**

When two computers communicate, one SMB connection is used for each user. However, within an SMB connection, there are a finite number of work items. Work items can be consumed in a variety of ways and for varying amounts of time. For example, performing an operation against a file (by using **CreateFile**, **GetFileAttributes**, or other similar Windows APIs) takes up an I/O work item for a short period of time, but asking for a change notification on a directory structure takes up a work item for as long as the connection is maintained.

`The network location cannot be reached. For information about network troubleshooting, see Windows Help.Error code: 0x800704CF and Not enough server storage is available to process this command. Error code: 0x8007046` errors usually can be fixed by changing the following registry entries, which are related to SMB configuration: MaxCmds, MaxMpxCt, and MaxWorkItems.

On the remote file server, you can update these registry entries in the following location: HKLM\System\CurrentControlSet\Services\LanmanServer\Parameters.

On the server running IIS, you can update these registry entries in the following location: HKLM\System\CurrentControlSet\Services\LanmanWorkstation\Parameters.

The MaxCmds, MaxMpxCt, and MaxWorkItems registry entries do not exist in the registry by default. To add them to the registry, use the registry editor, Regedit.exe.

| **Note** |
| --- |
| For these registry values to take effect, you must stop and start the Server service on the remote file server and the Workstation service on the server running IIS. You do not need to restart the computers. |

Before changing the MaxCmds, MaxMpxCt, and MaxWorkItems registry entries to troubleshoot work item shortages and system memory consumption, you need to understand how work items are consumed. Work item consumption occurs as follows:

- Only one SMB connection is created per Web server/file server connection per user.
- Each change notification instance uses a work item until the connection is ended.
- Each request from the Web server to the file server uses a work item temporarily.
- Typically, each work item takes up about 20K of non-paged pool memory. Although certain Microsoft Knowledge Base articles specify setting the value of the MaxWorkItems registry entry to 16000, doing so consumes approximately 320 MB of non-paged pool memory, which could overwhelm system resources. To increase the reliability of your system, always set this number lower than this recommended value.
- To calculate the value of the MaxCmds registry entry, use the following formula:

  (the number of distinct physical directories that IIS needs to monitor for change notifications) * (1 (if static files exist) + 1 (if ASP content exists) + 1 (if ASP.Net content exists) ) + 50 (for concurrent default/regular file IO)

| **Note** |
| --- |
| This formula approximates a recommended value. Depending on the amount of concurrent traffic, you might need to increase your values. |

Table 11.13 Values for SMB Settings lists the default and maximum values for the relevant SMB settings on Windows Server 2003. These SMB settings also apply to the Microsoft Windows® 2000 Server operating system.

**Table 11.13 Values for SMB Settings**

| Registry Entry | Default Value | Maximum Value |
| --- | --- | --- |

| | | |
|---|---|---|
| MaxCmds | 50 | 65535 |
| MaxMpxCt | 50 | 65535 |
| MaxWorkItems | Scaled on memory size, usually between 1KB and 4KB. | 65535 |

# Troubleshooting Logging Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Historically, IIS administrators have rarely had to troubleshoot logging problems. In earlier versions of IIS, log configuration was simple and straightforward, and in most cases, the default settings were adequate.

In IIS 6.0, new logging functionality, such as centralized binary logging and UTF-8 logging, and the fact that logging is now performed by HTTP.sys instead of the WWW Service (W3SVC) present new configuration options and architectural elements as well as new troubleshooting challenges. This section explores some of the problems that can occur with HTTP.sys logging.

Table 11.14 HTTP.sys Logging-Related Event Log Errors lists and describes HTTP.sys logging-related Event Log errors, and provides troubleshooting recommendations for each.

**Table 11.14 HTTP.sys Logging-Related Event Log Errors**

| Event ID | Description | Recommendation |
|---|---|---|
| 15000 | Unable to create log file *%2*. | Ensure that the logging directory is correct and this computer account has write access to that directory. |
| 15001 | Unable to create the log file for site W3SVC*%2*. | Ensure that the logging directory for the site is correct and this computer has write access to that directory. |
| 15002 | Unable to write to the log file *%2* for site W3SVC*%3*. The disk might be full. | If this is a network path, ensure that network connectivity is not broken. Otherwise, the disk is full. |
| 15003 | Unable to create the centralized binary log file. | Ensure that the logging directory is correct and this computer has write access to that directory. |
| 15004 | Unable to write to the centralized binary log file *%2*. The disk might be full. . | If this is a network path, make sure that network connectivity is not broken. Otherwise, the disk is full. |
| 15006 | Owner of the log file or directory *%2* is invalid. Another user might have already created the log file or the directory. | Check for the existence of the logging directory and ensure that the owner is the local Administrators group. |

**Logging Security Configuration**

One of the fundamental aspects of IIS logging design involves the expected security configuration of the log file directory or UNC share when logging to UNC.

**Configuration process**

Upon first receiving an HTTP request, HTTP.sys begins logging. On this initial request, if the appropriate logging subdirectory and file does not exist, HTTP.sys creates them, giving System and local Administrators full control. For each, the owner is the Local Administrators account. If the directory and file already exist, HTTP.sys performs an access check for security purposes and verifies that the owner of the file and directory is the local Administrators group. If not, HTTP.sys logs event ID 15006 to the event log and disables logging for that site. If the ownership check passes, HTTP.sys then ensures that System and local Administrators have full control.

When configuring logging to a UNC share, HTTP.sys does not perform an ownership check. Instead, the administrator is responsible for ensuring that security on the log file share and directory is configured appropriately. HTTP.sys sets the ACLs on the remote share to allow the Web servers system account the appropriate access.

**Event ID 15000, 15001, and 15003**

These errors occur when the log file and directory do not have proper security settings. When the IIS logging configuration settings are changed, if the file and directory security settings are not correct (if the System and Administrators do not have full control), HTTP.sys writes event ID 15001 or event ID 15003 (if binary logging is enabled) to the Event Log. HTTP.sys writes an event ID 15000 to the event log if security settings change during operation, for example, if the file ACLs are altered manually.

**Event ID 15002 and Event ID 15004**

Event ID 15002 and Event ID 15004 errors are similar. Both occur when HTTP.sys is unable to write to the log file because the

disk is full. When binary logging is enabled, HTTP.sys writes an event ID 15004 error to the Event Log. An event ID 15004 also is written to the Event Log if a network problem prevents HTTP.sys from writing to the log file.

**Logging Headers**
In the past, the logging headers that were written to a log file typically indicated the restarting of the Web service. In IIS 6.0 this is not the case. After waiting for 15 minutes for a given site, HTTP.sys stops logging. When the next request for that site arrives, HTTP.sys restarts logging and writes a new set of headers to the log file.

**Present in Log Files**
In rare cases, you might see in an IIS log file entry. When a query string or a header value is longer than 4 KB, HTTP.sys writes the string as instead of writing the entire string.

**UTF-8 Logging Problems**
When using the UTF-8 logging feature, note the following:

- A log file logged in UTF-8 does not contain a Byte Order Mark (BOM). File editors use this mark to identify text as UTF-8 text. Therefore, if you attempt to open a log file that is logged in UTF-8 in Notepad by double-clicking the file or by using the **Open With** option, the file might not display correctly. To open the file in a way that displays it correctly, use the **Open** command on the **File** menu and then select **UTF-8** in the **Encoding** box.

- Because IIS 6.0 now supports UTF-8 URLs, you can now log those URL requests to an ASCII log file. UTF-8 is a double-byte character set standard. Because ASCII is a single-byte character set standard, logging UTF-8 information to an ASCII file presents a problem. In such a case, ? is logged for the characters that cannot be converted to the codepage of the server.

# Troubleshooting HTTP.sys Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

HTTP.sys can provide information through three mechanisms: HTTP status codes, Windows Event Logs, and the HTTP error log. Preceding sections discussed the HTTP status codes and several event log errors that are related to logging. This section addresses the initial startup process of IP addresses binding and the mechanism other services use to ask HTTP to listen to specific URL endpoints through the HTTP API.

# Configuring the IP Inclusion List

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The HTTP.sys IP inclusion list allows administrators to limit the IP addresses to which HTTP.sys automatically binds when it starts. This provides functionality similar to the functionality provided by the **DisableSocketPooling** property that was available in IIS 5.0. At startup, HTTP.sys checks to determine if there are any entries in the IP inclusion list. If there are, HTTP.sys attempts to listen only on these IP addresses and only at initial startup. If the list has no entries, HTTP.sys listens on all available IP addresses.

To configure the IP inclusion list, use the HttpCnfg.exe utility. For information about HttpCfg.exe, see Httpcfg.exe: HTTP Configuration Utility.

Table 11.15 HTTP.sys IP Binding Event Log Errors lists and describes the HTTP.sys IP binding event log errors. Only the errors that require additional explanation are addressed below.

**Table 11.15 HTTP.sys IP Binding Event Log Errors**

| Event ID | Description |
|---|---|
| 15005 | Unable to bind to the underlying transport for *%2*. The IP Listen-Only list might contain a reference to an interface that might not exist on this computer. The data field contains the error number. |
| 15007 | Reservation for the namespace identified by URL prefix *%2* was successfully added. |
| 15008 | Reservation for namespace identified by URL prefix *%2* was successfully deleted. |
| 15009 | An error occurred while initializing namespace reservations. The error status code is contained within the returned data. |
| 15010 | An error occurred while initializing a namespace reservation identified by URL prefix *%2*. The error status code is contained within the returned data. |
| 15014 | Unable to convert IP Listen-Only list entry *%2*. The data field contains the error number. |
| 15015 | Unable to convert all entries on IP Listen-Only list. The driver will listen on all available interfaces. |

**Event ID 15014**

If the IP inclusion list contains entries, HTTP.sys iterates through the list and, for each entry, it first checks to ensure that the IP address is valid and is assigned to one of the systems network interfaces. If this check fails, HTTP.sys logs Event ID 15014 to the event log.

**Event ID 15015**

This error is logged to the event log when HTTP.sys parses the IP inclusion list and finds that all of the entries in the list are invalid. If this happens, as the description in Table 11.15 notes, HTTP.sys listens to all IP addresses.

Services that use the HTTP listening functionality — namely IIS — have to configure HTTP and, through available APIs, tell HTTP.sys which endpoints to listen to. If a service requests an endpoint where HTTP.sys is not listening, HTTP.sys logs an event to the event log that states this. In the case of IIS, the WWW service also makes note of these kinds of errors.

| **Note** |
|---|
| Once the IP inclusion list is set, HTTP.sys never reverts to listening on all IP addresses. |

# Troubleshooting HTTP.sys Communication Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In rare cases, the WWW service might encounter problems when communicating with the HTTP service. If this occurs, the WWW service logs errors to the event log. These errors are summarized in Table 11.16

**Table 11.16 WWW Service to HTTP Communication Errors**

| Event ID | Description |
|---|---|
| 1020 | The World Wide Web Publishing Service encountered difficulty configuring the HTTP.sys control channel property *%1*. The data field contains the error number. |
| 1109 | The World Wide Web Publishing Service failed to set the control channels filter configuration. The data field contains the error number. |
| 1062 | The World Wide Web Publishing Service encountered a failure configuring the logging properties on the HTTP Control Channel. Logging Enabled is *%1*. Log File Directory is *%2*. Log Period is *%3*. Log Truncate Size is *%4*. The data field contains the error number. |
| 1037 | A failure occurred while opening the HTTP control channel for the World Wide Web Publishing Service. The data field contains the error number. |

# Troubleshooting Miscellaneous IIS Problems

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Additional problems that might require troubleshooting include unexpected metabase site IDs, CGI process difficulties, server connection problems, and client request timeout and error-out problems.

# Metabase Site IDs Are Unexpected Numbers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you create a new Web site in IIS Manager, the newly generated site ID in the metabase is a random number. In earlier versions of IIS, the site ID was incremented with each new site. If you have an application that in some way relies on the old behavior, you can change the current behavior by adding the registry entry IncrementalSiteIDCreation, a DWORD value, to the registry with a value of 1. Add IncrementalSiteIDCreation to the following subkey:

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\InetMgr\Parameters

**Caution** Do not edit the registry unless you have no alternative. The registry editor bypasses standard safeguards, allowing settings that can damage your system, or even require you to reinstall Windows. If you must edit the registry, back it up first and see the Registry Reference in the Microsoft Windows Server 2003 Deployment Kit.

When generating a new site ID, IIS uses a hash of the Web site name. This new design ensures that all IIS 6.0 servers in a Web farm have a good chance of generating the same site identification numbers for sites with the same name. For more information, see Microsoft Knowledge Base article 332122, IIS 6.0: Web Site Identification Numbers Are Not Incremental.

# Anonymous Users Performance Counters in IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Current Anonymous Users performance counter is often used for capacity planning and performance troubleshooting. The counter is incremented differently in IIS 6.0 than it was in IIS 5.0.

In IIS 5.0**.** Current Anonymous Users is the number of current anonymous HTTP connections. This number decreases when the connection is closed (for various reasons, such as when the connection explicitly closes or times out).

In IIS 6.0**.** Current Anonymous Users is the number of current anonymous requests being processed. This number decreases when the request is completed. (HTTP.sys and IIS user mode both provide numbers for this counter.)

In short, IIS 6.0 counts each request as a user, whereas IIS 5.0 counts each connection as a user.

# CGI Processes Will Not Start

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In order for CGI processes to run, the account that starts the CGI processes (the worker process identity) must be assigned certain user rights. You can add the account as a member of the IIS_WPG group and assign the account these two necessary user rights:

- Adjust memory quotas for a process.
- Replace a process-level token.

For information about assigning user rights to an account on the local computer, see CGI processes do not start.

# Clients Cannot Connect to the Server

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003 provides a software-based firewall to help prevent unauthorized connections to your server from remote computers. By default, the Internet Connection Firewall (ICF) is disabled. However, if you have enabled the firewall in its default configuration after installing Windows Server 2003 and before installing IIS 6.0, clients will not be able to connect to your server. Use the following procedure to configure the ICF to allow clients to initiate Web and other IIS–related connections to your server.

For information about configuring ICF for IIS, see Before Configuring IIS.

# Client Requests Error Out or Time Out

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In IIS 6.0, settings are set to aggressive and secure defaults to minimize attacks due to timeouts and limits that were previously too generous. IIS enforces the following timeouts at the connection level:

- Limits on response buffering. The metabase property **ASPBufferingLimit** is 4 MB, by default. If ASP scripts buffer more than this, they generate an error. Prior to IIS 6.0, there was no limit to buffering.

- Limits on posts. The metabase property **AspMaxRequestEntityAllowed** enforces a maximum ASP POST size of 204800 bytes, with each individual field limited to 100 KB. Prior to IIS 6.0, there was no limit to posts.

- The **ServerListenTimeout**property is no longer available**.** The metabase property **ServerListenTimeout** has been replaced by the following metabase properties:

    - **ConnectionTimeout**. This property specifies the amount of time, in seconds, that the server waits before disconnecting an inactive connection.

    - **MinFileBytesPerSec**. When IIS responds to a client request, the **MinFileBytesPerSec** property determines the length of time that the client has to receive the entire response. If the client computer takes too long to receive the entire response, the kernel-mode driver, HTTP.sys, terminates the connection according to the timeout value.

    - **HeaderWaitTimeout**. When a client connects to the Web server, the client computer is given a time limit to send in all headers for the request (demarked by a final double \r\n). If the complete header set for the request is not received within the time period indicated by **HeaderWaitTimeout**, HTTP.sys resets the connection. You can configure the value of **HeaderWaitTimeout**.

- **Header size limitation**. By default, HTTP.sys accepts only requests where the size of the request header is less than 16 KB. This means that if HTTP.sys does not receive the terminating carriage return/line feed (CRLF) pair sequence within 16 KB, HTTP.sys considers the request malicious and terminates the connection. You can change the header size limitation by adjusting the value of the registry entry MaxRequestBytes. Note that this entry does not exist in the registry by default. To add it to the registry, use the registry editor, Regedit.exe.

# Advanced IIS Troubleshooting with Tracing and Debugging

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Up to this point, this section has explored problems and issues that are specific to IIS, its interaction with various Windows operating system mechanisms (like the file system and security), and its implementation of the HTTP protocol. These types of problems are identified by definitive error messages and demonstrate specific faulty behaviors. In addition, these types of problems usually reveal themselves early — during either application development or initial configuration of the IIS application environment. For example, problems with permissions usually appear during security configuration, which usually occurs during application deployment. Problems like these display symptoms immediately, making it is easy to identify the problem.

Today's Web-based applications often have many components and systems that interact. This complexity provides greater opportunity for components to fail or to behave in unexpected ways. Further complicating matters, large and complex applications often exhibit subtle or non-specific symptoms. The effects of such problems are abstract and might seem random. For example, a problem with data access synchronization might cause an application to stop responding in one instance, but a crash in another. Such "quirks" can occur deep within an application's processing, often masking or distorting symptoms and ultimately hiding the root cause of the problem.

IIS is the primary runtime environment for the execution of application logic implemented in custom ISAPI applications, ASP, ASP.NET, or a Web service. These components often communicate with middle-tier business logic servers and database servers. Consequently, IIS is often the main execution environment for the core workings of an application and, therefore, IIS is the environment where problems begin or symptoms are propagated.

This section discusses tracing and debugging, advanced troubleshooting techniques for isolating problems in applications and IIS components.

# Troubleshooting IIS 6.0 with Tracing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Windows operating system includes the Event Tracing for Windows (ETW) infrastructure to help individuals troubleshoot problems in the operating system, including problems in HTTP components. IIS HTTP components include Active Server Pages (ASP), Internet Server Application Programming Interface (ISAPI) extensions, and the Secure Sockets Layer (SSL) Filter service, to name a few. If an HTTP request in IIS fails or becomes unresponsive while ETW is enabled, you can view ETW trace data, called events, to determine which component caused the failure.

In Windows Server 2003 Service Pack 1 or later, IIS includes the following tracing features. These features leverage the ETW infrastructure.

- IIS Currently-executing Requests Tracing: This tracing feature provides general statistics and details about all requests executing on the server at the moment tracing was started. If the CPU on your server is spiking or if requests become unresponsive, currently-executing requests tracing can help you understand which URLs are being requested, which application pool the requests reside in, and other similar details. This feature does not include the option to specify which components or URLs to trace. For more information, see Currently Executing Requests Tracing.

- IIS Request-Based Tracing: This tracing feature tracks HTTP requests as they move through IIS components. Request-based tracing can help you target the IIS component processing a request when the request failed or became unresponsive. Request-based tracing allows you to define and trace a specific URL or a group of URLs. For more information, see IIS Request-Based Tracing.

Windows Server 2003 Service Pack 1 or later also includes a provider for tracing the IIS Admin service during startup and shutdown. The IIS Admin service provides access to the in-memory configuration store and other dependent services. If you experience problems while IIS is starting up or shutting down, the IIS: IIS Admin Service provider can help you understand the nature of the problem. For more information about this provider, see IIS providers.

# Currently Executing Requests Tracing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use currently-executing requests tracing to find out which requests are executing in a worker process when the worker process has become slow or unresponsive. When enabled, currently-executing requests tracing prompts worker processes to report statistics and details about each request in each worker process. Currently-executing requests tracing is enabled via the command-line.

To understand how Request Monitor works, consider the following scenario:

You are the administrator for an e-commerce Web application. The Web application is hosted on IIS 6.0 running Microsoft Windows Server 2003 Service Pack 1.

Your developers make substantial changes to the application for a planned upgrade. While testing the upgraded application in a test environment, you notice in Task Manager that an IIS worker process (W3wp.exe) is periodically spiking to consume 100% of the CPU cycles on the server. You don't know which requests are executing in the worker process or which URLs are being requested. In short, you have no idea where to begin searching for the source of this problem.

Previously, administrators in this situation could terminate the process in Task Manager and then check the HTTPERR log for clues as to what happened. Or, administrators may call Microsoft Product Support Services for assistance in attaching a debugger to the process to get a memory dump of the activity inside the worker process. This is not an ideal solution because of the time and expense involved in such a call.

With currently-executing requests tracing, you can narrow down the source of the problem by executing a command from a command prompt. For example, the administrator types the following command at a command prompt and then presses ENTER:

**logman start W3wpTrace -p IIS: "Request Monitor" -ets**

The administrator lets the trace session run for a few moments and then types the following at a command prompt and presses ENTER:

**logman stop W3wpTrace -ets**

Currently-executing requests tracing returns details about requests executing at the moment the command was executed. For example:

```
<WorkerProcessProcessID=3420
                    AppPoolId=DefaultAppPool
                    RequestsService=126
                    TotalWorkerThreads=4
                    AvailableWorkerThreads=4
                    ProcessUpTime=0:26:34
                                 >
<WebRequestList>
              <WebRequest ContextId={00000000-0000-0000-8f00-0060000000fe}
                     SiteId=1
LocalIPAddr=<data>
LocalPort=80
HostName=Contoso3
ConnectionID=1073741965
                     ProcessID=3420
ClientIP=<data>
Verb=Get
URL=/asp/asptest.asp
ProcessingState=processing
TimeElapsed=29723TimeFromLastState=29723

/>

      <WebRequestList>
             <WebRequest ContextId={00000000-0000-0000-2900-0060000000fb}
                     SiteId=1
LocalIPAddr=<data>
LocalPort=80
HostName=Contoso3
```

```
ConnectionID=1073741859
                    ProcessID=3420
ClientIP=<data>
Verb=Get
URL=/asp/asptest.asp
ProcessingState=processing
TimeElapsed=28281TimeFromLastState=28281
/>

</WebRequest>
</WebRequestList>
</WorkerProcess>
```

With this information, the administrator determines there are two separate requests for asptest.asp, the processing state for each request is processing, and both of these requests have been processing for more than 28 seconds. With this information, the administrator can focus their troubleshooting efforts on the asptest.asp page. For example, the administrator could send the Request Monitor data to the developer of asptest.asp and ask the developer to look for code errors.

| **Note** |
| --- |
| If you expect Request Monitor to return hundreds of request details, you can filter the data output using other parameters. |

For more information about tracing currently-executing requests with Request Monitor, including the step-by-step procedure for tracing requests and a detailed explanation of the command-line switches, see How to Trace All Requests Currently Executing in IIS Worker Processes.

# IIS Request-Based Tracing

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use IIS request-based tracing to track requests in IIS components like ASP, SSL filters, and ISAPI extensions. Request-based tracing also allows you to trace a request to a specific URL or a group of URLs, which can further refine your troubleshooting efforts.

When an HTTP request is picked up by an IIS user mode worker process (meaning the request was not served by the HTTP.sys response cache), the request passes through multiple components before a response is generated and IIS sends the response back to the client computer. Depending on the request type, the request is processed by the static file request handler, the CGI request handler, or an ISAPI extension handler. Requests that enter an ISAPI extension handler are processed further by Active Server Pages (ASP) or ASP.NET pages. If a request fails or becomes unresponsive as it makes its way through these components, error-reporting channels like the Windows NT Event Log and the HTTP Error log might not provide enough detail to help you locate the source of the problem. Requested-based tracing will provide the details you need to help locate the source of the problem.

In the context of Event Tracing for Windows (ETW), IIS components are called **providers** because they provide trace data or events to ETW.

From a high level, request-based tracing works as shown here:

1. The administrator enables a tracing session on the IIS server from a command prompt.

2. ETW notifies IIS providers to begin reporting trace events.

3. A request enters the IIS worker process. As the request moves through IIS, the providers report events to the ETW infrastructure. In this example, the worker process reports a request start event, ASP_Start_Request, and then each of the IIS components report Start and End events. Finally, the worker process reports a request end event, ASP_End_Request. ETW writes these events to the trace log. If a request experienced a change while processing, for example the client computer disconnected while the request was on the ASP queue, ASP would report the ASP_CLIENT_DISCONNECTED event. If a request experienced an error, ASP would report an event that described the source of the problem, for example, ASP_FILE_NOT_FOUND or ASP_FILE_ACCESS_DENIED.

4. The administrator stops the trace session and reviews the trace log to locate the source of the problem. Problems are typically identified by error events or a START event that does not contain a corresponding END event.

You can specify which providers report events to ETW during a specific trace session. You can also customize how much trace data providers report to ETW. For example, you can configure a trace session so IIS providers report error events only, or you can configure the trace session so providers report informational events and error events. You can also determine which URLs to trace, thereby focusing your troubleshooting efforts on a specific application.

# The IIS Request-Based Tracing Process

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This section describes, from a high level, the process of setting up, executing, and handling the post-processing for a request-based tracing session in IIS. This section is intended to give the reader an overview of the tracing process, including the technical details of tracing. This section does not include the step-by-step procedure for executing a trace in IIS. For the step-by-step procedure to execute a trace in IIS, see Advanced Troubleshooting with IIS Tracing.

Tracing a request in IIS involves the following:

- Configuring the IIS Request-Based Tracing Session
- Starting the IIS Request-Based Tracing Session
- Reproducing the Problem
- Stopping the IIS Request-Based Tracing Session
- Post-processing and Viewing IIS Request-Based Tracing Data

The following section discusses tracing using a **provider** file. A provider file is a simple text file that contains a list of the providers you want to trace. When you execute tracing, you can identify which providers (components) to trace at the command-line using switches, or, you can identify which providers to trace using a provider file. The provider file method is described here because a provider file reduces the amount of information you need to type if you plan to use tracing regularly.

# Configuring the IIS Request-Based Tracing Session

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Setting up a request-based tracing session in IIS requires that you first decide what you want to trace. Your decision on what to trace will be determined by the nature of your Web applications. For example, if your Web applications use Active Server Pages (ASP), then you would list this provider in the provider file. If your Web applications do not use ASP, then you would not want to list this provider in the provider file. After you start tracing, the components defined in the provider file report trace data to the ETW infrastructure.

Your decision on what to trace will also be determined by the nature of the problem you are troubleshooting. If you know which component is causing the problem you can create your provider file to target the problematic component. If you are having troubles with a specific application, you can trace the specific URL.

If you are not certain which URL or component(s) are causing the problem, use IIS currently executing requests to determine which URL is being requested when a worker process becomes unresponsive. Knowing which URL is causing the problem will also help you determine which other providers to define in the provider file. For example, if you know the problem exists in a URL that utilizes an ISAPI filter, then you would want to define that provider in the provider file. By explicitly defining which components to trace, you reduce the amount of data in the trace log, which makes troubleshooting easier.

This section discusses the following concepts related to setting up an IIS request-based trace session:

- The provider file
- IIS providers
- Verbosity levels

# The provider file

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The provider file is a simple text file that resides on the local computer and tells ETW which providers should report trace data. This file also tells ETW how verbose the trace reporting should be; that is, how much data the providers should report, as well as what flags or areas to trace for each provider.

The contents of a provider file contain the following:

- The names of the providers that will report trace data to ETW
- Provider flags (for applicable providers) that define which areas of the provider to trace
- A number that tells ETW how much trace data to collect for the specified provider, called verbosity level

| **Note** |
| --- |
| Providers, flags, and verbosity levels are described later in this section. |

In the following example, the first provider is WWW Server. The flag 0xFFFFFFFE denotes that all subcomponents of the WWW Server component should be traced, including authentication, security, compression, etc. The number five (5) denotes that the provider should report all tracing events for that provider, the most detailed trace information possible. For the other two providers, ASP and ISAPI extensions, the provider name is followed by zero and then five. The zero tells ETW not to trace any flags for the stated providers. The number five denotes the verbosity level for the providers.

```
"IIS: WWW Server" 0xFFFFFFFE 5
"IIS: Active Server Pages (ASP)" 0 5
"IIS: WWW Isapi Extension" 0 5
```

# IIS providers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Components that provide tracing events to ETW, like ASP and ISAPI extensions, are called providers. In Windows Server 2003, Service Pack 1, the following IIS providers report trace data to ETW:

- IIS: WWW Server
- IIS: SSL Filter
- IIS: ISAPI Extension
- IIS: Active Server Pages (ASP)
- IIS: IISAdmin
- IIS: Request Monitor

When you configure the trace session by creating the provider file, you define which providers report data. Components not listed in the provider file do not report trace data. Each of the providers listed here is described in greater detail later in this section.

If you are actively troubleshooting a problem on a busy production server, try to limit the number of providers defined in the provider file or use the IIS: WWW Server **UrlFilter** flag to restrict tracing to a specific URL. Doing so will result in a more manageable set of trace data in the trace log which should make it easier to locate the source of the problem.

If you are new to request-based tracing, run a few practice trace sessions on a test computer with multiple (or all) providers defined in the provider file so you can see what kind of events are generated with “normal” traffic and how quickly the trace log can fill with data.

**IIS: WWW Server**

This provider traces the following core WWW service functional areas. If you wish to trace one or more of these functional areas, you must define these areas in the provider file using the designated flag or the friendly flag. If a flag or friendly flag is not designated in the provider file, the functional area will not be traced. The following table lists all of the functional areas, the flags to enable them, and the "friendly" flag name of each functional area. Each of these functional areas is described in detail later in this section.

| Functional Area | Flag | Friendly Flag Name |
|---|---|---|
| UrlFilter | 1 | UseURLFilter |
| Authentication | 2 | IISAuthentication |
| Security | 4 | IISSecurity |
| ISAPI Filter | 8 | IISFilter |
| Static File | 10 | IISStaticFile |
| CGI | 20 | IISCGI |
| Compression | 40 | IISCompression |
| Cache | 80 | IISCache |
| WWW Server All | 0xFFFFFFFE | IISAll |

**Note**

You can identify more than one functional area in a provider file by adding the numeric flag values. For example, if you want to trace using the **Urlfilter** flag (1), the **Authentication** flag (2), and the **Security** flag (4), you can enter a flag value of 7 in your provider file to trace all of these areas.

**UseUrlFilter**

The **UseUrlFilter** flag allows you to specify which URL(s) to trace. If you do not enable this flag, request-based tracing traces all URLs. If you enable this flag and configure the TraceUriPrefix Metabase Property for the URL's you want to trace, you can preserve system resources like disk space and CPU overhead while narrowing your troubleshooting efforts to a much smaller data set in the trace log.

**Important**

If you plan to trace a specific URL or group of URLs using the **UseUrlFilter** flag, you must configure the **TraceUriPrefix** property in the IIS metabase with the URL's you want to trace. If you enable the **UseUrlFilter** flag and do not enable the **TraceUriPrefix** property, ETW will not trace any URLs. For information on how to enable the **TraceUriPrefix** metabase property, see How to Trace Requests for a Specific URL or Set of URLs.

**Authentication**

The **IISAuthentication** flag traces authentication actions, including the name of the authenticated user, the authentication scheme (anonymous, basic, etc) and the results of the authentication attempt (successful, failed, error, etc). If users are having problems authenticating on your Web application, use the **IISAuthentication** flag to understand what is happening with authentication on the server.

**Security**

The **IISSecurity** flag generates trace events when requests are rejected by the IIS server for security-related reasons, like a client request was denied access to a resource. Use this flag to understand why requests are being rejected for security reasons.

**ISAPI Filter**

The **IISFilter** flag traces calls into and out of ISAPI filters. Use this flag to understand how requests have been changed after entering an ISAPI filter, as well as how long requests are spending in the filters.

**Static File**

The **IISStaticFile** flag generates trace events when a request is for a static file.

**CGI**

The **IISCGI** flag generates trace events when a request is for a CGI file.

**Compression**

The **IISCompression** flag generates trace events when a response is compressed.

**Cache**

The **IISCache** flag generates trace events for cache operations associated with the request.

**WWW Server All**

The **IISAll** flag forces all of the WWW Server functional areas to generate trace events.

**IIS: SSL Filter**

This provider traces calls into and out of the Secure Sockets Layer (SSL) Filter, which is used for encrypting and decrypting SSL requests.

**IIS: WWW ISAPI Extension**

This provider traces ISAPI extension requests.

**IIS: Active Server Pages (ASP)**

This provider traces requests for Active Server Pages (ASP) files, including calls into and out of COM+ objects. The events captured by this provider are useful for diagnosing hangs or crashes caused by COM objects used in ASP pages.

**IIS: IISAdmin Service**

This provider traces the IIS Admin service during startup and shutdown. The IIS Admin service reads the IIS metabase.xml file which stores all IIS configuration data. Use this provider if you notice that the IISAdmin service has trouble starting up or shutting down.

This provider includes the following flags:

### Startup

The Startup flag forces ETW to trace IIS Admin service startup events.

### Shutdown

The Shutdown flag forces ETW to trace IIS Admin service shutdown events.

For more information about this provider, see Tracing Startup and Shutdown Problems in the IIS Admin Service.

#### IIS: Request Monitor

This provider traces all requests currently executing in worker processes at the moment tracing was started. For more information about this provider, see Currently Executing Requests Tracing.

# Verbosity levels

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Once you have established which providers will report data to the trace log, you must determine how much data each provider should report. You establish how much data each provider reports by setting the *verbosity level* in the provider file. The verbosity level is a number in the provider file, ranging from 0 to 5, where 0 is the least information and 5 is the most information. If you are troubleshooting a specific error and only want to see tracing events related to that error, you would probably choose verbosity level 1 or 2. If you are troubleshooting a problem and you need tracing to help you locate the source of the problem, you would probably choose verbosity level 3, 4, or 5. Table 11.3 describes verbosity levels in more detail.

If you plan to execute tracing using a provider file, you can specify different verbosity levels for different providers. For example, you could configure the **IIS:Active Server Pages (ASP)** provider to log trace events at verbosity level 5 and **IIS:WWW Server** at verbosity level 2. If you plan to execute tracing solely from the command line, you cannot specify different verbosity levels. **IIS:Active Server Pages (ASP)** and **IIS:WWW Server** would need to have the same verbosity level to execute the trace.

**Table 11.3**

| Level | Name | Description |
|---|---|---|
| 0 | General | IIS providers log only those few events required to provide some context to the request activity. These events include a **General_Request_Start** event that logs the URL and verb for the request and a **General_Request_End** event. |
| 1 | Fatal Error | IIS providers report events for actions that can cause a process to exit or actions that are about to cause a process to exit. |
| 2 | Error | IIS providers report events when components cannot continue processing a request. The request is immediately rejected.<br>**Note**<br>These events typically indicate a problem on the server side rather than a client-induced problem. |
| 3 | Warning | IIS providers report events when components experience an unexpected result/error but can continue processing the request. |
| 4 | Information | IIS providers report general information about requests. |
| 5 | Verbose | IIS providers report detailed information about requests. |

Once you have determined the providers you want to trace, the flags (if any), and the amount of information you want to collect in the trace log (the verbosity level), you enter these items in a provider file, for example, MyProviders.txt.

# Starting the IIS Request-Based Tracing Session

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS request-based tracing uses Log Manager (Logman.exe) to start, stop, and update trace sessions. Log Manager is a command-line tool included with Windows Server 2003. Log Manager can schedule trace collections on a local machine or on a remote machine.

| **Note** |
| --- |
| This section does not contain the step-by-step procedure for starting and stopping a trace session. This section describes some of the essential concepts for executing a trace session. For the step-by-step procedure to execute a trace session in IIS, see Advanced Troubleshooting with IIS Tracing. |

When you enable tracing, you enter a command at the command prompt with the following:

1. A command to start Log Manager (**Logman start trace**).
2. A file name where the trace data should be collected.
3. The provider file switch (**-pf**)
4. The name of the provider file, including the path to the provider file, if necessary.
5. A command to start the trace immediately (**-ets**)

The following is an example of a command that starts tracing with Log Manager:
**Logman start trace ISAPItrace -pf MyProvidersInputFile -ets**

After you enable a trace session, Logman creates the session in the kernel. When Logman has enough session data, it creates a trace log file (.etl extension) in the directory where you executed the start trace command. Log Manager assigns the file the name you entered after the **start trace** command, for example ISAPItrace.etl (in the command above).

After you start the trace session, Logman prints to the screen a few general statistics and details about the session you just started, as seen below. Notice that Logman tells you the name of the trace session, the file name and path where the trace data should be collected, and the details of the provider file.

```
D:\Documents and Settings\TestMachine>logman start trace ISAPItrace -pf
d:\MyProviders.txt -ets
Name:ISAPItrace
Age Limit:15
Buffer Size:8
Buffers Written:1
Clock Type:System
Events Lost:0
Flush Timer:0
Buffers Free:2
Buffers Lost:0
File Mode:Sequential
File Name: D:\Documents and Settings\TestMachine\ISAPItrace.etl
Logger Id:3
Logger Thread Id:1468
Maximum Buffers:25
Maximum File Size:0
Minimum Buffers:3
Number of buffers:3
Real Time Buffers Lost:0

Provider                          Flags                    Level
-----------------------------------------------------------------------
* "IIS: WWW Server" (IISAuthentication, IISSecurity, IISFilter,
IISStaticFile,IISCGI,IISCompression,IISCache,IISAll)0x05
```

```
{3A2A4E84-4C21-4981-AE10-3FDA0D9B0F83}  0x00000ffe0x05
* "IIS: WWW Isapi Extension"             0x000000000x05
{A1C2040E-8840-4C31-BA11-9871031A19EA}  0x000000000x05

The command completed successfully.
```

For information on Log Manager command-line syntax and parameters, type **Logman /?** at a command prompt and press ENTER. For a list of providers or to see the exact syntax required in the provider file, type **logman query providers** at a command prompt and press ENTER.

# Reproducing the Problem

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Once you have created your provider file and started the trace session, you must reproduce the problem. Reproducing the problem may be as simple as making one request from a client computer to a troublesome application, or as complex as using multiple clients to create load on the server.

Once you have reproduced the problem, you will be able to check the trace log file for details about the error or problem. If, after reproducing the problem, you do not find helpful details in the trace log, you may need to enable other providers or increase the verbosity level of your providers in the provider file. In short, if you have reproduced the problem, the events captured in the trace log should provide you the details of the problem.

For more information about tracing events and what they mean, see Tracing Events Reference.

# Stopping the IIS Request-Based Tracing Session

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Stop the trace session after you have reproduced the problem. If you are unable reproduce the problem, stop the trace session after a few minutes and then review the trace log. Be aware that tracing consumes system resources. On a server processing hundreds of requests per second, the trace log file created by ETW can grow in size to several megabytes after a few seconds, depending on the number of providers defined in the provider file. Immediately disable tracing on production servers after you have gathered enough data to help you isolate and troubleshoot the problem.

To stop the trace session, execute the **logman stop trace** command from the command prompt. For example:
**Logman stop trace ISAPItrace -ets**

| **Note** |
| --- |
| ETW does not support running multiple trace sessions with the same provider at the same time. You must stop an existing trace session before starting a new one. For example, you can not run two trace sessions where both sessions use the **IIS: WWW Server** provider. |

# Post-processing and Viewing IIS Request-Based Tracing Data

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Event Tracing for Windows writes trace data to the trace log (.etl log file) in a binary format. To view the trace data, the trace log must be processed by a tool. The tools described below process .etl log files.

**Trace Report (tracerpt.exe)**
Trace Report ships with Windows Server 2003. To process the trace log file with Trace Report, type tracerpt filename and press ENTER. For example:

**tracerpt NewTrace.etl**

Trace Report converts the binary trace data into text and produces two files in the directory where you executed the **tracerpt** command:

- Summary.txt contains general details about the trace session, including which providers were used.

- DumpFile.csv contains the actual trace data in a text format. Open DumpFile.csv in a text editor like Notepad to view the trace data. The data in DumpFile.csv is readable (shown below), but the formatting is not as reader-friendly as the format produced by Log Parser and DumpTraceReqs (described later in this topic):

```
Event Name,       Type,        TID,           Clock-Time, Kernel(ms),   User(ms), User
Data
  EventTrace,     Header, 0x000000EC,   127311198897300433,         10,         60,
8192, 33620485,     3790,        1, 127311199293485921,   100144,        0, 0x00000000,
6,        1,        4,        0,      730, 0x00B82930, 0x00B82944,                0,
3579545, 127311198897300433, 0x00000002,        0, 0, 0
  IISGeneral, GENERAL_REQUEST_START, 0x00000A74,   127311199074261949,          0,
0, {00000000-0000-0000-0200-0060000000ed},        1, "DefaultAppPool",
17077649788062662657,                0, "/ASPtest", "GET", 0, 0
   IISFilter, FILTER_START, 0x00000A74,   127311199074261949,          0,          0,
{00000000-0000-0000-0200-0060000000ed}, "D:\IISDebugTools\IISCHAgent.dll", 0, 0
   IISFilter, FILTER_PREPROC_HEADERS_START, 0x00000A74,   127311199074261949,
0,          0, {00000000-0000-0000-0200-0060000000ed}, 0, 0
   IISFilter, FILTER_PREPROC_HEADERS_END, 0x00000A74,   127311199074261949,          0,
0, {00000000-0000-0000-0200-0060000000ed}, 0, 0
   IISFilter, FILTER_END, 0x00000A74,   127311199074261949,          0,          0,
{00000000-0000-0000-0200-0060000000ed}
```

**Log Parser 2.2 and the DumpTraceReqs.js script**
Log Parser is a free tool for parsing and formatting log files or other files that contain large amounts of unformatted data. The DumpTraceReqs.js script, which is included with Log Parser 2.2 on the Microsoft Download Center, was written by the IIS team for the purpose of processing and formatting IIS request-based tracing logs. DumpTraceReqs.js groups all events per request in chronological order, and displays them per request. You do not have to be familiar with Log Parser and the sample script to format your trace logs. You simply execute a command from the command line and the tool processes the log file for you. Whenever possible, use Log Parser and DumpTraceReqs.js to process and view trace logs because the output is much easier to read than the output from tracerpt.exe. For example:

```
Microsoft (R) Windows Script Host Version 5.6
Copyright (C) Microsoft Corporation 1996-2001. All rights reserved.
---------------------------------------------------------------------
Request n.1: /ASPtest {00000000-0000-0000-0200-0060000000ed} 2004-5-7 22:11:47

  IISGeneral: GENERAL_REQUEST_START - IIS starts processing a new request
    SiteId: 1
    AppPoolId: DefaultAppPool
    ConnId: 1073741825
    RawConnId: 0
    RequestURL: /ASPtest
    RequestVerb: GET
    ContextIDSeq: 1
    Timestamp: 22:11:47.426.194900
```

```
IISFilter: FILTER_START - W3 filter starts
  FilterName: D:\IISDebugTools\IISCHAgent.dll
  ContextIDSeq: 1
  Timestamp: 22:11:47.426.194900

IISFilter: FILTER_PREPROC_HEADERS_START - Filter starts PREPROC_HEADERS notification
  ContextIDSeq: 1
  Timestamp: 22:11:47.426.194900

IISFilter: FILTER_PREPROC_HEADERS_END - Filter ends PREPROC_HEADERS notification
  ContextIDSeq: 1
  Timestamp: 22:11:47.426.194900

IISFilter: FILTER_END - W3 filter ends
  ContextIDSeq: 1
  Timestamp: 22:11:47.426.194900
```

Once Log Parser and DumpTraceReqs.js have processed your .etl file, Log Parser prints the data to the screen. Viewing the data on the screen may not be an optimal viewing experience, so it is recommended that you open the processed .etl file in Notepad, as described in How to Process and View Trace Log Files

Once you have opened the processed .etl file in Notepad, you will see that each request contains a list of the trace events that were recorded during the trace session. You can scroll down the page to view all the subsequent requests and events.

For the procedure to configure Log Parser 2.2 and process an .etl file using DumpTraceReqs.js, see How to Process and View Trace Log Files.

| **Note** |
| --- |
| DumpTraceReqs.js was not designed to process data from the IISAdmin provider. If you need to process and view IISAdmin trace data, use the Trace Report tool included with Windows Server 2003. |

For more information about the tracing events in your trace log file, see the Tracing Events Reference.

# Tracing Startup and Shutdown Problems in the IIS Admin Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In IIS 6.0, the IIS Admin Service loads the primary configuration file for IIS sites, called the IIS MetaBase.xml file, and related in-memory configuration services. The IIS Admin service also loads the following:

- The File Transport Protocol (FTP) service
- The Network News Transport Protocol (NNTP) service
- The Simple Mail Transfer Protocol (SMTP) service

If the IIS Admin Service experiences a problem (hangs) while starting up or shutting down, diagnosing the problem can be extremely difficult because there are potentially four services involved. In the past, troubleshooting IISADMIN startup or shutdown hangs usually required calling Microsoft Product Support Services who would then help the user collect a process dump of the IIS Admin Service.

Currently, the best way to troubleshoot hangs in the IIS Admin service is to trace the service using the IIS Admin provider. Once you have collected trace data in the trace log, you can view the trace log to learn specific details about when the service stops responding. You can trace the IIS Admin service during startup or shutdown by choosing the **Startup** or the **Shutdown** flag. If necessary, you can trace using both flags at the same time.

In order to capture data in the trace log, you need to enable IIS Admin tracing and then reproduce the problem on your IIS server. If the IIS Admin service is currently hung, you have two options:

1. If the IIS Admin service hung on startup, enable tracing as described in How to Trace the IIS Admin Service. Then use the **iisreset /no force***computername* command to restart the IIS server. After **iisreset** terminates the process and IIS restarts, the IIS Admin service will report trace data in the trace log. For more information about the **iisreset** command, see Restarting IIS.

2. If the IIS Admin service hung on shutdown, use the **iisreset /no force***computername* command to restart the IIS server. Once the IIS server has restarted, enable tracing and then shutdown the IIS Admin service.

| **Note** |
| --- |
| The IIS Admin service can be configured to restart automatically, a feature known as Automatic Restart. If you are attempting to trace the IIS Admin service to troubleshoot hangs, you may want to disable this feature until you have remedied the problem. For more information about this feature, see "Automatic Restart" in Restarting IIS. |

For information about the events listed in the trace log, see Tracing Events Reference.

# Troubleshooting IIS with a Debugger

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Advanced troubleshooting activities will sometimes require a debugging tool. A debugging tool allows you to peer inside an executing Win32 process to observe what is happening. You can use the debugging tool to capture a record of the memory space of the process that is hosting the faulty application. In IIS 6.0, the process is usually W3WP.EXE. This memory dump is written to a DMP file.

The Microsoft Debugging Tools for Windows include a script file, named Adplus.vbs, which is a scripted front-end to the Microsoft Console Debugger (CDB). Adplus.vbs makes capturing dump files easy.

The key to using any debugger is to understand the kind of problem that you are troubleshooting. Once you identify the kind problem you are troubleshooting, you can decide what to do with the debugger and what kind of dump file to obtain. After you have obtained a dump file, it is recommended that you then have it debugged by a developer or a Microsoft support professional.

The IIS Resource Kit Tools contain a tool called IISState. This tool is like a debugger and can also be used to look at a running process. IISState contains some heuristic functionality that attempts to figure out what is happening in the process for you. For more information, see the readme.txt that comes with IISState.

For detailed information about troubleshooting with Adplus.vbs, see Microsoft Knowledge Base article 286350, How To: Use ADPlus to Troubleshoot "Hangs" and "Crashes".

# Troubleshooting Low CPU Hangs with a Debugger

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

An application that becomes unresponsive to any kind of request while the process hosting the application is consuming little or no system processor(s) CPU time is in a low CPU hang state. This type of problem can be caused by unrecoverable lock situations in program code (deadlocks) or by threads that are waiting on an external resource, such as a database.

To capture a memory dump of the offending process, at a command prompt, type the following: **C:\debuggers\> cscript.exe adplus.vbs -hang -p** *pid*

If you know that the hung process is an IIS process but do not know which process is causing the problem, instead of specifying a specific PID or process name, specify the **-iis** parameter. Specifying this parameter will cause Adplus.vbs to capture all IIS–related processes.

# Troubleshooting High CPU Hangs with a Debugger

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

An application that becomes unresponsive to any kind of request while the process hosting the application is consuming a great deal of system processor(s) CPU time, usually near 100%, is in a high CPU hang state. This problem can be caused by an endless loop in script code or by some other intensive kind of processing.

In such a case, it is useful to identify the thread that is consuming the CPU before you attempt to capture a memory dump. To identify the offending thread, you can use a tool like QSlice.exe. For information about QSlice.exe, in Help and Support Center for Windows Server 2003, click **Tools**, and then click **Windows Support Tools**. Alternatively, you can check the .log file that is generated by the Adplus.vbs script. This log file contains output generated by the **!runaway** debugger command. The **!runaway** command lists the CPU consumption times of the various running threads. For information about debugging and the debugger commands, see Debugging Tools for Windows Help.

To capture a memory dump, at a command prompt, type the following: **C:\debuggers\> cscript.exe adplus.vbs -hang -p** *PID*

# Troubleshooting Crashes with a Debugger

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

A crash can occur when code executing in the process hosting the application encounters an unexpected event that causes an exception and results in a process shutdown. Examples of such events include a stack overflow, encountering an invalid memory address (an access violation), or executing an invalid instruction. Because these situations are unexpected and, thus, unobservable, you need to run Adplus.vbs in monitoring, or *crash*, mode before the problem occurs again.

To run Adplus.vbs in crash mode, at the command prompt, type: **C:\debuggers\> cscript.exe adplus.vbs -crash -p** *PID*

If you do not know which process is crashing, use the **-iis** parameter, which causes Adplus.vbs to monitor all of the IIS–related processes for crashes. When a crash occurs, the dump files are written to disk.

# Troubleshooting Memory Problems with a Debugger

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In a typical memory problem, application code consumes too much physical system memory or too much of the virtual address space for the process in which the application is running. These problems are called memory leaks. Memory leaks can also cause the other crash and hang problems, as described earlier in this section. High CPU hangs can occur when the memory allocations of the application are intensive and consume a disproportionately great amount of CPU time. Crashes can occur when memory has been mismanaged and corruption has occurred.

# IIS 6.0 Debugging Features

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ISAPI application developers that take advantage of the **ServerSupportFunction** callback function with the **HSE_REQ_REPORT_UNHEALTHY** parameter can make debugging their ISAPI applications easier. When worker process pinging is enabled, you can also enable orphaning to aide in obtaining memory dumps. This is explained in the next section.

The ASP and ASP.NET ISAPI extensions apply logic that takes advantage of this feature as well. For example, ASP monitors the status of its internal thread pool. If too many of its threads enter a blocking state, it reports itself as unhealthy, which triggers a worker process recycle if pinging is enabled for the application pool. ASP.NET also has several algorithms to detect an unhealthy state.

For more information about the ServerSupportFunction callback function, see ServerSupportFunction Extension Function in the IIS Platform SDK on MSDN.

# Enabling Debugging for IIS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By default, when a worker process is determined to be unhealthy, the WWW service terminates it and starts a new worker process to serve new or queued client requests. Optionally, you can allow an application pool to keep the worker process running, but release, or *orphan*, the worker process from the application pool for purposes of debugging while at the same time initializing a new worker process to handle incoming client requests. An orphaned worker process ceases to take new requests from HTTP.sys.

If you enable debugging on an application pool, the WWW service allows an unhealthy worker process to keep running when the WWW service releases the worker process from serving an application pool. When enabling debugging, you can also configure the WWW service to start an executable application or script for a released worker process. For example, the WWW service might start an application that sends you an e-mail notifying you of the failure.

To enable debugging, set the **OrphanWorkerProcess** property to **true**. Use the **OrphanActionExe** and **OrphanActionParams** properties to configure the application that will run when the worker process is orphaned. For example, to use Adplus.vbs to obtain a memory dump, you could set the properties as follows:

**OrphanActionExe: %SystemRoot%\System32\CScript.exe**

**OrphanActionParams: C:\debuggers\adplus.vbs -quiet -hang -p %1%**

Be sure to closely monitor any worker process that is released from its application pool but continues to run. The worker process can terminate because the WWW service leaves it running but no longer monitors it, which effectively tells the worker process to shut down without forcing it to do so. If the worker process recovers from its unhealthy state, it detects that it has no relationship to the WWW service and self-terminates. When an orphaned worker process self-terminates, you might find an event log entry stating that a worker process was released, but find no evidence of the worker process ever having run.

If you enable debugging on unhealthy worker processes, be sure to monitor these released worker processes, because IIS does not remove them from memory. If you do not correctly handle worker processes that you keep alive for debugging purposes, you can have many failed worker processes running on your computer. These worker processes can tie up resources needed by other processes. In such a case, you might need to terminate those worker processes quickly to free those resources. In some cases, these worker processes can block metabase access and cause problems with other worker processes or with the WWW service itself.

The **OrphanActionExe** and **OrphanActionParams** property settings shown above will leave an orphaned worker process running after obtaining a dump file. As an alternative, you can use CDB directly from a .cmd script file. For example, paste the following text into a new text file and save the file as *LocalDrive*\debuggers\action.cmd:

```
@if "%_echo%"==="" echo off
setlocal

set WORKINGDIR=c:\debuggers
set FILENAME=%WORKINGDIR%\crash.dmp
set LOG=%WORKINGDIR%\log.txt
set COMMAND=c:\debuggers\cdb.exe -c ".dump /o /mhf /u %FILENAME%;q" -p %1

echo %COMMAND% > %LOG%
%COMMAND%

Endlocal
```

Then you can set the orphaning properties as follows:

**OrphanActionExe: C:\Debuggers\action.cmd**

**OrphanActionParams: %%1%%**

Using the **.dump** command combined with the **q** command with the CDB debugger will capture the dump file and terminate the worker process.

# Limitations of Health Detection

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Health detection cannot be used to determine application failures that do not cause the worker process to crash or to block the available threads in the worker process. As an example, an application that returns invalid response codes, such as HTTP 500 errors, but otherwise functions normally, will still respond to being pinged from the WWW service, unless the application is a custom ISAPI extension that implements specific code to indicate its unhealthy state.

# Additional Resources for Troubleshooting IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to troubleshooting IIS 6.0.

  Install the Resource Kit Tools by running IIS60rkt.exe. When you perform a default installation of the Resource Kit Tools, the files are installed in the *LocalDrive*:\Program Files\IIS Resources folder.

- Windows Support Tools

  Obtain the Windows Support Tools by installing them from the \Support\Tools folder of the Windows Server 2003 operating system CD. See the Support Tools Help file for information about using these tools.

# Common IIS 6.0 Administrative Tasks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you are already familiar with running Internet Information Services (IIS) 6.0 and need only a quick refresher to perform an administrative task, or if you are learning how to use IIS and want to know the most common tasks that follow an IIS installation, use this appendix as a quick reference. IIS 6.0 provides a wealth of tools and features, many of which are outlined in this appendix, to help you create a strong and secure communications platform of dynamic network applications.

**In This Appendix**

Overview of Common Administrative Tasks

Important First Tasks after Installing IIS 6.0

Tasks New to IIS 6.0

Security-Related Tasks

Tasks for Managing Servers and Applications

Tasks for Administering Servers

**Related Resources**

- For information about configuring Web sites as well as the FTP, NNTP, and SMTP services, see Configuring Internet Sites and Services.
- For information about configuring IIS 6.0 programmatically, see IIS 6.0 Administration Scripts, Tips, and Tricks.

# Overview of Common Administrative Tasks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Although this appendix is a reference for the common tasks you frequently perform when administering IIS as your Web server, most tasks in this appendix do not include guidelines for their use or detailed explanations. A few tasks include brief conceptual information, although they are the exception. However, all topics include cross-references to IIS Operations Guide topics, and to other topics and appendices in this reference so that you can quickly find additional information on a task.

Table A.1 outlines the tasks that are included in this appendix.

**Table A.1 Overview of the Tasks in This Appendix**

| Task | Describes How To |
|---|---|
| **Important First Tasks In IIS 6.0** | |
| Starting IIS Manager | Open IIS Manager (provides three options). |
| Starting and stopping services and sites | Start and stop IIS services and sites. |
| Enabling dynamic content services | Enable dynamic content services, such as Active Server Pages and ASP.NET (includes information about default installations). |
| Creating a Web FTP site | Create Web site configurations, and install and use File Transfer Protocol (FTP) services. |
| Creating virtual directories | Create virtual directories within Web and FTP sites. |
| **Tasks New to IIS 6.0** (tasks that are new or significantly different than they were in IIS 5.0) | |
| Creating and isolating applications | Create and manage applications. |
| Creating application pools | Group Web applications into application pools. |
| Configuring recycling | Periodically restart worker processes assigned to an application pool. |
| Backing up and restoring metabase configurations | Save metabase and application configurations, including portable backups. |
| Saving and copying site configurations | Back up your site configurations. |
| **Security-related Tasks** | |
| Setting authentication settings | Set up and use user authentication methods. |
| Obtaining and backing up server certificates | Set up and use Secure Sockets Layer (SSL) certification on your sites. |
| Controlling access to applications | Help reduce the attack surface of your applications with permissions and restrictions. |
| **Tasks for Managing Servers and Applications** | |
| Hosting multiple Web sites | Create and host multiple Web sites. |

| | |
|---|---|
| Redirecting Web sites | Automatically direct users to the correct page on your site. |
| Assigning resources to applications | Control the amount of resources an application uses. |
| **Tasks for Administering Servers** | |
| Administering servers from the command line | Use powerful scripting and programming tools to access and configure settings. |
| Administering servers remotely | Use tools to remotely administer your sites. |

When performing these tasks — especially security-related tasks — be sure that you are familiar with best practice guidelines and that you apply those guidelines to these tasks.

To perform most of the tasks described in this appendix, you must be a member of the Administrators group on the local computer, or you must be delegated the appropriate authority. If you log on to your computer as a member of the Administrators group, you might make your system vulnerable to malicious programs that could cause security risks. Instead, use the **Run as** feature to perform administrative tasks so that you do not need to log on to your computer as a member of the Administrators group. Using this feature, you can open and execute a program that uses a different account and security context than the one you logged on with.

You can use **Run as** through the user interface (UI) or as a command-line tool. The **Run as** feature that is built into the UI is a shortcut that you access by right-clicking some programs (files with the .exe file name extension), some Control Panel items (files with the .cpl file name extension), and Microsoft Management Console (MMC) (files with the .msc file name extension) snap-ins.

**To use the Run as feature to run IIS Manager as an administrator**

1. From the **Start** menu, point to **Administrative Tools**, right-click **Internet Information Services (IIS) Manager**, and then click **Run as**.

The **runas** command provides the same capabilities as the built-in **Run as** feature.

**To use the runas command to run IIS Manager as an administrator**

1. From the **Start** menu, click **Run**.
2. In the **Open** box, type **cmd**, and then click **OK**.
3. At the command prompt, type the following:

   **runas /User:** *Administrative_AccountName* **"mmc %systemroot%\system32\inetsrv\iis.msc"**

**To use the runas command to run a command-line script as an administrator**

1. From the **Start** menu, click **Run**.
2. In the **Open** box, type **cmd**, and then click **OK**.
3. At the command prompt, type the following:

   **runas /profile /User:** *MyMachine* **** *Administrator* **cmd**

   A new command window, which has administrative rights, opens.
4. In the new command window, type the following at the command prompt:

   **cscript.exe** *ScriptName* (include the script's full path and any parameters)

For more information about using the **Run as** feature or the **runas** command to perform procedures, see "Using Run as", "Runas", and "Create a shortcut using the runas command" in Help and Support Center for Microsoft® Windows® Server 2003.

# Important First Tasks after Installing IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you install IIS, if you want to quickly build a few Web sites and virtual directories, this section introduces the following first steps for these basic tasks:

- Starting IIS Manager: Describes three ways to open IIS Manager.
- Starting and Stopping Services and Sites: Describes how to start and stop IIS services.
- Enabling and Disabling Dynamic Content: Describes how to enable Web service extensions, such as Active Server Pages (ASP) and Microsoft® ASP.NET, so you can serve dynamic content. Includes information about default installations.
- Creating a Web Site or an FTP Site: Describes how to create Web site configurations, and how to install and use FTP services.
- Creating IIS 6.0 Virtual Directories: Describes how to create virtual directories within Web and FTP sites.

# Starting IIS Manager

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS Manager is a graphical user interface (GUI) for configuring your application pools or your Web, FTP, Simple Mail Transfer Protocol (SMTP), or Network News Transfer Protocol (NNTP) sites. You can use IIS Manager to configure IIS security, performance, and reliability features. For example, you can add or delete sites; start, stop, and pause sites; back up and restore server configurations; and create virtual directories for better content management.

In earlier versions of IIS, this tool was called the Internet Service Manager. For information about starting IIS Manager, see IIS Manager.

# Starting and Stopping Services and Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Infrequently, you might make configuration changes in IIS 6.0 that require you to restart IIS before the changes can take effect. For example, if you change the application isolation mode in which your server is running, such as when you change from worker process isolation mode to IIS 5.0 isolation mode or vice versa, you need to restart IIS. If you make this configuration change by using IIS Manager, you are prompted to restart IIS after you click **OK** to confirm the change. If you make this configuration change by using a command-line utility, such as Adsutil.vbs, you can use the **IISReset** command-line utility to complete the change. Both methods — using the Restart IIS command in IIS Manager or using a command-line utility — allow you to stop, start, and restart IIS Internet services, as well as restart your computer.

When you restart the Internet service, all sessions connected to your Web server (including Internet, FTP, SMTP, and NNTP) are dropped. Any data held in Web applications is lost. All Internet sites are unavailable until Internet services are restarted. For this reason, avoid restarting, stopping, or rebooting your server.

For a list of features designed to improve IIS reliability and remedy the need to restart IIS, see the Alternatives to Restarting IIS section in the Restarting IIS topic in the IIS 6.0 Operations Guide, which is accessible from IIS Manager.

For information about restarting IIS services, and starting, stopping, or pausing individual sites, see Starting and Stopping Services.

**Saving Your Configuration to Disk**

As a safeguard, if you must stop or restart IIS, save your configuration to disk before you perform the restart. Your configuration is automatically saved if you enable the edit-while-running feature (this feature is not enabled by default). For more information about the edit-while-running feature, see IIS Metabase.

Alternatively, you can manually save your configuration to disk. For information about manually saving your configuration to disk, see Saving Configurations.

**If You Receive an Error Stating That IISReset Is Disabled**

If the **IISReset** command-line utility is disabled, then the command-line or IIS Manager calls that require IISReset.exe fail and return an error stating that **IISReset** is disabled. Actions that fail include the **Restart IIS** command in IIS Manager and Service Control Manager (SCM) recovery configuration actions that use the **IISReset** command-line utility (for example, the default IIS Admin SCM recovery path). However, SCM recovery actions that do not use the **IISReset** command-line utility continue to function (for example, the default World Wide Web Publishing Service [WWW service] SCM recovery path that restarts the WWW service).

# Enabling and Disabling Dynamic Content

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To help reduce the attack surface of systems, IIS 6.0 is not installed by default on the Microsoft® Windows® Server 2003, Standard Edition; Microsoft® Windows® Server 2003, Enterprise Edition; and Microsoft® Windows® Server 2003, Datacenter Edition. After installing these products, administrators must manually install IIS 6.0.

When you perform a clean installation of IIS 6.0, the default settings help protect your system from malicious users and attackers. When you install IIS 6.0, it is locked down — only request handling for static Web pages (HTTP content, such as .htm and .html files ) is enabled, and only the World Wide Web Publishing Service (WWW service) is installed. The request handlers that process dynamic content are disabled, which means that features like ASP, ASP.NET, server-side includes (SSI), FrontPage® 2002 Server Extensions from Microsoft, and Web Distributed Authoring and Versioning (WebDAV) do not work by default.

You can configure the request handlers (for example, Internet Server API [ISAPI] extensions or Common Gateway Interface [CGI] programs), which are called Web service extensions, by using the Web Service Extensions node in IIS Manager or by using the command-line script lisext.vbs, which is stored in the *systemroot*\System32 folder. You can individually enable or disable a Web service extension if it is registered in the Web Service Extensions node in IIS Manager.

For more information about using IIS Manager to administer dynamic content, including step-by-step documentation for adding new Web service extensions, allowing an application to call a Web service extension, or disabling all Web service extensions, see Enabling and Disabling Dynamic Content in IIS 6.0.

For more information about using the lisext.vbs command-line script to administer dynamic content, such as enabling, disabling, or listing Web service extensions and their files, see Managing Applications and Web Service Extensions Using Scripts.

# Enabling ASP Pages

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Active Server Pages (ASP) is a server-side scripting environment that you can use to create dynamic and interactive Web pages, and build powerful Web applications. When the server receives a request for an ASP file, it processes server-side script code contained in the file to build the Hypertext Markup Language (HTML) Web page that is sent to the browser. In addition to server-side script code, ASP files can contain HTML (including related client-side scripts), as well as calls to Component Object Model (COM) components that perform a variety of tasks, such as connecting to a database or processing business logic.

For information about enabling ASP, see Enabling ASP Pages in IIS 6.0. For an introduction to ASP concepts, see About ASP. For information about creating ASP pages and developing Web applications, see the Web Application Guide.

# Installing and Enabling ASP.NET

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Microsoft ASP.NET is a unified Web development platform that provides the services necessary for developers to build enterprise-class Web applications. Although ASP.NET is largely syntax compatible with ASP, it also provides a new programming model and infrastructure for more secure, scalable, and stable applications. You can augment your existing ASP applications by incrementally adding ASP.NET functionality to them.

ASP.NET is a compiled, .NET-based environment; you can author applications in any .NET compatible language, including Microsoft® Visual Basic® .NET, Microsoft® Visual C#®, and Microsoft® JScript® .NET.

For information about enabling ASP.NET, and installing ASP.NET on a server running Windows Server 2003, see Installing ASP.NET.

# Creating a Web Site or an FTP Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS creates a default Web site on your computer during installation. You can use the *LocalDrive*:\Inetpub\Wwwroot directory to publish your Web content, or you can create any directory or virtual directory you choose. Because the FTP service is not installed by default, you must first install and start the File Transfer Protocol (FTP) service to create an FTP site.

Creating a Web or FTP site by using IIS Manager does not create content but merely creates a directory structure and configuration files from which to publish the content. For information about creating Web sites and FTP sites, and installing FTP services, see Creating Web or FTP Sites.

For more information about configuring Web and FTP sites, see Configuring Internet Sites and Services, Web Site Setup and FTP Site Setup.

# Creating IIS 6.0 Virtual Directories

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In most cases, the content you publish to your Web or FTP site is located in a root or home directory on your computer, such as *LocalDrive*:\Inetpub\Wwwroot\. However, you might need to publish content that is located elsewhere, such as on a remote computer.

To publish from a directory that is not contained within your home or root directory, you can create a virtual directory. A virtual directory is a directory that is not contained in the home directory but appears to client browsers as though it were.

For information about creating Web and FTP virtual directories, see Creating Virtual Directories in IIS 6.0.

# Tasks New to IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you upgrade from an earlier version of IIS, you need to learn the tasks that are new to IIS 6.0. This section introduces the following basic tasks that are new, or significantly different, in IIS 6.0:

- Creating and Isolating Applications: Describes how to create and manage applications.
- Creating an Application Pool: Describes how to group Web applications into application pools.
- Configuring Recycling: Describes how to periodically restart worker processes assigned to an application pool.
- Backing Up and Restoring the Metabase Using Backup Files: Describes how to save metabase and application configurations.
- Saving and Copying Site Configurations: Describes how to copy site configurations for use on new sites.

# Creating and Isolating Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

To create an application, you designate a directory as the starting point (application root) for the application. You can then set properties for the application. Each application can have a friendly name; this name appears in IIS Manager and gives you a way to distinguish between applications.

Web sites are root-level applications by default. When you create a Web site, a default application is created at the same time. You can use this root-level application, remove it, or replace it with a new application by removing it and creating a new application.

To isolate an application means that you configure it to run in a process (memory space) separate from the Web server and other applications. You can run IIS 6.0 in one of two application isolation modes: *worker process isolation mode* or *IIS 5.0 isolation mode*. IIS cannot run both application isolation modes simultaneously on the same computer. If you have applications that require different modes, you must run them on separate computers.

Worker process isolation mode is the default application isolation mode that the server runs in on a clean installation. In this mode, you can isolate an application by adding it to an application pool that includes isolation settings.

IIS 5.0 isolation mode is provided for applications that depend on specific features and behaviors of IIS 5.0. Use this mode only if an application has a compatibility issue when it runs in worker process isolation mode and you cannot resolve the problem.

For more information about creating and isolating applications, see Creating Applications in IIS 6.0.

# Creating an Application Pool

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you run IIS 6.0 in worker process isolation mode, you can group Web applications into application pools. An *application pool* is a grouping of URLs routed to one or more worker processes that share the same configuration. Application pools allow you to apply specific configuration settings to groups of applications and the worker processes servicing those applications. Any Web site, Web directory or virtual directory can be assigned to an application pool.

By creating new application pools and assigning Web sites and applications to them, you can make your server more efficient and reliable. In addition, your other applications are always available, even when the applications in the new application pool terminate.

For more information about creating application pools and configuring worker processes, see Creating Application Pools in IIS 6.0, Configuring Application Pool Identity with IIS 6.0, and Running IIS 6.0 as an Application Server.

# Configuring Recycling

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In worker process isolation mode, you can configure IIS to periodically restart the worker processes that are assigned to an application pool in order to manage faulty Web applications. Recycling keeps problematic applications running smoothly, especially when it is not practical to modify the application code. Recycling ensures that application pools remain healthy and that system resources are recovered.

You can configure worker processes to restart based on one of several options, including elapsed time, number of requests served, scheduled times, and memory usage; or you can configure worker processes to start on demand. In IIS 6.0, worker process recycling is available only when IIS is running in worker process isolation mode.

For more information about configuring recycling for worker processes, see Configuring Worker Processes for Recycling, and Running IIS 6.0 as an Application Server.

# Backing Up and Restoring the Metabase Using Backup Files

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Metabase backup files provide a way to restore your metabase configuration and schema data if your metabase becomes corrupted. You can create backup files by using IIS Manager or an administration script. The backup files are copies of the metabase configuration file (MetaBase.xml) and the matching metabase schema file (MBSchema.xml). Use the metabase configuration backup and restore feature to restore the metabase from backup files.

You can create two types of metabase backups:

- Portable backups. When you create a portable backup, you provide a password that is used by IIS to encrypt the backup files. IIS encrypts the password and stores it in the header of the backup file. Only the administrator password and secure properties within the backup files are encrypted; all other information within the backup files are plaintext. After the backup file is encrypted, you cannot change the password of the backup file.

- Non-portable backups. When you create a non-portable backup, you do not supply a password. Therefore, IIS encrypts non-portable backup files with a blank password, which allows any member of the Administrators group to restore the metabase by using non-portable backup files. Only the blank password and secure properties are encrypted; all other information within the backup file is plaintext.

You can restore a metabase backup to the computer on which the backup was made or to a different computer that is running Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; and Windows® Server 2003, Web Edition. However, before you restore a metabase backup from one computer to another, you must first delete the machine-specific information from the metabase file. For more information about restoring a metabase backup to a different computer, see Machine-Specific and System-Specific Information in the IIS 6.0 Operations Guide, which is accessible from IIS Manager.

Before you create a backup of the metabase, consider the following:

- A non-portable backup can only be restored to the computer on which the backup was made.

- The metabase is locked while the backup is in progress.

- Backup files contain only configuration data; they do not include your content.

To back up your content, use the Windows Backup feature. For more information about Windows Backup, see "Backing up and Restoring Data" in Help and Support Center for Windows Server 2003.

For more information about backing up and restoring the metabase, see Backing Up and Restoring the Metabase in IIS 6.0.

# Saving and Copying Site Configurations

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After your site and applications are running the way you want, you can save all or part of the configurations for a backup copy, or for import and export to other sites or computers. You can use the following procedure to save site configurations for Web or FTP sites, as well as Web or FTP virtual directories.

IIS automatically makes a backup copy of the metabase configuration and schema files each time you make changes to the metabase. Backup files contain only configuration data; they do not include your content (.asp files, .htm files, .dll files, and so on). You can also create backup files on demand, or create backup copies of individual site or application configurations and then export and import them to and from other sites or computers.

For more information about backing up the metabase, see Saving Configurations and IIS Metabase.

# Security-Related Tasks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 and Windows Server 2003 provide several ways to help secure your application servers and their content. This section provides information about the following security-related topics:

- Setting Web Site Authentication: Describes how to set up Web site authentication for your Web sites.
- Setting FTP Site Authentication: Describes how to set up FTP site authentication to validate users who request access to your FTP sites.
- Obtaining and Backing Up Server Certificates: Describes how to set up Secure Sockets Layer (SSL) certification on your sites. SSL certificates enable Web servers and users to authentication each other before establishing a connection.
- Controlling Access to Applications: Describes how to reduce the attack surface of your applications with permissions and restrictions, and how to control which users and computers are allowed to access your Web server and its resources.

Before you do any of these security-related tasks, be sure that you are familiar with best practice guidelines and that you apply those guidelines to these tasks. If you are new to using IIS or if you are unfamiliar with any of the following security-related tasks, be sure to read the cross-references to additional information that are provided in this section.

# Setting Web Site Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can require users to provide a valid Windows user account name and password before they access any information on your server. This identification process is called *authentication*. Authentication, like many of the features in IIS, can be set at the Web site, directory, or file level.

This section contains step-by-step procedures for configuring Web site authentication. For information about configuring FTP sites, see Setting FTP Site Authentication later in this appendix.

To set Web authentication, choose from the following authentication methods:

- Anonymous authentication. This authentication method gives users access to the public areas of your Web site without prompting them for a user name or password.
- Basic authentication. This authentication method requires a previously assigned Windows account user name and password, also known as *credentials*.
- Digest authentication. This authentication method offers the same functionality as Basic authentication, while providing an additional level of security because the user's credentials are not sent over the network in plaintext.
- Advanced Digest authentication. This authentication method offers similar functionality to Digest authentication; however, collects user credentials and stores them on the domain controller as an MD5 hash, or message digest. Advantages of this authentication are that the worker process does not need to run as local system and the user password is not stored as plaintext on the domain controller. This authentication method requires a Windows Server 2003 domain controller infrastructure.
- Integrated Windows authentication. This authentication method collects information through a method where the user name and password are hashed before being sent across the network.
- Certificate authentication. This authentication method adds SSL security through client or server certificates. For information about this type of authentication, see Obtaining and Backing Up Server Certificates.
- .NET Passport authentication. This authentication method provides a single sign-in service that is HTTP cookie-based.

# Configuring Anonymous Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Anonymous authentication gives users access to the public areas of your Web or FTP site without prompting users for a user name or password. When a user attempts to connect to your public Web or FTP site, your Web server assigns the connection to the Windows user account IUSR_*computername*, where *computername* is the name of the computer on which IIS is running. By default, the IUSR_*computername* account is included in the Users and Guests user groups.

For information about enabling Anonymous authentication and changing the account used for Anonymous authentication, see Anonymous Authentication in IIS 6.0.

# Configuring Basic Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Basic authentication method transmits user names and passwords across the network in an unencrypted form. You need to use SSL, in combination with Basic authentication, to encrypt user account information that is transmitted across the network.

Configuration settings made at the Web Sites folder level can be inherited by all Web sites unless you specify otherwise at the individual Web site level. Enabling Basic authentication does not automatically configure your Web server to authenticate users. You must also create Windows user accounts and set NTFS permissions.

For information about enabling Basic authentication, see Enabling Basic Authentication and Configuring the Realm Name.

# Configuring Digest Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Digest authentication offers the same functionality as Basic authentication; however, Digest authentication provides a means to help ensure that user credentials are not sent across the network in plaintext. Digest authentication transmits credentials across the network as an MD5 hash, or message digest, where the original user name and password cannot be deciphered from the hash. Digest authentication is available to WebDAV directories.

Digest authentication is enabled by default for upgrades from an earlier version of IIS. If you need to enable Digest authentication on a server running IIS 6.0, do the following:

1. Enable Digest authentication for Windows domain servers.

2. Configure the realm name.

**Configuring the Realm Name**

In addition to using IIS Manager to enable Digest authentication on a Windows domain server, you can use scripting to configure the realm name at any level of the metabase, as shown in the Table A.2.

If a child key in the metabase is not configured with a realm name, that child key inherits the realm name from the next parent key that has the realm name configured. If the realm name is not configured, IIS sends its own computer name as the realm name. If IIS sends its own name as the realm name and IIS is not running on a Windows Server 2003 domain controller with Active Directory® directory service, Digest authentication fails. As a best practice, avoid running IIS on a domain controller; whenever possible, physically separate a server that is running IIS from a domain controller.

**Table A.2 Configuring the Realm Name at Any Level of the Metabase**

| Metabase Level | Description |
|---|---|
| W3SVC | The W3SVC level, also known as the IISWebService level, is the highest level in the metabase where Digest authentication can be configured. Lower levels that do not have specific configuration settings inherit configurations set at this level. |
| W3SVC/*n* | The W3SVC/*n* level, also known as the IISWebService level, is a specific Web site, where *n* is the number of the site. Sites are numbered starting at 1. The default Web site is 1. |
| W3SVC/*n*/root | The W3SVC/*n*/Root level, known as the IISWebVirtualDir level, is the starting point for a Web Site, where *n* is the number of the site. |
| W3SVC/*n*/root/vdir | The W3SVC/*n*/Root/WebVirtualDir level, known as the IISWebVirtualDir level, is a virtual directory within a Web Site, where *n* is the number of the site. |
| W3SVC/*n*/root/vdir/webdir | The W3SVC/*n*/Root/WebVirtualDir/WebDir level, also known as the IISWebDirectory level, is a physical directory within a virtual directory within a Web site, where *n* is the number of the site. |
| W3SVC/*n*/root/vdir/file | The W3SVC/*n*/Root/Vdir/file level is an individual file within the W3SVC/*n*/Root/WebVirtualDir level, where *n* is the number of the site. |
| W3SVC/*n*/root/vdir/webdir/file | The W3SVC/*n*/Root/Vdir/file level is an individual file within the W3SVC/*n*/Root/WebVirtualDir/WebDir level, where *n* is the number of the site. |

You can configure either single or multiple realm names on a server running IIS. You might want to configure multiple realm names if the domains do not have a trusted relationship. If you configure multiple realm names, you must configure them at different levels of the metabase.

For information about enabling Digest authentication and configuring the realm name, see Configuring Digest Authentication in IIS 6.0.

# Configuring Advanced Digest Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Under Advanced Digest authentication, user credentials are stored on the domain controller as an MD5 hash. Because credentials are stored in Active Directory as an MD5 hash, user passwords cannot be discovered by anyone with access to the domain controller, not even by the domain administrator. Advanced Digest authentication is available to WebDAV directories.

In IIS 6.0, Advanced Digest authentication is preferred over Digest authentication; however, you can use Digest authentication where your systems do not meet the requirements for Advanced Digest authentication.

Advanced Digest authentication is enabled by default on a clean installation of IIS 6.0. If you need to enable Advanced Digest authentication on a server running IIS 6.0, do the following:

1. Enable Digest authentication for Windows domain servers.
2. Configure the realm name.
3. Set the **UseDigestSSP** metabase property to **TRUE**.

| **Important** |
| --- |
| If you perform the two procedures that precede this note but do not configure the **UseDigestSSP** metabase key, you are using Digest authentication, not Advanced Digest authentication.<br><br>For information about enabling Advanced Digest authentication, see Advanced Digest Authentication in IIS 6.0. |

# Configuring Integrated Windows Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Integrated Windows authentication (formerly called NTLM, and also referred to as Windows NT Challenge/Response authentication) is a form of authentication that hashes the user name and password before they are sent across the network. When you enable Integrated Windows authentication, the client submits the password through a cryptographic exchange with your Web server that involves hashing. Integrated Windows authentication is the default authentication method used in Windows Server 2003.

Integrated Windows authentication has the following limitations:

- Only Microsoft® Internet Explorer version 2.0 and later support this authentication method.
- This authentication method might not work over HTTP proxy connections.

Therefore, Integrated Windows authentication is best suited for an intranet environment, where both user and Web server computers are in the same domain and where administrators can ensure that every user has Internet Explorer version 2.0 or later.

For information about enabling Integrated Windows authentication, see Configuring Integrated Windows Authentication in IIS 6.0.

# Enabling .NET Passport Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can enable Microsoft® .NET Passport authentication on a Web site by using IIS Manager. When .NET Passport is enabled, requests coming into IIS must contain .NET Passport credentials on either the query string or within a cookie. The credentials also have to be valid, meaning the ticket has not expired. If IIS does not detect .NET Passport credentials, requests are redirected to the .NET Passport sign-in page.

.NET Passport uses cookies, which contain information that can be compromised. However, you can use .NET Passport authentication over a SSL connection, which reduces the potential of replay attacks.

For information about enabling .NET Passport authentication, see Enabling .NET Passport Authentication in IIS 6.0.

# Setting FTP Site Authentication

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Based on your security requirements, you can select an IIS authentication method to validate users who request access to your FTP sites. To set FTP site authentication, choose from the following authentication methods:

- Anonymous FTP authentication. This authentication method gives users access to the public areas of your FTP site without prompting them for a user name or password.

- Basic FTP authentication.This authentication method requires users to log on with a user name and password corresponding to a valid Windows user account.

You cannot use Digest or Integrated Windows authentication with FTP sites, and you must set available authentication settings at the site level for FTP sites.

**Enabling Anonymous FTP Authentication**
You can configure your FTP server to allow anonymous access to FTP resources. If you select Anonymous FTP authentication for a resource, all requests for that resource are accepted without prompting the user for a user name or password. This is possible because IIS automatically creates a Windows user account called IUSR_*computername*, where *computername* is the name of the server on which IIS is running. This is very similar to Web-based Anonymous authentication. If Anonymous FTP authentication is enabled, IIS always try to use it first, even if you enable Basic FTP authentication.

For information about enabling Anonymous FTP authentication, see Configuring Anonymous FTP Authentication. For more information about creating Windows user accounts and setting NTFS permissions, see Securing Files with NTFS Permissions and Setting NTFS Permissions for Directories or Files.

**Enabling Basic FTP Authentication**
To establish an FTP connection with your Web server by using Basic FTP authentication, users must log on with a user name and password corresponding to a valid Windows user account. If the FTP server cannot verify a user's identity, the server returns an error message. Basic FTP authentication transmits the user name and password across the network in an unencrypted form.

For information about enabling Basic FTP authentication, see Configuring Basic FTP Authentication.

# Obtaining and Backing Up Server Certificates

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Server certificates contain information used in establishing identities over a network, which is a process called *authentication*. Similar to conventional forms of identification, certificates enable Web servers and users to authenticate each other before establishing a SSL connection.

*Server certificates* contain information about the server that allows the client to positively identify the server before sharing sensitive information. *Client certificates* contain personal information about the clients requesting access to your site that allow you to positively identify them before allowing them access to the site.

Certificates include *keys* used in establishing an SSL secure connection. A *key* is a unique value used to authenticate the server and the client in establishing an SSL connection. A *public key* and a *private key* form an SSL *key pair*. Your Web server uses this key pair to negotiate a secure connection with the user's Web browser to determine the level of encryption required for securing communications.

You can obtain a server certificate in one of two ways: issue your own server certificate or obtain a server certificate from a certification authority.

To request and install your own server certificate, use the Web Server Certificate Wizard to create a customizable service for issuing and managing certificates. You can create server certificates for the Internet or for corporate intranets, giving your organization complete control over certificate management policies.

To obtain a server certificate from a certification authority, follow these steps:

1. Do either of the following:

   - Find a certification authority that provides services that meet your business needs and request a server certificate.

     –Or–

   - Use the Web Server Certificate Wizard to create a certificate request that you can send to the certification authority.

2. After the certificate is processed and returned to you, use the Web Server Certificate Wizard to install the certificate.

For more information about SSL certificates, including how to obtain, install, and back up server certificates, see Certificates_IIS_SP1_Ops. For more information about Microsoft Certificate Services, see "Certificate Services" in Help and Support Center for Windows Server 2003.

# Controlling Access to Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can control which users and computers are allowed to access your Web server and its resources. You can use both the NTFS file system and Web server security features to assign users specific permissions to directories and files. You can also use IP address restrictions to limit access by specific computers or groups of computers.

- Securing your files with NTFS permissions. With the NTFS file system, you can limit access to your Web server's files and directories. You can configure the file and directory permissions that set the access level assigned to a particular user account or user group. For example, you can configure your Web server to enable a specific user to view and execute a file, while excluding all other users from accessing that file.

- Securing your Web site with Web permissions. Web permissions, unlike NTFS permissions, apply to all users accessing your Web sites. NTFS permissions apply only to a specific user or group of users with a valid Windows account. NTFS controls access to physical directories on your server, whereas Web permissions control access to virtual directories on your Web site.

- Restricting access to your Web site by using IP addresses. With IP address restrictions, you can configure your Web server to assign or deny specific computers, groups of computers, or domains access to Web sites, directories, or files. For example, if your intranet server is connected to the Internet, you can prevent Internet users from accessing your Web server by assigning access only to members of your intranet, and explicitly denying access to outside users.

# Securing Your Files with NTFS Permissions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can control access to your Web site's directories and files by setting NTFS access permissions. You can use NTFS permissions to define the level of access that you want to assign to specific users, and groups of users. Correct configuration of file and directory permissions is crucial for preventing unauthorized access to your resources. For information about securing a Web site by using NTFS permissions, see Securing Files with NTFS Permissions.

With NTFS permissions, you also have the choice of assigning special permissions to groups or users. Special permissions are permissions on a more detailed level. For better management, assign broad-level permissions to users or groups, where it is applicable. For descriptions of permissions, see "Permissions for Files or Folders" in Help and Support Center for Windows Server 2003.

# Securing Your Web Site with Web Permissions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can also use Web permissions to help secure your Web site. When you configure your Web site's access permissions for specific sites, directories, and files, keep in mind the following:

- Web permissions are not meant to be used in place of NTFS permissions; instead, use Web permissions with NTFS permissions.

  Although you can use Web permissions with both the NTFS and FAT file systems, use NTFS whenever possible.

- Unlike NTFS permissions, Web permissions affect everyone who tries to access your Web site.

- Disabling permissions restricts all users. For example, disabling the Read permission restricts all users from viewing a file, regardless of the NTFS permissions applied to those users' accounts. However, enabling the Read permission can allow all users to view that file, unless NTFS permissions that restrict access have also been applied.

- If Web permissions conflict with NTFS permissions for a directory or file, the more restrictive settings are applied. For example, if you set both IIS and NTFS permissions, the permissions that explicitly deny access take precedence over permissions that grant access.

- If you want to set permissions for a WebDAV directory, keep in mind the following:

  - You must enable WebDAV before you can publish in a WebDAV directory.

  - You must turn off Anonymous access to your WebDAV directory. Protect your WebDAV directory by using one of the following authentication methods in IIS 6.0, such as Integrated Windows authentication and the discretionary access control lists (DACL) in NTFS. For more information about WebDAV security, see Managing WebDAV Security in the IIS 6.0 Operations Guide, which is accessible from IIS Manager.

For information about setting permissions for Web content (including WebDAV), see Securing Sites with Web Site Permissions.

# Restricting Access to Your Web Site by Using IP Addresses

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

You can configure your Web site to grant or deny specific computers, groups of computers, or domains access to Web sites, directories, or files. For example, if your intranet server is connected to the Internet, you can prevent Internet users from accessing your Web server by assigning access only to members of your intranet, and explicitly denying access to outside users.

IP address restrictions apply only to Internet Protocol version 4 (IPv4) addresses.

For information about granting or denying access to computers and domains, see Granting or Denying Access to a Computer and Granting or Denying Access to a Domain.

# Tasks for Managing Servers and Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the following tasks in this section to manage your servers and applications:

- Using Host Header Names to Host Multiple Web Sites: Describes how to create and host multiple Web sites.
- Redirecting Web Sites: Describes how to automatically direct users to the correct page on your site.
- Assigning Resources to Applications: Describes how to control the amount of resources an application uses.

# Using Host Header Names to Host Multiple Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS supports multiple Web sites on a single server. To create and host multiple Web sites, you must configure a unique identity for each site on the server. To assign a unique identity, distinguish each Web site with at least one of three unique identifiers: a host header name, an IP address, or a TCP port number.

One method for providing each site with a unique identifier is to use IIS Manager to assign multiple host header names. Browsers must comply with HTTP 1.1 to support the use of host header names. Microsoft® Internet Explorer 3.0, Netscape Navigator 2.0, and later versions of both browsers support host header names.

| **Important** |
| --- |
| Avoid assigning a host header name to the Default Web Site; instead, use an IP address of All Unassigned, a TCP port of 80, and no host header name. |

Table A.4 briefly describes and compares the three ways that you can uniquely identify your Web sites.

**Table A.4 Ways You Can Uniquely Identify Multiple Web Sites**

| Web Site Identifier | Description |
| --- | --- |
| Host header name | Recommended for most situations. Requires that your computer or network use a name resolution system. Organizations typically use DNS name resolution. |
| Unique IP Address | Used primarily for Internet services that host SSL on the local server. Typically, only large corporations and Internet service providers (ISPs) obtain and maintain multiple IP addresses. |
| Nonstandard TCP port number | Generally not recommended. Can be used for private Web site development and testing purposes but rarely used on production Web servers because users must add the port to the URL and the port must be opened on the firewall. |

Choose one method of uniquely identifying Web sites for each server. Using one method for each server improves performance by optimizing cache and routing lookups. Conversely, using any combination of host headers, unique IP addresses, or non-standard port numbers to identify multiple Web sites degrades the performance of all Web sites on the server.

If you use host header names to identify a new Web site, select a unique name as follows:

- **On the Internet.** The host header must be a publicly available DNS name, such as support.microsoft.com. Register a public DNS name with an authorized Internet name authority. For more information about using DNS names to identify your site, see Domain Name Resolution in the IIS 6.0 Operations Guide, which is accessible from IIS Manager.

- **On a private network.** The host header can be an intranet site name. To resolve host names to an IP address, register the host header name with your intranets DNS administrator. Alternatively, you can resolve host names to an IP address by using a locally stored database file called the Hosts file, which is located in the *systemroot*\System32\Drivers\Etc folder. The following is an example of the contents of a Hosts file:

```
#
# Table of IP addresses and host names
#
# IP Address     TCP Port   Host Header Name
#
192.168.0.100    80         www.example1.com
192.168.0.100    80         example1.com
```

Use Windows Explorer to create a home directory for your Web site content. Create subdirectories to store HTML pages, image files, and other content as needed. To organize home directories for multiple Web sites on the same server, you can create a top-level directory for storing all home directories, and then create subdirectories for each site.

**Important** You must be a member of the Administrators group on the local computer to perform the following procedure or procedures. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run IIS Manager as an administrator. At a command prompt, type **runas /user:***Administrative_AccountName* **"mmc %systemroot%\system32\inetsrv\iis.msc"**.

**To assign multiple host header names to a single Web site**

1. In IIS Manager, expand the local computer, click the **Web Sites** folder, right-click the Web site for which you want to assign a host header name, and then click **Properties.**
2. Click the **Web Site** tab.
3. In the **IP Address**list, select the IP address that you want assigned to this Web site.
4. Click **Advanced**.
5. Under **Multiple identities for this Web Site**, select the IP address, and then click **Edit**.
6. In the **Host Header Value** box, type the host header name (for example, www.contoso.com).
7. Click **OK** twice.

For more information about using host header names to host multiple Web sites, see Hosting Multiple Web Sites on a Single Server. Also see Knowledge Base article 324287, Use Host Header Names to Configure Multiple Web Sites in Internet Information Services 6.0.

# Redirecting Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When a browser requests a page or program on your Web site, the Web server locates the page identified by the URL and returns it to the browser. When you move a page on your Web site, you cannot always correct all the links that refer to the old URL. To make sure that browsers can find the page at the new URL, you can instruct the Web server to *redirect* the browser to the new URL.

You can redirect requests for files in one directory to a different directory, to a different Web site, or to another file in a different directory. When the browser requests the file at the original URL, the Web server instructs the browser to go to the new URL.

For information about redirecting requests to other Web sites or directories, redirecting requests to a single file, or redirecting requests to a program, see Redirecting Web Sites in IIS 6.0.

# Assigning Resources to Applications

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

There are several ways to assign, or limit, the amount of resources an application can use. You can use application property sheets to control performance, cache, and process options of individual applications, or you can use *bandwidth throttling* to limit resources for an entire site or application pool. A third alternative is to control access to your application through the NTFS file system and Web server security features.

For information about assigning resources by using property sheets, globally assigning resources by using bandwidth throttling, or assigning resources to an individual Web site by using bandwidth throttling, see Assigning Resources to Applications in IIS 6.0 and Throttling Bandwidth.

# Tasks for Administering Servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 and Windows Server 2003 provide several tools to help you administer your servers. This section provides the following task-based information:

- Administering Servers from the Command Line: Describes how to use the following powerful scripting and programming tools to access and configure settings.
    - Supported command-line scripts. Supplied scripts for the IIS Windows Management Instrumentation (WMI) provider to manage and set IIS metabase configurations.
    - Adsutil.vbs IIS administration utility. Uses VBScript and Active Directory Service Interfaces (ADSI) as a learning tool to manipulate the IIS configuration.
- Administering Servers Remotely: Describes how to use the following tools to remotely administer your sites.
    - IIS Manager. Remotely connect to and administer an intranet server.
    - Terminal Services. After you use Terminal Services to connect to the server that is running IIS, you can use IIS Manger on the Web server as if you were logged on locally.
    - Remote Administration (HTML) tools. Administer your IIS Web server from Web browsers on your intranet.
    - Supported command-line scripts. Use with the IIS WMI provider to remotely manage an IIS machine. Each command-line script supports the **/s** parameter, which you can use to specify the remote server against which you want to perform the command.

# Administering Servers from the Command Line

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS provides powerful scripting and programming tools that you can use to access and configure settings from within a command-line script or compiled application. You can use these tools to create, delete, start, stop, pause, and list various sites and applications, as well as to copy, import, and export configurations.

**Important** You must be a member of the Administrators group on the local computer to run scripts and executables. As a security best practice, log on to your computer by using an account that is not in the Administrators group, and then use the **runas** command to run your script or executable as an administrator. At a command prompt, type **runas /profile /user:***MyComputer******Administrator* **cmd** to open a command window with administrator rights and then type **cscript.exe** *ScriptName* (include the script's full path and any known parameters).

IIS provides the following command-line tools:

- Supported command-line scripts. Use the supplied scripts for the IIS WMI provider to manage and set IIS metabase configurations.

- Adsutil.vbs IIS administration utility. Uses Microsoft® Visual Basic® Scripting Edition (VBScript) with ADSI to manipulate the IIS configuration.

# Supported Command-Line Scripts

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS 6.0 includes supported scripts that you can find in the *systemroot*\System32 directory. These VBScript scripts use the IIS WMI provider to manage configuration settings in the IIS metabase.

When you use these scripts to create a new site or virtual directory, you can specify the basic properties that are needed to create the site or directory and identify its contents. The scripts apply the same default properties that IIS Manager uses to create new sites or virtual directories, and they adhere to the same rules for inheriting properties.

To configure more advanced properties for a site or virtual directory, use IIS Manager. Alternatively, you can build an XML template that contains the properties you want to apply to a new Web site or virtual directory and then use the Iiscnfg.vbs script to apply this template to any Web site or virtual directory in the IIS metabase.

The computer that runs the command must be running Microsoft® Windows® XP Professional or Windows Server 2003. The computer that the command affects must be running Windows Server 2003 with IIS 6.0. You cannot use these scripts to manage IIS 6.0 on clients running Windows XP Professional because Windows XP runs with IIS 5.1.

Table A.5 lists the supported command-line scripts for IIS 6.0.

**Table A.5 Supported Command-Line Scripts for IIS 6.0**

| Script | For These Areas | Tasks | IIS Operations Guide Topics |
|---|---|---|---|
| Iisweb.vbs | Web sites | Create, delete, start, stop, pause, and query or list Web sites. | Managing Web Sites |
| Iisftp.vbs | FTP sites | Create, delete, start, stop, pause, and query or list FTP sites.<br>Query and set Active Directory properties for a users FTP home directory (use in FTP user isolation). | Managing FTP Sites<br>Setting Active Directory User Isolation |
| Iisvdir.vbs | Web virtual directories | Create, delete, or list the Web virtual directories of a given root. | Managing Web Virtual Directories |
| Iisftpdr.vbs | FTP virtual directories | Create, delete, or list the FTP virtual directories of a given root. | Managing FTP Virtual Directories |
| iisback.vbs | Back up and restore IIS configuration | Create, delete, restore, and list backup copies of IIS configuration. | Managing IIS Configurations |
| Iiscnfg.vbs | Export or import IIS configuration | Export or import an IIS configuration to or from an XML file; copy the metabase and schema to another computer; and save configuration changes to disk. | Managing IIS Configurations |
| Iisext.vbs | Applications and dynamic content services | Configure and manage applications, Web service extensions (like ASP and ASP.NET), and individual files. | Managing Applications and Web Service Extensions |
| Iisapp.vbs | Application pools and their worker processes | List the worker processes (W3wp.exe) currently running and the application pool each one serves. | Listing Running Web Applications |

# Adsutil.vbs IIS Administration Utility

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Adsutil.vbs is an IIS administration utility that uses VBScript with ADSI to manipulate the IIS configuration and modify the metabase. You must run this script by using CScript, which is installed with Windows Script Host.

Adsutil.vbs is a flexible and generic command-line tool. Because Adsutil.vbs is not supported (its documentation and format can change at any time), use Adsutil.vbs primarily as a learning tool.

For more information about how to use Adsutil.vbs, including Adsutil.vbs syntax, parameters, commands and examples, see IIS 6.0 Administration Scripts, Tips, and Tricks in this reference.

# Administering Servers Remotely

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you run IIS on an intranet or the Internet, you can administer your server remotely by using the following tools:

- IIS Manager. Use on your server to remotely connect to and administer an intranet server running IIS 5.*x* or IIS 6.0.
- Terminal Services. Does not require you to install IIS Manager on the remote client computer because, after you are connected to the server that is running IIS, you can use IIS Manager on the Web server as if you are logged on locally.
- Remote Administration (HTML) tool. Use to administer your IIS Web server from any Web browser on your intranet. This version of the tool runs only on servers running IIS 6.0.
- Supported command-line scripts. Use the IIS-supported command-line scripts with the IIS WMI provider to remotely manage a server running IIS. Each command-line script supports the */s* parameter, which you can use to specify the remote server against which you want to perform the command.

For information about enabling the Remote Administration (HTML) tool, and administering servers remotely through IIS Manager, Terminal Services, and the Remote Administration (HTML) tool, see Administering Servers Remotely in IIS 6.0.

For more information about remotely managing servers by using this tool, from the **Help** menu in the Remote Administration (HTML) tool, click **Help Topics**.

# Using FrontPage 2002 Server Extensions with IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage® 2002 Server Extensions from Microsoft® is a technology that works with Internet Information Services (IIS) to support administering, authoring, and browsing Web sites. FrontPage Server Extensions provides you with tools for managing site security, organizing your content into subwebs, and checking site usage. Users who are running the FrontPage client can create and manage professional-looking Web pages for corporate Internet or intranet sites.

**In This Appendix**

Overview of FrontPage 2002 Server Extensions

Preparing to Extend Web Sites

# Overview of FrontPage 2002 Server Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions is a set of server-side applications that extend the functionality of a Web server and support authoring in Microsoft FrontPage. FrontPage 2002 Server Extensions enables you and your customers to use advanced features without writing complex *server-side* programs, which are applications and programs that run on the Web server rather than on the client computer. Using this technology allows you to deploy content over HTTP without requiring a virtual private network (VPN) or an unsecured method, such as File Transfer Protocol (FTP).

FrontPage 2002 Server Extensions includes new features, such as roles and user rights, and server health monitoring.

A FrontPage client (a computer that is running FrontPage) communicates with a Web server by using WinSock and TCP/IP and with the server extensions by using HTTP. FrontPage implements a remote procedure call mechanism on top of the HTTP POST request, so that the FrontPage client can request documents, add new authors, and so on.

A Web server with FrontPage 2002 Server Extensions recognizes POST requests addressed to the server extensions Internet Server API (ISAPI) or Common Gateway Interface (CGI) applications and directs those requests accordingly. FrontPage can communicate between clients and servers even through proxy servers (firewalls).

# Why Use FrontPage 2002 Server Extensions?

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you use FrontPage 2002 Server Extensions on your Web server, you can divide Web content on a single server into multiple content areas, called *subwebs*, each with its own set of authors and users. In addition, if you build and maintain Web sites for customers and you coordinate with multiple authors, the features included with FrontPage 2002 Server Extensions can help you do the following:

- Host Web sites that are created by using FrontPage-based Web authoring.
- Manage Web sites either on the local server or remotely by using HTML administration pages or a command-line interface.
- Grant authoring, browsing, site management, or other user rights to authenticated users.
- Create, delete, and rename FrontPage-extended subwebs.
- Analyze site usage to find out who is viewing the site and how often.

When you install FrontPage 2002 Server Extensions on your Web server, your users can do the following:

- Create Web pages and subwebs directly on your Web server.
- Enhance their sites with FrontPage components, such as hit counters, link bars, form handlers, full-text searches, and top 10 lists.
- Publish content directly to your Web servers by means of the Internet.
- Collaborate with other users on the same Web site and check files in and out of a FrontPage-extended subweb.
- Save directly to a Web server when using Microsoft Office programs.
- Use search functionality that provides a full-text index.

For more information about how you can use FrontPage 2002 Server Extensions in your organization, see the FrontPage 2002 Server Extensions Support Center.

# FrontPage Server Extensions Terminology

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions uses the term *virtual server* to describe what IIS documentation typically calls an extended Web site. In this appendix, the term *extended Web site,* rather than the term *virtual server,* is used to describe a Web site that is extended with FrontPage Server Extensions. However, where using IIS terminology might be confusing, such as when documenting procedures that use the FrontPage 2002 Server Extensions user interface, this appendix refers to an extended Web site as a virtual server. Just remember that an IIS extended Web site is the same as a FrontPage 2002 Server Extensions virtual server.

A FrontPage-extended Web site is also known as the *rootweb* because it is the top-level content directory of one or more subwebs. Hence, if you are using FrontPage terminology, every virtual server contains a rootweb, which can have many levels of subdirectories and subwebs that contain its content.

When you extend a Web site with FrontPage 2002 Server Extensions, each extended Web site can have multiple subwebs. A *subweb* is a subdirectory of the rootweb or of another subweb. Subwebs are the FrontPage mechanism for breaking up a Web site so that different areas can be owned and maintained by different people or groups. Each subweb can have many levels of subdirectories.

Several extended Web sites, or rootwebs, can reside on one server. Each extended Web site has its own name and can be accessed through its domain name, IP address, or host header. For more information about using host headers, see Common IIS 6.0 Administrative Tasks.

# Preparing to Extend Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions provides Web-based and command-line administration for extending Web sites, which enables site owners to author Web sites in FrontPage and delegate site ownership and administration credentials. *Extending* a Web site means enabling FrontPage 2002 Server Extensions features to augment how you manage the content development and security of your sites. Extending a Web site can add an additional level of security management to a Web site and enable a FrontPage client to open the site and author it in FrontPage.

Before you can extend a Web site by using server extensions, you need to install and enable FrontPage 2002 Server Extensions.

# Installing and Enabling FrontPage Server Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By default, IIS 6.0 is installed in a *locked* mode that serves only static HTTP content, thus protecting your systems from malicious users and attackers. When your server receives a default installation, the request handlers that process dynamic content are disabled, which means that features like FrontPage Server Extensions and ASP.NET do not work.

If you use the Configure Your Server Wizard to install IIS 6.0, you can elect to install and enable FrontPage Server Extensions at the time you configure your server role. If you do not install FrontPage Server Extensions at that time, you can add them to your application server at a later time.

**IIS 6.0 Application Isolation Modes**
An IIS 6.0 Web server always runs in one of two mutually exclusive *application isolation modes*. When you install FrontPage 2002 Server Extensions on an IIS 6.0 Web server, the server extensions run in the application isolation mode that you have chosen to run on the server. The application isolation mode you choose depends on what mode best fits your needs, and you can change the isolation mode after installation. At the time you install IIS 6.0, a default application isolation mode is assigned as follows:

- For clean installations, *worker process isolation* mode is the default mode.
- For upgrade installations, *IIS 5.0 isolation mode* is the default mode.

For more information about choosing an IIS 6.0 isolation mode, see Running IIS 6.0 as an Application Server.

**Installing FrontPage 2002 Server Extensions**
Before you install FrontPage 2002 Server Extensions, consider the following guidelines:

- You must run FrontPage 2002 Server Extensions on a computer that uses only the NTFS file system.

  Before you install FrontPage 2002 Server Extensions on an application server, verify that all disk volumes on the computer are formatted with the NTFS file system. Windows provides a conversion utility (Convert.exe) that you can use to convert an existing file allocation table (FAT) or FAT32 volume to NTFS without losing data. If you try to install FrontPage 2002 Server Extensions to a disk drive that is formatted with FAT, your default Web site is not extended.

  For more information about converting FAT or FAT32 volumes to NTFS, see Reformatting or converting a partition to use NTFS in Help and Support Center for Windows Server 2003.

- If you upgrade from an earlier version of FrontPage Server Extensions, you must manually upgrade each FrontPage-extended Web site.

  If you are running multiple extended Web sites and you upgrade from FrontPage 2000 Server Extensions running on the Microsoft® Windows® 2000 Server operating system to FrontPage 2002 Server Extensions running on Microsoft® Windows® Server 2003, Standard Edition; Microsoft® Windows® Server 2003, Enterprise Edition; Microsoft Windows Server 2003, Web Edition; or Microsoft® Windows® Server 2003, Datacenter Edition operating system, you must manually upgrade each FrontPage-extended Web site. If you have a single FrontPage-extended Web site and you upgrade to FrontPage 2002 Server Extensions running on Windows Server 2003, the extended Web site automatically upgrades to FrontPage 2002 Server Extensions.

If you have a Web server that runs on Windows Server 2003 and that has multiple extended Web sites, you must upgrade all your extended Web sites to FrontPage 2002 Server Extensions.

| **Note** |
| --- |
| In FrontPage2002 Server Extensions, the lightweight server extensions option is no longer supported. When you upgrade an extended Web site to FrontPage2002 Server Extensions, it receives a full (not a lightweight) implementation. |

For more information about upgrading your FrontPage-extended Web sites, see Upgrading from FrontPage Server Extensions and Office Server Extensions.

**To install and enable FrontPage 2002 Server Extensions**

1. From the **Start** menu, click **Control Panel**.
2. Double-click **Add or Remove Programs**.
3. Click **Add/Remove Windows Components**.
4. In the Windows Components Wizard, double-click **Application Server**, double-click **Internet Information Services**, and then select the **FrontPage 2002 Server Extensions** check box.
5. Click **OK** twice, click **Next**, and then click **Finish**.

For more information about installing and setting up FrontPage 2002 Server Extensions, including sample scripts to automate installation, see IIS 6.0 Administration Scripts, Tips, and Tricks.

**Enabling Web Service Extensions**

If you have FrontPage 2002 Server Extensions installed on your Web server but they do not work, check that you have them enabled. For information about enabling Web service extensions, see Enabling Web Service Extensions. For more information about enabling dynamic content, such as FrontPage Server Extensions, see Enabling and Disabling Dynamic Content in IIS 6.0.

# Creating Web Sites to Extend as Virtual Servers

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Before you can use FrontPage 2002 Server Extensions with your Web sites, you must create one or more IIS Web sites to contain them. By default, IIS provides a working Web site called *Default Web Site*, which points to the content directory *systemroot*\Inetpub\Wwwroot. To create a new Web site, you must create a content directory.

Be sure that you do not nest Web sites that you want to extend as FrontPage virtual servers because FrontPage Server Extensions does not recognize Web sites nested within each other. For example, if you need to create two extended Web sites, you can locate the first content directory in *systemroot*\Inetpub*Test* and the second content directory in *systemroot*\Inetpub*Test2*. If you place the *Test2* directory within the *Test* directory, the permissions in the *Test* directory overwrite all the permissions in the *Test2* directory.

When you create new Web sites, assign them to the default IIS application pool (DefaultAppPool) or to another IIS application pool of your choice.

| **Important** |
| --- |
| Do not use, or make changes to, the MSSharePointAppPool, which is created by default in IIS Manager when you enable FrontPage2002 Server Extensions. MSSharePointAppPool holds special files that are used internally by FrontPage Server Extensions. |

FrontPage 2002 Server Extensions does not support Unicode content directory names or Web Distributed Authoring and Versioning (WebDAV).

# Securing FrontPage 2002 Server Extensions

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions relies on the security features of the Windows Server 2003 family to provide security for Web site content. FrontPage Server Extensions uses the following two elements of Windows security:

- **User authentication.** Validates the user account that is attempting to gain access to a Web site or network resource.
- **File system security**. Controls which users can access specific files and folders in the file system.

In addition to these elements of Windows security, FrontPage 2002 Server Extensions includes a new security feature: *user roles*. With user roles, you do not have to control the file and folder permissions separately or be concerned about keeping your local groups synchronized with your list of Web users. You use roles to give users permissions on your Web site, and use FrontPage 2002 Server Extensions administration tools to add new users directly. For more information about managing users and user roles, see Using Roles to Manage User Rights later in this appendix.

**User Authentication**

When you use FrontPage 2002 Server Extensions with IIS 6.0 on a computer running Windows Server 2003, user authentication is based on one or more of the following Windows authentication methods: Anonymous authentication, Basic authentication, Integrated Windows authentication, Digest authentication, Advanced Digest authentication, or Certificate authentication.

When you set up your Web server, choose the authentication method you want to use for FrontPage 2002 Server Extensions. With the exception of Anonymous authentication, you cannot change the authentication method by using the FrontPage 2002 Server Extensions administration tools; you must instead use IIS Manager to change the authentication method.

FrontPage 2002 Server Extensions supports connectivity through firewalls. Make sure your firewall is open for the standard HTTP ports 80 and 443 (which port you use depends on your configuration). If you use a firewall and want to use NTLM Integrated Windows authentication (formerly called NTLM and also referred to as Windows NT Challenge/Response authentication), make sure your firewall supports NTLM. Otherwise, configure your Web sites with Basic authentication, preferably with SSL.

For more information about these authentication methods, including brief descriptions of each, see Common IIS 6.0 Administrative Tasks. For additional information about security options for IIS 6.0, see Managing a Secure IIS 6.0 Solution.

**File System Security**

FrontPage 2002 Server Extensions relies in part on the Windows operating system to help secure the file system for your Web sites. The Windows Server 2003 family uses access control lists (ACLs) to help secure files and folders. Because ACLs require the NTFS file system, your Web servers must use NTFS when you run FrontPage 2002 Server Extensions on IIS 6.0. For more information about access control, see Understanding access control in Help and Support Center for Windows Server 2003. For more information about setting ACLs for FrontPage 2002 Server Extensions, see Windows Security Model.

| **Caution** |
| --- |
| When you build FrontPage-extended Web sites and subwebs, all the ACLs for those sites are maintained by FrontPage Server Extensions. Do not try to change the ACLs in Windows Server2003. Instead, in order to maintain security, always make permissions changes and other security-related changes by using the FrontPage2002 Server Administration tools. |

# Extending and Configuring Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After you install FrontPage 2002 Server Extensions, you can extend a Web site and then customize the Web site by configuring several options. To configure FrontPage Server Extensions, use one of the HTML administration pages, such as the Server Administration page, which you can access through Microsoft SharePoint Administrator. You can also use the FrontPage Server Extensions command-line tools. For more information about using the command-line tools, see Using Command-Line Tools later in this appendix.

The HTML administration pages, which are automatically created when you install FrontPage 2002 Server Extensions, replace the Microsoft Management Console (MMC) interface for administering the FrontPage 2000 Server Extensions. You must be a member of the Administrators group on the local computer to view and use these HTML administration pages. For more information about accessing the HTML administration pages, see Extending Web sites later in this appendix.

Microsoft SharePoint Administrator provides the following HTML administration pages to help you administer your FrontPage-extended Web sites:

- **Server Administration pages.** Allow you to extend a Web site (make it a FrontPage virtual server) and administer settings for your Web server. You can also view a list of virtual servers on your Web server and obtain information about each one.

  For example, you can specify default settings for extended Web sites. You can also reset user passwords and specify which rights are available to assign to roles and users.

- **Virtual Server Administration pages.** Allow you to globally control settings for any extended Web site (FrontPage virtual server) on your computer.

  A newly created extended Web site inherits settings from defaults set on the Server Administration pages. You can use the Virtual Server Administration pages to change these default settings and to specify what settings to use for subwebs of the extended Web site. For example, you can individually upgrade an extended Web site to FrontPage 2002 Server Extensions. You can also change configuration settings and set user account limits.

- **Site Administration pages.** Control settings for each individual Web site that is part of a FrontPage rootweb or subweb.

  For example, you can manage users and roles; perform usage analysis tasks; create, merge, or delete subwebs; and perform server health checks on virtual servers.

# Extending Web sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

After creating a Web site in IIS, you can use the Server Administration pages provided by FrontPage 2002 Server Extensions to extend the Web site and administer settings for your Web server.

For information about extending a Web site by using the Server Administration pages, see Using FrontPage Server Extensions to Extend Web Sites.

# Configuring Extended Web Sites

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Any changes that you make to an extended Web site at the rootweb level affect all sites and subwebs for that rootweb. You can set the following options at the rootweb level by using the Virtual Server Administration pages.

- **Authoring options.** Turn authoring on or off for an extended Web site. When authoring is turned on, users can add new pages, edit pages, and remove pages for a Web site. When authoring is turned off, FrontPage client users cannot perform any of these tasks.

- **Mail settings.** Specify the Simple Mail Transfer Protocol (SMTP) mail server, the mail encoding option, and the **From** and **Reply-to** address to use for e-mail messages related to FrontPage Server Extensions.

- **Performance tuning options.** Use default settings to manage the performance of your FrontPage-extended Web sites, or specify settings for several performance tuning options, including caching limits for documents, images, and files.

- **Client scripting options.** Control the types of scripts that authors can run on your site, including ISAPI, CGI, ASP, and others.

- **Security settings.** Change security options, track authoring data by creating logs, and specify whether users can store executable files on your server.

If you do not change these configuration settings, the extended Web site inherits the settings from the Set Installation Defaults administration page (in the Server Administration pages). Use the Change Configuration Settings page in the Virtual Server Administration pages to configure your extended Web site.

**To configure FrontPage-extended Web sites by using the Virtual Server Administration pages**

1. From the **Start** menu, point to **Administrative Tools**, and then click **Microsoft SharePoint Administrator**.
2. On the **Server Administration** page, next to the FrontPage-extended Web site name, click **Administration**.
3. Click **Change configuration settings**.
4. On the **Change Configuration Settings** page, click the options you want, and then click **Submit**.

# Configuring Web Sites under the Rootweb

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to configuring the settings for an extended Web site (FrontPage virtual server), you can configure the settings for individual Web sites that are part of a rootweb (these Web sites become extended because they are contained in, or in a subdirectory of, the rootweb). Use the Site Administration page or the command-line tools to configure the following features:

- **User and role settings**. Add or delete users and roles, and change which roles a user is assigned to. For more information about how FrontPage 2002 Server Extensions manages user rights, see Using Roles to Manage User Rights later in this appendix.

- **Usage analysis settings**. Configure usage analysis to track how many users visit your site; track the type and number of hits that your site receives, and track other site-usage information. The usage reports rely on a log file that is generated by your IIS application server.

- **Server health check settings**. Detect and repair certain functionalities relating to extended Web sites, such as checking role configurations, managing security, or checking anonymous access.

**To configure Web sites by using the Site Administration page**

1. If you are a server administrator

    a. From the **Start** menu, point to **Administrative Tools**, and then click **Microsoft SharePoint Administrator**.

    b. On the **Server Administration** page, click the name of the extended Web site (FrontPage virtual server) that you want to manage, which takes you to the Site Administration page for the rootweb of that extended Web site.

2. If you are a site administrator

    a. Open your Web site in the FrontPage client.

    b. On the **Tools** menu, point to **Server**, and then click **Administration Home**.

# Using Command-Line Tools

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions provides two new tools for command-line administration:

- **Owsadm.exe**. Administers FrontPage 2002 Server Extensions from the local server. You must have administrative credentials on the local server to use this tool.

- **Owsrmadm.exe**. Administers FrontPage 2002 Server Extensions from a remote computer. The Web server must be running before you can use this tool. You must have administrative credentials on the server to use this tool. In addition, you must have a copy of the tool on your local computer, which must be running Windows.

When you run Owsadm.exe, you supply an operation and a set of command-line parameters in the following form:

**-operation CommandName -parameter value**

Each parameter for the command line also has a short form that you can use instead of the full parameter name. For example, you can use the following command to add a specified user to the Web site on port 80:

**Owsadm.exe -o users -c add -u username -p 80**

To configure settings for an extended Web site (FrontPage virtual server) from the command line, use the **SetProperty** parameter with Owsadm.exe or Owsrmadm.exe. You can set authoring, performance tuning, client scripting, mail settings, and security settings properties by using the command line. For example, to turn on authoring for an extended Web site at port 1088, configure the **Authoring** property by using the following command:

**Owsadm.exe -o setproperty -p 1088 -pn Authoring -pv enabled**

For more information about using these command-line tools to extend and administer sites, including links to command-line parameters, operations, and properties, see "Command-line Administration" in the SharePoint Team Services Administrator's Guide. For more information about using FrontPage 2002 Server Extensions with IIS 6.0 and for additional links to FrontPage-related Web sites, see Using FrontPage Server Extensions to Extend Web Sites.

# Configuring Advanced Security and Customization

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to choosing a Windows authentication method for your extended Web sites, you need to manage user access by configuring user rights. FrontPage 2002 Server Extensions are designed to be scalable so that you can configure Web site permissions to be as simple or as complex as you need.

FrontPage 2002 Server Extensions also provides advanced customization, which Internet service providers (ISPs) and Web Presence Providers (WPPs) might find especially useful. For example, you can authenticate users separately for each extended Web site (FrontPage virtual server), which allows you to better manage anonymous user access to Web sites on separate virtual servers. In addition, you can create extended Web sites that have access to shared folders on your network by using the Universal Naming Convention (UNC) standards. Customizing FrontPage 2002 Server Extensions by using UNC network shares can be helpful if your Web server is hosting many large Web sites and subwebs.

All these advanced customizations are intended for experienced IT administrators who are familiar with Windows authentication methods and with configuring FrontPage 2002 Server Extensions.

| **Note** |
| --- |
| Registered WPPs for Microsoft® FrontPage® version2002 are companies that provide hosting services for FrontPage–based sites. Many WPPs also provide technical support, training and consulting, 24-hour monitoring, maintenance and traffic reporting, security management, or other Web-based services. |

# Using Roles to Manage User Rights

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

FrontPage 2002 Server Extensions uses roles to manage user rights. Each user is assigned at least one role with corresponding rights. You can edit or customize the rights assigned to a role, create a new role, or delete an unused role.

You can add users to a Web site without assigning them to a role. For example, if you are creating new user accounts for a Web site, you can create the user accounts and then assign or remove roles at any time.

Not only does FrontPage 2002 Server Extensions offer greater flexibility in assigning roles, it also provides user-friendly management tools. In earlier versions, you managed user roles from within the Microsoft FrontPage client by using the **Security** command on the **Tools** menu. With FrontPage 2002 Server Extensions, you can manage roles by using the HTML administration pages or the command-line tool.

You must be both a Web site administrator and an administrator on the local computer to perform administrative tasks that affect settings for all extended Web sites and subwebs in a rootweb. FrontPage 2002 Server Extensions includes the following roles by default:

- **Browser**. Has rights to view pages, view Web document discussions, and read lists.
- **Author**. Has Browser rights, plus rights to edit pages, directories, and lists.
- **Advanced Author**. Has Author rights, plus rights to define and apply themes and borders, link style sheets, and recalculate a Web site (check the links). This role appears as "advauthor" on the command line.
- **Administrator**. Has all Browser, Author, and Advanced Author rights, plus rights to configure roles, create local computer user accounts, manage source control, create subwebs, manage server health, and manage usage analysis. This role appears as "admin" on the command line and is a Web site administrator role, not a server administrator role.

For more information about user roles, including a complete list of user rights, their default settings, and how to configure them, see "Managing Roles," "Managing Users," and "User Rights" in the SharePoint Team Services Administrator's Guide.

# Authenticating Users Separately for Each Extended Web Site

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you use FrontPage 2002 Server Extensions on Windows Server 2003, you can take advantage of a new feature that allows you to better manage anonymous user access for Web sites on separate extended Web sites (FrontPage virtual servers). You can use group accounts to separate anonymous access for each extended Web site, so that only anonymous users and registered users on the same extended Web site have access to the source files. When you use this new feature, the users on one extended Web site can no longer read source files on another extended Web site.

This is an advanced feature and is intended for use by Internet service providers (ISPs) and Web Presence Providers (WPPs) who allow users to have direct access to the file system of their Web sites through methods such as FTP, ASP, and Perl.

To take advantage of this new feature, you must create a group account to track all user accounts that have access to a virtual server. To turn on this feature and to specify the name for the group account, you must edit the Windows registry. For more information about using this new feature, including step-by-step instructions for enabling group accounts, see "Authenticating Users Separately for Each Virtual Server" in the Windows® SharePoint® Services Administrator's Guide.

# Connecting Web Sites to UNC Network Shares

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you run FrontPage 2002 Server Extensions on Windows Server 2003, you can create FrontPage-extended Web sites that have access to shared folders on your network by using the Universal Naming Convention (UNC) standard. A configuration that uses UNC shares is often advantageous when you set up a server that hosts many large Web sites and subwebs. You can create Web sites on your Web server and have the files for the Web sites distributed across multiple file servers on your network. Connecting Web sites to UNC network shares requires that you configure the file server and the Web server.

You must be a local administrator of both servers to perform the steps needed for this advanced configuration. Both servers must be running Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Advanced Edition; or Windows® Server 2003 Enterprise Edition.

For more information about connecting a FrontPage extended Web site to a UNC network share, see "Connecting Web Sites to UNC Network Shares," in the Windows® Sharepoint® Services Administrator's Guide.

For more information about configuring Web sites that have content stored on a file server, see Deploying and Configuring Internet Information Services (IIS) 6.0 with Remotely Stored Content on UNC Servers and NAS Devices.

# IPv6 and IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) 6.0 provides Internet services to clients connecting over the next generation of Internet Protocol (IP) — known as IP version 6 (IPv6). When you use IPv6 with IIS on a server running the Microsoft® Windows® Server 2003 operating system, your sites can respond to both IPv6 requests and Internet Protocol version 4 (IPv4) requests. Although current demand for IPv6 is limited, the adoption of new Internet-connected devices, such as phones and handheld computers, is expected to quickly exhaust the remaining IPv4 address space and speed the transition to IPv6.

**In This Appendix**

Summary of Protocol Changes from IPv4 to IPv6

Comparing IPv4 and IPv6 Addresses

How IIS 6.0 Supports IPv6

Securing IPv6 Networks

Installing or Removing IPv6

Additional Resources for IPv6 and IIS 6.0

**Related Information**

- For more information about IIS 6.0 architecture, including HTTP.sys, see IIS 6.0 Architecture.

# Summary of Protocol Changes from IPv4 to IPv6

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In response to concern about the finite number of IPv4 addresses, the Internet Engineering Task Force (IETF) developed a suite of protocols and standards known as Internet Protocol version 6 (IPv6). IPv6 was designed to replace IPv4, which is more than 20 years old. Because IPv6 is expected to become increasingly important as the Internet continues to grow, IPv6 functionality is included in the Microsoft® Windows® XP and the Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Datacenter Edition; and Windows® Server 2003, Web Edition operating systems.

The Internet Protocol (IP) is the network-layer protocol used by TCP/IP for addressing and routing packets of data between hosts. The current version of the IP, IPv4, has remained primarily unchanged since RFC 791 was published in 1981. IPv4 is robust, easily implemented, and interoperable, and it scales well. However, continued dramatic growth of the Internet is pushing the limits of IPv4 design. Concerns with IPv4 include the scarcity of public IPv4 addresses for use on the Internet, the size and complexity of its backbone routing tables, and the need for simpler, more automatic configuration.

IPv6, previously named IP Next Generation (IPng), was developed primarily to allow for larger (128-bit) IP addresses. Additional enhancements include the following:

- A more efficient routing infrastructure that allows backbone routers to maintain much smaller routing tables.
- A new header format that reduces header overhead and provides more efficient processing at intermediate routers.
- A simplified host configuration that uses both stateful and stateless address configuration.
- Built-in security provided by Internet Protocol security (IPsec). (In IPv4, IPsec is optional.)
- Better support for Quality of Service (QoS), which is the set of methods or processes that a service-based organization uses to maintain a specific level of quality.
- A way to efficiently manage the interaction of neighboring nodes by using multicast and unicast messaging.
- Extension headers for adding new features to IPv6.

Table G.1 lists pertinent IPv6 RFCs and serves as a useful reference to the source documents.

**Table G.1 Summary of Useful Source Documents for Migrating from IPv4 to IPv6**

| Version | Date | RFC | RFC Title |
|---|---|---|---|
| IPv4 | September, 1981 | RFC 791 | Internet Protocol<br>(Protocol specification) |
| IPv6[1] | January, 1995 | RFC 1752 | The Recommendation for the IP Next Generation Protocol<br>(Standards track for IPv6 General RFCs) |
| IPv6 | December, 1995 | RFC 1883 | Internet Protocol, Version 6 (IPv6) Specification<br>(Proposed standard — made obsolete by RFC 2460) |
| IPv6 | December, 1995 | RFC 1886 | DNS Extensions to support IP version 6<br>(IPv6 applications RFCs) |

| | | | |
|---|---|---|---|
| IPv6 | July, 1998 | RFC 2373<br>RFC 3513[2] | IP Version 6 Addressing Architecture<br>Internet Protocol Version 6 (IPv6) Addressing Architecture<br>(Standards track for IPv6 addressing RFCs) |
| IPv6 | December, 1998 | RFC 2460[3] | Internet Protocol, Version 6 (IPv6) Specification<br>(Standards track for the Network Layer RFCs and Internet drafts) |

[1] IPv5 was an experimental non-IP real-time stream protocol called ST, which was never widely used.

[2] RFC 3513 supercedes RFC 2373; however Windows Server 2003 does not implement its changes with regard to site-local addresses.

[3] In RFC 2460, Internet Protocol, Version 6 (IPv6) Specification, IPv6 is described as a connectionless, unreliable datagram protocol that is used primarily for addressing packets and routing them between hosts. *Connectionless* means that a session is not established before data exchange begins. *Unreliable* means that delivery is not guaranteed. IPv6, like IPv4, always makes a best-effort attempt to deliver a packet, but an IPv6 packet might be lost, delivered out of sequence, duplicated, or delayed. IPv6 itself does not attempt to recover from these types of errors; the acknowledgment of packet delivery and the recovery of lost packets is done by a higher-layer protocol, such as TCP. TCP performs reliably over both IPv4 and IPv6.

For more information about the design changes needed by IPv4 to accommodate the increasing demands of network traffic, see Introduction to IPv6 in Help and Support Center for Windows Server 2003. For more information about IPv6, see IPv6 features in Help and Support Center for Windows Server 2003.

For more information about RFCs, see RFC-Editor.org.

# Comparing IPv4 and IPv6 Addresses

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The size of an IPv6 address is 128 bits, which is four times larger than an IPv4 address. In theory, the 32-bit address space that IPv4 uses provides 4,294,967,296 possible addresses; however, previous and current allocation practices limit the number of public IPv4 addresses to a few hundred million. By contrast, the 128-bit address space that IPv6 uses provides $3.4 \times 10^{38}$ possible addresses.

The size of the IPv6 address allows for subdividing the address into a hierarchical routing structure that reflects the current topology of the Internet. This structure provides great flexibility for hierarchical addressing and routing, which the IPv4-based Internet lacks.

# Comparing Address Formats

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IPv4 addresses are represented in a *dotted-decimal format*, in which the 32-bit address is divided into four 8-bit sections. Each set of 8 bits is converted into its decimal equivalent and is separated from adjacent 8-bit decimal equivalents by periods. The following is an example of an IPv4 address:

```
131.107.16.200
```

In IPv6, the 128-bit address is divided into eight 16-bit blocks, each of which is converted to a 4-digit hexadecimal number that is separated from adjacent blocks by colons. The resulting representation is called *colon-hexadecimal format*.

The following is an IPv6 address in binary form:

```
0010000111011010000000001101001100000000000000000001011110011101 1
0000001010101010000000001111111111111110001010001001110001011010
```

First, the 128-bit address is divided into eight 16-bit blocks, as follows:

```
0010000111011010   0000000011010011   0000000000000000   0010111100111011
0000001010101010   0000000011111111   1111111000101000   1001110001011010
```

Then, each of the eight 16-bit blocks is converted to hexadecimal and delimited with colons. The result is the following:

```
21DA:00D3:0000:2F3B:02AA:00FF:FE28:9C5A
```

An IPv6 address can be further simplified by removing the leading zeros within each 16-bit block. However, each block must have at least a single digit. With leading zero suppression, the address used in this example becomes the following:

```
21DA:D3:0:2F3B:2AA:FF:FE28:9C5A
```

**Compressing Zeros in IPv6 Addresses to the Double-Colon Format**

IPv6 addressing conventions also allow you to simplify an address that contains long sequences of zeros. If an address contains consecutive groups of 16-bit blocks that are set to 0 in the colon-hexadecimal format, you can compress the consecutive blocks to :: (known as double-colon) to simplify the address. To avoid ambiguity, use zero compression only once within any one address. Otherwise, you cannot determine the number of 0 bits represented by each instance of a double-colon (::).

Table G.2 provides two examples of IP addresses and shows how zero compression changes each address.

**Table G.2 Effect of Zero Compression on Sample IP Addresses**

| Address Before Zero Compression | Address After Zero Compression |
|---|---|
| FE80:0:0:0:2AA:FF:FE9A:4CA2 | FE80::2AA:FF:FE9A:4CA2 |
| FF02:0:0:0:0:0:0:2 | FF02::2 |

To determine how many 0 bits are represented by the double-colon in a compressed address, count the number of blocks in the address, subtract this number from 8, and then multiply the result by 16. For example, the address FF02::2 contains two blocks (the FF02 block and the 2 block). Therefore, the number of bits expressed by the double-colon is 96 (96 = (8 - 2) 16).

**Understanding Prefixes**

IPv4 implementations commonly use a dotted-decimal representation of the network prefix length, which is called the subnet mask. IPv6 does not use subnet masks; it supports only prefix length notation.

The *prefix* is the part of an IP address where the bits have fixed values or are the bits of a route or subnet identifier. Prefixes for IPv6 routes and subnet identifiers are expressed in the same way as classless inter-domain routing (CIDR) notation is expressed for IPv4, that is, *address/prefix length*. The *prefix length* specifies the number of left-most bits that make up the subnet prefix. For example, an IPv6 prefix can be represented as follows:

```
3FFE:2900:D005:F28B::/64
```

In this example, the first 64 bits of the global unicast address are the prefix, and the remaining 64 bits (128 - 64 = 64) are the interface ID.

For more information about the architecture of IPv6 addresses, see RFC 2373, IP Version 6 Addressing Architecture.

# Comparing Address Types

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you install IPv6 on a computer that is not connected to a network in which an IPv6 router is present, the computer automatically configures a link-local IPv6 address, which is a type of address that allows you to communicate with computers on your subnet. If you connect your computer to a subnet in which an IPv6 router is present, the router assigns your computer an IPv6 global or site-local address. The *site-local address* allows your computer to communicate within your intranet. The *global address* allows your computer to communicate with computers on the IPv6 Internet.

The left-most bits of an IP address are called the *format prefix* (FP), which indicates the specific type of IPv6 address. IPv6 accommodates many address types, including the following:

- **Unicast addresses**. Provide point-to-point, directed communication between two hosts on a network.
- **Multicast addresses**. Provide a method for sending a single IP packet to multiple hosts in a group. A multicast address is used for one-to-many communication.
- **Anycast addresses**. Provide a method of delivering a packet to the nearest member of a group. Currently, anycast addresses are used only as destination addresses and are assigned only to routers. An anycast address is used for one-to-one-of-many communication.

Table G.3 compares some basic elements of IPv4 and IPv6 addressing.

**Table G.3 Comparison of IPv4 and IPv6 Addressing Elements**

| Address Space Element | IPv4 Address | IPv6 Address |
|---|---|---|
| Unspecified address | 0.0.0.0 | 0:0:0:0:0:0:0:0: or :: |
| Loopback address | 127.0.0.1 | 0:0:0:0:0:0:0:1: or ::1 |
| Address type | Public IPv4 addresses | Global addresses (aggregatable global unicast addresses) |
| • Address type | Private IPv4 addresses, such as:<br>• 10.0.0.0/8<br>• 172.16.0.0/12<br>192.168.0.0/16 | Site-local addresses, which always begin with FEC0::/48) |
| Address type | Automatic Private IP Addressing (APIPA), which uses the 169.254.0.0/16 prefix | Link-local addresses, which always begin with FE80::/64Text representation |
| Text representation | Dotted-decimal format | Colon-hexadecimal format with suppression of leading zeros and zero compression. IPv4-compatible addresses are expressed in dotted-decimal notation. |
| Network bits representation | Subnet mask in dotted-decimal format or prefix-length notation | Prefix-length notation only |

| | | |
|---|---|---|
| DNS name resolution | IPv4 host address (A) resource record[1] | IPv6 host address (AAAA) resource record[2] |

[1] An A resource record, which is stored on your DNS servers, enables mapping from a host name to an IPv4 32-bit address.

[2] AAAA (quad-A) resource records enable mapping from a host name to an IPv6 128-bit address.

**Unicast Addresses**
Unicast addresses identify a single interface within the scope of a particular type of unicast address. The scope of an address is the region of the IPv6 network over which the address is unique. With the appropriate unicast routing topology, packets addressed to a unicast address are delivered only to a single interface.

The following are types of unicast IPv6 addresses:

- **Aggregatable global unicast addresses**. Identified by the format prefix (FP) of 001, these addresses are equivalent to public IPv4 addresses.
- **Local-use unicast addresses**. Provide two types of addresses:
  - **Link-local addresses**. Identified by the FP of 1111 1110 10, these addresses are used by nodes when they are communicating with neighboring nodes on the same link.
  - **Site-local addresses**. Identified by the FP of 1111 1110 11, these addresses are equivalent to the IPv4 private address space. Use these addresses between nodes that communicate with other nodes in the same site.
- **Unspecified address**. Used only to indicate the absence of an address; this type of address cannot be assigned to a node. The IPv6 unspecified address, 0:0:0:0:0:0:0:0 or ::, is equivalent to the IPv4 unspecified address of 0.0.0.0.
- **Loopback address**. Used to identify a loopback interface, which enables a node to send packets to itself. The IPv6 loopback address, 0:0:0:0:0:0:0:1 or ::1, is equivalent to the IPv4 loopback address of 127.0.0.1.
- **Transition, or compatibility, addresses**. Provided to help you migrate from IPv4 to IPv6; these addresses allow both types of hosts to coexist on your network.

**Types of Transition IPv6 Addresses**
To help you transition from IPv4 to IPv6 and to facilitate the coexistence of both types of hosts, IPv6 defines the following transition IPv6addresses.

**IPv4-compatible addresses**
*IPv4-compatible addresses* are used by IPv6/IPv4 nodes that communicate with IPv6 over an IPv4 infrastructure. *IPv6/IPv4 nodes* are nodes that run both the IPv4 and IPv6 protocols. The format for an IPv4-compatible address is 0:0:0:0:0:0:w.x.y.z or ::w.x.y.z (where w.x.y.z is the dotted-decimal representation of a public IPv4 address). The IPv6 protocol for Windows XP and Windows Server 2003 provides support for IPv4-compatible addresses, but support is not enabled by default.

**IPv4-mapped addresses**
*IPv4-mapped addresses* are used to represent an IPv4-only node to an IPv6 node. The IPv4-mapped address is never used as a source or destination address for an IPv6 packet. It is used only for internal representation. The format for an IPv4-mapped address is 0:0:0:0:0:FFFF:w.x.y.z or ::FFFF:w.x.y.z. The IPv6 protocol for Windows XP and Windows Server 2003 does not support IPv4-mapped addresses.

**6to4 addresses**
*6to4 addresses* are used for communicating between two nodes that are running both IPv4 and IPv6 over the Internet. The 6to4 address is formed by combining the prefix 2002::/16 with the 32 bits of the public IPv4 address of the node or the site of the node, thus forming a 48-bit prefix. For example, for the IPv4 address of 131.107.0.1, the 6to4 address prefix is 2002:836B:1::/48 (where 836B:1 is the colon hexadecimal notation for 131.107.0.1). Support for 6to4 addresses is provided by the IPv6 Helper service (known as the *6to4 service*) that is included with the IPv6 protocol for Windows XP and Windows Server 2003.

**Global Addresses**
*Global addresses*, which are identified by an FP of 001, and which are also called aggregatable global unicast addresses, are

equivalent to public IPv4 addresses. Global addresses are globally routable and reachable on the IPv6 Internet.

As the name implies, you can aggregate, or summarize, global addresses to produce an efficient routing infrastructure. Unlike the current IPv4-based Internet, which has a mixture of both flat and hierarchical routing, the IPv6-based Internet is designed to support efficient hierarchical addressing and routing. The *scope* of a global address, which is the region of the IPv6 internetwork over which the address is unique, is the entire IPv6 Internet.

Figure G.1 illustrates the structure of an IPv6 global address.

**TLA ID field**
Indicates the Top Level Aggregation Identifier (TLA ID) for the address. The size of this field is 13 bits. The TLA ID identifies the highest level in the routing hierarchy. TLA IDs are administered by the Internet Assigned Numbers Authority (IANA) and allocated to local Internet registries that, in turn, allocate individual TLA IDs to large, global Internet service providers (ISPs). A 13-bit field allows up to 8,192 different TLA IDs. Routers in the highest level of the IPv6 Internet routing hierarchy (called default-free routers) do not have a default route — only routes with 16-bit prefixes corresponding to the allocated TLA IDs and additional entries for routes based on the TLA ID assigned to the routing region where the router is located.

**Res field**
Reserves space for future expansion of either the TLA ID or the NLA ID field. The size of this field is 8 bits.

**NLA ID field**
Indicates the Next Level Aggregation Identifier (NLA ID) for the address. The NLA ID identifies a specific customer site. The size of this field is 24 bits. The NLA ID allows an ISP to create multiple levels of addressing hierarchy to organize addressing and routing and to identify sites. The structure of the ISP's network is not visible to default-free routers.

**SLA ID field**
Indicates the Site Level Aggregation Identifier (SLA ID) for the address. The SLA ID is used by an individual organization to identify subnets within its site. The size of this field is 16 bits. An organization can use this field to create 65,536 subnets or multiple levels of addressing hierarchy. Being assigned an SLA Id is equivalent to being allocated an IPv4 Class A network ID (assuming that the last octet is used for identifying nodes on subnets). The structure of the customer's network is not visible to the ISP.

**Interface ID field**
Identifies the interface of a node on a specific subnet. The size of this field is 64 bits.

For more information about IPv6 addressing, see RFC 2373, IP Version 6 Addressing Architecture, at the Internet Engineering Task Force Web site.

# How IIS 6.0 Supports IPv6

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Except for the differences in functionality outlined in this section, IIS 6.0 provides the same Web services to clients that connect by using IPv6 as it does for clients that connect by using IPv4.

Differences in IIS Functionality Between IPv4 and IPv6

IIS 6.0 provides the same core functionality for users of IPv6 as it does for users of IPv4. However, only a subset of IIS 6.0 functionality is available for users of IPv6. The following are the most significant differences:

- **The IIS Manager user interface does not support IPv6 addresses**. IIS Manager does not display IPv6 addresses as it does IPv4 addresses; that is, the IIS user interface does not provide a way to work with or manipulate IPv6 addresses. However, manipulating literal hexadecimal IPv6 addresses is usually not recommended, so lack of this functionality is unlikely to prevent you from installing and using IPv6.

- **The IP Address Restrictions feature is not supported**. The IP Address Restrictions feature in IIS 6.0 does not support IPv6 addresses or IPv6 prefixes.

- **Bandwidth throttling is not supported for responses sent over IPv6 addresses**. If you change the **MaxBandwidth** and **MaxGlobalBandwidth** metabase properties, you do not affect IPv6 network traffic. However, connection limits and connection time-outs, which are related IIS 6.0 features, are supported.

- **The ServerBindings and SecureBindings metabase properties do not support IPv6 addresses**. Both properties specify strings that IIS 6.0 uses to determine which network endpoints are used by the server instance. The string format for the **ServerBindings** property is *IPAddress:Port:HostName*. Both the *IPAddress* and *HostName* parameters of the string are optional; however, the *IPAddress* component of the string is limited to storing an IPv4 address. Any unspecified parameters default to an all-inclusive wildcard.

  Because of the limitations in IPv6 functionality for these metabase properties, IIS 6.0 functionality for IPv6 is affected as follows:

  - **Site routing is limited to host headers only**. You cannot configure sites to route on an IPv6 address or on a combination of an IPv6 address and host header. This limitation also affects sites that are configured to route based on an IPv4 address. When you install IPv6, sites that are already specifically configured for IPv4 site-based routing do not respond to requests that come in over IPv6.

  - **The number of Secure Sockets Layer (SSL) sites is limited to one**. Due to the IP routing restriction for IPv6, IIS deployments designed for IPv6 addresses are limited to one SSL site per computer.

- **File Transfer Protocol (FTP), Simple Mail Transfer Protocol (SMTP), and Network News Transfer Protocol (NNTP) services are not supported**. IPv6 is supported only for the WWW service. The FTP, SMTP, and NNTP services do not have IPv6 support in IIS 6.0.

- **If you install IPv6 on a computer that is running IIS 6.0, all sites on the computer respond to IPv6 clients**. You cannot configure individual sites or virtual directories to respond to IPv6 traffic while others on the same server respond to IPv4 traffic.

- **Logging tools must support IPv6 address formats in order to function correctly**. IIS writes IPv6 addresses to the log file when IPv6 is enabled and client computers connect to the server by using IPv6 addresses. Log parsing tools that are to be used with log files for IPv6 sites must support IPv6 address formats.

- **The EnableReverseDnsLookup property is not supported**. For IPv4, a value of **true** for the **EnableReverseDnsLookup** metabase property allows reverse DNS lookup to determine the DNS name of the client computer. For IPv6, however, this functionality is not enabled.

| Note |
| --- |
| Setting the **EnableReverseDnsLookup** metabase property to **true** does not cause the REMOTE_HOST server variable to return the DNS name of the client, as it does for IPv4. REMOTE_HOST always contains the IPv6 address, regardless of the **EnableReverseDNSLookup** property setting. |

Using the IPv6-Aware ISAPI Server Variables

When you install IPv6 on a server running IIS 6.0, Internet Server API (ISAPI) server variables provide support for IPv6. The ISAPI framework provides the appropriate local-host and remote-host server variables for IPv6 network addresses: LOCAL_ADDR and REMOTE_ADDR. When clients connect over IPv6, these variables store the IPv6 address.

It is important to note that IPv6 addresses can be longer than IPv4 addresses, so you need to take steps to prevent buffer overruns when you install IPv6.

| Important |
| --- |
| Buffer overruns are one of the most common causes of security breaches. Preventing buffer overruns helps protect your server from being attacked. |

To prevent buffer overruns, you must allocate more space to hold the string representation of IPv6 addresses. For example, the longest possible IPv4 string looks something like 123.123.123.123 (16 characters, including the trailing zero required to express the string in some programming languages), whereas the longest IPv6 string looks like 1111:2222:3333:4444:5555:6666:123.123.123.123%1234567890, which is 57-characters long, including the trailing zero. Therefore, when you allocate buffers, use 16 characters for IPv4 addresses and 57 characters for IPv6 addresses.

| Note |
| --- |
| The "%1234567890" portion of the string indicates the zone ID, which is an integer that specifies the scope, or zone, of the destination. The zone ID is needed when you are specifying a link-local destination address or a site-local destination address (if you are using multiple sites). For link-local addresses, the zone ID is typically equal to the interface index of the desired sending interface. For site-local addresses, the zone ID is equal to the site number. |

Both ISAPI server variables (LOCAL_ADDR and REMOTE_ADDR) use the typical IP address format for the applicable IP version (IPv4 or IPv6). For example, for an IPv6 request, both server variables use an IPv6 IP address in the colon-hexadecimal format; for an IPv4 request, both server variables use an IPv4 IP address in the dotted-decimal format. Note that the IPv6 address is simply a string variable, which can contain the % character. For example, fe80::1:1:1:1%4 is an acceptable IPv6 address.

How Installing IPv6 Affects Web Browser Use and Client Connectivity

When you install IPv6 on a computer in your network, two limitations of Internet Explorer 6 (the version provided with Windows Server 2003) can affect the computers ability to use the Internet Explorer Web browser:

- **Internet Explorer 6 does not connect when literal IPv6 addresses are used in the URL**. Internet Explorer 6 does not support the format for literal IPv6 addresses in URLs that is described in RFC 2732, Format for Literal IPv6 Addresses in URLs. However, Internet Explorer does support IPv6 by means of DNS name resolution. Therefore, you should create DNS AAAA resource records that resolve Web server names to an IPv6 address and then use Web server names in the URL.

- **Internet Explorer 6 cannot browse IPv6 Web sites by using a proxy server if the proxy server is not IPv6-enabled**. When Internet Explorer is configured to use a proxy server, all name resolution requests for Web sites are forwarded to the proxy server. If the proxy server is not IPv6-enabled, proxy-based requests for local or remote IPv6 Web pages are unsuccessful. For information about how to configure Internet Explorer to operate without the use of a proxy server, see Internet Explorer Help.

Table G.4 shows the network protocol that clients use to connect to different IP configurations.

**Table G.4 Client Connectivity Matrix for IPv6**

| Client IPv6 Awareness | Type of Client Operating System | IIS 6.0 without IPv6 Installed | IIS 6.0 with IPv6 Installed |
| --- | --- | --- | --- |

| | | | | |
|---|---|---|---|---|
| Client is IPv6 unaware | IPv4-only | Connect over IPv4 | Connect over IPv4 | |
| | | IPv6-only | No connectivity | No connectivity |
| | | IPv4/IPv6 | Connect over IPv4 | Connect over IPv4 |
| Client is IPv6 aware[1] | IPv4-only | Connect over IPv4 | Connect over IPv4 | |
| | | IPv6-only | No connectivity | Connect over IPv6 |
| | | IPv4/IPv6 | Connect over IPv4 | Connect over IPv6 or IPv4[2] |
| Client is IPv6-only | IPv4-only | No connectivity | No connectivity | |
| | | IPv6-only | No connectivity | Connect over IPv6 |
| | | IPv4/IPv6 | No connectivity | Connect over IPv6 |

[1] IPv6 aware means that the client can also communicate over IPv4.

[2] When the DNS AAAA server returns the IPv6 and IPv4 addresses to the client, the client uses the connection protocol that applies to the address that is listed first.

# Securing IPv6 Networks

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003 currently supports the use of IPv6 only when IPv4 is also installed. Because TCP/IP internetworks are susceptible to a variety of attacks, ranging from passive attacks, such as eavesdropping, to active attacks, such as denial-of-service attacks, be sure to follow best practices for security when using IPv6 on your network. A few general and IPsec-related IPv6 security suggestions follow.

**General Recommendations for Securing IPv6 Networks**

Be aware of the following known security risks for IPv6, and consider reconfiguring your system to meet the recommendation that is shown for each:

- **The installation of an unauthorized router can cause reconfiguration of clients and rerouting of IPv6 traffic**.

  To communicate with IPv6 nodes on other network segments, IPv6 must use a default router. A default router is automatically assigned based on the receipt of a router advertisement. Malicious users with physical access to the IPv6-enabled network can install an unauthorized IPv6 router on the network segment, enabling a denial of service attack on IPv6 hosts. The unauthorized IPv6 router can reconfigure IPv6 clients, set itself as the default router, reroute link traffic, and disrupt other network services.

  **Recommendation**: Ensure that unauthorized individuals do not have physical or wireless access to your network. For more information, see Best practices for security in Help and Support Center for Windows Server 2003.

- Internet Connection Firewall (ICF) and Basic Firewall cannot filter or block IPv6 traffic.

  - **ICF**, which is available in the 32-bit versions of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition, restricts the traffic that can enter your network from the Internet. Because ICF can filter only IPv4 traffic, IPv6 traffic might get through the firewall and enter your network.

  - **Basic Firewall**, which is a component of Routing and Remote Access, can be enabled for public interfaces. Because Basic Firewall filters only IPv4 traffic, IPv6 traffic might get through the firewall and enter your network.

  **Recommendation**: If you are running IPv6 on your network, use firewall software or hardware that can filter and block IPv6 traffic.

- On-link computers (computers on a link, or LAN segment) can take control of another IPv6 address, causing on-link devices to create an incorrect entry in their neighbor cache.

  Nodes on an IPv6 link use address resolution to resolve a neighboring nodes IPv6 address to its link-layer address in the same way that nodes on an IPv4 link resolve addresses in IPv4. The resolved link-layer IPv6 address becomes an entry in a nodes neighbor cache (equivalent to the ARP cache in IPv4). If an attacker causes an IPv6 node to maliciously use another nodes address, it can cause other computers on the link to add a false entry to their neighbor cache. All traffic that is intended for the original computer goes instead to the attacker's computer, and the attacker can appear to send traffic from the original computer.

  **Recommendation**: Ensure that unauthorized individuals do not have physical or wireless access to your network. For more information, see Best practices for security in Help and Support Center for Windows Server 2003.

- When native IPv6 connectivity is not present (that is, when an IPv6 router does not exist on the network segment), it is easier to *spoof*, or appear to use, off-link IPv6 source addresses.

  A common defense against IP source address spoofing involves using packet-filtering routers. However, because traffic between hosts on the same link does not cross a router, this protective filtering is not used and spoofing might go undetected.

  Although spoofing can occur in native IPv4 or IPv6 networks, where on-link hosts can spoof off-link addresses in

communication with other hosts on the link, the threat is greater outside the native IPv6 network. Outside the native IPv6 network, encapsulation technologies are used. Because the logical link used for packet encapsulation spans a large portion of an IPv4 network (often the entire IPv4 Internet), an attacker can be anywhere on that IPv4 network and still spoof off-link addresses.

**Recommendation**: Ensure that an IPv6 router is present on the network segment.

For more information about IPv6 security, see "Security information for IPv6" in Help and Support Center for Windows Server 2003.

**Securing with IPsec on IPv6 Networks**

The IPv6 protocol for Windows Server 2003 incorporates Internet Protocol security (IPsec), which protects IPv6 data as it is sent over the network. *IPsec* is a set of Internet standards that uses cryptographic security services to provide the following:

- **Confidentiality**. Captured IPsec traffic cannot be deciphered without the appropriate encryption key.
- **Data origin authentication**. IPsec traffic contains a cryptographic checksum that incorporates a shared encryption key so that the receiver can verify that it was actually sent by the apparent sender.
- **Data integrity**. The cryptographic checksum is also used by the receiver to verify that the packet was not modified in transit.

IPsec in IPv6 is separate from, and does not interoperate with, IPsec for TCP/IP. IPsec policies that are configured with the IP Security Policies or Group Policy snap-ins have no effect on IPv6 traffic. You need to manually configure IPsec policies, security associations (SAs), and keys for IPv6. For more information about IPsec for TCP/IP, see Internet Protocol security (IPsec) in Help and Support Center for Windows Server 2003. For an example of configuring IPsec for IPv6, see "Using IPsec between two local link hosts" in Help and Support Center for Windows Server 2003.

In addition to the general security recommendations listed in the preceding section, follow these guidelines when you use IPv6 with IPsec:

- **Do not use IPsec for IPv6 in a production environment**. The current implementation of IPsec for IPv6 is not recommended for use in a production environment because it relies on static keying, which means that it has no provisions for updating encryption keys when sequence numbers are reused.
- **Use random numbers to configure SPIs**. When you manually configure IPsec Security Parameters Indexes (SPIs) for IPv6, always use random numbers so that you do not compromise the security of your IPsec for IPv6 policies.
- **Use only supported Encapsulating Security Payload (ESP) (ESP with NULL encryption)**. The IPv6 protocol for Windows Server 2003 does not support the use of IPsec ESP data encryption. However, the use of ESP with NULL encryption is supported. Although NULL encryption uses the ESP header, only data origin authentication and data integrity services are provided.

For more information about IPv6 security features, see "Security features for IPv6" in Help and Support Center for Windows Server 2003.

# Installing or Removing IPv6

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

When you initially install IPv6 on a computer in your network, be sure to install it first in a test environment so that you can configure and test the IPv6 protocol before installing it in your production environment. For more information about setting up a test lab, including typical test lab tasks and a sample infrastructure, see Setting up an IPv6 test lab in Help and Support Center for Windows Server 2003.

**To install IPv6**

1. In Control Panel, double-click **Network Connections**.
2. Right-click any local area connection, and then click **Properties**.
3. Click **Install**.
4. In the **Select Network Component Type** dialog box, click **Protocol**, and then click **Add**.
5. In the **Select Network Protocol** dialog box, click **Microsoft TCP/IP version 6**, and then click **OK**.
6. Click **Close** to save changes to your network connection.

After you install the IPv6 protocol, IIS automatically supports IPv6 on your Web server. However, if a Web site is already running when you install IPv6, you must restart IIS before the site begins listening for IPv6 requests. Sites that you create after you enable IPv6 support automatically listen for IPv6.

For more information about how to install the IPv6 network protocol stack, see IP version 6 in Help and Support Center for Windows Server 2003. For information about restarting IIS, see Restarting IIS.

**To remove IPv6**

1. In Control Panel, double-click **Network Connections**.
2. Right-click any local area connection, and then click **Properties**.
3. Click **Microsoft TCP/IP version 6** in the list of installed components, and then click **Uninstall.**
4. In the **Uninstall Microsoft TCP/IP version 6** dialog box, click **Yes**.
5. Click **Close** to save changes to your network connection.
6. Click **Yes** to restart your computer.

   Windows prompts you to restart your computer so that the new settings can take effect.

# Additional Resources for IPv6 and IIS 6.0

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

These resources contain additional information and tools related to IPv6.

**Related Information**

- Davies, J. *Understanding IPv6*. Redmond, WA: Microsoft Press, 2003 for information about using IPv6 with Windows Server 2003 and Windows XP.
- Howard, Michael & LeBlanc, David. *Writing Secure Code*. Second Edition. Redmond, WA: Microsoft Press, 2003 for information about buffer overruns.
- Huitema, Christian. *IPv6: The New Internet Protocol*. Second edition. Upper Saddle River, NJ: Prentice Hall PTR, 1998 for information about IPv6.
- The Internet Engineering Task Force (IETF) for a repository of RFCs.
- Miller, M. *Implementing IPv6: Supporting the Next Generation of Protocols*. Second edition. Foster City, CA: M&T Books, 2000 for information about using IPv6.

**Related Windows Server 2003 Help Topics**

For best results in identifying Help topics by title, in Help and Support Center, under the **Search** box, click **Set search options**. Under **Help Topics**, select the**Search in title only** check box.

- Internet Protocol security (IPsec) in Help and Support Center for Windows Server 2003.
- Introduction to IPv6 in Help and Support Center for Windows Server 2003.
- IP version 6 in Help and Support Center for Windows Server 2003 for information about the IPv6 protocol and how you can use it with Windows Server 2003 and IIS 6.0.
- IPv6 features in Help and Support Center for Windows Server 2003.
- Security information for IPv6 in Help and Support Center for Windows Server 2003.
- Security features for IPv6 in Help and Support Center for Windows Server 2003.
- Setting up an IPv6 test lab in Help and Support Center for Windows Server 2003.

**Related Tools**

- Ipsec6.exe

  Use the Ipsec6.exe command-line tool to configure IPsec policies and security associations. For more information about Ipsec6.exe, see IPv6 utilities in Help and Support Center for Windows Server 2003.

- Netsh.exe

  Use the command-line tool Netsh.exe to configure interfaces, addresses, caches, and routes for IPv6 and to display them on your screen. For more information about Netsh.exe, see Windows Support Tools Help on the Windows Server 2003 operating system CD.

# Running 32-bit Applications on 64-bit Windows

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Windows Server 2003™, Service Pack 1 enables IIS 6.0 to run 32-bit Web applications on 64-bit Windows using the Windows-32-on-Windows-64 (WOW64) compatibility layer. IIS 6.0 using WOW64 is intended to run 32-bit personal productivity applications needed by software developers and administrators, including 32-bit Internet Information Services (IIS) Web applications.

On 64-bit Windows, 32-bit processes cannot load 64-bit DLLs, and 64-bit processes cannot load 32-bit DLLs. If you plan to run 32-bit applications on 64-bit Windows, you must configure IIS to create 32-bit worker processes. Once you have configured IIS to create 32-bit worker processes, you can run the following types of IIS applications on 64-bit Windows:

- Internet Server API (ISAPI) extensions
- ISAPI filters
- Active Server Page (ASP) applications (specifically, scripts calling COM objects where the COM object can be 32-bit or 64-bit)
- ASP.NET applications

IIS can, by default, launch Common Gateway Interface (CGI) applications on 64-bit Windows, because CGI applications run in a separate process.

**Configuring IIS to run 32-bit Web applications on 64-bit Windows**
Before you configure IIS to run 32-bit applications on 64-bit Windows, note the following:

- IIS only supports 32-bit worker processes in Worker Process Isolation mode on 64-bit Windows.
- On 64-bit Windows, the World Wide Web Publishing service can run 32-bit and 64-bit worker processes. Other IIS services like the IIS Admin service, the SMTP service, the NNTP service, and the FTP service run 64-bit processes only.
- On 64-bit Windows, the World Wide Web Publishing service does not support running 32-bit and 64-bit worker processes concurrently on the same server.

For the procedure to run 32-bit Web applications on 64-bit Windows, see Configuring IIS to Run 32-bit Applications on 64-bit Windows.

**After configuring IIS to run 32-bit Web applications on 64-bit Windows**
After you configure IIS 6.0 to run 32-bit Web applications, IIS stores 32-bit DLLs and ISAPIs in the *%windir%*\syswow64\inetsrv directory. All other IIS files, including the MetaBase.xml file, are stored in the *%windir%*\system32\inetsrv directory. File access to the System32 and sub directories are transparently redirected based on the bitness of the process making that file access (64-bit processes have full access, while 32-bit processes have access to System32 redirected to Syswow64). If your legacy applications have specific 32-bit file access needs and you notice application failures, see if the application needs to reference the new *%windir%*\syswow64\inetsrv to resolve the problem.

# IIS 6.0 Administration Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The reference section provides detailed information about the interfaces, objects, and data structures available for programming and administering IIS.

**In This Section**

This section contains the following topics:

- Metabase Property Reference: This section defines the metabase properties used for IIS and includes code examples that show how to access the properties.
- IIS 6.0 Registry Reference: This section defines the registry entries that pertain to IIS.
- Events Reference: This section describes the events that IIS lists in the Event Viewer and explains how to use them to monitor your Web server.
- IIS 6.0 Event Messages: This section describes the Error, Warning, and Information event messages generated by IIS 6.0, and the logs to use to monitor Web server performance.
- Performance Counters Reference: This section describes the counters that you can enable in the System Monitor MMC snap-in, allowing you to evaluate the performance of your Web server.
- IIS 6.0 Performance Counters: This section describes performance objects, the components that generate the data, and how you can use Windows Management Instrumentation (WMI) to view these counters.
- Timeouts Reference: This section defines the IIS time-out properties and explains how to individually set them to configure your Web server for different tasks.
- Redirect Reference: This section explains how to format a server redirection correctly. For reference topics related to ASP, see the IIS Web Application Technology Reference section of the IIS Software Developer Kit (SDK).
- Tracing Events Reference: This reference describes the events that can be recorded in the trace log when using request-based tracing or IIS Admin tracing.

# Metabase Property Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This section contains reference pages for each of the Internet Information Services (IIS) 6.0 metabase properties. Most of these properties can be changed using IIS Manager. You can also use the methods of the IIS Windows Management Instrumentation (WMI) provider or the IIS Active Directory Service Interfaces (ADSI) provider in command-line scripts to change these properties.

As an alternative to writing your own command-line scripts, IIS installs Command-Line Administration Scripts that provide enough functionality to help you administer your server. Before you use any of these methods, please review the IIS Metabase section.To view a particular property, click the property name from the table of contents, or from the table below.

**Key**
@Application-level property: Application-level properties, when set, apply to the entire application regardless of the isolation mode in which your IIS server is running. Setting an application-level property in one location does not affect the entire application pool (see individual property topics for exceptions).

#Process-level property: Process-level properties only have an effect on IIS behavior if they are set at the service level (for both isolation modes), or at the server level (for IIS 5.0 isolation mode, if the application is set to High isolation). The documentation might list other locations where IIS allows you to set these properties, but they have no effect on IIS behavior.

# Code Examples to Configure Metabase Properties

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following examples demonstrate the syntax for setting a metabase property using different technologies, such as Windows Management Instrumentation (WMI) and Active Directory Service Interfaces (ADSI). The code examples are written in Microsoft® Visual Basic® Scripting Edition (VBScript), JScript®, and Perl.

The examples are simplified to show the essential code that is needed to change a metabase property. If you use these examples, add error checking code and security checking code before using them to configure your server.

**Implementation Guidelines**
**To implement one of the VBScript, JScript, or Perl examples in a command-line administration script**

- For VBScript: Save the script file with the file name extension of .vbs and call a script with "cscript //nologo *filename*.vbs".
- For JScript: Save the script file with the file name extension of .js and call a script with "cscript //nologo *filename*.js".
- For Perl: Save the script file with the file name extension of .pl and call a script with "perl *filename*.pl".

**To implement one of the VBScript, JScript, or Perl examples in an ASP page**

1. Set security on the Web application to disable anonymous access. Anonymous access to metabase properties is not allowed. The user requesting the ASP page should be an Administrator. In addition, the process executing the ASP page must have permission to modify the metabase.
2. Add the following lines of ASP code, where the first line is at the top of the file, and "*language*" is "Microsoft Visual Basic Scripting Edition (VBScript)", "JScript", or "PerlScript":

```
<%@ Language="language" %>
<%
insert the example code here
%>
```

3. Change instances of **WScript.Echo** to **Response.Write**, and **print** to **$Response->Write**.
4. Change the file name extension of your file to .asp.
5. Install ActivePerl with PerlScript to run the Perl examples. ActivePerl can be downloaded from the ActiveState Web site.

**Code Examples**
In the following examples, there are italicized words that must be replaced by a valid string for the example to execute properly. Replace *property_name_1* and *property_name_2* with metabase property names. Replace *numeric_or_Boolean_value* and *String_value* with a valid data types for that property.

These examples demonstrate how to set a metabase property to a string, number, or Boolean value. These examples do not cover WMI situations where you need to pass in an object.

**WMI**

| | |
|---|---|
| Microsoft Visual Basic Scripting Edition (VBScript) | `var providerObj=GetObject("winmgmts:/root/MicrosoftIISv2");`<br>`var vdirObj=providerObj.get("IIsWebVirtualDirSetting='W3SVC/1/ROOT'");`<br>`// Print out the current value of some properties:`<br>`WScript.Echo("Before: " + vdirObj.property_name_1 + ", " + vdirObj.property_name_2);`<br>`// Set some properties:`<br>`vdirObj.property_name_1=numeric_or_Boolean_value;`<br>`vdirObj.property_name_2="String_value";`<br>`// Save the property changes in the metabase:`<br>`vdirObj.Put_();`<br>`WScript.Echo("After: " + vdirObj.property_name_1 + ", " + vdirObj.property_name_2);` |
| JScript | `var providerObj=GetObject("winmgmts:/root/MicrosoftIISv2");`<br>`var vdirObj=providerObj.get("IIsWebVirtualDirSetting='W3SVC/1/ROOT'");`<br>`// Print out the current value of some properties:`<br>`WScript.Echo("Before: " + vdirObj.property_name_1 + ", " + vdirObj.property_name_2);`<br>`// Set some properties:`<br>`vdirObj.property_name_1=numeric_or_Boolean_value;`<br>`vdirObj.property_name_2="String_value";`<br>`// Save the property changes in the metabase:`<br>`vdirObj.Put_();`<br>`WScript.Echo("After: " + vdirObj.property_name_1 + ", " + vdirObj.property_name_2);` |
| Perl | `use Win32;`<br>`use Win32::OLE;`<br>`my $providerObj=Win32::OLE -> GetObject("winmgmts:/root/MicrosoftIISv2");`<br>`my $vdirObj=$providerObj->Get("IIsWebVirtualDirSetting='W3SVC/1'");`<br>`# Print out the current value of some properties:`<br>`print "Before: ", $vdirObj->{"property_name_1"}, ", ", $vdirObj->{"property_name_2"}, "\n";`<br>`# Set some properties:`<br>`$vdirObj->{"property_name_1"}=numeric_or_Boolean_value;`<br>`$vdirObj->{"property_name_2"}="String_value";`<br>`# Save the property changes in the metabase:`<br>`vdirObj->Put_();`<br>`print "After: ", $vdirObj->{"property_name_1"}, ", ", $vdirObj->{"property_name_2"}, "\n";` |

**ADSI**

| | |
|---|---|
| Microsoft Visual Basic Scripting Edition (VBScript) | `set vdirObj=GetObject("IIS://localhost/W3svc/1/Root")`<br>`' Print out the current value of some properties:`<br>`WScript.Echo "Before: " & vdirObj.property_name_1 & ", " & vdirObj.property_name_2`<br>`' Set some properties:`<br>`vdirObj.Put "property_name_1", numeric_or_Boolean_value`<br>`vdirObj.Put "property_name_2", "String_value"`<br>`' Save the property changes in the metabase:`<br>`vdirObj.SetInfo`<br>`WScript.Echo "After: " & vdirObj.property_name_1 & ", " & vdirObj.property_name_2` |
| JScript | `var vdirObj=GetObject("IIS://localhost/W3svc/1/Root");`<br>`// Print out the current value of some properties:`<br>`WScript.Echo("Before: " + vdirObj.property_name_1 + ", " + vdirObj.property_name_2);`<br>`// Set some properties:`<br>`vdirObj.Put("property_name_1", numeric_or_Boolean_value);`<br>`vdirObj.Put("property_name_2", "String_value");`<br>`// Save the property changes in the metabase:`<br>`vdirObj.SetInfo();`<br>`WScript.Echo("After: " + vdirObj.property_name_1 + ", " + vdirObj.property_name_2);` |

| | |
|---|---|
| Perl | `use Win32;`<br>`use Win32::OLE;`<br>`my $vdirObj=Win32::OLE ->`<br>`GetObject("IIS://localhost/W3SVC/1/Root");`<br>`# Print out the current value of some properties:`<br>`print "Before: ", $vdirObj->{"property_name_1"}, ", ",`<br>`$vdirObj->{"property_name_2"}, "\n";`<br>`# Set some properties:`<br>`$vdirObj->{"property_name_1"}=numeric_or_Boolean_value;`<br>`$vdirObj->{"property_name_2"}="String_value";`<br>`# Save the property changes in the metabase:`<br>`$vdirObj->SetInfo();`<br>`print "After: ", $vdirObj->{"property_name_1"}, ", ", $vdirObj-`<br>`>{"property_name_2"}, "\n";` |

You may encounter errors when running example code that you have altered. The following table lists possible errors and their causes.

| Error Code | Possible Cause |
|---|---|
| 0x80005006 | The property does not exist, or it does not exist at the access location where you are attempting to set it.<br><br>For example, you cannot set the AdminServer Metabase Property at the Web site level (W3SVC/1, W3SVC/1/ROOT) or the virtual directory level (W3SVC/1/ROOT/vdir); you can set it only at the World Wide Web Publishing Service (WWW service) level. You cannot set the AdminEmail Metabase Property on any Web, File Transfer Protocol (FTP), or Simple Mail Transfer Protocol (SMTP) metabase key; you can set it only on a Network News Transfer Protocol (NNTP) metabase key.<br><br>See the Metabase Property Reference for the metabase property that you are trying to set. Use the Access Locations table to verify that you are accessing the property at a valid location. Or, you can open the MetaBase.xml file on your server and search for the property to see what locations it is set on. |
| 0x8000500C | The data type of the property is different than the data type to which you are attempting to set it.<br><br>For example, you cannot set the AspCodepage Metabase Property property to a string ("English"); you can set it only to a number representing a code page (1252). |

**Related Information**

# AccessFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AccessFlags** property contains flags for configuring file access permissions, which are defined in the Flags section. The last four flags augment the first four flags in that they relate to access granted to remote computers. You can enable local access without remote access, but you cannot enable remote access without local access.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ACCESS_PERM |
| Attributes | INHERIT |
| Default Value | accessread |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6016 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/MSFTPSVC/*n*/ROOT /LM/MSFTPSVC/*n*/ROOT/*virtual_directory_name* | IIsFtpVirtualDir |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

| | |
|---|---|
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/ROOT /LM/SMTPSVC/*n*/ROOT/*virtual_directory_name* | IIsSmtpVirtualDir |

**Flags**

| **Flag Name** | **AccessExecute** |
|---|---|
| Description | A value of **true** indicates that the file or the contents of the folder may be executed, regardless of file type. |
| Metabase Bitmask Identifier | MD_ACCESS_EXECUTE |
| Decimal Value | 4 |
| Hexadecimal Value | 0x00000004 |

| **Flag Name** | **AccessSource** |
|---|---|
| Description | A value of **true** indicates that users are allowed to access source code if either Read or Write permissions are set. Source code includes scripts in Microsoft Active Server Pages (ASP) applications. |
| Metabase Bitmask Identifier | MD_ACCESS_SOURCE |
| Decimal Value | 16 |
| Hexadecimal Value | 0x00000010 |

| **Flag Name** | **AccessRead** |
|---|---|
| Description | A value of **true** indicates that the file or the contents of the folder may be read through Microsoft Internet Explorer. |
| Metabase Bitmask Identifier | MD_ACCESS_READ |
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| **Flag Name** | **AccessWrite** |
|---|---|
| Description | A value of **true** indicates that users are allowed to upload files and their associated properties to the enabled directory on your server or to change content in a Write-enabled file. Write can be implemented only with a browser that supports the PUT feature of the HTTP 1.1protocol standard. |
| Metabase Bitmask Identifier | MD_ACCESS_WRITE |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| Flag Name | AccessScript |
| --- | --- |
| Description | A value of **true** indicates that the file or the contents of the folder may be executed if they are script files or static content. A value of **false** only allows static files, such as HTML files, to be served. |
| Metabase Bitmask Identifier | MD_ACCESS_SCRIPT |
| Decimal Value | 512 |
| Hexadecimal Value | 0x00000200 |

| Flag Name | AccessNoRemoteExecute |
| --- | --- |
| Description | A value of **true** indicates that remote requests to execute applications are denied; only requests from the same computer as the IIS server succeed if the **AccessExecute** property is set to **true**. You cannot set **AccessNoRemoteExecute** to false to enable remote requests, and set **AccessExecute** to **false** to disable local requests. |
| Metabase Bitmask Identifier | MD_ACCESS_NO_REMOTE_EXECUTE |
| Decimal Value | 8192 |
| Hexadecimal Value | 0x00000400 |

| Flag Name | AccessNoRemoteRead |
| --- | --- |
| Description | A value of **true** indicates that remote requests to view files are denied; only requests from the same computer as the IIS server succeed if the **AccessRead** property is set to **true**. You cannot set **AccessNoRemoteRead** to **false** to enable remote requests, and set **AccessRead** to **false** to disable local requests. |
| Metabase Bitmask Identifier | MD_ACCESS_NO_REMOTE_READ |
| Decimal Value | 4096 |
| Hexadecimal Value | 0x00001000 |

| Flag Name | AccessNoRemoteWrite |
| --- | --- |
| Description | A value of **true** indicates that remote requests to create or change files are denied; only requests from the same computer as the IIS server succeed if the **AccessWrite** property is set to **true**. You cannot set **AccessNoRemoteWrite** to **false** to enable remote requests, and set **AccessWrite** to **false** to disable local requests. |
| Metabase Bitmask Identifier | MD_ACCESS_NO_REMOTE_WRITE |
| Decimal Value | 1024 |
| Hexadecimal Value | 0x00000400 |

| Flag Name | AccessNoRemoteScript |
| --- | --- |
| Description | A value of **true** indicates that remote requests to view dynamic content are denied; only requests from the same computer as the IIS server succeed if the **AccessScript** property is set to **true**. You cannot set **AccessNoRemoteScript** to **false** to enable remote requests, and set **AccessScript** to **false** to disable local requests. |
| Metabase Bitmask Identifier | MD_ACCESS_NO_REMOTE_SCRIPT |
| Decimal Value | 16384 |
| Hexadecimal Value | 0x00004000 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AccessSSLFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AccessSSLFlags** property contains the Secure Sockets Layer (SSL) file permission flags as seen in the Flags section. The default value of 0 means that no SSL permissions are set.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SSL_ACCESS_PERM |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6030 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/ROOT /LM/SMTPSVC/*n*/ROOT/*virtual_directory_name* | IIsSmtpVirtualDir |

**Flags**

| **Flag Name** | **AccessSSL** |
|---|---|
| Description | A value of **true** indicates that file access requires SSL file permission processing with or without a client certificate. |
| Metabase Bitmask Identifier | MD_ACCESS_SSL |
| Decimal Value | 8 |
| Hexadecimal Value | 0x00000008 |

| **Flag Name** | **AccessSSL128** |
|---|---|
| Description | A value of **true** indicates that file access requires SSL file permission processing with a minimum key size of 128 bits, with or without a client certificate. |
| Metabase Bitmask Identifier | MD_ACCESS_SSL128 |
| Decimal Value | 256 |
| Hexadecimal Value | 0x00000100 |

| **Flag Name** | **AccessSSLNegotiateCert** |
|---|---|
| Description | A value of **true** indicates that SSL file access processing requests a certificate from the client. A value of **false** indicates that access continues if the client does not have a certificate. Some versions of Internet Explorer will close the connection if the server requests a certificate and a certificate is not available (even if **AccessSSLRequireCert** is also set to **false**). |
| Metabase Bitmask Identifier | MD_ACCESS_NEGO_CERT |
| Decimal Value | 32 |
| Hexadecimal Value | 0x00000020 |

| **Flag Name** | **AccessSSLRequireCert** |
|---|---|
| Description | A value of **true** indicates that SSL file access processing requests a certificate from the client. If the client provides no certificate, the connection is closed. **AccessSSLNegotiateCert** must also beset to **true** when using **AccessSSLRequireCert**. |
| Metabase Bitmask Identifier | MD_ACCESS_REQUIRE_CERT |
| Decimal Value | 64 |
| Hexadecimal Value | 0x00000040 |

| **Flag Name** | **AccessSSLMapCert** |
|---|---|
| Description | A value of **true** indicates that SSL file permission processing maps a client certificate to a Microsoft Windows operating system user-account. The **AccessSSLNegotiateCert** property must also be set to **true** for the mapping to occur. |

| | |
|---|---|
| Metabase Bitmask Identifier | MD_ACCESS_MAP_CERT |
| Decimal Value | 128 |
| Hexadecimal Value | 0x00000080 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

AccessFlags Metabase Property

# ADConnectionsPassword Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ADConnectionsPassword** property is used when the FTP property, UserIsolationMode Metabase Property, is set to 2, which makes FTP user isolation dependent upon the Active Directory directory service. Set **ADConnectionsUserName** to the user name that has access to the domain controller, and set **ADConnectionsPassword** to the corresponding password.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AD_CONNECTIONS_PASSWORD |
| Attributes | INHERIT \| SECURE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5015 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

UserIsolationMode Metabase Property

# ADConnectionsUserName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ADConnectionsUserName** property is used when the FTP property, UserIsolationMode Metabase Property, is set to 2, which makes FTP user isolation dependent upon Active Directory. Set **ADConnectionsUserName** to the user name that has access to the domain controller, and set **ADConnectionsPassword** to the corresponding password.

**ADConnectionsUserName** must be in the *domain\user* format.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AD_CONNECTIONS_PASSWORD |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5014 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

# AddNoHeaders Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AddNoHeaders** property disables adding the Received header. Normally, a server adds a Received header to the top of a message when it receives the message.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37000 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/ SMTPSVC | IIsSmtpService |
| /LM/ SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AdminACL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AdminACL** property contains a Windows discretionary access control list (DACL) that controls access to any metabase key. This property grants read access, restricted write access, or unrestricted write access. For information about the possible values that can be set for this property, see the Bitmask Values table.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | NTACL |
| WMI Data Type | NTACL |
| ADSI Data Type | NTACL |
| ABO Data Type | NTACL |
| ABO Metabase Identifier | MD_ADMIN_ACL |
| Attributes | INHERIT \| SECURE \| REFERENCE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 6027 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/MSFTPSVC/*n*/ROOT /LM/MSFTPSVC/*n*/ROOT/*virtual_directory_name* | IIsFtpVirtualDir |
| /LM/logging | IIsLogModules |
| /LM/W3SVC/Info | IIsWebInfo |

| | |
|---|---|
| /LM/MSFTPSVC/Info | IIsFtpInfo |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| / | IIS_ROOT |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_ACR_READ | 0x00000001 | Enables read access to all properties. |
| MD_ACR_WRITE | 0x00000002 | Enables write access to all properties. |
| MD_ACR_ENUM_KEYS | 0x00000008 | Enables key enumeration. |
| MD_ACR_RESTRICTED_WRITE | 0x00000020 | See the Remarks section following this table. |
| MD_ACR_UNSECURE_PROPS_READ | 0x00000080 | Enables read access to properties that do not have the METADATA_SECURE attribute set. |
| MD_ACR_WRITE_DAC | 0x00040000 | Enables write access to **AdminACL** for security descriptor creator. |

**Remarks**

MD_ACR_RESTRICTED_WRITE enables restricted write access to the following properties.

| | |
|---|---|
| AdminACL Metabase Property | AppIsolated Metabase Property |
| Path Metabase Property | AccessFlags Metabase Property |
| AnonymousUserName Metabase Property | AnonymousUserPass Metabase Property |
| MaxBandwidth Metabase Property | MaxBandwidthBlocked Metabase Property |
| SecureBindings Metabase Property | ServerBindings Metabase Property |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AdminACLBin Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AdminACLBin** property is used by Microsoft Exchange Server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | binary |
| WMI Data Type | binary |
| ADSI Data Type | binary |
| ABO Data Type | binary |
| ABO Metabase Identifier | MD_VPROP_ADMIN_ACL_RAW_BINARY |
| Attributes | INHERIT \| SECURE \| REFERENCE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 6286 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/MSFTPSVC/*n*/ROOT<br>/LM/MSFTPSVC/*n*/ROOT/*virtual_directory_name* | IIsFtpVirtualDir |

| | |
|---|---|
| /LM/logging | IIsLogModules |
| /LM/W3SVC/Info | IIsWebInfo |
| /LM/MSFTPSVC/Info | IIsFtpInfo |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AdminEmail Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AdminEmail** property corresponds to the "Administrator e-mail account" option, which is on the **Settings** tab of the Network News Transfer Protocol (NNTP) virtual server Properties.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45060 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AdminName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AdminName** property holds the name of the NNTP administrator.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45061 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AdminServer Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AdminServer** property identifies the Web server instance that is being administered by the remote administration program.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_ADMIN_INSTANCE |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2115 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/Info | IIsWebInfo |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AllowAnonymous Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AllowAnonymous** property specifies whether the FTP server will allow anonymous access.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ALLOW_ANONYMOUS |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5005 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AllowClientPosts Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AllowClientPosts** property corresponds to **Allow client posting** on the **Settings** tab of NNTP virtual server Properties.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45062 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AllowControlMsgs Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AllowControlMsgs** property corresponds to **Allow control messages** on the **Settings** tab of NNTP virtual server Properties.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45064 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AllowFeedPosts Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AllowFeedPosts** property corresponds to **Allow feed posting** on the **Settings** tab of NNTP virtual server Properties.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45063 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AllowKeepAlive Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AllowKeepAlive** property specifies whether Keep-Alive processing is permitted.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ALLOW_KEEPALIVES |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 6038 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AllowPathInfoForScriptMappings Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AllowPathInfoForScriptMappings** property indicates whether clients are permitted to specify path information in script-mapped requests.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ALLOW_PATH_INFO_FOR_SCRIPT_MAPPINGS |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2095 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AlwaysUseSsl Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AlwaysUseSsl** property is used by the Microsoft Exchange Server messaging system.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_ SERVER |
| ID | 36924 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AnonymousOnly Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AnonymousOnly** property specifies whether the service or server restricts access to anonymous FTP users. If the value is set to **true**, only anonymous users will be allowed to log on to the FTP server. If set to **false**, users will be allowed to log on using a valid user name, as well as anonymously.

| **Note** |
| --- |
| If the value of **AnonymousOnly** is set to **true**, and the value of the AllowAnonymous Metabase Property is set to **false**, no users will be permitted to log on to the FTP server. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ANONYMOUS_ONLY |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_ SERVER |
| ID | 5006 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AnonymousPasswordSync Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AnonymousPasswordSync** property indicates whether IIS should handle the user password for anonymous users attempting to access resources. The following list details the behavior of this property:

- If **AnonymousPasswordSync** is set to **false**, the administrator must manually set the **AnonymousUserPass** property to the anonymous user password; otherwise anonymous access will not function properly.
- If **AnonymousPasswordSync** is set to **true**, the anonymous user password is set by IIS.
- If **AnonymousPasswordSync** is set to **true** and the value of the AllowAnonymous Metabase Property is set to **false**, no users will be permitted to log on to the FTP server.
- For anonymous password synchronization to work when the domain controller for the IIS server is running Microsoft Windows 2000, you must have subauthentication enabled. For more information, see Configuring Subauthentication in a Windows 2000 Domain.

| **Important** |
| --- |
| Setting **AnonymousPasswordSync** on a server running IIS 6.0 has no effect unless you run your application under the System identity and enable subauthentication. However, it is strongly recommended that you never run an application under the System identity because of the security risk. If your application contains a buffer-overrun, malicious users can do anything they want under the guise of the System identity. Also, subauthentication is not enabled by default on a new installation of IIS 6.0. (See Configuring Subauthentication.) This new default behavior of IIS 6.0 might break old applications that use Anonymous authentication. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ANONYMOUS_USE_SUBAUTH |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_ FILE |
| ID | 6022 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AnonymousUserName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AnonymousUserName** property specifies the name of the registered local user that is used to authenticate anonymous users. The server associates a user name and password with every server action.

**AnonymousUserName** must be in the *domain\user* format.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_ANONYMOUS_USER_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_ FILE |
| ID | 6020 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |

# AppAllowClientDebug Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppAllowClientDebug** property specifies whether ASP client-side debugging is enabled. This property is independent of AppAllowDebugging Metabase Property, which applies to server-side debugging.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLECLIENTDEBUG |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7019 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppAllowDebugging Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppAllowDebugging** property specifies whether ASP debugging is enabled on the server. This property is independent of the AppAllowClientDebug Metabase Property, which applies to client-side debugging.

| **Note** |
| --- |
| IIS application threads are serialized when server-side debugging is enabled: Only one thread at a time is allowed to run for each application. This could adversely affect server performance on busy sites. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLESERVERDEBUG |

**Related Information**

AppPackageName Metabase Property

# AppIsolated Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppIsolated** property indicates whether an application is to run in-process, out-of-process, or in a pooled-process. A value of 0 indicates that the application is to run in-process, a value of 1 indicates out-of-process, and a value of 2 indicates a pooled-process. Use the application management methods of the **IIsWebVirtualDir** and **IIsWebDirectory** objects to set the process space for your application.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APP_ISOLATED |
| Attributes | INHERIT |
| Default Value | 2 |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | iis_md_ut_wam |
| ID | 2104 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

**Related Information**

InProcessIsapiApps Metabase Property

# ApplicationDependencies Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ApplicationDependencies** property contains the Application Dependencies list for the items in the Web Service Restriction List. If an application is contained in this property, the application has dependencies on an item (or multiple items) in the Web Service Restriction List.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_APP_DEPENDENCIES |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2167 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppOopRecoverLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The AppOopRecoverLimit Metabase Property specifies the maximum number of times an out-of-process application will be restarted after a failure. The server will not service requests from components that have exceeded this limit. This property does not apply to applications or extensions that are run in-process.

| **Note** |
| --- |
| IIS must be restarted before changes to this property take effect. |

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APP_OOP_CRASH_LIMIT |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 2110 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

InProcessIsapiApps Metabase Property

# AppPackageID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPackageID** property provides the COM+ application identifier (ID) for a transaction. This ID is used in all transactions managed by Component Services.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APP_PACKAGE_ID |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | iis_md_ut_wam |
| ID | 2106 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

AppPackageName Metabase Property

# AppPackageName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPackageName** property provides the COM+ application name for a transaction.

Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APP_PACKAGE_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 2107 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppPoolAutoStart Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPoolAutoStart** property indicates to the World Wide Web Publishing Service (WWW service) to automatically start an application pool when the application pool is created or when IIS is started, if the value of this property is set to **true**.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_AUTO_START |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9028 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppPoolCommand Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPoolCommand** property allows an application to send commands to the application pool to start or stop the application pool. Applications can read the value of the AppPoolState Metabase Property to determine if the application pool has responded to the command issued by the use of this property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_COMMAND |
| Attributes | VOLATILE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9026 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_APPPOOL_COMMAND_START | 0x00000001 | Starts the application pool. |
| MD_APPPOOL_COMMAND_STOP | 0x00000002 | Stops the application pool. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppPoolId Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPoolId** property specifies the application pool where the application is routed.

| **Note** |
| --- |
| If an **AppPoolId** is not specified for a particular application; the application inherits the **AppPoolId** from a parent key that has the **AppPoolId** property set. If none of the application's parents have this property set, the application pool inherits this setting from the site level, or from the World Wide Web Publishing Service (WWW service) level. If no valid **AppPoolId** is available through inheritance, the application pool fails and an error is written in the event log. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APP_APPPOOL_ID |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9101 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/n/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppPoolIdentityType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPoolIdentityType** property allows application pools to run as LocalSystem, LocalService, NetworkService, or a specific user account. For the possible values to use in setting this property, see the Bitmask Values table below.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_IDENTITY_TYPE |
| Attributes | INHERIT |
| Default Value | 2 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9021 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Bitmask Values**

| Constant | Value | Description |
|---|---|---|
| MD_APPPOOL_IDENTITY_TYPE_LOCALSYSTEM | 0x00000000 | The application pool runs as LocalSystem. |
| MD_APPPOOL_IDENTITY_TYPE_LOCALSERVICE | 0x00000001 | The application pool runs as LocalService. |
| MD_APPPOOL_IDENTITY_TYPE_NETWORKSERVICE | 0x00000002 | The application pool runs as NetworkService. |
| MD_APPPOOL_IDENTITY_TYPE_SPECIFICUSER | 0x00000003 | The application pool runs as a specified user account. |

**Remarks**

MD_ACR_RESTRICTED_WRITE enables write access to the following properties:

| | |
|---|---|
| AdminACL Metabase Property | AppIsolated Metabase Property |

| | |
|---|---|
| Path Metabase Property | AccessFlags Metabase Property |
| AnonymousUserName Metabase Property | AnonymousUserPass Metabase Property |
| MaxBandwidth Metabase Property | MaxBandwidthBlocked Metabase Property |
| SecureBindings Metabase Property | ServerBindings Metabase Property |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppPoolQueueLength Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

The **AppPoolQueueLength** property indicates to HTTP.sys how many requests to queue up for an application pool before rejecting future requests. When the limit for this property is exceeded, IIS rejects the additional requests with a 503 error.

| **Note** |
| --- |
| For Windows Server 2003 with Service Pack 1 (SP1), the default value of this property has changed from 4000 to 1000. If you had IIS 6.0 installed before applying SP1 to your server, the value will not be changed; however, you should consider lowering the value for performance reasons. |

| **Note** |
| --- |
| If you set this property to a value outside the range, you receive a 1041 error in the event log. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_UL_APPPOOL_QUEUE_LENGTH |
| Attributes | INHERIT |
| Default Value | 1000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9017 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppPoolState Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppPoolState** property value is used by applications to determine the state of an application pool. The possible states are listed below in the Bitmask Values table.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_STATE |
| Attributes | VOLATILE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9027 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |

**Bitmask Values**

| Constant | Value | Description |
| --- | --- | --- |
| MD_APPPOOL_STATE_STARTING | 0x00000001 | The application pool is starting. |
| MD_APPPOOL_STATE_STARTED | 0x00000002 | The application pool has started. |
| MD_APPPOOL_STATE_STOPPING | 0x00000003 | The application pool is stopping. |
| MD_APPPOOL_STATE_STOPPED | 0x00000004 | The application pool has stopped. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppRoot Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppRoot** property contains the metabase path to the application root. For example, the metabase path for the application root of your Default Web Site is **/LM/W3SVC/1/ROOT**. To configure a key as an application root, use the application management methods of the **IIsWebVirtualDir** and **IIsWebDirectory** objects.

| **Important** |
|---|
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APP_ROOT |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | IIS_MD_UT_FILE |
| ID | 2103 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AppWamClsid Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AppWamClsid** property provides the class ID for the application's Web Application Management (WAM) interface.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APP_WAM_CLSID |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 2105 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ArticleTableFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ArticleTableFile** property specifies the location on the file system of the article hash table.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45158 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNNtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ArticleTimeLimit Metabase Property

Updated: July 7, 2006

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ArticleTimeLimit** property corresponds to ArticleTimeLimit registry key described in Microsoft Knowledge Base article, XADM: Registry Setting to Allow the Pulling of Newsfeed Articles Older Than 30 Days at URL.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45056 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspAllowOutOfProcComponents Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In IIS 4.0, the **AspAllowOutOfProcComponents** property specifies whether an ASP script is allowed to call out-of-process components, which are executables that are launched from within an application. This property was made obsolete in IIS 5.0 and its value is ignored. However, scripts using this property will continue to function normally.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ALLOWOUTOFPROCCOMPONENTS |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7014 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspAllowSessionState Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspAllowSessionState** property enables session state persistence for the ASP application. If the value is set to true, the server creates a new Session object for each connection, session state is accessible, session storage is allowed, **Session_OnStart** and **Session_OnEnd** occurs, and the ASPSessionID cookie is sent to the client. If the value is set to false, state access and storage are not allowed, events are not processed, and no cookie is sent.

| **Note** |
| --- |
| The ASP page directive, **@ENABLESESSIONSTATE**, can be used to override this metabase property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ALLOWSESSIONSTATE |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7011 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspAppServiceFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspAppServiceFlags**property contains the flags that must be set to enable COM+ services on your IIS applications. Once you enable the flags, you may also need to set other properties. For more information, see Configuring Applications to Use COM+ Services. Set this property at the application level.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_SERVICE_FLAGS |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7044 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Flags**

| Flag Name | AspEnableTracker |
|---|---|
| Description | A value of **true** enables COM+ tracker, which allows administrators or developers to debug ASP applications. For more information, see the COM+ Software Development Kit (SDK) and see Configuring Applications to Use COM+ Services. |
| Metabase Bitmask Identifier | MD_ASP_SERVICE_FLAG_TRACKER |

| | |
|---|---|
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| **Flag Name** | **AspEnableSxs** |
|---|---|
| Description | A value of **true** enables COM+ side-by-side assemblies, which allow ASP applications to specify which version of a system DLL or classic COM component to use, such as WinHTTP 5.1, Shell Common Controls version 6.0 (Comctl32.dll), GDI Plus version 1.0 (GDIplus.dll), and Visual C++ Run-time Libraries version 6.0. For more information, see the COM+ Software Development Kit (SDK) and see Configuring Applications to Use COM+ Services. |
| Metabase Bitmask Identifier | MD_ASP_SERVICE_FLAG_FUSION |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| **Flag Name** | **AspUsePartition** |
|---|---|
| Description | A value of **true** enables COM+ partitioning, which can be used to isolate Web applications into their own COM+ partitions. COM+ partitions can hold different versions of your own custom COM components. If you set this flag, also set the AspPartitionID Metabase Property. For more information, see Configuring Applications to Use COM+ Services. |
| Metabase Bitmask Identifier | MD_ASP_SERVICE_FLAG_PARTITIONS |
| Decimal Value | 4 |
| Hexadecimal Value | 0x00000004 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspBufferingLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspBufferingLimit** property sets the maximum size of the ASP buffer. If response buffering is turned on, this property controls the maximum number of bytes that an ASP page can write to the response buffer before a flush occurs.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_BUFFER_LIMIT |
| Attributes | INHERIT |
| Default Value | 4194304 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7052 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspBufferingOn Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspBufferingOn** property specifies whether output from an ASP application will be buffered. If the value is set to **true**, all output from the application is collected in the buffer before the buffer is flushed to the client browser. With buffering on, the ASP application has to completely process the ASP script before the client browser receives any output. For this reason, applications that have buffering enabled may seem slower to users than those applications that have buffering disabled, even though the total time taken for the buffered script is less. Therefore, if buffering is turned on, consider using the Flush method of the ASP built-in Response object to pass the user pieces of content as the script is being processed.

If this property is set to **false**, output from an ASP script is written to the client browser as it becomes available. If buffering is turned off, any methods that modify existing HTTP headers or generate new headers must be executed before the content body is sent to the client browser. If buffering is turned on, this restriction is unnecessary.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_BUFFERINGON |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_APP |
| ID | 7000 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspCalcLineNumber Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspCalcLineNumber** property specifies whether ASP should calculate and store the line number of each executed line of code in order to provide the number in an error report.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_CALCLINENUMBER |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_APP |
| ID | 7050 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspCodepage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspCodepage** property specifies the default code page for an application. This setting can be overridden at the page level by using the ASP page directive, **@CODEPAGE**, for literal strings, or one of the **Codepage** properties of the ASP built-in Session and Response objects for dynamic data. If this property is set to 0 at any node, the system default code page (CP_ACP) is inferred.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_CODEPAGE |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_APP |
| ID | 7016 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspDiskTemplateCacheDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

**AspDiskTemplateCacheDirectory** contains the name of the directory that ASP uses to store compiled ASP templates to disk after overflow of the in-memory cache. If the default directory is changed, then the administrator must ensure that the identity of the processes running Asp.dll has been assigned full control rights to the new directory. Typically, the identity of the processes running Asp.dll is the IWAM_*USER* and System accounts.

**AspDiskTemplateCacheDirectory** can only be set to a local path. ASP template caching fails if this property is set to a UNC or mapped network path.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | EXPANDSZ |
| WMI Data Type | String |
| ADSI Data Type | EXPANDSZ |
| ABO Data Type | EXPANDSZ |
| ABO Metabase Identifier | MD_ASP_DISKTEMPLATECACHEDIRECTORY |
| Attributes | INHERIT |
| Default Value | %windir%\system32\inetsrv\asp compiledtemplates |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7036 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspEnableApplicationRestart Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspEnableApplicationRestart** determines whether an ASP application can be automatically restarted. When changes are made to Global.asa or metabase properties that affect an application, the application will not restart unless the **AspEnableApplicationRestart** property is set to **true**.

| **Important** |
| --- |
| When this property is changed from **false** to **true**, the application immediately restarts. |

IIS also provides an ADSI method, **IIsWebDirectory.AspAppRestart**, which can be used to restart the application. For more information about this method, see the IIS ADSI Provider reference section of the IIS Software Development Kit (SDK)

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLEAPPLICATIONRESTART |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7027 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspEnableAspHtmlFallback Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspEnableAspHtmlFallback** property controls the behavior of ASP when a new request is to be rejected due to a full request queue. A **true** value for this property will cause an .htm file with a similar name as the requested .asp file, if it exists, to be sent instead of the .asp file. The naming convention for the .htm file is the name of the .asp file with _asp appended. For example, if the .asp file is hello.asp, then the .htm file should be hello_asp.htm

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLEASPHTMLFALLBACK |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7021 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspEnableChunkedEncoding Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspEnableChunkedEncoding** property specifies whether HTTP 1.1 chunked transfer encoding is enabled for the World Wide Web Publishing Service (WWW service). The WWW service setting for this property is inheritable by all in-process and pooled out-of-process applications, at all levels below the key where this property is set. Metabase settings at the Web server level or lower are ignored for in-process and pooled out-of-process applications. However, settings at the Web server level or lower will be used if that key is an isolated out-of-process application.

| **Note** |
| --- |
| Even if **AspEnableChunkedEncoding** is set to **true**, chunked transfer encoding is used only by browsers that support and have HTTP 1.1 enabled. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLECHUNKEDENCODING |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7022 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspEnableParentPaths Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspEnableParentPaths** property specifies whether an ASP page allows paths relative to the current directory (using the ..\ notation). If set to **true**, this property constitutes a potential security risk, because an include path could access critical or confidential files outside the root directory of the application.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLEPARENTPATHS |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | SP_MD_UT_APP |
| ID | 7008 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspEnableTypelibCache Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspEnableTypelibCache** property specifies whether type libraries are cached on the server. The World Wide Web Publishing Service (WWW service) setting for this property is applicable to all in-process and pooled out-of-process application nodes, at all levels. Metabase settings at the Web server level or lower are ignored for in-process and pooled out-of-process applications. However, settings at the Web server level or lower are used if that node is an isolated out-of-process application.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ENABLETYPELIBCACHE |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_WAM |
| ID | 7023 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspErrorsToNTLog Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspErrorsToNTLog** property specifies which ASP errors are written to the Windows event Log. ASP errors are written to the client browser and to the IIS log files by default.

**AspErrorsToNTLog** is set to **FALSE** by default, and modifies the **AspLogErrorRequests** property in the following way:

- If **AspLogErrorRequests** is set to **FALSE**, then ASP errors are not written to the Windows event log, regardless of the value of **AspErrorsToNTLog**.
- If **AspLogErrorRequests** is set to **TRUE**, then if IIS fails to write an item to the IIS log file, the item is written to the Windows event log as a warning, regardless of the value of **AspErrorsToNTLog**.
- If **AspLogErrorRequests** is set to **TRUE** and **AspErrorsToNTLog** is set to **FALSE**, then only the most serious ASP errors are sent to the Windows event log. Serious ASP errors are numbers 100, 101, 102, 103, 104, 105, 106, 107, 115, 190, 191, 192, 193, 194, 240, 241, and 242.
- If **AspLogErrorRequests** is set to **TRUE** and **AspErrorsToNTLog** is set to **TRUE**, then all ASP errors are written to the Windows event log.

| **Note** |
| --- |
| This property does not control logging requests to the IIS log files. To accomplish this see the **LogType** and **DontLog** properties. Also, this property does not control IIS Event Messages, which are always sent to the Windows event log. |

This property is a process-level property.

If this property set at the Web service level, it is applicable to all in-process application keys. Metabase property settings at the Web site level or lower are ignored for in-process applications unless the Web site key is isolated as an out-of-process application.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ERRORSTONTLOG |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7024 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspExceptionCatchEnable Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspExceptionCatchEnable** property specifies whether ASP pages trap exceptions thrown by components. If set to **false** (or, **disabled**), the Microsoft Script Debugger tool does not catch exceptions sent by the component that you are debugging.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_EXCEPTIONCATCHENABLE |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7015 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspExecuteInMTA Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP is capable of running all of its threads in a multi-threaded apartment (MTA). If your COM components are primarily free-threaded or both-threaded, running the ASP threads as MTA can improve performance significantly.

By default, the **AspExecuteInMTA** property is set to 0, which means that ASP does not execute in MTA. Set this property to 1 at the application level to enable ASP to run in MTA.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_EXECUTEINMTA |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7041 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspKeepSessionIDSecure Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspKeepSessionIDSecure** property, when enabled, ensures that a SessionID is sent as a secure cookie if assigned over a secure channel.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_KEEPSESSIONIDSECURE |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| StartingNumber | Not applicable |
| EndingNumber | Not applicable |
| ID | 7043 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspLCID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspLCID** property specifies the default locale identifier (LCID) for an application. LCIDs define how dates, times, and currencies are formatted. LCIDs are not the same for each geographical locale.

Override this setting at the page level by using the ASP page directive, @LCID for literal strings, or one of the **LCID** properties of the ASP built-in Response or Session objects for dynamic data. If this property is set to 0 at any node, the system default locale (LOCALE_SYSTEM_DEFAULT) is inferred. Setting **AspLCID** changes the locale for both the ASP application and the scripting engine. Using the Microsoft Visual Basic Scripting Edition (VBScript) function setLocale() only changes the locale for the scripting engine.

| **Note** |
| --- |
| The locale group has to be installed on the Web server before its locale identifier can be specified in a Web page or application. Use the **Regional and Language Options** item in Control Panel to install locale groups. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_LCID |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7042 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspLogErrorRequests Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspLogErrorRequests** property controls whether the Web server writes ASP errors to the application section of the Windows event log. ASP errors are written to the client browser and to the IIS log files by default.

**AspLogErrorRequests** is set to **TRUE** by default, and is modified by the **AspErrorsToNTLog** property in the following way:

- If **AspLogErrorRequests** is set to **FALSE**, then ASP errors are not written to the Windows event log, regardless of the value of the AspErrorsToNTLog Metabase Property.
- If **AspLogErrorRequests** is set to **TRUE**, then if IIS fails to write an item to the IIS log file, the item is written to the Windows event log as a warning, regardless of the value of the **AspErrorsToNTLog** property.
- If **AspLogErrorRequests** is set to **TRUE** and the **AspErrorsToNTLog** property is set to **FALSE**, then only the most serious ASP errors are sent to the Windows event log. Serious ASP errors are numbers 100, 101, 102, 103, 104, 105, 106, 107, 115, 190, 191, 192, 193, 194, 240, 241, and 242.
- If **AspLogErrorRequests** is set to **TRUE** and the **AspErrorsToNTLog** property is set to **TRUE**, then all ASP errors are written to the Windows event log.

| **Note** |
| --- |
| This property does not control logging requests to the IIS log files. To accomplish this see the **LogType** and **DontLog** properties. Also, this property does not control IIS Event Messages, which are always sent to the Windows event log. |

This property is a process-level property.

| ASP error code | ASP error | Description |
| --- | --- | --- |
| ASP 0100 | Out of memory | Unable to allocate required memory. |
| ASP 0101 | Unexpected error | The function returned (*exception name*). |
| ASP 0102 | Expecting string input | The function expects a string as input. |
| ASP 0103 | Expecting numeric input | The function expects a number as input. |
| ASP 0104 | Operation not Allowed | Operation not Allowed |
| ASP 0105 | Index out of range | An array index is out of range. |
| ASP 0106 | Type Mismatch | An unhandled data type was encountered. |
| ASP 0107 | Stack Overflow | The data being processed is over the allowed limit. |
| ASP 0115 | Unexpected error | A trappable error (*exception name*) occurred in an external object. The script cannot continue running. |
| ASP 0190 | Unexpected error | A trappable error occurred while releasing an external object. |
| ASP 0191 | Unexpected error | A trappable error occurred in the **OnStartPage** method of an external object. |

| | | |
|---|---|---|
| ASP 0192 | Unexpected error | A trappable error occurred in the **OnEndPage** method of an external object. |
| ASP 0193 | OnStartPage Failed | An error occurred in the **OnStartPage** method of an external object. |
| ASP 0194 | OnEndPage Failed | An error occurred in the **OnEndPage** method of an external object. |
| ASP 0240 | Script Engine Exception | A script engine threw exception (*exception name*) in (*object name*) from (*object name*). |
| ASP 0241 | CreateObject Exception | The **CreateObject** of (*object name*) caused exception (*exception name*). |
| ASP 0242 | Query OnStartPage Interface Exception | Querying object's (*object name)* **OnStartPage** or **OnEndPage** methods caused exception (*exception name*). |

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_LOGERRORREQUESTS |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7001 |

**Configurable Locations**
You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**
For general code examples, see Code Examples to Configure Metabase Properties.

# AspMaxDiskTemplateCacheFiles Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The value of the **AspMaxDiskTemplateCacheFiles** property specifies the maximum number of compiled ASP templates that can be stored. The directory that stores the compiled templates is configured by the AspDiskTemplateCacheDirectory Metabase Property property. This is a per process setting, so if ASP is hosted in more than one process, the number of files in this directory could exceed the individual maximum.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | Boolean |

**Related Information**

AspDiskTemplateCacheDirectory Metabase Property

# AspMaxRequestEntityAllowed Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspMaxRequestEntityAllowed** property specifies the maximum number of bytes allowed in the entity body of an ASP request. If a Content-Length header is present and specifies an amount of data greater than the value of **AspMaxRequestEntityAllowed**, IIS returns a 403 error response. This property is related in function to **MaxRequestEntityAllowed**, but is specific to ASP request. Whereas you might set the **MaxRequestEntityAllowed** property to 1 MB at the general World Wide Web Publishing Service (WWW Service) level, you may choose to set **AspMaxRequestEntityAllowed** to a lower value, if you know that your specific ASP applications handle a smaller amount of data.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_MAX_REQUEST_ENTITY_ALLOWED |
| Attributes | INHERIT |
| Default Value | 200000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7053 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspPartitionID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

COM+ partitions are used to isolate Web applications into their own COM+ partitions. COM+ partitions hold different versions of your own custom COM components.

Set the **AspPartitionID** property to the Globally Unique Identifier (GUID) of the COM+ partition. Also, set the **AspUsePartition** flag of the **AspAppServiceFlags** metabase property. Set both properties at the application level.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_ASP_SERVICE_PARTITION_ID |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7048 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspProcessorThreadMax Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspProcessorThreadMax** property specifies the maximum number of worker threads per processor that IIS may create.

| **Note** |
| --- |
| This setting can dramatically influence the scalability of your Web applications, and the performance of your server in general. Because this property defines the maximum number of ASP requests that can execute simultaneously, this setting should remain at the default value unless your ASP applications are making extended calls to external components. In this case, you may increase the value of **AspProcessorThreadMax**. Doing so allows the server to create more threads to handle more concurrent requests. |

If the value of this property is changed, the Web server instance must be stopped and restarted for the change to take effect. The World Wide Web Publishing Service (WWW service) setting for this property is applicable to all in-process and pooled out-of-process application nodes, at all levels. Metabase settings at the Web server level or lower ignores in-process and pooled out-of-process applications. However, settings at the Web server level or lower are used if that node is an isolated out-of-process application.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_PROCESSORTHREADMAX |
| Attributes | INHERIT |
| Default Value | 10 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7025 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |

| | |
|---|---|
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspQueueConnectionTestTime Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS places all ASP requests into a queue. If the request is queued longer than the number of seconds specified by the **AspQueueConnectionTestTime** property, ASP checks to determine whether the client is still connected before executing the request. If the client is no longer connected, the request is not processed and is deleted from the queue.

| **Note** |
| --- |
| Most often, users do not wait more than a few seconds for ASP pages to process. Although the maximum waiting time varies from user to user, the generally accepted maximum is approximately 10 seconds. You can use the **AspQueueConnectionTestTime** property to ensure that IIS does not waste time processing a request that has been abandoned by the user. This property is useful for making ASP processing efficient only up to the point at which ASP begins to process the script. Once the script is running, however, your application should continue to check for client connection at appropriate times, by using the **IsClientConnected** method of the ASP built-in **Response** object. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_QUEUECONNECTIONTESTTIME |
| Attributes | INHERIT |
| Default Value | 3 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7028 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspQueueTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspQueueTimeout** property specifies the amount of time (in seconds) that an ASP script request is allowed to wait in the queue. When requests are pulled from the queue, they are checked to see if they have expired (have waited longer than the value of this parameter). Expired requests are rejected with a message indicating the server is too busy.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_QUEUETIMEOUT |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7013 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspRequestQueueMax Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspRequestQueueMax** property specifies the maximum number of concurrent ASP requests that are permitted into the queue. Any client browser that attempts to request ASP files when the queue is full is given an HTTP 500 - Server Too Busy error.

In IIS 6.0 ASPRequestQueueMax can be set at lm/w3svc/AppPools and lm/w3svc/AppPools/<AppPoolName>.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_REQEUSTQUEUEMAX |
| Attributes | INHERIT |
| Default Value | 500 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_MD_UT_APP |
| ID | 7026 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7051 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspScriptEngineCacheMax Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The AspScriptEngineCacheMax Metabase Property specifies the maximum number of scripting engines that ASP pages will keep cached in memory.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_SCRIPTENGINECACHEMAX |
| Attributes | INHERIT |
| Default Value | 120 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7005 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

# AspScriptErrorMessage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspScriptErrorMessage** property specifies the error message to send to the browser if specific debugging errors are not sent to the client (if AspScriptErrorSentToBrowser Metabase Property is set to **false**).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_ASP_SCRIPTERRORMESSAGE |
| Attributes | INHERIT |
| Default Value | An error occurred on the server when processing the URL. Please contact the system administrator. |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- AspScriptErrorSentToBrowser Metabase Property

# AspScriptErrorSentToBrowser Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspScriptErrorSentToBrowser** property specifies whether the Web server writes debugging specifics (file name, error, line number, description) to the client browser, in addition to logging them to the Windows Event Log. The **AspScriptErrorMessage** property provides the error message to be sent if this property is set to false.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_SCRIPTERRORSSENTTOBROWSER |

**Related Information**

AspScriptErrorMessage Metabase Property

# AspScriptFileCacheSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspScriptFileCacheSize** property specifies the number of precompiled script files to cache. If set to 0, no script files are cached. If set to 4294967295, all script files requested are cached. This property is used to tune performance, depending on the amount of available memory and the amount of script file traffic.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_SCRIPTFILECACHESIZE |
| Attributes | INHERIT |
| Default Value | 500 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7004 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

# AspScriptLanguage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspScriptLanguage** property specifies the default script language for all ASP applications running on the Web server. The scripting engine for this language will be used for ASP code within the script language delimiters (<% and %>), unless specifically overridden by the following directive which must appear as the first line in any ASP page.

**<%@ LANGUAGE = ScriptingLanguage %>**

| **Note** |
| --- |
| IIS issues an error if *ScriptingLanguage* name is not registered on the system. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_ASP_SCRIPTLANGUAGE |
| Attributes | INHERIT |
| Default Value | VBScript |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7012 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspScriptTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspScriptTimeout** property specifies (in seconds) the default length of time that ASP pages allow a script to run before terminating the script and writing an event to the Windows Event Log. ASP script can override this value by using the **ScriptTimeout** property of the ASP built-in **Session** object. The **ScriptTimeout** property allows your ASP application to set a higher script timeout value. For example, you can use this setting to adjust the timeout once a particular user establishes a valid session by logging in or ordering a product.

| **Note** |
| --- |
| The minimum value for this property is one second. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_SCRIPTTIMEOUT |
| Attributes | INHERIT |
| Default Value | 90 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7006 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

AspSessionTimeout Metabase Property

# AspSessionMax Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspSessionMax** property specifies the maximum number of concurrent sessions that IIS will permit. If a client attempts to establish a new session with IIS once this limit is reached, the client will receive an HTTP 500 - Server Too Busy error.

| **Note** |
| --- |
| ASP requires a certain amount of memory overhead for each session maintained. Although you could use **AspSessionMax** to limit this memory overhead, it is generally more appropriate to manage the lifetime of session objects within IIS by using the AspSessionTimeout Metabase Property property, so that client browsers will be rejected once the limit is reached. |

If an incoming request does not have an ASP session cookie, or has a session cookie that does not match an existing session, the incoming request is considered a new session request. Setting this property at the **IIsWebService** level applies to all in-process and pooled out-of-process application keys, at all levels. Metabase settings at the **IIsWebService** level or lower are ignored for in-process and pooled out-of-process applications. However, settings at the **IIsWebService** level or lower are used if that key is an isolated out-of-process application.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ASP_SESSIONMAX |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7029 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

| | |
|---|---|
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

AspSessionTimeout Metabase Property

# AspSessionTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspSessionTimeout** property specifies (in minutes) the default amount of time that a Session object is maintained after the last request associated with the object is made. You can override this property in script by using the Timeout property of the ASP built-in Session object.

| **Note** |
| --- |
| You can use **AspSessionTimeout** to fine tune your ASP applications. Because Session objects consume memory resources, using this property to limit the lifetime of an individual Session makes your applications more scalable. |

Setting this property at the **IIsWebService** level applies to all in-process and pooled out-of-process application keys, at all levels. Metabase settings at the **IIsWebServer** level or lower are ignored for in-process and pooled out-of-process applications. However, settings at the **IIsWebServer** level or lower are used if that key is an isolated out-of-process application.

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |

**Related Information**

AspScriptTimeout Metabase Property

# AspSxsName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspSxsName** property enables side-by-side (SxS) assemblies. SxS assemblies allow ASP applications to specify which version of a system DLL or classic COM component to use, such as WinHTTP 5.1, Shell Common Controls version 6.0 (Comctl32.dll), GDI Plus version 1.0 (GDIplus.dll), and Visual C++ Run-time Libraries version 6.0.

Set the **AspSxsName** metabase property to the name of the COM+ application. Also, set the **AspEnableSxs** flag of the AspAppServiceFlags Metabase Property. Set both metabase properties at the application level.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_ASP_SERVICE_SXS_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | ASP_MD_UT_APP |
| ID | 7049 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AspTrackThreadingModel Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AspTrackThreadingModel** property specifies whether IIS checks the threading model of any components that your application creates.

| **Important** |
| --- |
| This metabase property is usually best left at the default value (**false**), so that ASP will not use system resources to track the threading model and your ASP application provides the best possible performance. If this property is set to **false**, and you give application scope to components that you create, those components must aggregate the free-threaded marshaler. If you do not aggregate the free-threaded marshaler, ASP generates an error when you try to create an instance of the component. For more information about this topic, see the "Building Components for ASP" section in the Platform SDK. |

Another reason to leave this property at the default setting (**false**), is that any objects that are created in your ASP application without the **OnStartPage** or **OnEndPage** method are released earlier than they would be otherwise and there is degradation of your application's scalability. For more details about improving performance, see Performance Tuning. Also with this property set to **false** ASP is prevented from writing the response before destroying the component.

| **Note** |
| --- |
| In IIS 4.0, the default value for this property was **true**. |

Setting this property at the **IIsWebService** level applies to all in-process and pooled out-of-process application keys, at all levels. Metabase settings at the **IIsWebServer** level or lower are ignored for in-process and pooled out-of-process applications. However, settings at the **IIsWebServer** level or lower are used if that key is an isolated out-of-process application.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ASP_ID_LAST |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | iis_md_ut_wam |
| ID | 7020 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |

| | |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthChangeURL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthChangeURL** property contains the URL to be invoked when a user enters a new password.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AUTH_CHANGE_URL |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 2060 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthExpiredURL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthExpiredURL** property contains a URL that will be invoked when a user's password has expired. It will be invoked in a secure (HTTPS) manner.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AUTH_EXPIRED_URL |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 2061 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthExpiredUnsecureURL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthExpiredUnsecureURL** property contains a URL that will be invoked when a user's password has expired.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AUTH_EXPIRED_UNSECUREURL |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 2067 |

**Configurable Locations**
You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**
For general code examples, see Code Examples to Configure Metabase Properties.

# AuthFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthFlags** property contains the settings for the Windows authentication schemes that are returned to clients as being available. This property contains the file access authentication flags, which are listed below in the Flags section.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_AUTHORIZATION |
| Attributes | INHERIT |
| Default Value | authanonymous |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6000 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/file_name /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Flags**

| Flag Name | AuthAnonymous |
|---|---|
| Description | Specifies Anonymous authentication as one of the possible Windows authenticationschemes returned to clients as being available. |
| Metabase Bitmask Identifier | MD_AUTH_ANONYMOUS |
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| Flag Name | AuthBasic |
|---|---|
| Description | Specifies Basic authentication as one of the possible Windows authenticationschemes returned to clients as being available. |
| Metabase Bitmask Identifier | MD_AUTH_BASIC |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| Flag Name | AuthMD5 |
|---|---|
| Description | Specifies Digest authentication and Advanced Digest authentication as one of the possible Windows authentication schemes returned to clients as being available. |
| Metabase Bitmask Identifier | MD_AUTH_MD5 |
| Decimal Value | 16 |
| Hexadecimal Value | 0x00000010 |

| Flag Name | AuthNTLM |
|---|---|
| Description | Specifies Integrated Windows authentication (also known as Challenge/Response or NTLMauthentication) as one of the possible Windows authentication schemes returned to clients as being available. |
| Metabase Bitmask Identifier | MD_AUTH_NT |
| Decimal Value | 4 |
| Hexadecimal Value | 0x00000004 |

| Flag Name | AuthPassport |
|---|---|
| Description | A value of **true** indicates that Microsoft .NET Passport authentication is enabled. For more information, see .NET Passport Authentication in IIS 6.0. |
| Metabase Bitmask Identifier | MD_AUTH_PASSPORT |
| Decimal Value | 64 |
| Hexadecimal Value | 0x00000040 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthNotifyPwdExpUnsecureURL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthNotifyPwdExpUnsecureURL** property contains a URL that will be invoked if the user's password expires sooner than the number of days specified in **PasswordExpirePreNotifyDays**.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AUTH_NOTIFY_PWD_EXP_UNSECUREURL |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 2069 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthNotifyPwdExpURL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthNotifyPwdExpURL** property contains a URL that will be invoked if the user's password expires sooner than the number of days specified in **PasswordExpirePreNotifyDays**. It will be invoked in a secure (HTTPS) manner.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AUTH_NOTIFY_PWD_EXP_URL |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 2062 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthPersistence Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthPersistence** property specifies authentication persistence across requests on a connection using NTLM authentication. The default for NTLM is **false (0)**, for legacy reasons, while all other authentication schemes assume the single request to be **true (1)**. When the **AuthPersistSingleRequest** flag is set to **true** on this property, IIS 6.0 automatically reauthenticates every request, even those on the same connection. This behavior is different on IIS 5.0 and IIS 5.1, where there were two other flags for the **AuthPersistence** property specifying persistence based on the existence of a proxy server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_AUTHORIZATION_PERSISTENCE |
| Attributes | INHERIT |
| Default Value | authpersistsinglerequest |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6031 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Flags**

| **Flag Name** | **AuthPersistSingleRequest** |
|---|---|
| Description | Setting this flag to **true** specifies that authentication persists only for a single request on a connection. IIS resets the authentication at the end of each request, and forces re-authentication on the next request of the session. |

| | |
|---|---|
| Metabase Bitmask Identifier | MD_AUTH_SINGLEREQUEST |
| Decimal Value | 64 |
| Hexadecimal Value | 0x00000040 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AuthTurnList Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AuthTurnList** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36966 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AutoShutdownAppPoolExe Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AutoShutdownAppPoolExe** property specifies an executable to run when the World Wide Web Publishing Service (WWW service) shuts down an application pool for rapid fail protection. You can use the **AutoShutdownAppPoolParams** property to send parameters to the executable.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_AUTO_SHUTDOWN_APPPOOL_COMMAND |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9035 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AutoShutdownAppPoolParams Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AutoShutdownAppPoolParams** property specifies any command-line parameters for the executable that is specified in the AutoShutdownAppPoolExe Metabase Property. You can use these two properties in the following way to send e-mail, for example, when the World Wide Web Publishing Service (WWW service) shuts down an application pool for rapid fail protection:

AutoShutdownAppPoolExe = "C:\LogAndSendMail.bat"

AutoShutdownAppPoolParams = "-AppPoolName %1%"

where %1% represents the application pool name.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APPPOOL_STATE_STOPPED |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9036 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AzEnable Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AzEnable** property enables URL Authorization for the virtual directory, application, or URL corresponding to the entry in the metabase.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_ENABLE_URL_AUTHORIZATION |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6048 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/n/ROOT/*file_name* /LM/W3SVC/n/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AzImpersonationLevel Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AzImpersonationLevel** property determines the impersonation behavior for the application, allowing the Web application to be configured to impersonate the client user, the IIS worker process, or the IUSER_* account for the worker process.

| **Note** |
| --- |
| Take care in setting this value, as each setting significantly changes the environment and implied design of the Web application. |

| Impersonation Level | Numeric value of the Field |
| --- | --- |
| Client User | 0 |
| IIS Worker Process | 1 |
| IUSER_* | 2 |

| Attribute Name | Attribute Value |
| --- | --- |
| Attribute Name | Attribute Value |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_URL_AUTHORIZATION_IMPERSONATION_LEVEL |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6053 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |

| | |
|---|---|
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AzScopeName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AzScopeName** property associates the virtual directory, application, or URL with a scope. If no scope or an empty string is specified, the default scope of the IIS 6.0 URL Authorization will be used.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_URL_AUTHORIZATION_SCOPE_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6050 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# AzStoreName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **AzStoreName** property associates an Authorization Manager policy store with the virtual directory, application, or URL. This string value must specify the store type and path to the policy store (i.e. **"msxml://c:\mystore.xml"** or **"msldap://CN=MyAzStore, CN=Program Data, DC=mydomain, DC=com"**).

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_URL_AUTHORIZATION_STORE_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6049 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# BadMailDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **BadMailDirectory** property contains the directory where undeliverable mail messages are placed. This corresponds to "Badmail directory" on the **Message** tab.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36909 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# BannerMessage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **BannerMessage** property specifies the message text an FTP server transmits to a client once the client connects to the FTP server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_BANNER_MESSAGE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5011 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# BinSchemaTimeStamp Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **BINSchemaTimeStamp** property is used internally by IIS to keep the MBSchema.xml file in sync with the binary schema file.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | binary |
| WMI Data Type | binary |
| ADSI Data Type | binary |
| ABO Data Type | binary |
| ABO Metabase Identifier | MD_GLOBAL_BINSCHEMATIMESTAMP |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 9991 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| . | IIS_Global |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CacheControlCustom Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CacheControlCustom** property specifies custom HTTP 1.1 cache control directives. Multiple directives can be specified if they are separated by carriage return/line feed (CRLF) pairs. There should not be a trailing carriage return/line feed after the final directive.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_CC_OTHER |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6043 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CacheControlMaxAge Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CacheControlMaxAge** property specifies the HTTP 1.1 cache control maximum age value. The value of this property ranges from 0 to 4294967295 (or unlimited), measured in seconds.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_CC_MAX_AGE |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6042 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CacheControlNoCache Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Reference topic for IIS CacheControlNoCache metabase properties.

The **CacheControlNoCache** property specifies the HTTP 1.1 directive to prevent caching of content.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_CC_NO_CACHE |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6041 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CacheISAPI Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CacheISAPI** property indicates whether ISAPI extensions are cached in memory after first use. If the value of this property is set to **true**, ISAPI extensions, once loaded, remain in the cache until the server is stopped. If the value is set to **false**, extensions are unloaded from memory after the ISAPI extension is no longer in use.

ISAPI extensions are cached or not cached based on the value of this property at the time they were loaded into memory for use. Thus, if this property is changed after an extension has been loaded and cached, the change will have no effect on that extension until the Web server is restarted.

| **Important** |
|---|
| There are severe performance implications to setting the value of this property to **false**. Also, some extensions cannot work properly when this property is set to **false**. |

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_CACHE_EXTENSIONS |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6034 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CentralBinaryLoggingEnabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CentralBinaryLoggingEnabled** property is a global flag to denote that IIS will generate one centralized binary log file rather than a separate file per Web site.

| **Note** |
| --- |
| This parameter is not inheritable and only exists on the parent node. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_GLOBAL_BINARY_LOGGING_ENABLED |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4016 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CentralW3CLoggingEnabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CentralW3CLoggingEnabled** metabase property configures W3C centralized logging on the server, a global configuration where all Web sites write data to a single log file. This single log file uses the W3C Extended log file format and can be viewed in a text editor. In contrast, centralized binary logging writes data in a binary format and requires a parsing tool to view the data. W3C centralized logging is available in Windows Server 2003 Service Pack 1 or later.

| **Note** |
| --- |
| This parameter is not inheritable and only exists on the parent node. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | XX |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2119 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CertCheckMode Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The CertCheckMode Metabase Property enables or disables Certificate Revocation List (CRL) checking. **CertCheckMode** is set to 0 by default (**CertCheckMode**=0), which means that IIS by default searches for an updated CRL.

This metabase property is closely related to the RevocationFreshnessTime Metabase Property and the RevocationURLRetrievalTimeout Metabase Property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_CERT_CHECK_MODE |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2160 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_CERT_NO_REVOC_CHECK | 0x00000001 | Certificate revocation checking is not performed. |
| MD_CERT_CACHE_RETRIEVAL_ONLY | 0x00000002 | During certificate revocation verification, the CRL will not be updated from a remote location, such as a CRL at an external URL. In this case, the CRL that is cached on the client is used. If the CRL is expired, the certificate revocation verification fails. |

| | | |
|---|---|---|
| MD_CERT_CHECK_REVOCATION_FRESHNESS_TIME | 0x00000004 | The client CRL is replaced by the CRL at a remote location, even if the CRL that is cached on the client is valid. The value of the RevocationFreshnessTime Metabase Property determines the frequency of this action. |
| MD_CERT_NO_USAGE_CHECK | 0x00010000 | The certificate provided by the client is not verified as valid. |

**Important**

The MD_CERT_NO_REVOC_CHECK, MD_CERT_CACHE_RETRIEVAL_ONLY, and MD_CERT_CHECK_REVOCATION_FRESHNESS_TIME flags are mutually exclusive.

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Topics**

- For more information about using SSL and certificates with IIS 6.0, see Encryption in IIS 6.0.
- For more information about certificate revocation and CRLs, see Revoking Certificates and Publishing CRLs in Windows Server 2003 documentation.

# CgiRestrictionList Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is controlled by IIS.

| Attribute Name | Attribute Value |
|---|---|
| ADSI/WMI Data Type | MULTISZ |
| ABO Data Type | MULTISZ_METADATA |
| Schema Default | **null** |
| Internal Default | 0 |
| Upper Bound | Not specified |
| Lower Bound | Not specified |
| Internal ID | 2164 |
| Friendly ID | MD_CGI_RESTRICTION_LIST |
| Property Attributes | NO_ATTRIBUTES |
| User Type | IIS_MD_UT_SERVER |

**Configurable Locations**
This property is not configurable at any location in the metabase.

**Flags**
There are no flags for this property.

# CGITimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CGITimeout** property specifies the timeout (in seconds) for CGI applications. The value range is 10 seconds to &H80000000 (2.1 million seconds).

| **Note** |
| --- |
| &H represents Microsoft Visual Basic Scripting Edition (VBScript) hexadecimal format. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SCRIPT_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 300 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6033 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ChangeNumber Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ChangeNumber** property is used internally by IIS to keep track of changes to the metabase.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_GLOBAL_CHANGE_NUMBER |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 9997 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| . | IIS_Global |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ClientPostHardLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ClientPostHardLimit** property contains the number of bytes the server will take before breaking the session.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45165 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ClientPostSoftLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ClientPostSoftLimit** property contains the largest post the server will take.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45166 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ClusterEnabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ClusterEnabled** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_CLUSTER_ENABLED |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1025 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CollectionComment Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CollectionComment** property exposes comments in the metabase.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_COMMENTS |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9990 |

**Configurable Locations**
This property cannot be configured.

**Code Example**
For general code examples, see Code Examples to Configure Metabase Properties.

# ConnectResponse Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ConnectResponse** property changes the banner response issued at connection to Microsoft Exchange. You must restart the service for this to take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36907 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ConnectionTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ConnectionTimeout** property assumes the functional role of the IIS 5.0 **ServerListenTimeout** property.

In IIS 6.0, use this property in conjunction with the **HeaderWaitTimeout** property, and for Web service nodes, use the **MinFileBytesPerSec** property instead of the **ServerListenTimeout** property.

The **ConnectionTimeout** property specifies the time in seconds that IIS waits before it disconnects a connection considered inactive for any of the following reasons:

- Timer_ConnectionIdle

  The connection was closed because there was not activity and the Timer_ConnectionIdle timer expired.

- Timer_EntityBody

  The connection was closed because no data was received, and the Timer_EntityBody timer expired.

  If a request has an entity body, HTTP.sys begins a Timer_EntityBody timer, and sets the **ConnectionTimeout** value to match the timer. When HTTP.sys receives data on the request, it resets the Timer_EntityBody timer and **ConnectionTimeout**.

- Timer_AppPool

  The connection was closed because the request waited longer than the **ConnectionTimeout** value while sitting in an Application Pool queue, waiting to be processed. Increasing the **ConnectionTimeout** value increases the time a request can wait in an application pool queue before being disconnected.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_CONNECTION_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 120 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1013 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ContentIndexed Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ContentIndexed** property specifies whether the installed content indexer should index content under this directory tree.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_IS_CONTENT_INDEXED |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6039 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CPUAction Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CPUAction** property configures the action(s) that IIS takes when Microsoft Windows NT job objects run. Only one Windows NT job object exists per application pool, therefore the **CPUAction** property is configured on a per application pool basis.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_CPU_ACTION |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9022 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Values**

| **Important** |
|---|
| Only one value from the following table should be used per application pool. |

| Constant | Value | Description |
|---|---|---|
| MD_CPU_NO_ACTION | 0x00000000 | No action is taken except that a warning is written to the event log when the CPU limit is exceeded. |
| MD_CPU_KILL_W3WP | 0x00000001 | Application pool worker processes that exceed their CPU limit will be forced to shut down. |
| MD_CPU_TRACE | 0x00000002 | Enables capacity tracing for the application pool when 80%of the CPU limit is reached. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CPULimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CPULimit** property configures the maximum percentage of CPU time (in 1/1000ths of a percent) that the worker processes in an application pool are allowed to consume over a period of time as indicated by the CPUResetInterval Metabase Property property. If the limit set by the **CPULimit** property is exceeded, an event is written to the event log and an optional set of events can be triggered as determined by the CPUAction Metabase Property property.

| **Note** |
| --- |
| Setting the value of this property to 0 disables limiting the worker processes to a percentage of CPU time. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_CPU_LIMIT |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9023 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CPUResetInterval Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CPUResetInterval** property specifies the reset period (in minutes) for CPU monitoring and throttling limits on the application pool. When the number of minutes elapsed since the last process accounting reset equals the number specified by this property, IIS will reset the CPU timers for both the logging and limit intervals. Setting the value of this property to 0 disables CPU monitoring.

| **Important** |
| --- |
| The value in **CpuResetInterval** must be greater than the time between logging operations, otherwise IIS will reset counters before logging has occurred, and process accounting will not occur. |

| **Note** |
| --- |
| Because process accounting in IIS uses Windows Job Objects to monitor CPU times for an entire process, process accounting will log and throttle only applications that are isolated in a separate process from IIS. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_CPU_RESET_INTERVAL |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2144 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CreateCGIWithNewConsole Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CreateCGIWithNewConsole** property indicates whether a CGI application runs in its own console. If the value is set to **true**, each CGI application creates a new console when started. A value of **false** indicates that CGI applications should run without a console.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_CREATE_PROC_new_CONSOLE |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6036 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CreateProcessAsUser Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CreateProcessAsUser** property specifies whether a CGI process is created as the application pool identity or the identity of the requesting user.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_CREATE_PROCESS_AS_USER |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6035 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CSideEtrnDomains Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **CSideEtrnDomains** property lists the domains that will be sent when this Simple Mail Transfer Protocol (SMTP) virtual server sends the **ETRN** command, acting as a client.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36968 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# CustomErrorDescriptions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The value of the **CustomErrorDescriptions** property is a list of custom error messages. Each string in the list specifies an error code and subcode for the custom message, what the specific error text and subcode error text is, and whether the custom message is supported by file or URL, or by file only. Each string value is in the format *ErrorCode*, *ErrorSubcode*, *ErrorText*, *ErrorSubcodeText*, followed by another comma and either a 0 for file and URL support, or a 1 for file support only.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_CUSTOM_ERROR_DESC |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2120 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Info | IIsWebInfo |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DefaultDoc Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DefaultDoc** contains one or more file names of default documents that will be returned to the client if no file name is included in the client's request. The default document will be returned if the **EnableDefaultDoc** flag of the DirBrowseFlags Metabase Property is set to **true** for the directory. This property can contain a list of default document file names separated by a comma and a space, for example Default.htm, Default.asp.

| **Important** |
| --- |
| If the **EnableDefaultDoc** flag is not set in the DirBrowseFlags Metabase Property property, the server will not search for a default document. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_DEFAULT_LOAD_FILE |
| Attributes | INHERIT |
| Default Value | default.htm |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6006 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT<br><br>/LM/W3SVC/*n*/ROOT/virtual_directory_name | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/physical_directory_name<br><br>/LM/W3SVC/*n*/virtual_directory_name/physical_directory_name | IIsWebDirectory |

**Code Example**

**Related Information**

- DirBrowseFlags Metabase Property

# DefaultDocFooter Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DefaultDoc** contains one or more file names of default documents that will be returned to the client if no file name is included in the client's request. The default document will be returned if the **EnableDefaultDoc** flag of the DirBrowseFlags Metabase Property is set to **true** for the directory. This property can contain a list of default document file names separated by a comma and a space, for example Default.htm, Default.asp.

| **Important** |
|---|
| If the **EnableDefaultDoc** flag is not set in the **DirBrowseFlags** property, the server will not search for a default document. |

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_DEFAULT_LOAD_FILE |

# DefaultDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DefaultDomain** property specifies the default domain for logon to an SMTP server. If this value is not specified, the default domain is the domain name controlled by the computer, if the computer is a domain controller. If the computer is not a domain controller, the default domain is the computer name.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_DEFAULT_LOGON_DOMAIN |
| Attributes | INHERIT |

| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36908 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DefaultLogonDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In Web, FTP, and NNTP servers, the **DefaultLogonDomain** property is used to specify the default domain that the server uses to authenticate users (in a Web hosting scenario where **UserIsolationMode** = 2). If the value of **DefaultLogonDomain** is not specified, the default domain will be the domain name controlled by the computer, if the computer is a domain controller. If the computer is not a domain controller, the default domain will be the computer name.

In the case of FTP, IIS uses this domain name to query the corresponding Active Directory for the two properties required for each user in the Web hosting scenario: msIIS-FTPRoot and msIIS-FTPDir.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_DEFAULT_LOGON_DOMAIN |
| Attributes | INHERIT |

# DemandStartThreshold Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DemandStartThreshold** property specifies the maximum number of worker processes allowed to run concurrently on a machine.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_DEMAND_START_THRESHOLD |
| Attributes | NO_ATTRIBUTES |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9207 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/ | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DirBrowseFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DirBrowseFlags** metabase property contains flags, as seen in the Flags section, that control whether directory browsing is enabled, how much directory and file information is provided if browsing is enabled, and whether there is a default page in the directory.

| **Note** |
| --- |
| If a client accesses the directory and does not provide a file name, and the **EnableDefaultDoc** flag is set to **true**, the server will look for a default file specified in the DefaultDoc Metabase Property. If a default file does not exist in the directory, and the **EnableDirBrowsing** flag is set to **true**, then directory browsing is enabled. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_DIRECTORY_BROWSING |
| Attributes | INHERIT |

For general code examples, see Code Examples to Configure Metabase Properties.

# DirectoryLevelsToScan Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DirectoryLevelsToScan** property specifies the number of virtual directory levels to scan in the metabase from the root virtual directory for a server in order to build a list of directories to be monitored for file system changes. If a virtual directory is not included in the list, then the IIS cache will not be flushed when a file change occurs in the directory. This list is also used for down-level remote administration from earlier versions of IIS. The value of this property ranges from 0 to 4294967295 (or unlimited).

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, Microsoft Visual Basic Scripting Edition (VBScript) represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LEVELS_TO_SCAN |
| Attributes | NO_ATTRIBUTES |
| Default Value | 2 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1022 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DisableNewNews Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DisableNewNews** property is set to disable the NEWNEWS command. Administrators may want to disable NEWNEWS for performance reasons so that other servers are not pulling entire feeds.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45068 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DisableSocketPooling Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Because the **DisableSocketPooling** property is defined as a valid property in the IIS 6.0 metabase schema (MBSchema.xml), you can still set this property, but the setting has no effect. In IIS 6.0, the HTTP listener is in the new kernel-level driver, HTTP.sys. To configure HTTP.sys, you must modify an IP inclusion list by using Httpcfg.exe. For more information, see Microsoft Knowledge Base article Q813368, IIS 6.0: Setting Metabase Property DisableSocketPooling Has No Effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_DISABLE_SOCKET_POOLING |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1029 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DisableStaticFileCache Metabase Property

Updated: August 19, 2013

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DisableStaticFileCache** property specifies the caching of static files for a directory and is disabled on a per-request basis. If **DisableStaticFileCache** = 1, static files are not cached for the specified directory. Note: Active Server Pages (ASP) files and templates are cached independently of this setting. This property may be set on any valid virtual directory and applies to the virtual directory root and any subdirectories.

The **DisableStaticFileCache** property is used when multiple virtual directories are created on Universal Naming Convention (UNC) shares and are secured with individual identities and access control lists (ACLs) to fully secure files from access by unauthorized users. For this configuration scenario, not setting this property would potentially allow unauthorized access to a site's files in the cache through other security identities.

The **DisableStaticFileCache** property may also be set to permit case-sensitive requests for files that are stored in virtual directories located on network file system (NFS) volumes and accessed through an NFS client, such as one provided by Services For Unix (SFU).

The static file cache may alternatively be disabled at the machine level through the registry key HKLM\System\CurrentControlSet\Services\inetinfo\parameters\DisableMemoryCache.

Disabling the static file cache will, in most cases, reduce the Web server request handling performance. However, the effect may be negligible if requests are broadly and randomly distributed across a large number of files.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_VR_NO_CACHE |

| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 3007 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DisallowOverlappingRotation Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DisallowOverlappingRotation** property specifies whether or not the World Wide Web Publishing Service (WWW Service) should start up another worker process to replace the existing worker process while it is shutting down. The value of this property should be set to **true** if the worker process loads any application code that does not support multi-instance.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_DISALLOW_OVERLAPPING_ROTATION |
| Attributes | INHERIT |
| Default Value | **false** |

# DisallowRotationOnConfigChange Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DisallowRotationOnConfigChange** property specifies whether or not the World Wide Web Publishing Service (WWW Service) should rotate worker processes in an application pool when the configuration has changed. This means that the worker processes will not pick up application pool changes to values passed to the worker process, such as IdleTimeout Metabase Property and PeriodicRestartRequests Metabase Property. The value of **DisallowRotationOnConfigChange** should be set to **true** if the worker process loads any application code that does not support multi-instance.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_DISALLOW_ROTATION_ON_CONFIG_CHANGE |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9018 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br><br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DoDynamicCompression Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DoDynamicCompression** property performs the same function as the global **HcDoDynamicCompression** property, but it is used for enabling and disabling static content compression at the individual site or site element level.

Before you can use **DoDynamicCompression** to customize compression at the site or site element level, at least one compression scheme (gzip or deflate) must be enabled in the **HcDoDynamicCompression** property at the **IIsCompressionScheme** level. This setting determines which compression schemes IIS will support for dynamic content: gzip, deflate, or both.

You can either enable compression of dynamic content server-wide and then disable it at specific locations, or you can disable compression of dynamic content server-wide and then enable it only at the locations you specify. For more information about these two approaches, see the HcDoDynamicCompression Metabase Property.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_DO_NAMESPACE_DYNAMIC_COMPRESSION |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 2255 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT<br><br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br><br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |

| | |
|---|---|
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br><br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DomainRouting Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DomainRouting** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36920 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DoMasquerade Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DoMasquerade** property toggles domain masquerading.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36913 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DontLog Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DontLog** property specifies whether client requests are written to the IIS log files. By default, logging is enabled by the **LogType** property on a service or server node. Set the **DontLog** property to **TRUE** on child directories or files to exempt them from logging.

ASP and ODBC errors do not get logged to the IIS log files.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_DONT_LOG |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6023 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |

# DoStaticCompression Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DoStaticCompression** property performs the same function as the global **HcDoStaticCompression Metabase Property** property, but is used for enabling or disabling static content compression at the individual site or site element level.

Before you can use **DoStaticCompression** to customize compression at the site or site element level, at least one compression scheme (gzip or deflate) must be enabled in the **HcDoStaticCompression** property at the **IIsCompressionScheme** level. This setting determines which compression schemes IIS will support for static content: gzip, deflate, or both.

You can either enable compression of static content server-wide and then disable it at specific locations, or you can disable compression of static content server-wide and then enable it only at the locations you specify. For more information about these two approaches, see HcDoStaticCompression Metabase Property.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_DO_NAMESPACE_STATIC_COMPRESSION |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 2256 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT<br><br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |

# DownlevelAdminInstance Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DownlevelAdminInstance** indicates the server instance for remote administration clients.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_DOWNLEVEL_ADMIN_INSTANCE |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1021 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# DropDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **DropDirectory** property lists the location of the Drop directory.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36882 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# Enable32BitAppOnWin64 Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **Enable32BitAppOnWin64** property indicates whether IIS creates 32-bit worker processes or 64-bit worker processes on 64-bit Windows. This property is only relevant on 64-bit Windows with IIS 6.0 running in Worker Process Isolation mode.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_32_BIT_APP_ON_WIN64 |
| Attributes | INHERIT |
| Default Value | **FALSE** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9040 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

# EnableDocFooter Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **EnableDocFooter** property enables or disables custom footers specified by the DefaultDocFooter Metabase Property. Setting **EnableDocFooter** to **false** disables custom footers, and results in higher performance.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_FOOTER_ENABLED |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6010 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

**Related Information**

- DefaultDocFooter Metabase Property

# EnableEditWhileRunning Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **EnableEditWhileRunning** property is used to enable the edit-while-running feature. The **EnableHistory** property must also be set to **true** for the edit-while-running feature to be enabled. For more information about the edit-while-running feature, see Enabling Edit-While-Running in IIS 6.0.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ROOT_ENABLE_EDIT_WHILE_RUNNING |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9998 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM | IIsComputer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- EnableHistory Metabase Property

# EnableHistory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **EnableHistory** property enables or disables the metabase history feature. Setting this property to **true** enables metabase history. Setting the MaxHistoryFiles property to 0 (zero) effectively disables the metabase history feature. For more information, see Configuring the Metabase History Feature in IIS 6.0.

| **Important** |
| --- |
| If this property is set to **false** when EnableEditWhileRunning Metabase Property is set to **true**, IIS will write a warning to the event log and reset this property to **true**. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ROOT_ENABLE_HISTORY |

# EnableReverseDns Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **EnableReverseDns** property enables or disables reverse Domain Name Server (DNS) lookups for the World Wide Web Publishing Service (WWW service). Reverse lookups involve looking up the domain name when the IP address is known. Reverse DNS lookups can use significant resources and time.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_DO_REVERSE_DNS |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6029 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# EnableReverseDnsLookup Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **EnableReverseDnsLookup** property corresponds to the **Perform reverse DNS lookup on incoming messages** check box in the **Advanced Delivery** dialog box.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_REVERSE_NAME_LOOKUP |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36884 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# EtrnDays Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **EtrnDays** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ETRN_DAYS |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36918 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |

# ExMdbGuid Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ExMdbGuid** property is used by the Microsoft Exchange driver.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46162 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT<br>/LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ExpireNewsgroups Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ExpireNewsgroups** property lists newsgroups for which this expiration policy applies.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45658 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Expires/expire *n* | IIsNntpExpire |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ExpirePolicyName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ExpirePolicyName** property contains the name of the News Network Transport Protocol (NNTP) expiration policy.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45659 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Expires/expire *n* | IIsNntpExpire |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ExpireSpace Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ExpireSpace** property contains the size limit for expiration by size. This property is not currently supported.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45656 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Expires/expire *n* | IIsNntpExpire |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ExpireTime Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ExpireTime** property contains the amount of elapsed time before article expiration begins.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45657 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Expires/expire *n* | IIsNntpExpire |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedAccountName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedAccountName** property contains the user name when authentication is required for a feed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45461 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedAdminError Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedAdminError** property contains the error text displayed after an administrative error.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45481 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedAllowControlMsgs Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedAllowControlMsgs** property allows control messages from a remote feed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45466 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedAuthenticationType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedAuthenticationType** contains the feed authentication type (cleartext or none).

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45460 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedConcurrentSessions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedConcurrentSessions** property contains the number of concurrent sessions allowed from feed server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45470 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedCreateAutomatically Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedCreateAutomatically** property controls whether groups are created automatically.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45467 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedDisabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedDisabled** property controls whether the feed is enabled or disabled.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45468 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedDistribution Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedDistribution** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45469 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedErrParmMask Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedErrParmMask** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45482 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedFeedpairId Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedFeedpairId** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45479 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedHandshake Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedHandshake** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45480 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedInterval Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedInterval** property corresponds to the "Run Interval" box on the **Schedule** tab of feed properties. The property defines how often the feed runs.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45465 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedMaxConnectionAttempts Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedMaxConnectionAttempts** property contains the number of times feed tries to connect without success before disabling the feed.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45471 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedNewsgroups Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedNewsgroups** property corresponds to the list of newsgroups that the feed accepts, asks for, or pushes.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45458 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedNextPullHigh Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedNextPullHigh** contains the high DWORD of the time of the next pull feed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45474 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedNextPullLow Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedNextPullLow** contains the low DWORD of the time of the next pull feed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45475 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedOutgoingPort Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedOutgoingPort** property corresponds to "Outbound IP Port" of the feed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45478 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedPassword Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If authentication is required for feed, the **FeedPassword** property contains the password for the account.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | SECURE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45462 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedPeerGapSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedPeerGapSize** property contains the gap size to leave in the file before the article.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45477 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedPeerTempDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedPeerTempDirectory** property contains the temporary directory used for the feed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45476 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds | IIsNntpFeeds |
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedPostHardLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedPostHardLimit** property corresponds to **Limit connection size** for the feed on the **Settings** tab of NNTP virtual server Properties. Units are in kilobytes.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45167 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedPostSoftLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedPostSoftLimit** property corresponds to **Limit post size** for the feed on the **Settings** tab of NNTP virtual server Properties. Units are in kilobytes.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45168 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedReportPeriod Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedReportPeriod** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45180 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedSecurityType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedSecurityType** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45459 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedServerName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedServerName** property corresponds to **Remote Server Name** on **General** tab of feed properties.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45456 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedStartTimeHigh Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedStartTimeHigh** property contains the high DWORD of the feed start time.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45463 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedStartTimeLow Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedStartTimeLow** property contains the low DWORD of the feed start time.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45464 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedTempDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedTempDirectory** contains the temporary directory used for feeds.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45473 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedType** property specifies whether the remote server is a master server, subordinate server, or peer server in relation to the local server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45457 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FeedUucpName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FeedUucpName** property corresponds to **Unique path ID generated by remote server** on the **General** tab of feed properties.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45472 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n*/Feeds/feed *n* | IIsNntpFeed |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterDescription Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The value of **FilterDescription** contains the description of the corresponding filter.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_FILTER_DESCRIPTION |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2045 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/*filter_name*<br><br>/LM/W3SVC/*n*/Filters/*filter_name* | IIsFilter |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterEnableCache Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FilterEnableCache** property can be set on individual filters to mark them cache friendly to HTTP.sys. *Cache friendly* means that the filter does not conditionally reroute URLs for /default.htm to either /default-1.htm or /default-2.htm, which would break the HTTP.sys cache. By default, filters are considered unfriendly to the HTTP.sys cache.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_FILTER_ENABLE_CACHE |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2046 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/*filter_name*<br><br>/LM/W3SVC/*n*/Filters/*filter_name* | IIsFilter |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterEnabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FilterEnabled** indicates whether the installed filter is enabled.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_FILTER_ENABLED |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2043 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/*filter_name*<br><br>/LM/W3SVC/*n*/Filters/*filter_name* | IIsFilter |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FilterFlags** property contains flags that indicate the events that are registered to notify the installed ISAPI filter, which are defined in the Flags section.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

For more information, see "Developing ISAPI Filters" in the Platform SDK.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_FILTER_FLAGS |
| Attributes | NO_ATTRIBUTES |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2044 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/Filters/*filter_name*<br><br>/LM/W3SVC/*n*/Filters/*filter_name* | IIsFilter |

**Flags**

| **Flag Name** | **NotifySecurePort** |
| --- | --- |
| Description | Notify only if port secure. |
| Metabase Bitmask Identifier | MD_NOTIFY_SECURE_PORT |
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| Flag Name | NotifyNonSecurePort |
| --- | --- |
| Description | Notify only if port nonsecure. |
| Metabase Bitmask Identifier | MD_NOTIFY_NONSECURE_PORT |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| Flag Name | NotifyReadRawData |
| --- | --- |
| Description | Notify if reading raw data. |
| Metabase Bitmask Identifier | MD_NOTIFY_READ_RAW_DATA |
| Decimal Value | 32768 |
| Hexadecimal Value | 0x00008000 |

| Flag Name | NotifyPreProcHeaders |
| --- | --- |
| Description | Notify if preprocessing headers. |
| Metabase Bitmask Identifier | MD_NOTIFY_PREPROC_HEADERS |
| Decimal Value | 16384 |
| Hexadecimal Value | 0x00004000 |

| Flag Name | NotifyAuthentication |
| --- | --- |
| Description | Notify if performing authentication. |
| Metabase Bitmask Identifier | MD_NOTIFY_AUTHENTICATION |
| Decimal Value | 8192 |
| Hexadecimal Value | 0x00002000 |

| Flag Name | NotifyUrlMap |
| --- | --- |
| Description | Notify if mapping URL to physical path. |
| Metabase Bitmask Identifier | MD_NOTIFY_URL_MAP |
| Decimal Value | 4096 |
| Hexadecimal Value | 0x00001000 |

| Flag Name | NotifyAccessDenied |
| --- | --- |
| Description | Notify if server sending HTTP error 401 to client. |
| Metabase Bitmask Identifier | MD_NOTIFY_ACCESS_DENIED |
| Decimal Value | 2048 |
| Hexadecimal Value | 0x00000800 |

| Flag Name | NotifySendResponse |
| --- | --- |
| Description | Notify if response being sent to client. |
| Metabase Bitmask Identifier | MD_NOTIFY_SEND_RESPONSE |

| | |
|---|---|
| Decimal Value | 64 |
| Hexadecimal Value | 0x00000040 |

| **Flag Name** | **NotifySendRawData** |
|---|---|
| Description | Notify if sending raw data. |
| Metabase Bitmask Identifier | MD_NOTIFY_SEND_RAW_DATA |
| Decimal Value | 1024 |
| Hexadecimal Value | 0x00000400 |

| **Flag Name** | **NotifyLog** |
|---|---|
| Description | Notify if logging. |
| Metabase Bitmask Identifier | MD_NOTIFY_LOG |
| Decimal Value | 512 |
| Hexadecimal Value | 0x00000200 |

| **Flag Name** | **NotifyEndOfRequest** |
|---|---|
| Description | Notify if request has ended. |
| Metabase Bitmask Identifier | MD_NOTIFY_END_OF_REQUEST |
| Decimal Value | 128 |
| Hexadecimal Value | 0x00000080 |

| **Flag Name** | **NotifyEndOfNetSession** |
|---|---|
| Description | Notify if network session is ending. |
| Metabase Bitmask Identifier | MD_NOTIFY_END_OF_NET_SESSION |
| Decimal Value | 256 |
| Hexadecimal Value | 0x00000100 |

| **Flag Name** | **NotifyOrderHigh** |
|---|---|
| Description | High priority for notifications. |
| Metabase Bitmask Identifier | MD_NOTIFY_ORDER_HIGH |
| Decimal Value | 524288 |
| Hexadecimal Value | 0x00080000 |

| **Flag Name** | **NotifyOrderMedium** |
|---|---|
| Description | Medium priority for notifications. |
| Metabase Bitmask Identifier | MD_NOTIFY_ORDER_MEDIUM |
| Decimal Value | 262144 |
| Hexadecimal Value | 0x00040000 |

| Flag Name | NotifyOrderLow |
| --- | --- |
| Description | Low priority for notifications. |
| Metabase Bitmask Identifier | MD_NOTIFY_ORDER_LOW |
| Decimal Value | 131072 |
| Hexadecimal Value | 0x00020000 |

| Flag Name | NotifyAuthComplete |
| --- | --- |
| Description | Notify if the client's identity has been negotiated with the client. Because of the timing of this notification, the AUTH_USER server variable can be used to reliably obtain the identity of the user. If the value of this property is 1, then the filter registers for the SF_NOTIFY_AUTH_COMPLETE notification. If the value is 0, the filter does not. |
| Metabase Bitmask Identifier | MD_NOTIFY_AUTH_COMPLETE |
| Decimal Value | 67108864 |
| Hexadecimal Value | 0x04000000 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterLoadOrder Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The value of **FilterLoadOrder**, is a comma-delimited list, which specifies the order that filters are to be loaded, such as Filter1, Filter2, and so on.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_FILTER_LOAD_ORDER |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2040 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters<br>/LM/W3SVC/*n*/Filters | IIsFilters |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterPath Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FilterPath** property specifies the full path to a filter DLL; for example C:\Wwwroot\Bin\Filter.dll.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_FILTER_IMAGE_PATH |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2041 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters<br><br>/LM/W3SVC/*n*/Filters | IIsFilters |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FilterState Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FilterState** property indicates whether the installed filter is loaded or unloaded, as defined in the Bitmask Values table.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_FILTER_STATE |
| Attributes | NO_ATTRIBUTES |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2042 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/Filters/*filter_name*<br><br>/LM/W3SVC/*n*/Filters/*filter_name* | IIsFilter |

**Values**

| Constant | Value | Description |
| --- | --- | --- |
| MD_FILTER_STATE_LOADED | 0x00000001 | Filter is loaded. |
| MD_FILTER_STATE_UNLOADED | 0x00000004 | Filter is unloaded. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FrontPageWeb Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FrontPageWeb** property indicates whether a server instance will be targeted by Microsoft FrontPage. Setting **FrontPageWeb** to **true** causes FrontPage Manager to create the files required for FrontPage Server Extensions. Setting **FrontPageWeb** to **false** causes these files to be deleted.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_FRONTPAGE_WEB |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2072 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br><br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| LM/W3SVC/*n*/ROOT/*physical_directory_name*<br><br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FsPropertyPath Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FsPropertyPath** property contains the path to driver property files.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46158 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT<br>/LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FtpDirBrowseShowLongDate Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FtpDirBrowseShowLongDate** indicates whether to display two-digit or four-digit years when browsing directories.

| **Note** |
| --- |
| The **MSDOSDirOutput** property allows UNIX-style directory browsing, and if set to **false**, **FtpDirBrowseShowLongDate** will have no effect. **FtpDirBrowseShowLongDate** is valid only when **MSDOSDirOutput**=**true**, which sets the directory output to MS-DOS format. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_SHOW_4_DIGIT_YEAR |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 5010 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/MSFTPSVC/*n*/ROOT<br>/LM/MSFTPSVC/*n*/ROOT/*virtual_directory_name* | IIsFtpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FtpLogInUtf8 Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FtpLogInUtf8** property is used by IIS.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_FTP_LOG_IN_UTF_8 |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5013 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# FullyQualifiedDomainName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **FullyQualifiedDomainName** contains the fully qualified domain name (FQDN) of the Simple Mail Transfer Protocol (SMTP) virtual server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_FQDN_VALUE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36935 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# GreetingMessage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **GreetingMessage** property specifies the message text an FTP server transmits to a client once the client logs in to the FTP server and is authenticated.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_GREETING_MESSAGE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5002 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# GroupHelpFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **GroupHelpFile** property contains the path to the descript.txt file, which is currently unused.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |

# GroupListFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **GroupListFile** property contains the path to the *group.lst* file.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45157 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# GroupvarListFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **GroupvarListFile** property contains the path to the *groupvar.lst* file.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45182 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcCacheControlHeader Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcCacheControlHeader** property specifies the directive that IIS adds to the Cache-Control header. This header, along with the Expires header specified by HcExpiresHeader Metabase Property, is included with every compressed file that is sent to a client browser.

The **HcCacheControlHeader** property specifies a header that overrides the HTTP Expires header, which is specified by **HcExpiresHeader**, and is included to ensure that older clients and proxy servers do not attempt to cache compressed files.

Neither the header specified by **HcCacheControlHeader** nor the header specified by **HcExpiresHeader** is sent with a response if the metabase property HcSendCacheHeaders Metabase Property is set to **false**.

The World Wide Web Publishing Service (WWW service) must be restarted before changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_HC_CACHE_CONTROL_HEADER |
| Attributes | NO_ATTRIBUTES |
| Default Value | max-age=86400 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2211 |

**Configurable Locations**
You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**
For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

# HcCompressionBufferSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcCompressionBufferSize** property specifies the size of the compression buffer (in bytes) that IIS uses for receiving compressed data. This buffer is used for on-demand compression of static content, as well as dynamic content compression. A larger buffer yields slightly faster compression performance, but at the cost of using additional memory.

The size limit specified by **HcCompressionBufferSize** is used by IIS, only if either HcDoOnDemandCompression Metabase Property or HcDoDynamicCompression Metabase Property are set to **true**. The maximum allowable size of the compression buffer is 1,048,576 bytes (1 MB).

The World Wide Web Publishing Service (WWW service) must be restarted before changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_COMPRESSION_BUFFER_SIZE |
| Attributes | NO_ATTRIBUTES |
| Default Value | 8192 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2223 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- HcDoDynamicCompression Metabase Property

# HcCompressionDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcCompressionDirectory** property specifies the directory where compressed versions of static files are temporarily cached. If compression is enabled for IIS, every time IIS receives a request for a static file, such as an .htm or .txt file, the server searches the compression directory for an already compressed version of the requested static file.

To force IIS to recompress all outgoing static files, delete all files found in the compression directory specified by **HcCompressionDirectory**.

| **Important** |
| --- |
| It is strongly recommended that the directory specified by **HcCompressionDirectory** reside on an NTFS file system volume, not on a FAT volume. If the file being requested resides on an NTFS volume, and you have set **HcCompressionDirectory** to specify a FAT volume, IIS will not perform HTTP compression on that file. This behavior is due to a number of differences between FAT and NTFS volumes, such as time stamping and access control mechanisms. In addition, NTFS handles directories that contain a large number of files more efficiently than FAT volumes do. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | EXPANDSZ |
| WMI Data Type | String |
| ADSI Data Type | EXPANDSZ |
| ABO Data Type | EXPANDSZ |
| ABO Metabase Identifier | MD_HC_COMPRESSION_DIRECTORY |
| Attributes | NO_ATTRIBUTES |
| Default Value | %windir%\iis temporary compressed files |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2210 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

# HcCompressionDll Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcCompressionDll** property specifies the fully qualified file system path and file name of the compression DLL associated with the compression scheme.

The World Wide Web Publishing Service (WWW service) must be restarted before changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | EXPANDSZ |
| WMI Data Type | String |
| ADSI Data Type | EXPANDSZ |
| ABO Data Type | EXPANDSZ |
| ABO Metabase Identifier | MD_HC_COMPRESSION_DLL |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2237 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip<br>/LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcCreateFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcCreateFlags** property contains a flag that is passed to the **HcCompressionDLL** property. This flag identifies the compression schema to be used (either "gzip" or "deflate").

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_CREATE_FLAGS |
| Attributes | NO_ATTRIBUTES |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2243 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip /LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcDoDiskSpaceLimiting Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcDoDiskSpaceLimiting** allows you to limit the amount of disk space that all compressed files, which are stored in the compression directory specified by HcCompressionDirectory Metabase Property can occupy. If **HcDoDiskSpaceLimiting** is set to **true**, IIS will not allow compressed files to occupy more than the number of bytes specified by HcMaxDiskSpaceUsage Metabase Property. Once the limit is reached, compressed files are removed from the compression directory on an LRU (least-recently) basis. If **HcDoDiskSpaceLimiting** is set to **false**, no limit is enforced on the amount of disk space that the files in the compression directory can occupy.

| **Note** |
| --- |
| Limiting the use of disk space has a significant impact on performance because additional overhead is required to check for the limit. Use this feature only when you lack adequate disk space to cache all content files on your Web server. |

**HcDoDiskSpaceLimiting** is relevant only if you have set the property HcDoOnDemandCompression Metabase Property to **true**.

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_DO_DISK_SPACE_LIMITING |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2216 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

# HcDoDynamicCompression Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcDoDynamicCompression** property specifies whether responses to requests for dynamic content, such as scripts in ASP pages and ISAPI extensions are compressed. Setting **HcDoDynamicCompression** to **true**, indicates that dynamic content is compressed when requested by a client. If dynamic compression is enabled, each request for dynamic content that contains the "Accept-Encoding: gzip" or "Accept-Encoding: deflate" header causes the content to be compressed, as long as the compression scheme that is specified in the header is enabled in IIS. If the request does not contain this header, or the header specifies a compression scheme that is not enabled in IIS, the content is not compressed.

| **Note** |
| --- |
| Because dynamic content is always changing, IIS does not cache compressed versions of dynamic content. Dynamic compression consumes considerable CPU time and memory resources, and should only be used on servers that have slow network connections and CPU time to spare. |

At the individual compression scheme level (**IIsCompressionScheme**), the **HcDoDynamicCompression** property determines which compression schemes IIS will support for dynamic content: gzip, deflate, or both.

You can either enable compression of dynamic content server-wide and then disable it at specific locations, or you can disable compression of dynamic content server-wide and then enable it only at the locations you specify. To enable and disable dynamic compression by using the **HcDoDynamicCompression** property, do the following:

- To enable dynamic content compression server-wide, set the **HcDoDynamicCompression** property to **true** at the **IIsCompressionSchemes** level. You can then disable dynamic content compression settings for an individual Web site or site element, for example, a virtual directory or file, by using the DoDynamicCompression Metabase Property at the individual site or site element level.

- To disable dynamic content compression server-wide, set the **HcDoDynamicCompression** property to **false** at the **IIsCompressionSchemes** level. You can then enable dynamic content compression settings for an individual Web site or site element, for example, a virtual directory or file, by using the DoDynamicCompression Metabase Property at the individual site or site element level.

| **Important** |
| --- |
| If you change the value of the **HcDoDynamicCompression**property at the **IIsCompressionScheme** level, the World Wide Web Publishing Service (WWW service) must be restarted before the change takes effect. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_DO_DYNAMIC_COMPRESSION |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |

| | |
|---|---|
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2213 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip<br><br>/LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcDoOnDemandCompression Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcDoOnDemandCompression** property specifies whether static files, such as .htm and .txt files, are compressed if a compressed version of the file does not exist in the compression directory specified by HcCompressionDirectory Metabase Property.

For on-demand compression of static files to occur, **HcDoOnDemandCompression** must be set to **true** at the global (**IIsCompressionSchemes**) level and at least one compression scheme (**IIsCompressionScheme**) level. The supported compression schemes are gzip and deflate. For information about the levels that this property can be set, see the Access Locations table.

If **HcDoOnDemandCompression** is set to **true** at the **IIsCompressionScheme** level and at least one **IIsCompressionSchemes** level, and IIS receives a request for static content, IIS checks the compression directory. If a corresponding compressed version of the requested file is not found, IIS will send an uncompressed version of the requested file to the client browser, while a background thread compresses the requested file. The newly compressed file is then stored in the compression directory, and subsequent requests for that file are serviced directly from the compression directory. In other words, an uncompressed version of the file is returned to the client, unless a compressed version of the file already exists in the compression directory.

If **HcDoOnDemandCompression** is set to **false**, at the global level, IIS does not compress static content files when a corresponding compressed version is not found in the compression directory.

If you change the value of **HcDoOnDemandCompression** at the individual compression scheme level, the World Wide Web Publishing Service (WWW service) must be restarted for the change to take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_DO_ON_DEMAND_COMPRESSION |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2215 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip /LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- HcCompressionDirectory Metabase Property

# HcDoStaticCompression Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcDoStaticCompression** property specifies whether responses to requests for static content, such as such as .htm and .txt files are compressed. Setting **HcDoStaticCompression** to **true**, indicates that static content is compressed when requested by a client. If static compression is enabled, each request for static content that contains the "Accept-Encoding: gzip" or "Accept-Encoding: deflate" header causes the content to be compressed, so long as the compression scheme specified in the header is enabled in IIS. If the request does not contain this header, or the header specifies a compression scheme that is not enabled in IIS, the content is not compressed.

If IIS determines that the response should be compressed, IIS checks the compression directory specified by the HcCompressionDirectory Metabase Property. If a fresh, compressed version of the static file is found in the directory, it is sent to the client browser. If a fresh, compressed version of the file is not found, and on-demand compression is enabled with HcDoOnDemandCompression Metabase Property, IIS sends the requested file in uncompressed form, and adds that file to the background compression queue.

At the individual compression scheme level (**IIsCompressionScheme**), the **HcDoStaticCompression** property determines which compression schemes IIS will support for static content: gzip, deflate, or both.

You can either enable compression of static content server-wide and then disable it at specific locations, or you can disable compression of static content server-wide and then enable it only at the locations you specify. To enable and disable static compression by using the **HcDoStaticCompression** property, do the following:

- To enable static compression server-wide, set the **HcDoStaticCompression** property to **true** at the **IIsCompressionSchemes** level. You can then disable static file compression settings for an individual Web site or site element -- for example, a virtual directory or file -- by using the DoStaticCompression property at the individual site or site element level.

- To disable static compression server-wide, set the **HcDoStaticCompression** property to **false** at the **IIsCompressionSchemes** level. You can then enable static file compression for an individual Web site or site element -- for example, a virtual directory or file -- by using the DoStaticCompression property at the individual site or site element level.

| **Important** |
| --- |
| If you change the value of the **HcDoStaticCompression** property at the **IIsCompressionScheme** level, the World Wide Web Publishing Service (WWW service) must be restarted before the change takes effect. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |

# HcDynamicCompressionLevel Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcDynamicCompressionLevel** property specifies the compression level for the compression scheme, when the scheme is compressing dynamic content. Low compression levels produce slightly larger compressed files, but with lower overall impact on CPU and memory resources. Higher compression levels generally result in smaller compressed files, but with higher CPU and memory usage.

The World Wide Web Publishing Service (WWW service) must be restarted for any changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_DYNAMIC_COMPRESSION_LEVEL |
| Attributes | NO_ATTRIBUTES |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2241 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip /LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcExpiresHeader Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcExpiresHeader** property specifies the content of the HTTP Expires header that is sent with all requested compressed files, along with the Cache-Control header discussed in HcCacheControlHeader Metabase Property.

The combination of **HcExpiresHeader** and **HcCacheControlHeader** ensures that older clients and proxy servers do not attempt to cache compressed files.

Neither the header specified by **HcCacheControlHeader**, nor the header specified by **HcExpiresHeader**, is sent with the response if the metabase property HcSendCacheHeaders Metabase Property is set to **false**.

The World Wide Web Publishing Service (WWW service) must be restarted before any changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_HC_EXPIRES_HEADER |

# HcFileExtensions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcFileExtensions** indicates which file name extensions are supported by the compression scheme. Only static files with the specified file extensions are compressed by IIS. If this setting is empty, no static files are compressed.

In addition to file name extension matches, HcDoOnDemandCompression Metabase Property and HcDoStaticCompression Metabase Property must be set to **true** for compression to be performed.

The World Wide Web Publishing Service (WWW service) must be restarted for any changes to this property take effect.

| Attribute Name | Attribute Value |

- HcScriptFileExtensions Metabase Property

# HcFilesDeletedPerDiskFree Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcFilesDeletedPerDiskFree** property specifies the number of compressed files that are deleted from the compression directory when IIS determines that the compression directory has grown beyond its limits. IIS deletes a number of files equal to the setting of this property, starting with the LRU (least-recently used) files.

The **HcFilesDeletedPerDiskFree** property is relevant only if HcDoDiskSpaceLimiting Metabase Property is set to **true**, and HcMaxDiskSpaceUsage Metabase Property is set to something other than 0xFFFFFFFF (unlimited). The maximum allowable value of **HcFilesDeletedPerDiskFree** is 1024.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_FILES_DELETED_PER_DISK_FREE |
| Attributes | NO_ATTRIBUTES |
| Default Value | 256 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2225 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcIoBufferSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcIoBufferSize** property specifies the size of the buffer (in bytes) that IIS uses to read uncompressed files. A larger buffer yields slightly faster compression performance, but at the cost of additional memory usage.

**HcIoBufferSize** is used by IIS only if HcDoOnDemandCompression Metabase Property is set to **true**. The maximum allowable value is 1,048,576 bytes (1 MB).

The World Wide Web Publishing Service (WWW service) must be restarted before any changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_IO_BUFFER_SIZE |
| Attributes | NO_ATTRIBUTES |
| Default Value | 8192 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2222 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcMaxDiskSpaceUsage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcMaxDiskSpaceUsage** property specifies whether IIS limits the number of bytes of disk space occupied by compressed files in the compression directory.

Disk space limiting is performed, and **HcMaxDiskSpaceUsage** is checked by IIS, only if HcDoDiskSpaceLimiting Metabase Property is set to **true**. If **HcMaxDiskSpaceUsage** is set to 4294967295, there will be no limit on the number of bytes occupied by compressed files.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_MAX_DISK_SPACE_USAGE |
| Attributes | NO_ATTRIBUTES |
| Default Value | 1000000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2221 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcMaxQueueLength Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS performs on-demand compression of static content in the background. When a static file is requested, and IIS has determined that a previously compressed version of the requested file does not already exist in the compression directory, the request is put into a simple FIFO (first in, first out) queue. The **HcMaxQueueLength** property specifies how many concurrent background compression requests can be in the queue. If the queue is full, additional compression requests are ignored until there is room in the queue.

If **HcMaxQueueLength** is set to 4294967295, there is no limit to the number of pending requests in the queue.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_MAX_QUEUE_LENGTH |
| Attributes | NO_ATTRIBUTES |
| Default Value | 1000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2224 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcMinFileSizeForComp Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcMinFileSizeForComp** allows you to specify the minimum number of bytes a file must contain for it to be compressed using on-demand compression. Very small files do not compress well, and in some cases, compression may even make the file larger than it was initially.

If **HcMinFileSizeForComp** is set to 0 (zero), all files are compressed.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_MIN_FILE_SIZE_FOR_COMP |
| Attributes | NO_ATTRIBUTES |
| Default Value | 256 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2226 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcNoCompressionForHttp10 Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcNoCompressionForHttp10** property disables compression for requests containing an HTTP 1.0 version number. HTTP 1.0, as described in RFC 1945, provides a minimal level of support for certain types of compression. However, some confusion exists around HTTP 1.0 compression, especially with regard to proxy servers. To minimize the chance of inappropriately returning a compressed file to a client that cannot decompress it, you can use this metabase property to disable compression in questionable scenarios.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_NO_COMPRESSION_FOR_HTTP_10 |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2217 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcNoCompressionForProxies Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcNoCompressionForProxies** allows you to disable the HTTP 1.1 response for compression requests that have come through proxy servers. Certain HTTP proxy servers, including some advertised as HTTP 1.1 compliant, do not correctly handle the caching of compressed objects.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_NO_COMPRESSION_FOR_PROXIES |
| Attributes | NO_ATTRIBUTES |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2218 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcNoCompressionForRange Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcNoCompressionForRange** property specifies how IIS handles HTTP Range requests. The HTTP 1.1 Request for Comment, RFC 2068, is ambiguous about whether Range requests apply to the compressed or uncompressed version of a file. Some browsers could be unprepared for compressed Range responses. As a result, IIS, by default, does not send compressed responses to Range requests, to avoid problems with browser misbehavior.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_NO_COMPRESSION_FOR_RANGE |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2219 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcOnDemandCompLevel Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcOnDemandCompLevel** property specifies the compression level for the compression scheme, when the scheme is to compress static content on demand. Low compression levels produce slightly larger compressed files, but with lower overall impact on CPU and memory resources. Higher compression levels generally result in small compressed files but with higher CPU and memory usage.

Valid compression levels range from 1 to 10.

The World Wide Web Publishing Service (WWW service) must be restarted before any changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_ON_DEMAND_COMP_LEVEL |
| Attributes | NO_ATTRIBUTES |
| Default Value | 10 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2242 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip /LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- HcDynamicCompressionLevel Metabase Property

# HcPriority Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcPriority** property specifies the priority rating assigned to a particular compression scheme. If your installation of IIS has multiple compression schemes installed and a client browser indicates, in the Accept-Encoding header, that it can handle multiple compression schemes, IIS uses the priority numbers specified in **HcPriority** to determine which scheme to use for the request. In that case, IIS uses the matching scheme that has the highest priority number.

Valid priority numbers range from 1 to 10. In general, if you have multiple compression schemes installed with IIS, you should assign each compression scheme a different priority number.

The World Wide Web Publishing Service (WWW service) must be restarted before any changes to this property take effect.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HC_PRIORITY |
| Attributes | NO_ATTRIBUTES |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2240 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Filters/Compression/gzip /LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HcScriptFileExtensions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcScriptFileExtensions** indicates which file name extensions are supported by the compression scheme. The output from dynamic files with the file extensions specified in this property are compressed by IIS.

| **Important** |
| --- |
| Setting this parameter to an empty string can have an adverse effect on your server's performance. |

If this parameter is empty, all dynamic responses are sent compressed. In addition, any static file type not specified in HcFileExtensions Metabase Property is dynamically compressed and therefore, not cached.

Also, HcDoDynamicCompression Metabase Property must be set to **true** for dynamic compression to be performed.

The World Wide Web Publishing Service (WWW service) must be restarted before any changes to this property take effect.

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_HC_SCRIPT_FILE_EXTENSIONS |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2244 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/Filters/Compression/gzip /LM/W3SVC/Filters/Compression/deflate | IIsCompressionScheme |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- HcFileExtensions Metabase Property

# HcSendCacheHeaders Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HcSendCacheHeaders** property specifies whether the headers specified by HcCacheControlHeader Metabase Property and HcExpiresHeader Metabase Property are sent with each compressed response. If this property is set to **true**, Cache-Control and Expires headers are sent with all compressed responses. If this property is set to **false**, however, only the HTTP 1.1 Vary header is sent.

| **Important** |
| --- |
| In general, the Cache-Control and Expires HTTP headers are included with compressed responses to prevent inappropriate caching of compressed files, especially by proxy servers and older browsers. If you choose to disable these headers, you should also set HcNoCompressionForProxies Metabase Property and HcNoCompressionForHttp10 Metabase Property to **true**. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_HC_SEND_CACHE_HEADERS |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2220 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/Filters/Compression/Parameters | IIsCompressionSchemes |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HeaderWaitTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HeaderWaitTimeout** property specifies the amount of time (in seconds) the server waits for all HTTP headers for the request (indicated by a double carriage return) to be received before disconnecting the client. The purpose of this property is to help prevent a common variant of the Denial of Service (DoS) attack that attempts to max out connection limits and keep those connections connected.

In IIS 6.0, use this property in conjunction with the **ConnectionTimeout** property, and for Web service nodes, use the **MinFileBytesPerSec** property instead of the **ServerListenTimeout** property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HEADER_WAIT_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9204 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HistoryExpiration Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HistoryExpiration** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45057 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HistoryMajorVersionNumber Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HistoryMajorVersionNumber** is used internally only by IIS to keep track of the major version number of the MetaBase.xml and MBSchema.xml files. The major version number is also used to version and name history files.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_GLOBAL_EDIT_WHILE_RUNNING_MAJOR_VERSION_NUMBER |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| StartingNumber | Not applicable |
| EndingNumber | Not applicable |
| ID | 9994 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| . | IIS_Global |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HistoryTableFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HistoryTableFile** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45159 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HonorClientMsgIds Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HonorClientMsgIds** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45058 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HopCount Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HopCount** property specifies the number of hops that are allowed before a message is determined to be in a looping condition and marking for non-delivery.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_HOP_COUNT |
| Attributes | INHERIT |
| Default Value | 10 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36886 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/n | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HttpCustomHeaders Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HttpCustomHeaders** property contains custom headers that are sent to the client, in addition to the default header of the HTML file. Each string in this property is formatted as a key name and value pair: *Keyname: Value*.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_HTTP_CUSTOM |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6004 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HttpErrors Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HttpErrors** property specifies the custom error string sent to clients in response to HTTP 1.1 errors. Each string in the list specifies the HTTP error code and subcode, indicates whether the handler will be a URL or a file, and specifies which URL or file the client will be sent. Each string can be in either format: a URL or a file.

To send a URL to the client, use *HTTPErrorCode*, *HTTPErrorSubcode*, URL, *HandlerURL*. To send a file, use *HTTPErrorCode*, *HTTPErrorSubcode*, FILE, *Filename*.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_CUSTOM_ERROR |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6008 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- CustomErrorDescriptions Metabase Property

# HttpExpires Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HttpExpires** property specifies the expiration of HTML document content by returning the value to the browser in the HTML file header. The browser compares the given value with the current date to determine whether to display a cached page or to request an updated page from the server. This property can be made relative, or dynamic, by using the format D, *#SecondsUntilExpiration*, with 0xFFFFFFFF indicating no expiration date. It can also be absolute, with the format *S,ValidGMTstring*.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_HTTP_EXPIRES |
| Attributes | INHERIT |
| Default Value | d, 0x15180 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6002 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HttpPics Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HttpPics** property specifies the World Wide Web Consortium (W3C) Platform for Internet Content Selection (PICS) rating header. For more information about PICS, see the World Wide Web Consortium Web site.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_HTTP_PICS |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# HttpRedirect Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **HttpRedirect** property specifies the directory or URL to which a client is redirected when attempting to access a specific resource. There are two general forms that the value for this property can take.

The simple format is *Destination,Flag*.

- Where Destination can specify either a URL or a virtual path to a file.
- Where *Flag* can have one of four values:
- EXACT_DESTINATION indicates that the value provided for *Destination* should be considered an absolute target location.
- CHILD_ONLY indicates that the value should be added to the beginning of the file name of the request to be redirected.
- PERMANENT indicates that this redirection is permanent for this resource.
- TEMPORARY indicates that this redirection is temporary for this resource.

The more complex form involves the use of wildcards. The format is *; *Wildcard1*; *Destination1*; *Wildcard2*; *Destination2*, *Flag*. Each *Wildcard*; *Destination* pair indicates that requests matching the wildcard are redirected to the specified destination. *Flag* can have the same values as the simple string format.

| **Important** |
| --- |
| Setting **HttpRedirect** at the site or service level has no affect. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_HTTP_REDIRECT |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6011 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |

# IdleTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **IdleTimeout** property specifies how long (in minutes) a worker process should run idle if no new requests are received and the worker process is not processing requests. After the allotted time passes, the worker process should request to be shut down by the World Wide Web Publishing Service (WWW Service).

| **Note** |
| --- |
| If the value of this property is less than the value of PeriodicRestartTime Metabase Property, IIS sets both properties to their default values. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_IDLE_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 20 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9005 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# Iis5IsolationModeEnabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **IIs5IsolationModeEnabled** property specifies whether to run in IIS 5.0 isolation mode. Setting this property to **true** causes IIS to run in IIS 5.0 isolation mode. Setting this property to **false** causes IIS to run in worker process isolation mode.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_GLOBAL_STANDARD_APP_MODE_ENABLED |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9203 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ImapClearTextProvider Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is reserved for future use by Microsoft Exchange.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 49375 |

**Configurable Locations**

Currently, this property is not configurable at any location in the IIS metabase.

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ImapDefaultDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is reserved for future use by Microsoft Exchange.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |

**Configurable Locations**

Currently, this property is not configurable at any location in the IIS metabase.

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# InProcessIsapiApps Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **InProcessIsapiApps** property specifies a list of ISAPI filters and extensions that must be run in the Web server process. The string format is either *Fullpath\Appname*.dll, or just *Appname*.dll. ISAPI DLL entries without a qualifying path will match any ISAPI request that contains the DLL name, regardless of the physical path specified in the request.

For example, any of the following would be a valid list for this property: "D:\winnt\system32\inetsrv\ssinc.dll", "D:\winnt\system32\inetsrv\httpodbc.dll", "author.dll", "shtml.dll", "admin.dll".

| **Note** |
| --- |
| This property only indicates which ISAPI applications are required to run in the Web server process. The inclusion of an application in this list does not imply that the application is automatically run when starting up the server. There can be significant performance issues if too many applications are forced to run outside of the server process. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_IN_PROCESS_ISAPI_APPS |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2073 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- AppIsolated Metabase Property

# IPSecurity Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **IPSecurity** property specifies the IP access restrictions for a URL. This property can be used to assign or deny access to browsers, based on either their IP address or DNS host name. For more information about managing this property, see the **IIsIPSecurity** object in the IIS ADSI Provider reference section of the IIS Software Development Kit (SDK).

There are no flags for this property.

# KeyType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **KeyType** property specifies the type of metabase key and the IIS Admin Object that relates to that key. The **KeyType** property specifies the class of the object associated with the key, such as **IIsWebServer** or **IIsWebVirtualDir**. The **KeyType** determines the set of properties accessible at the key.

| **Note** |
| --- |
| The **KeyType** property is accessible by all IIS Admin Objects. The value is the name of the IIS Admin Object accessed, and is the same as the ADSI Class property. |

| **Attribute Name** | **Attribute Value** |

# LimitRemoteConnections Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LimitRemoteConnections** property specifies the maximum number of inbound remote connections allowed at one time for a given virtual server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36926 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ListFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ListFile** property contains the path to the *listfile.hsh* file.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45172 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LoadBalancerCapabilities Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LoadBalancerCapabilities** property specifies behavior when a service is unavailable. A setting of 1 terminates the connection. A setting of 2 sends error code 503.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOAD_BALANCER_CAPABILITIES |
| Attributes | INHERIT |
| Default Value | 2 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9034 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LocalDomains Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LocalDomains** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36919 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LocalRetryAttempts Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LocalRetryAttempts** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOCAL_RETRY_ATTEMPTS |
| Attributes | INHERIT |
| Default Value | 48 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36896 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LocalRetryInterval Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LocalRetryInterval** property specifies the number of minutes between retries for local delivery.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOCAL_RETRY_MINUTES |
| Attributes | INHERIT |
| Default Value | 60 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36897 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogAnonymous Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogAnonymous** property specifies whether anonymous requests are logged to the event log.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_LOG_ANONYMOUS |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5007 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyDataType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyDataType** property contains bitmask values that indicate the data type of a custom logging field. The bitmask values are listed in the Bitmask Values section.

For more information about custom logging fields, see "Setting Metabase Properties for Logging" in the Platform SDK.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGCUSTOM_SERVICES_string |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4505 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br>/LM/logging/Custom Logging/Date<br>/LM/logging/Custom Logging/Time<br>/LM/logging/Custom Logging/Extended Properties<br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_LOGCUSTOM_DATATYPE_INT | 0x00000000 | Datatype is int. |
| MD_LOGCUSTOM_DATATYPE_UINT | 0x00000001 | Datatype is unsigned int. |
| MD_LOGCUSTOM_DATATYPE_LONG | 0x00000002 | Datatype is long. |
| MD_LOGCUSTOM_DATATYPE_ULONG | 0x00000003 | Datatype is unsigned long. |

| | | |
|---|---|---|
| MD_LOGCUSTOM_DATATYPE_FLOAT | 0x00000004 | Datatype is float. |
| MD_LOGCUSTOM_DATATYPE_DOUBLE | 0x00000005 | Datatype is double. |
| MD_LOGCUSTOM_DATATYPE_LPSTR | 0x00000006 | Datatype is long pointer to string array. |
| MD_LOGCUSTOM_DATATYPE_LPWSTR | 0x00000007 | Datatype is lpwstr. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyHeader Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyHeader** property indicates which header string will be written to the log file for the custom logging field.

For more information about custom logging fields, see "Setting Metabase Properties for Logging" in the Platform SDK.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOGCUSTOM_PROPERTY_HEADER |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4502 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br>/LM/logging/Custom Logging/Date<br>/LM/logging/Custom Logging/Time<br>/LM/logging/Custom Logging/Extended Properties<br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyID** property specifies the ABO Metabase identifier of the metabase property that determines if logging is enabled or disabled for the logging field in question. Consult the metabase property reference page, to obtain the ABO Metabase identifier for a particular property.

For instance, the ABO Metabase identifier for LogExtFileFlags Metabase Property is MD_LOGEXT_FIELD_MASK, and the ID number is 4013.

When a logging module is called to log custom information fields, the logging module accesses the property specified by **LogCustomPropertyID**, and checks the individual flag bits, specified by LogCustomPropertyMask Metabase Property, to determine if that particular field is currently enabled or disabled.

For more information about custom logging fields, see "Setting Metabase Properties for Logging" in the Platform SDK.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGCUSTOM_PROPERTY_ID |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4503 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br>/LM/logging/Custom Logging/Date<br>/LM/logging/Custom Logging/Time<br>/LM/logging/Custom Logging/Extended Properties<br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyMask Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyMask** property specifies the bitmask that can be used against the metabase property, specified by LogCustomPropertyID Metabase Property, to determine whether the particular logging field is currently enabled or disabled.

When a logging module logs custom information fields, the logging module accesses the property specified by **LogCustomPropertyID**, and checks the individual flag bits, specified by **LogCustomPropertyMask**, to determine if that particular field is currently enabled or disabled.

For more information about custom logging fields, see "Setting Metabase Properties for Logging" in the Platform SDK.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGCUSTOM_PROPERTY_MASK |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4504 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br>/LM/logging/Custom Logging/Date<br>/LM/logging/Custom Logging/Time<br>/LM/logging/Custom Logging/Extended Properties<br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyName** property specifies the name of the custom logging information field. Typically, this name is the same as the name used in the logging module user interface.

For more information about custom logging fields, see "Setting Metabase Properties for Logging" in the Platform SDK.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOGCUSTOM_PROPERTY_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| StartingNumber | Not applicable |
| EndingNumber | Not applicable |
| ID | 4501 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br>/LM/logging/Custom Logging/Date<br>/LM/logging/Custom Logging/Time<br>/LM/logging/Custom Logging/Extended Properties<br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyNodeID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyNodeID** property contains the numeric ID of the logging information field for identification purposes. Each field has a corresponding flag in the **LogExtFileFlags** property which should be set if you want the information logged.

| Information Field | Numeric ID of the Field |
|---|---|
| Bytes Received | 17 |
| Bytes Send | 16 |
| Client IP Address | 5 |
| Cookie | 22 |
| Date | 1 |
| Extended Properties | 3 |
| Host | 20 |
| Method | 11 |
| Protocol Status | 14 |
| Protocol Version | 19 |
| Referer | 23 |
| Server IP Address | 9 |
| Server Name | 8 |
| Server Port | 10 |
| Service Name | 7 |
| Time | 2 |
| Time Taken | 18 |
| URI Query | 13 |
| URI Stem | 12 |
| User Agent | 21 |
| User Name | 6 |

| | |
|---|---|
| Win32 Status | 15 |

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_NOTIFY_ORDER_MASK |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4508 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br>/LM/logging/Custom Logging/Date<br>/LM/logging/Custom Logging/Time<br>/LM/logging/Custom Logging/Extended Properties<br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogCustomPropertyServicesString Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogCustomPropertyServicesstring** property specifies to which services the custom logging fields apply.

For more information about custom logging fields, see "Setting Metabase Properties for Logging" in the Platform SDK.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_LOGCUSTOM_SERVICES_string |
| Attributes | INHERIT |
| Default Value | w3svc<br>msftpsvc<br>smtpsvc<br>nntpsvc |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4506 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Custom Logging<br><br>/LM/logging/Custom Logging/Date<br><br>/LM/logging/Custom Logging/Time<br><br>/LM/logging/Custom Logging/Extended Properties<br><br>/LM/logging/Custom Logging/Extended Properties/*extended_property_name* | IIsCustomLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogEventOnRecycle Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogEventOnRecycle** property specifies that IIS should log an event when an application pool is recycled. Application pools recycle for a variety of reasons. In order for IIS to log the event, the **LogEventOnRecycle** property must have a bit set corresponding to the reason for the recycle.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APP_POOL_LOG_EVENT_ON_RECYCLE |
| Attributes | INHERIT |
| Default Value | APPPOOLRECYCLEMEMORY |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9037 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Flags**

| Flag Name | AppPoolRecycleTime |
|---|---|
| Description | **Important** This feature of IIS 6.0 is available only when IIS is running in worker process isolation mode. For more information, see Recycling Worker Processes with IIS 6.0.<br><br>Setting this flag to **true** causes IIS to log the event (the worker process is recycled after a specified elapsed time). |
| Metabase Bitmask Identifier | MD_APP_POOL_RECYCLE_TIME |

# LogExtFileFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogExtFileFlags** property contains flags that determine which categories of information are written to either the log file or ODBC data source during logging events. The flags are described in the Flags section.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGEXT_FIELD_MASK |
| Attributes | INHERIT |
| Default Value | logextfiletime \| logextfileclientip \|logextfilemethod \| logextfileuristem \| logextfilehttpstatus |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9013 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Flags**

| Flag Name | LogExtFileDate |
|---|---|
| Description | Log the date. |
| Metabase Bitmask Identifier | MD_EXTLOG_DATE |

| | |
|---|---|
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| **Flag Name** | **LogExtFileHost** |
|---|---|
| Description | Log the name of host server. |
| Metabase Bitmask Identifier | MD_EXTLOG_HOST |
| Decimal Value | 1048576 |
| Hexadecimal Value | 0x00100000 |

| **Flag Name** | **LogExtFileTime** |
|---|---|
| Description | Log the time. |
| Metabase Bitmask Identifier | MD_EXTLOG_TIME |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| **Flag Name** | **LogExtFileClientIp** |
|---|---|
| Description | Log the client IP address. |
| Metabase Bitmask Identifier | MD_EXTLOG_CLIENT_IP |
| Decimal Value | 4 |
| Hexadecimal Value | 0x00000004 |

| **Flag Name** | **LogExtFileUserName** |
|---|---|
| Description | Log the username. |
| Metabase Bitmask Identifier | MD_EXTLOG_USERNAME |
| Decimal Value | 8 |
| Hexadecimal Value | 0x00000008 |

| **Flag Name** | **LogExtFileSiteName** |
|---|---|
| Description | Log the site name. |
| Metabase Bitmask Identifier | MD_EXTLOG_SITE_NAME |
| Decimal Value | 16 |
| Hexadecimal Value | 0x00000010 |

| **Flag Name** | **LogExtFileComputerName** |
|---|---|
| Description | Log the local computer name. |
| Metabase Bitmask Identifier | MD_EXTLOG_COMPUTER_NAME |
| Decimal Value | 32 |
| Hexadecimal Value | 0x00000020 |

| Flag Name | LogExtFileServerIp |
|---|---|
| Description | Log the server's own IP address. |
| Metabase Bitmask Identifier | MD_EXTLOG_SERVER_IP |
| Decimal Value | 64 |
| Hexadecimal Value | 0x00000040 |

| Flag Name | LogExtFileMethod |
|---|---|
| Description | Log the protocol method. |
| Metabase Bitmask Identifier | MD_EXTLOG_METHOD |
| Decimal Value | 128 |
| Hexadecimal Value | 0x00000080 |

| Flag Name | LogExtFileUriStem |
|---|---|
| Description | Log the Universal Resource Identifier (URI) stem information. The URI stem usually consists of the actual resource being requested. |
| Metabase Bitmask Identifier | MD_EXTLOG_URI_STEM |
| Decimal Value | 256 |
| Hexadecimal Value | 0x00000100 |

| Flag Name | LogExtFileUriQuery |
|---|---|
| Description | Log the Universal Resource Identifier (URI) query information. The URI query usually consists of parameters passed to the URL by using the URL?Parameters format. |
| Metabase Bitmask Identifier | MD_EXTLOG_URI_QUERY |
| Decimal Value | 512 |
| Hexadecimal Value | 0x00000200 |

| Flag Name | LogExtFileHttpStatus |
|---|---|
| Description | Log the HTTP status. |
| Metabase Bitmask Identifier | MD_EXTLOG_HTTP_STATUS |
| Decimal Value | 1024 |
| Hexadecimal Value | 0x00000400 |

| Flag Name | LogExtFileWin32Status |
|---|---|
| Description | Log the current Microsoft Win32 error status. |
| Metabase Bitmask Identifier | MD_EXTLOG_WIN32_STATUS |
| Decimal Value | 2048 |
| Hexadecimal Value | 0x00000800 |

| **Flag Name** | **LogExtFileBytesSent** |
| --- | --- |
| Description | Log the total bytes sent. |
| Metabase Bitmask Identifier | MD_EXTLOG_BYTES_SENT |
| Decimal Value | 4096 |
| Hexadecimal Value | 0x00001000 |

| **Flag Name** | **LogExtFileBytesRecv** |
| --- | --- |
| Description | Log the total bytes received. |
| Metabase Bitmask Identifier | MD_EXTLOG_BYTES_RECV |
| Decimal Value | 8192 |
| Hexadecimal Value | 0x00002000 |

| **Flag Name** | **LogExtFileTimeTaken** |
| --- | --- |
| Description | Log the total time taken for a request to be completed. |
| Metabase Bitmask Identifier | MD_EXTLOG_TIME_TAKEN |
| Decimal Value | 16384 |
| Hexadecimal Value | 0x00004000 |

| **Flag Name** | **LogExtFileServerPort** |
| --- | --- |
| Description | Log the active server port. |
| Metabase Bitmask Identifier | MD_EXTLOG_SERVER_PORT |
| Decimal Value | 32768 |
| Hexadecimal Value | 0x00008000 |

| **Flag Name** | **LogExtFileUserAgent** |
| --- | --- |
| Description | Log the contents of the user agent field sent by the client. |
| Metabase Bitmask Identifier | MD_EXTLOG_USER_AGENT |
| Decimal Value | 65536 |
| Hexadecimal Value | 0x00010000 |

| **Flag Name** | **LogExtFileCookie** |
| --- | --- |
| Description | Log information from the client cookie. |
| Metabase Bitmask Identifier | MD_EXTLOG_COOKIE |
| Decimal Value | 131072 |
| Hexadecimal Value | 0x00020000 |

| **Flag Name** | **LogExtFileReferer** |
| --- | --- |
| Description | Log the referrer field sent by the client. |

| | |
|---|---|
| Metabase Bitmask Identifier | MD_EXTLOG_REFERER |
| Decimal Value | 262144 |
| Hexadecimal Value | 0x00040000 |

| **Flag Name** | **LogExtFileProtocolVersion** |
|---|---|
| Description | Log the client server protocol version. |
| Metabase Bitmask Identifier | MD_EXTLOG_PROTOCOL_VERSION |
| Decimal Value | 64 |
| Hexadecimal Value | 0x00080000 |

| **Flag Name** | **LogExtFileHttpSubStatus** |
|---|---|
| Description | Log the sub-status code of the HTTP error. For example, for the 500.18 HTTP error, the status code is 500 and the sub-status code is 18. |
| Metabase Bitmask Identifier | na |
| Decimal Value | 2097152 |
| Hexadecimal Value | 0x00200000 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogFileDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogFileDirectory** property specifies the default logging directory, where the log file and logging-related support files are stored.

| **Important** |
| --- |
| The specified log-file directory must be on the local computer. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | EXPANDSZ |
| WMI Data Type | String |
| ADSI Data Type | EXPANDSZ |
| ABO Data Type | EXPANDSZ |
| ABO Metabase Identifier | MD_LOGFILE_DIRECTORY |
| Attributes | INHERIT |
| Default Value | %windir%\system32\logfiles |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4001 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogFileLocaltimeRollover Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogFileLocaltimeRollover** property specifies IIS log file rollover behavior for W3C Extended logging. If the property is set to **false**, the default rollover behavior will be in effect, meaning a new log file will be created based on Coordinated Universal Time (UTC), not local time. If this property is set to **true**, a new log file will be created based on local time, not UTC. UTC was formerly called Greenwich Mean Time, or GMT.

| **Note** |
| --- |
| Regardless of the setting, the time stamp for each W3C Extended Logging log record is UTC-based. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_DEFAULT_EXTLOG_FIELDS |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4015 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogFilePeriod Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogFilePeriod** property specifies how often IIS creates a new log file. This property can be set to the following values as seen in the Bitmask Values section: 1 (daily), 2 (weekly), 3 (monthly), or 4 (hourly). If this property is set to 0, a new file will be created when the maximum size designated in LogFileTruncateSize Metabase Property is reached.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGFILE_PERIOD |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_LOGFILE_PERIOD_MAXSIZE | 0x00000000 | Create new log file after reaching the maximum size. |

| | | |
|---|---|---|
| MD_LOGFILE_PERIOD_DAILY | 0x00000001 | Create new log file daily. |
| MD_LOGFILE_PERIOD_WEEKLY | 0x00000002 | Create new log file weekly. |
| MD_LOGFILE_PERIOD_MONTHLY | 0x00000003 | Create new log file monthly. |
| MD_LOGFILE_PERIOD_HOURLY | 0x00000004 | Create a new log file hourly. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- LogFileTruncateSize Metabase Property

# LogFileTruncateSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogFileTruncateSize** property specifies the maximum size of the log file (in bytes). A new log file is created if a logging event causes the original log file to exceed the size specified in this property.

| **Note** |
| --- |
| The minimum file size allowed is 131,072 bytes. If this property is set to a value less than 131,072 bytes, the default value is implicitly assumed as 131,072 bytes. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGFILE_TRUNCATE_SIZE |
| Attributes | INHERIT |
| Default Value | 2000000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4004 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogInUTF8 Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is controlled by IIS.

| Attribute Name | Attribute Value |
|---|---|
| ADSI/WMI Data Type | BOOL |
| ABO Data Type | DWORD_METADATA |
| Schema Default | **FALSE** |
| Internal Default | **FALSE** |
| Upper Bound | Not specified |
| Lower Bound | Not specified |
| Internal ID | 9206 |
| Friendly ID | MD_GLOBAL_LOG_IN_UTF_8 |
| Property Attributes | NO_ATTRIBUTES |
| User Type | IIS_MD_UT_SERVER |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Flags**

There are no flags for this property.

# LogModuleId Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogModuleId** property specifies the CLSID for the logging module.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOG_PLUGIN_MOD_ID |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4005 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Microsoft IIS Log File Format<br>/LM/logging/NCSA Common Log File Format<br>/LM/logging/ODBC Logging<br>/LM/logging/W3C Extended Log File Format | IIsLogModule |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- LogModuleUiId Metabase Property

# LogModuleList Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogModuleList** property specifies a string that contains a comma-delimited list that names the available logging modules.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOG_PLUGINS_AVAILABLE |
| Attributes | INHERIT |
| Default Value | NCSA common log file format, IIS log fileformat, W3C extended log file format |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4012 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogModuleUiId Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogModuleUiId** property specifies the CLSID for the logging module's user interface.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOG_PLUGIN_UI_ID |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4006 |

**Configurable Locations**
You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/logging/Microsoft IIS Log File Format /LM/logging/NCSA Common Log File Format /LM/logging/ODBC Logging /LM/logging/W3C Extended Log File Format | IIsLogModule |

**Code Example**
For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- LogModuleId Metabase Property

# LogNonAnonymous Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogNonAnonymous** property specifies whether non-anonymous hits are logged to the event log.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_LOG_NONANONYMOUS |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5008 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogOdbcDataSource Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogOdbcDataSource** property specifies the name of the ODBC data source to which Microsoft Windows writes data during logging events.

| **Important** |
| --- |
| The logging module's CLSID determines whether Microsoft Windows logs to an ODBC data source or to the file system. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOGSQL_DATA_SOURCES |
| Attributes | INHERIT |
| Default Value | httplog |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4007 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogOdbcPassword Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogOdbcPassword** property specifies the ODBC database password to be used when writing information to the database during logging events.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOGSQL_PASSWORD |
| Attributes | INHERIT \| SECURE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4010 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

# LogOdbcTableName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogOdbcTableName** property specifies the name of the ODBC database table to which Microsoft Windows writes information during logging events.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOGSQL_TABLE_NAME |
| Attributes | INHERIT |
| Default Value | internetlog |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4008 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogOdbcUserName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogOdbcUserName** property specifies the ODBC database user name to be used when writing information to the database during logging events.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOGSQL_USER_NAME |
| Attributes | INHERIT |
| Default Value | internetadmin |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4009 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

# LogonMethod Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogonMethod** property contains an integer that specifies the logon method for cleartext logons. Valid settings are:

- 0 for interactive logon (defined in iiscnfg.h as MD_LOGON_INTERACTIVE).
- 1 for batch logon (defined in iiscnfg.h as MD_LOGON_BATCH).
- 2 for network logon (defined in iiscnfg.h as MD_LOGON_NETWORK).
- 3 for cleartext logon (defined in iiscnfg.h as MD_LOGON_NETWORK_CLEARTEXT).

For more information about logon methods, see UNC Authentication in IIS 6.0.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOGON_METHOD |
| Attributes | INHERIT |
| Default Value | 3 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6013 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name*<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |

| | |
|---|---|
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br><br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |
| /LM/W3SVC/AppPools/DefaultAppPool<br><br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogPluginClsid Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogPluginClsid** property specifies the order of precedence for the logging modules.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_LOG_PLUGIN_ORDER |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4011 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# LogType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **LogType** property indicates whether logging to the IIS log files is enabled. IIS log files are stored in *systemroot*\system32\Logfiles\. This property is read-write.

If **LogType** is set to 0, then logging is disabled. If **LogType** is set to 1, then logging is enabled. To disable logging for child nodes under a parent node for whom **LogType** is set to 1, set the **DontLog** property to **TRUE** on the child nodes.

ASP and ODBC errors do not get logged to the IIS log files.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_LOG_TYPE |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 4000 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MajorIIsVersionNumber Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MajorIIsVersionNumber** property specifies the major version number of IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_VERSION_MAJOR |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 1101 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/Info | IIsWebInfo |
| /LM/MSFTPSVC/Info | IIsFtpInfo |
| /LM/NNTPSVC/Info | IIsNntpInfo |
| /LM/SMTPSVC/Info | IIsSmtpInfo |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MasqueradeDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MasqueradeDomain** property specifies the domain name used for non-delivery reports.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_MASQUERADE_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36912 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxBandwidth Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxBandwidth** property specifies the maximum network bandwidth used for IIS. You can use this setting to help prevent overloading the network with IIS activity. This is not an inheritable property, but the value set at the machine level is globally available to all server instances. **MaxBandWidth** can be set individually, so that specific server instances are used instead of the global value, and can exceed the global setting established at the machine level.

The World Wide Web Publishing Service (WWW service) must be restarted before changes to this property take effect.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_BANDWIDTH |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1000 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM | IIsComputer |
| /LM/W3SVC | IIsWebService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxBandwidthBlocked Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxBandwidthBlocked** property specifies the maximum number of asynchronous requests to be queued in the outstanding idle queue when the maximum bandwidth of the server is exceeded. The value range for this property is 0 to 4294967295 (unlimited).

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Important** |
| --- |
| This is not an inheritable property and cannot be set at child nodes. **MaxBandwidthBlocked** is set at the machine level, and is globally available to all server instances. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_BANDWIDTH_BLOCKED |
| Attributes | NO_ATTRIBUTES |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM | IIsComputer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxBatchedMessages Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxBatchedMessages** property limits the number of messages per connection.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 36871 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxClientsMessage Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxClientsMessage** property contains a string that is displayed to an FTP client when there are too many FTP clients accessing the server. You can configure the maximum number of FTP clients by using the **MaxConnections** property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_MAX_CLIENTS_MESSAGE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxConnections Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxConnections** property specifies the maximum number of simultaneous connections to a server. The valid range is 0 to 4294967295 (unlimited). The **MaxClientsMessage** property can be used to send a message to clients when this value has been exceeded.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, Microsoft Visual Basic Scripting Edition (VBScript) represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_CONNECTIONS |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1014 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- MaxClientsMessage Metabase Property

# MaxDirChangeIOSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxDirChangeIOSize** property determines the size of the pickup directory buffer. This property is used for debugging purposes.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36878 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxEndpointConnections Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxEndpointConnections** property specifies the maximum number of "listen" sockets that will be aggregated on a network endpoint. For example, if this value is set to 15, then a maximum of 15 total connections can be made to a single port, even if more than one domain is bound to the port.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_ENDPOINT_CONNECTIONS |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1024 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxErrorFiles Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxErrorFiles** property specifies the maximum number of error files. When a syntax error occurs as a result of an edit to Metabase.XML, an error file is generated in systemroot\system32\inetsrv\history. If more than **MaxErrorFiles** files need to be created, the oldest files are deleted to ensure that this limit is not exceeded.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_ERROR_FILES |
| Attributes | NO_ATTRIBUTES |
| Default Value | 10 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9988 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM | IIsComputer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxGlobalBandwidth Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxGlobalBandwidth** property specifies the maximum total bandwidth for the server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_GLOBAL_BANDWIDTH |
| Attributes | NO_ATTRIBUTES |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9201 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxHistoryFiles Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxHistoryFiles** property specifies the maximum number of paired history files that are saved in the history folder. A pair of history files consists of a MetaBase.xml and a MBSchema.xml file, named with the same major and minor version number, and stored in the history folder.

| **Important** |
| --- |
| If the EnableEditWhileRunning Metabase Property property is set to **true**, the **MaxHistoryFiles** property should not be configured to a value less than 10. Setting the value of the **MaxHistoryFiles** property to a value lower than 10 may cause edit-while-running to fail, whereas setting the value too high may have an impact on disk capacity. |

Before increasing the value of the **MaxHistoryFiles** property above the value of 10, ensure that you have adequate hard disk space on the drive volume that the history folder is located on. You can estimate the amount of hard disk space required by multiplying the average combined file size of the MetaBase.xml and MBSchema.xml files by the number of versions that you want to store in the history folder. For information about configuring metabase history, see Configuring the Metabase History Feature in IIS 6.0.

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ROOT_MAX_HISTORY_FILES |
| Attributes | NO_ATTRIBUTES |
| Default Value | 10 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9995 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM | IIsComputer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- EnableHistory Metabase Property

# MaxMailObjects Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxMailObjects** property specifies the number of inbound connections allowed at one time. This key is used for debugging purposes.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36873 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxMessageSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxMessageSize** property specifies the maximum message size the server accepts. **MaxMessageSize** is also the value sent by the SMTP service in response to the EHLO command.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_MSG_SIZE |
| Attributes | INHERIT |
| Default Value | 33554432 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36891 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxOutConnections Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxOutConnections** property specifies the maximum number of concurrent outbound connections.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_OUTBOUND_CONNECTION |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36894 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxOutConnectionsPerDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxOutConnectionsPerDomain**property specifies the maximum number of concurrent outbound connections per outbound domain.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_OUT_CONN_PER_DOMAIN |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36925 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxProcesses Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxProcesses** property determines the maximum number of worker processes an application pool allows to service requests for an application pool.

| **Note** |
| --- |
| A Web Garden is an application pool with a **MaxProcesses** setting higher than 1. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_MAX_PROCESS_COUNT |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxRecipients Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxRecipients** property specifies the maximum number of recipients for a given message for a given virtual server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 100 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36895 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxRequestEntityAllowed Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxRequestEntityAllowed** property specifies the maximum number of bytes allowed in the entity body of a request. If a Content-Length header is present and specifies an amount of data greater than the value of **MaxRequestEntityAllowed**, IIS sends a 403 error response.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MAX_REQUEST_ENTITY_ALLOWED |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6051 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxSearchResults Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxSearchResults** property specifies the maximum number of results for a search command.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45181 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxSessionSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxSessionSize** property specifies the maximum amount of data per SMTP session for a given virtual server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 268435456 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36892 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxSmtpErrors Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxSmtpErrors** property specifies the maximum number of SMTP errors that can occur in one session before the server drops the connection.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36887 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MaxSmtpLogonErrors Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MaxSmtpLogonErrors** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36945 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| | |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_0 Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_0** property is used by IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | unknown_usertype |
| ID | 0 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| | |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_1001 Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_1001** property is used by IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MEMORY_CACHE_SIZE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_SERVER |
| ID | 1001 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM | IIsComputer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_APP_LAST_OUTPROC_PID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_APP_LAST_OUTPROC_PID** property contains a value that is stored in an application package ID to denote that the application package has been moved from out-of-process to in-process. In some cases, when an application is moved from out-of-process to in-process, the application's corresponding package may not be deleted by IIS. In this case, IIS stores the application package ID with the value of the **MD_APP_LAST_OUTPROC_PID** property so that if the application is later moved out-of-process, IIS can use the existing package in MTS/COM+.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APP_LAST_OUTPROC_PID |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | iis_md_ut_wam |
| ID | 2108 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_ETAG_CHANGENUMBER Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS uses the value specified in the **MD_ETAG_CHANGENUMBER** property to generate a portion of the entity tags (ETags) that are sent to clients in server response headers. By setting a matching value for **MD_ETAG_CHANGENUMBER** on all the Web servers in a Network Load Balanced (NLB) cluster, the value of the entity tag (ETag) will become the same on all the servers, preventing clients from having to re-download content that already exists in the client cache when a conditional request is sent to a different Web server in the cluster.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ETAG_CHANGE_NUMBER |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_SERVER |
| ID | 2039 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_IISADMIN_EXTENSIONS Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_IISADMIN_EXTENSIONS** property contains a list of CLSIDs for all registered administration extensions installed on the server.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_SECURE_PORT |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_SERVER |
| ID | 1028 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| | |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_ISM_ACCESS_CHECK Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_ISM_ACCESS_CHECK** property is used by IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ISM_ACCESS_CHECK |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_FILE |
| ID | 6269 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_METADATA_ID_REGISTRATION Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_METADATA_ID_REGISTRATION** property is used by IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_METADATA_ID_REGISTRATION |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_SERVER |
| ID | 1030 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| | |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_SERVER_CAPABILITIES Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_SERVER_CAPABILITIES** property is used by IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_CAPABILITIES |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_SERVER |
| ID | 1103 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/Info | IIsWebInfo |
| /LM/MSFTPSVC/Info | IIsFtpInfo |
| /LM/NNTPSVC/Info | IIsNntpInfo |
| /LM/SMTPSVC/Info | IIsSmtpInfo |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MD_SERVER_PLATFORM Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MD_SERVER_PLATFORM** property is used by IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_PLATFORM |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | hidden |
| User Type | IIS_MD_UT_SERVER |
| ID | 1100 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/Info | IIsWebInfo |
| /LM/MSFTPSVC/Info | IIsFtpInfo |
| /LM/NNTPSVC/Info | IIsNntpInfo |
| /LM/SMTPSVC/Info | IIsSmtpInfo |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MimeMap Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MimeMap** property provides a list of the file name extensions for Multipurpose Internet Mail Extensions (MIME) mappings. The **MimeMap** key at the local machine level of the metabase establishes the default list, which can be overridden at the World Wide Web Publishing Service (WWW service) and Web server level keys. For more information about managing this property, see the **IIsMimeMap** object in the IIS ADSI Provider reference section of the IIS Software Development Kit (SDK).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | MIMEMAP |
| WMI Data Type | MIMEMAP |
| ADSI Data Type | MIMEMAP |
| ABO Data Type | MIMEMAP |
| ABO Metabase Identifier | MD_MIME_MAP |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6015 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT<br>/LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM | IIsComputer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/MimeMap | IIsMimeMap |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MinFileBytesPerSec Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MinFileBytesPerSec** property is used to configure the minimum throughput rate that HTTP.sys enforces when sending data from the client to the server, and back from the server to the client. The **MinFileBytesPerSec** property prevents malicious or malfunctioning software clients from consuming resources by holding a connection open with minimal data. If the throughput rate is below the **MinFileBytesPerSec** setting, the connection is terminated.

In IIS 6.0, use this property in conjunction with the **ConnectionTimeout** property, and for Web service nodes, use the **HeaderWaitTimeout** property instead of the **ServerListenTimeout** property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_MIN_FILE_BYTES_PER_SEC |
| Attributes | INHERIT |
| Default Value | 240 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9205 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MinorIIsVersionNumber Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MinorIIsVersionNumber** property specifies the minor version number of IIS.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 1102 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/Info | IIsWebInfo |
| /LM/MSFTPSVC/Info | IIsFtpInfo |
| /LM/NNTPSVC/Info | IIsNntpInfo |
| /LM/SMTPSVC/Info | IIsSmtpInfo |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ModeratorFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ModeratorFile** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45160 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# MSDOSDirOutput Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **MSDOSDirOutput** property specifies the style of directory output for a list operation request from an FTP client. If the value is **true**, the format is in MS-DOS style, if **false**, it is produced in UNIX style.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_MSDOS_DIR_OUTPUT |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5004 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NameResolutionType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NameResolutionType** property tells SMTP how to resolve a host name. The default is 1. Valid values are:

1= UNCACHEDNS

2= GETHOSTBYNAME

3= DNS_GETHOSTBYNAME

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36885 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NewsCrawlerTime Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NewsCrawlerTime** property specifies the time between expiration runs, in minutes.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45069 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NewsDropDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NewsDropDirectory** property specifies the directory where NNTP puts mail that needs to go out.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45176 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NewsFailedPickupDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NewsFailedPickupDirectory** property specifies the directory where NNTP puts invalid posts from the pickup directory.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45174 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NewPickupDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NewsPickupDirectory** property specifies the directory where NNTP looks to pick up posts.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45173 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NntpClearTextProvider Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NntpClearTextProvider** property specifies the clear text authentication provider.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45179 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NntpCommandLogMask Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NntpCommandLogMask** property specifies the path to the moderatr.txt file, currently unused.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45067 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NntpOrganization Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NntpOrganization** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45171 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NntpServiceVersion Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NntpServiceVersion** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45175 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NntpUucpName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **NntpUucpName** property contains the NNTP hub name (UUCP name).

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45170 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NotDeletable Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is not valid in IIS 6.0. In earlier versions of IIS, the **NotDeletable** property indicates whether a server can be deleted by using IIS Manager. If this property is set to **true**, an attempt to delete the affected server instance using IIS Manager results in an error.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_NOT_DELETABLE |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2116 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# NTAuthenticationProviders Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

When Integrated Windows authentication is enabled, the **NTAuthenticationProviders** property contains a comma-delimited list of Windows authentication providers that you can attempt to use, including Integrated Windows authentication (also known as NTLM) and Kerberos.

| **Important** |
| --- |
| Integrated Windows authentication is disabled by default if you install Windows Server 2003 Service Pack 1 (SP1) as part of a slipstream installation of a Windows Server 2003 operating system. If you install Windows Server 2003 SP1 by itself as an upgrade to a Windows Server 2003 operating system, the setting for Integrated Windows authentication is unchanged from its Windows Server 2003 setting. Integrated Windows authentication is enabled by default for Windows Server 2003 operating systems. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_NTAUTHENTICATION_PROVIDERS |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6032 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC /LM/W3SVC/*n* /LM/*W3SVC/n/ROOT /LM/W3SVC/n/ROOT/MyApp* | IIsWebService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# OrphanActionExe Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **OrphanActionExe** property specifies an executable to run when the World Wide Web Publishing Service (WWW service) orphans a worker process. You can use the OrphanActionParams Metabase Property to send parameters to the executable.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APPPOOL_ORPHAN_ACTION_EXE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9031 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# OrphanActionParams Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **OrphanActionParams** property specifies command-line parameters for the executable specified by the OrphanActionExe Metabase Property. To specify the process ID of the orphaned process, use %1%.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_APPPOOL_ORPHAN_ACTION_PARAMS |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9032 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- OrphanActionExe Metabase Property

# OrphanWorkerProcess Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **OrphanWorkerProcess** property, when set to true, notifies the World Wide Web Publishing Service (WWW Service) not to terminate a worker process that fails to respond to pings, but to instead orphan the worker process in the application pool if the worker process suffers fatal errors.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_ORPHAN_PROCESSES_FOR_DEBUGGING |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9009 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PassivePortRange Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PassivePortRange** property specifies the range of data ports to be used by the FTP service in response to PASV commands.

PASV FTP requires the server to open a data port for the client to make a second connection. This is a separate connection than the typical port 21 that is used for the control channel. The second connection is used when data files are transferred back to the client. By configuring the port range, you can write firewall and router rules to allow external clients access only to the ports they need and reduce the attack surface available to malicious users. In other words, if you have applications other than FTP that are using the default port range of 1025-5000, and do not want to expose these ports through your firewall in order to enable PASV FTP, you can use this value to change the range that you must open through your firewall. If this value is not specified, or is set to an empty string, the default value of 1025-5000, as specified by Winsock, is used. If this property is specified, the valid range that FTP will validate is from 5001 to 65535 (see **StartingNumber** and **EndingNumber** below), and may be a range or a single number.

| **Important** |
| --- |
| This property can be set only at the service level. In order to make the changes effective, the service must be restarted. If the value is invalid, the service will invalidate it and will not restart. |

For more information, see Modes and Data Transmission.

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_PASSIVE_PORT_RANGE |
| Attributes | INHERIT |
| Default Value | 1025-5000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5016 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PassportRequireADMapping Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PassportRequireADMapping** property specifies how IIS handles Microsoft .NET Passport authentication and Active Directory mapping.

By default, IIS 6.0 with .NET Passport authentication enabled tries to map the .NET Passport user to an account in Active Directory. This default behavior can create performance overhead for sites that do not accept .NET Passport Active Directory mapping. The mapping behavior can be controlled by the **PassportRequireADMapping** flag. The flag values are:

- **PassportRequireADMapping** set to 0: IIS does not attempt Active Directory mapping. The request is handled as Anonymous User.
- **PassportRequireADMapping** set to 1 (default setting): In this situation, the worker process must have TCB privileges (meaning, the worker process acts as part of the operating system). IIS then attempts to map to an Active Directory account (called LsaLogonUser). If this attempt fails, the request is handled as Anonymous User.
- **PassportRequireADMapping** set to 2: IIS enforces a mapping from the .NET Passport account to an Active Directory account before returning the requested Web page. If the mapping fails, IIS returns a 401 error.

For more information, see Setting Up .NET Passport in IIS 6.0. Also, the AuthFlags Metabase Property contains the available settings for Windows authentication schemes and the file access authentication flags.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_PASSPORT_REQUIRE_AD_MAPPING |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6052 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |

| | |
|---|---|
| /LM/W3SVC | IIsWebService |

| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PasswordCacheTTL Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PasswordCacheTTL** property is used for password types of security authentication schemes. The value specifies the amount of time (in seconds) that an expired password will be held in the memory cache.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ADV_CACHE_TTL |
| Attributes | INHERIT |
| Default Value | 600 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2064 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

# PasswordChangeFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PasswordChangeFlags** property contains flags, as seen in the Flags section, that control password expiration and password change processing between the server and client. A value of 0, which is the default, indicates that an SSL connection is required, 1 indicates that changing is allowed on nonsecure ports, 2 indicates that changing is disabled, and 4 indicates that password expiration notification is disabled.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_AUTH_CHANGE_FLAGS |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2068 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Flags**

| Flag Name | AuthChangeUnsecure |
|---|---|
| Description | Password changing allowed on nonsecure ports. |
| Metabase Bitmask Identifier | MD_AUTH_CHANGE_UNSECURE |
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| Flag Name | AuthChangeDisable |
|---|---|
| Description | Password changing disabled. |

| | |
|---|---|
| Metabase Bitmask Identifier | MD_AUTH_CHANGE_DISABLE |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| **Flag Name** | **AuthAdvNotifyDisable** |
|---|---|
| Description | Advance notification of password expiration disabled. |
| Metabase Bitmask Identifier | MD_AUTH_ADVNOTIFY_DISABLE |
| Decimal Value | 4 |
| Hexadecimal Value | 0x00000004 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.RapidFailProtectionInterval Metabase Property

**Related Information**

PasswordExpirePrenotifyDays Metabase Property

# PasswordExpirePrenotifyDays Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PasswordExpirePrenotifyDays** property specifies the number of days remaining before the client's password expires, and indicates when a password prenotification message is sent.

| **Note** |
| --- |
| This property is dependant on the PasswordChangeFlags Metabase Property being enabled. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_ADV_NOTIFY_PWD_EXP_IN_DAYS |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PeriodicRestartMemory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PeriodicRestartMemory** property specifies the amount of virtual memory (in KB) that a worker process can use before the worker process recycles. The maximum value supported for this property is 4,294,967 KB.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_PERIODIC_RESTART_MEMORY |
| Attributes | INHERIT |
| Default Value | 512000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9024 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PeriodicRestartPrivateMemory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PeriodicRestartPrivateMemory** property specifies the amount of private memory (in KB) that a worker process can use before the worker process recycles. The maximum value supported for this property is 4,294,967 KB.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_PERIODIC_RESTART_PRIVATE_MEMORY |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9038 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PeriodicRestartRequests Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PeriodicRestartRequests** property indicates the number of requests the OOP application should process, after which it is recycled.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_PERIODIC_RESTART_REQUEST_COUNT |
| Attributes | INHERIT |
| Default Value | 10000 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9002 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PeriodicRestartSchedule Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PeriodicRestartSchedule** property specifies the time (in 24 hour format) that the application will be rotated. Each time is in local time and is specified in the following format:

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_APPPOOL_PERIODIC_RESTART_SCHEDULE |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9020 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PeriodicRestartTime Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PeriodicRestartTime** property specifies the period of time, in minutes, after which IIS rotates an isolated OOP application. Setting the value of this property to 0 disables the property. The maximum supported value for this property is 71,582.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_PERIODIC_RESTART_TIME |
| Attributes | INHERIT |
| Default Value | 60 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9001 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- IdleTimeout Metabase Property

# PickupDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PickupDirectory** property specifies the path to the directory that is used to pick up inbound mail.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_MAIL_PICKUP_DIR |

| User Type | IIS_MD_UT_SERVER |
| ID | 36880 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PingingEnabled Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PingingEnabled** property specifies whether the World Wide Web Publishing Service (WWW Service) should periodically monitor the health of a worker process. Setting the value of this property to true indicates to the WWW service to monitor the worker processes to ensure that they are running and healthy.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_PINGING_ENABLED |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9004 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PingInterval Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PingInterval** property specifies the period of time (in seconds) between health-monitoring pings that the World Wide Web Publishing Service (WWW Service) sends to a worker process.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_PING_INTERVAL |
| Attributes | INHERIT |
| Default Value | 240 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9013 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PingResponseTime Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PingResponseTime** property specifies the amount of time (in seconds) that a worker process is given to respond to a health monitoring ping. After the time limit is exceeded, the World Wide Web Publishing Service (WWW Service) terminates the worker process.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_PING_RESPONSE_TIMELIMIT |
| Attributes | INHERIT |
| Default Value | 60 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9014 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# PoolIdcTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PoolIdcTimeout** property specifies the timeout value (in seconds) for Internet database connection pooling. A value of 0 (zero) specifies that no pooling is implemented.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_POOL_IDC_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6037 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# Pop3ClearTextProvider Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is reserved for future use by Microsoft Exchange.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 41182 |

**Configurable Locations**

Currently, this property is not configurable at any location in the IIS metabase.

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# Pop3DefaultDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is reserved for future use by Microsoft Exchange.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |

# PrettyNamesFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **PrettyNamesFile** property contains the path to the prettynm.txt file, which is currently unused.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45178 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ProcessNTCRIfLoggedOn Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ProcessNTCRIfLoggedOn** property enables processing of Integrated Windows authentication (NTLM), even if a user has already logged on using an alternate authentication scheme.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_PROCESS_NTCR_IF_LOGGED_ON |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2070 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# QueueDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **QueueDirectory** property designates the directory where mail queues are held.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36875 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

# RapidFailProtection Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Setting the **RapidFailProtection** property to **true** instructs the World Wide Web Publishing Service (WWW service) to put all applications in an application pool out of service if the number of worker process crashes has reached the maximum specified by the RapidFailProtectionMaxCrashes Metabase Property, within the number of minutes specified by the RapidFailProtectionInterval Metabase Property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_RAPID_FAIL_PROTECTION_ENABLED |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9006 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RapidFailProtectionInterval Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RapidFailProtectionInterval** property specifies the number of minutes before the failure count for a process is reset. See RapidFailProtection Metabase Property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_RAPID_FAIL_PROTECTION_INTERVAL |
| Attributes | INHERIT |
| Default Value | 5 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9029 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RapidFailProtectionMaxCrashes Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RapidFailProtectionMaxCrashes** property specifies the maximum number of failures allowed within the number of minutes specified by the RapidFailProtectionInterval Metabase Property. See RapidFailProtection Metabase Property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_RAPID_FAIL_PROTECTION_MAX_CRASHES |
| Attributes | INHERIT |
| Default Value | 5 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9030 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# Realm Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **Realm** property specifies the realm that IIS should use to authenticate a client that is attempting to access a resource secured with Digest authentication or Advanced Digest authentication.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_REALM |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6001 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RedirectHeaders Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RedirectHeaders** property specifies additional redirection headers. Each string in the string array represents a header and its value.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_REDIRECT_HEADERS |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6044 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RelayForAuth Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RelayForAuth** property corresponds to the **Allow all computers which successfully authenticate to relay, regardless of the list above** check box in the **Relay Restrictions** dialog box. This value is set to -1 if the check box is selected (that is, allow relay to all those who have authenticated) and is set to 0 if the check box is not selected.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36973 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RelayIpList Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RelayIpList** property is an octet string containing a list of IPs allowed or denied for relay listed in the Relay Restrictions dialog box.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | IPSECLIST |
| WMI Data Type | IPSECLIST |
| ADSI Data Type | IPSECLIST |
| ABO Data Type | IPSECLIST |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | inherit \| reference |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 36970 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RemoteRetryAttempts Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RemoteRetryAttempts** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 48 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36898 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RemoteRetryInterval Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RemoteRetryInterval** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 60 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36899 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RemoteSmtpPort Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RemoteSmtpPort** property determines which port is used when a virtual server connects to a remote server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 25 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36914 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RemoteSmtpSecurePort Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RemoteSmtpSecurePort** property is obsolete.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 465 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36929 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RemoteTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RemoteTimeout** property sets the timeout for outbound connections, which correspond to the timeout value in the **Outbound Connections** dialog box.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36921 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RestrictionListCustomDesc Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is controlled by IIS.

| Attribute Name | Attribute Value |
|---|---|
| ADSI/WMI Data Type | MULTISZ |
| ABO Data Type | MULTISZ_METADATA |
| Schema Default | **null** |
| Internal Default | Not specified |
| Upper Bound | Not specified |
| Lower Bound | Not specified |
| Internal ID | 2165 |
| Friendly ID | No friendly name. Use the Internal ID attribute listed above. |
| Property Attributes | NO_ATTRIBUTES |
| User Type | IIS_MD_UT_SERVER |

**Configurable Locations**
This property is not configurable at any location in the metabase.

**Flags**
There are no flags for this property.

# RevocationFreshnessTime Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the value of the CertCheckMode Metabase Property is set to **MD_CERT_CHECK_REVOCATION_FRESHNESS_TIME**, the client's CRL is replaced by the CRL on the CA, even if the CRL that is cached on the client is valid. The value of this metabase property, **RevocationFreshnessTime**, in seconds, determines the frequency of this action.

The *freshness time* for a CRL is the period of time for which it is valid. If you set this property to a very short period of time, IIS makes many requests for an updated CRL, which can cause network delays. Setting a longer period of time for the **RevocationFreshnessTime** metabase property is recommended.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_REVOCATION_FRESHNESS_TIME |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2161 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- For more information about using SSL and certificates with IIS 6.0, see IIS 6.0 Encryption.

For more information about certificate revocation and CRLs, see Revoking Certificates and Publishing CRLs.

# RevocationURLRetrievalTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If the value of the CertCheckMode Metabase Property is set to **MD_CERT_CHECK_REVOCATION_FRESHNESS_TIME**, the client's CRL is replaced by the CRL on the CA, even if the CRL that is cached on the client is valid. The default timeout interval for downloading the CRL is 0 unless you use this metabase property, **RevocationURLRetrievalTimeout**, to specify a different timeout interval (in milliseconds). If the CRL is a large file, a higher value for this metabase property allows more time for downloading the file before a timeout occurs.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_REVOCATION_URL_RETRIEVAL_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 2162 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- For more information about using SSL and certificates with IIS 6.0, see Encryption in IIS 6.0.
- For more information about certificate revocation and CRLs, see Revoking Certificates and Publishing CRLs.

# RouteAction Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RouteAction** property flags the various SMTP options. This gives properties to a connector.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36946 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RouteActionString Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RouteActionstring** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36947 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RoutePassword Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For outbound connections, the **RoutePassword** property sets the password used to connect to a remote server (this value is listed for a given connector, for example /smtpsvc/1/domain/username.com).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT \| SECURE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36949 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RouteUserName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

For outbound connections, the **RouteUserName** property sets the account name used to connect to a remote server (this value is listed for a given connector, for example /smtpsvc/1/domain/username.com).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36948 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/Domain | IIsSmtpDomain |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RoutingDll Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RoutingDll** property is obsolete.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36883 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# RoutingSources Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **RoutingSources** property is obsolete.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | iis_md_ut_wam |
| ID | 36910 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SaslLogonDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SaslLogonDomain** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36940 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ScriptMaps Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ScriptMaps** property specifies the file name extensions of applications used for script processor mappings. The list string is written in the following format:

```
"Extension, ScriptProcessor, Flags, IncludedVerbs"
```

Where Extension is the file name extension, such as .htm, *ScriptProcessor* is the full path to the DLL, *Flags* is the integer value corresponding to the requested behavior described in the Bitmask Table, and *IncludedVerbs* is a list of the verbs that a particular ISAPI DLL processes.

For example, to specify the file extension for the ISAPI "Test.dll" with a file extension of ".htm", you might provide the following list (string):

```
".htm,C:\Windows40\System32\Inetsrv\Test.dll,5,GET, HEAD, POST"
```

Note IIS allows an "*" in place of the file name extension, which effectively routes all requests though the designated *ScriptProcessor*. This feature is useful when applying a custom ISAPI extension that will handle requests from all file types.

In IIS version 4.0 and earlier, the syntax was to list excluded verbs rather than included verbs. In version 5.0 and later, if no verbs are listed, a value of "all verbs" is assumed. You should list the verbs you want your ISAPI filter or extension to handle.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_SCRIPT_MAPS |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6014 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

| | |
|---|---|
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_SCRIPTMAPFLAG_SCRIPT | 0x00000001 | Scripts are allowed to run in directories given Script permission. If this value is not set, then the script can only be run in directories that are flagged for Execute permission. |
| MD_SCRIPTMAPFLAG_CHECK_PATH_INFO | 0x00000004 | The server attempts to access the PATH_INFO portion of the URL, as a file, before starting the scripting engine. If the file can't be opened, or doesn't exist, an error is returned to the client. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SecureBindings Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SecureBindings** property specifies a string that is used by IIS to determine which secure network endpoints are used by the server instance. The string format is IP:Port.

| **Note** |
| --- |
| The IP component of each string is optional. If it is not provided, IIS assumes that any IP address is allowable (wildcard). |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |

# SecuritySetupRequired Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

| **Important** |
| --- |
| The **SecuritySetupRequired** property is not supported in IIS 6.0. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 2166 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| | |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SendBadTo Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SendBadTo** property sets the alias to which bad mail is sent. The default is "Postmaster."

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36923 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

# SendNdrTo Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SendNdrTo** property corresponds to "Send copy of Non-Delivery Report to" on the **Messages** tab.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36922 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ServerAutoStart Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerAutoStart** property indicates if the server instance should start automatically when the service is started.

This property is reset automatically when a server instance is stopped or restarted, to maintain state across service restarts. For example, if a server is stopped, the value of this property is set to **false** so that if the service is stopped and restarted, the server will remain stopped. Likewise, if a server is started, this property is set to **true**, allowing the server to remain running whenever the service is running.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_SERVER_AUTOSTART |
| Attributes | NO_ATTRIBUTES |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1017 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

# ServerBindings Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerBindings** property specifies a string that IIS uses to determine which network endpoints are used by the server instance. The string format is IP:Port:Hostname.

| **Note** |
| --- |
| Both the IP and Hostname parameters of the string are optional. Any unspecified parameters default to an all-inclusive wildcard. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |

# ServerCommand Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerCommand** property can be set to start, stop, continue, or pause a site. The commands, and the corresponding codes, are listed in the Bitmask Values table.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_COMMAND |
| Attributes | VOLATILE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1012 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Bitmask Values**

| Value | Description |
|---|---|
| 1 | Start site. |
| 2 | Stop site. |
| 4 | Pause site. |
| 8 | Continue site. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ServerComment Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerComment** property specifies a comment for the server instance.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_SERVER_COMMENT |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1015 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ServerConfigFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerConfigFlags** property contains flags, as seen in the Flags section, that specify the server configuration established at startup.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_CONFIGURATION_INFO |
| Attributes | NO_ATTRIBUTES |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1027 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/Info | IIsWebInfo |

**Flags**

| Flag Name | ServerConfigSSL40 |
|---|---|
| Description | A value of **true** indicates that 40-bit Secure Sockets Layer (SSL) processing is installed on the server. |
| Metabase Bitmask Identifier | MD_SERVER_CONFIG_SSL_40 |
| Decimal Value | 1 |
| Hexadecimal Value | 0x00000001 |

| Flag Name | ServerConfigSSL128 |
|---|---|
| Description | A value of **true** indicates that 128-bit Secure Sockets Layer (SSL) processing is installed on the server. |

| | |
|---|---|
| Metabase Bitmask Identifier | MD_SERVER_CONFIG_SSL_128 |
| Decimal Value | 2 |
| Hexadecimal Value | 0x00000002 |

| **Flag Name** | **ServerConfigSSLAllowEncrypt** |
|---|---|
| Description | A value of **true** indicates that the locality allows encryption. |
| Metabase Bitmask Identifier | MD_SERVER_CONFIG_ALLOW_ENCRYPT |
| Decimal Value | 4 |
| Hexadecimal Value | 0x00000004 |

| **Flag Name** | **ServerConfigAutoPWSync** |
|---|---|
| Description | A value of **true** indicates that the server can perform automatic anonymous user password synchronization between the Web authentication manager (WAM) and the Microsoft Windows authentication manager. |
| Metabase Bitmask Identifier | MD_SERVER_CONFIG_AUTO_PW_SYNC |
| Decimal Value | 8 |
| Hexadecimal Value | 0x00000008 |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ServerID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is reserved for future use by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| ADSI/WMI Data Type | STRING |
| ABO Data Type | STRING_METADATA |
| Schema Default | **null** |
| Internal Default | Not specified |
| Upper Bound | Not specified |
| Lower Bound | Not specified |
| Internal ID | 130010 |
| Friendly ID | No friendly name. Use the Internal ID attribute listed above. |
| Property Attributes | NO_ATTRIBUTES |
| User Type | IIS_MD_UT_SERVER |

**Configurable Locations**
You can configure this property at the following locations in the IIS metabase.

**Flags**
There are no flags for this property.

# ServerListenBacklog Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerListenBacklog** property specifies the number of outstanding sockets that can be queued. The value is based on the *AcceptEx* operating system parameter, and the server size specified in the ServerSize Metabase Property. Valid values for this property range from 5 to 500.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_LISTEN_BACKLOG |
| Attributes | INHERIT |
| Default Value | 40 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1019 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- ServerSize Metabase Property

# ServerListenTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerListenTimeout** property specifies the amount of time (in seconds) the server waits for a client to send data. After the allotted amount of time passes, the server disconnects the client. This property is not used by the WWW service in IIS 6.0, but it remains available for the FTP, SMTP, and NNTP services.

In IIS 6.0, this property does not apply to the Web service (IIsWebService, IIsWebServer). Use ConnectionTimeout Metabase Property, HeaderWaitTimeout Metabase Property, and MinFileBytesPerSec Metabase Property instead.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_LISTEN_TIMEOUT |
| Attributes | INHERIT |
| Default Value | 120 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1020 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ServerSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerSize** property specifies the general size of the server, in terms of the number of client requests processed per day. A value of 0 (zero) indicates a small Web site that expects to receive fewer than 10,000 requests per day; a value of 1 indicates a medium site handling between 10,000 and 100,000 requests per day; and a value of 2 designates a large site, processing more than 100,000 requests a day. The value of this property is used in calculating the value for the ServerListenBacklog Metabase Property.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_SIZE |
| Attributes | INHERIT |
| Default Value | 1 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1018 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/W3SVC | IIsWebService |
| /LM/MSFTPSVC | IIsFtpService |

**Values**

| Constant | Value | Description |
|---|---|---|
| MD_SERVER_SIZE_SMALL | 0x00000000 | Anticipate fewer than 10,000 requests per day. |
| MD_SERVER_SIZE_MEDIUM | 0x00000001 | Anticipate 10,000 to 100,000 requests per day. |
| MD_SERVER_SIZE_LARGE | 0x00000002 | Anticipate more than 100,000 requests per day. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- ServerListenBacklog Metabase Property

# ServerState Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ServerState** property presents the current state of the server instance. The state codes, and the corresponding states, are as follows:

1 (starting)

2 (started)

3 (stopping)

4 (stopped)

5 (pausing)

6 (paused)

7 (continuing)

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_SERVER_STATE |
| Attributes | VOLATILE |
| Default Value | 4 |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1016 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Bitmask Values**

| Constant | Value | Description |
|---|---|---|

| | | |
|---|---|---|
| MD_SERVER_STATE_STARTING | 0x00000001 | Server starting. |
| MD_SERVER_STATE_STARTED | 0x00000002 | Server started. |
| MD_SERVER_STATE_STOPPING | 0x00000003 | Server stopping. |
| MD_SERVER_STATE_STOPPED | 0x00000004 | Server stopped. |
| MD_SERVER_STATE_PAUSING | 0x00000005 | Server pausing. |
| MD_SERVER_STATE_PAUSED | 0x00000006 | Server paused. |
| MD_SERVER_STATE_CONTINUING | 0x00000007 | Server continuing. |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SessionKey Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SessionKey** property is used for the encryption of secure metabase properties.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | binary |
| WMI Data Type | binary |
| ADSI Data Type | binary |
| ABO Data Type | binary |
| ABO Metabase Identifier | MD_GLOBAL_SESSIONKEY |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 9999 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| . | IIS_Global |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ShouldDeliver Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ShouldDeliver** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36881 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ShouldPickupMail Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ShouldPickupMail** property determines if mail is picked up from the Pickup directory.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36876 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ShouldPipelineIn Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ShouldPipelineOut** property allows pipelining of outgoing commands (Boolean value).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36901 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ShouldPipelineOut Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ShouldPipelineIn** property allows pipelining of incoming commands (Boolean value).

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36902 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ShutdownLatency Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ShutdownLatency** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45070 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC | IIsNntpService |
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# ShutdownTimeLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **ShutdownTimeLimit** property specifies the amount of time (in seconds) after a recycle threshold has been reached that IIS waits for all old requests to finish running in a worker process before terminating the worker process.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_SHUTDOWN_TIMELIMIT |
| Attributes | INHERIT |
| Default Value | 90 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9012 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n*/*virtual_directory_name*/*physical_directory_name* | IIsWebDirectory |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmartHost Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmartHost** property corresponds to "Smart host" in the Advanced Delivery dialog box (for a given virtual server, not in the general SmtpSvc container).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36906 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmartHostType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmartHostType** property corresponds to the "Attempt direct delivery before sending to smart host" check box in the **Advanced Delivery** dialog box. If no smart host is specified in the smart host text box, **SmartHostType** will be set to 0. When the smart host is specified and the check box is not selected, **SmartHostType** will be set to 2 (always) and the smart host will be used to send mail without consulting the DNS server. When the smart host is specified and the check box is selected, **SmartHostType** will be set to 1 (that is, direct delivery through DNS lookup first; if DNS fails to look up the domains of the recipients, the smart host entry of the SMTP virtual server is used).

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36905 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SMPAffinitized Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Setting the **SMPAffinitized** property to true indicates that a particular worker process assigned to an application pool should be assigned to a given CPU. This property is used in conjunction with the SMPProcessorAffinityMask Metabase Property to configure a particular processor a worker process will be assigned to.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_APPPOOL_SMP_AFFINITIZED |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9007 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- SMPProcessorAffinityMask Metabase Property

# SMPProcessorAffinityMask Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SMPProcessorAffinityMask** property configures the hexadecimal processor mask. The hexadecimal processor mask indicates to which CPU the worker processes in an application pool should be bound. Before this property takes affect, the SMPAffinitized Metabase Property must be set to **true** for the application pool.

| **Note** |
| --- |
| Do not set this property to zero. Doing so causes no SMP affinity to be configured, creating an error condition. |

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_SMP_AFFINITIZED_PROCESSOR_MASK |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9008 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

- SMPAffinitized Metabase Property

# SmtpAdvQueueDll Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpAdvQueueDll** property indicates the string containing the location of the advanced queuing DLL. The default is *systemroot*\Inetsrv\Aqueue.dll.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36987 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpAqueueWait Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpAqueueWait** property key is for debugging purposes only.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36990 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpAuthTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpAuthTimeout** property sets the amount of time the server waits after a client issues this command before hanging up because of inactivity.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37006 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpBdatTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpBdatTimeout** property sets the amount of time the server waits after a client issues this command before hanging up because of inactivity.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37005 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpClearTextProvider Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpClearTextProvider** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36942 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpCommandLogMask Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpCommandLogMask** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36864 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpConnectTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpConnectTimeout** property sets the amount of time, after a client makes a connection, that the server will wait before hanging up because of inactivity.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37001 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDataTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDataTimeout** property sets the amount of time, after a client issues this command, that the server will wait before hanging up because of inactivity.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37004 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDisableRelay Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDisableRelay** property controls whether mail may be relayed. Note that the Boolean flag value is reversed.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36974 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDomainValidationFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Setting the **SmtpDomainValidationFlags** property key to a nonzero value causes the domain passed to the EHLO command to be checked to determine if it is well formatted.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36992 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDotStuffPickupDirFiles Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDotStuffPickupDirFiles** property specifies if SMTP will process dotstuffed files in the Pickup directory.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37030 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsAccount Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsAccount** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36957 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsBindType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsBindType** property specifies whether to authenticate to a remote LDAP server or not.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36953 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsDataDirectory Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsDataDirectory** property is obsolete.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36951 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsDefaultMailRoot Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsDefaultMailRoot** property is obsolete.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36952 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsDomain** property sets the domain to use to authenticate to a remote LDAP server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36993 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsFlags Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsFlags** property determines special flags passed to set options on an LDAP connection.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37024 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsHost Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsHost** property sets the host name of a remote LDAP server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36955 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsNamingContext Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsNamingContext** property sets the LDAP base naming context to search in on a remote LDAP server.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36956 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDSNLanguageID Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDSNLanguageID** property indicates the language ID that the SMTP virtual server uses when sending Delivery Status Notifications.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37022 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDSNOptions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDSNOptions** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37021 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsPassword Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsPassword** property sets the password to use to bind to a remote LDAP server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT \| SECURE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36958 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsPort Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsPort** property sets the port on which a remote LDAP server listens.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37023 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsSchemaType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsSchemaType** property specifies which directory schema to use.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36954 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpDsUseCat Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpDsUseCat** property enables the Categorizer.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36994 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpEventlogLevel Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpEventlogLevel** property sets the event logging level:

0=none

1=minimum

3=medium

5=maximum

7=field engineering

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37027 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpFlushMailFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpFlushMailFile** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36866 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpHeloNoDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpHeloNoDomain** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36981 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpHeloTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpHeloTimeout** property determines how long the server waits, after a client issues this command, before hanging up because of inactivity.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37012 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpInboundCommandSupportOptions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This property is reserved for future use by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 7697601 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36998 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpIpRestrictionFlag Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpIpRestrictionFlag** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37031 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpLocalDelayExpireMinutes Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpLocalDelayExpireMinutes** property corresponds to where users set the local "Delay notification" time period on the **Delivery** tab. The value in the key is in minutes. This property is listed for both the \smtpsvc and \smtpsvc\1. Changing the setting changes the value of the key for the individual virtual server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 60 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37017 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpLocalNDRExpireMinutes Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpLocalNDRExpireMinutes** property corresponds to where users set the local "Expiration timeout" time period on the **Delivery** tab. The value in the key is in minutes. This property is listed for both the \smtpsvc and \smtpsvc\1. Changing the setting changes the value of the key for the individual virtual server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 2880 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37018 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpMailFromTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpMailFromTimeout** property determines how long the server will wait, after a client issues this command, before hanging up because of inactivity.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37002 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpMailNoHelo Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpMailNoHelo** property allows a "mail from" to be issued without issuing an EHLO (or HELO).

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36982 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpMaxRemoteQThreads Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpMaxRemoteQThreads** property is for debugging purposes only.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36964 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpOutboundCommandSupportOptions Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpOutboundCommandSupportOptions** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 7697601 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36999 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpRcptToTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRcptToTimeout** property determines how long the server waits, after a client issues this command, before hanging up because of inactivity.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37003 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpRemoteDelayExpireMinutes Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRemoteDelayExpireMinutes** property corresponds to where users set the remote "Delay notification" time period on the **Delivery** tab. The value in the key is in minutes. This property is listed for both the \smtpsvc and \smtpsvc\1. Changing the setting changes the value of the key for the individual virtual server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 60 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37019 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpRemoteNDRExpireMinutes Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRemoteNDRExpireMinutes** property corresponds to where users set the remote "Expiration timeout" time period on the **Delivery** tab. The value in the key is in minutes. This property is listed for both the \smtpsvc and \smtpsvc\1. Changing the setting changes the value of the key for the individual virtual server.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |

# SmtpRemoteProgressiveRetry Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRemoteProgressiveRetry** property corresponds to where users set "First retry interval," "Second retry interval," "Third retry interval," and "Subsequent retry interval" for an SMTP message on the **Delivery** tab. This property exists for \smtpsvc and \smtpsvc\1. Setting the value changes the metabase setting for the individual virtual server, not the whole smtpsvc.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36996 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpRemoteRetryThreshold Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRemoteRetryThreshold** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 3 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36995 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpRoutingTableType Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRoutingTableType** property is obsolete.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | ldap |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36950 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC/*n*/RoutingSources | IIsSmtpRoutingSource |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpRsetTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpRsetTimeout** property determines how long the server waits, after a client issues this command, before hanging up because of inactivity.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37010 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpSaslTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpSaslTimeout** property determines how long the server waits, after a client issues this command, before hanging up because of inactivity.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37007 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpServer Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpServer** property contains the address of the SMTP server for use when sending e-mail to a moderator.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45059 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpServiceVersion Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpServiceVersion** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36931 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpSSLCertHostnameValidation Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Certificates have a "common name" that matches the name of the computer that owns it. The **SmtpSSLCertHostnameValidation** property verifies that the "common name" of a certificate matches the name of the remote computer that sent the certificate.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37026 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpSSLRequireTrustedCA Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpSSLRequireTrustedCA** property enables verification of a certificate that a remote host gives you when you connect to it. It makes sure this certificate is in your trusted certificate root on your computer. If not, it ends the SSL session and the handshake is rejected.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37025 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SmtpTurnTimeout Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpTurnTimeout** property determines how long the server waits, after a client issues this command, before hanging up because of inactivity.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 37009 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase PropertiesCode Examples to Configure Metabase Properties.

# SmtpUseTcpDns Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SmtpUseTcpDns** property specifies if SMTP uses TCP for DNS. The value can be 0 (IE UDP only), 1 (TCP only), 2 (try UDP and then TCP), or others.

The metabase represents unlimited as the DWORD value of 4294967295 (0xFFFFFFFF); however, VBScript represents unlimited in hexadecimal format as &HFFFFFFFF. Previous versions of IIS represented unlimited as -1.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | Boolean |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | 4294967295 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 36997 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SSIExecDisable Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SSIExecDisable** property specifies whether server-side include (SSI) #exec directives are disabled under this path.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_SSI_EXEC_DISABLED |
| Attributes | INHERIT |
| Default Value | **FALSE** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6028 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name* /LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SSLAlwaysNegoClientCert Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SSLAlwaysNegoClientCert** property controls SSL client connection negotiations. If this property is set to **true**, any time SSL connections are negotiated, the server will immediately negotiate a client certificate, preventing an expensive renegotiation. Setting **SSLAlwaysNegoClientCert** also helps eliminate client certificate renegotiation deadlocks, which may occur when a client is blocked on sending a large request body when a renegotiation request is received.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | BOOL |
| WMI Data Type | BOOL |
| ADSI Data Type | BOOL |
| ABO Data Type | BOOL |
| ABO Metabase Identifier | MD_SSL_ALWAYS_NEGO_CLIENT_CERT |
| Attributes | INHERIT |
| Default Value | **FALSE** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5521 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SSLCertHash Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SSLCertHash** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | binary |
| WMI Data Type | binary |
| ADSI Data Type | binary |
| ABO Data Type | binary |
| ABO Metabase Identifier | MD_SSL_CERT_HASH |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5506 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SslCtlIdentifier Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SslCtlIdentifier** property contains a unique value that identifies a specific certificate trust list (CTL). It must be used with SslCtlStoreName Metabase Property to accurately reference a CTL.

| **Attribute Name** | **Attribute Value** |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5512 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SslCtlStoreName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SslCtlStoreName** property contains the name of the CryptoAPI store that contains certificate trust lists (CTL). It must be used with SslCtlIdentifier Metabase Property to accurately reference a CTL.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_SSL_CERT_STORE_NAME |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5517 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SSLStoreName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SSLStoreName** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_SSL_CERT_STORE_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5511 |

**Configurable Locations**

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# SslUseDsMapper Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **SslUseDsMapper** property specifies whether IIS is to use the Windows Directory Service certificate mapper or IIS certificate mapper. If **SSLUseDSMapper** is set to **false**, IIS uses the IIS certificate mapper.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_SSL_USE_DS_MAPPER |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5019 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# StartupTimeLimit Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The value of the **StartupTimeLimit** property specifies the amount of time (in seconds) that the World Wide Web Publishing Service (WWW Service) should wait for a worker process to finish starting up and reporting to the WWW Service.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_APPPOOL_STARTUP_TIMELIMIT |
| Attributes | INHERIT |
| Default Value | 90 |
| MetaFlagsEx | CACHE_PROPERTY_CLEARED |
| User Type | IIS_MD_UT_SERVER |
| ID | 9011 |

**Configurable Locations**

# SuppressDefaultFTPBanner Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By default, the FTP service sends a "220 Microsoft FTP Service" banner when clients connect to the server. The **SuppressDefaultFTPBanner** property allows you to disable the display of the default FTP banner.

When **SuppressDefaultFTPBanner** is set to **true**, the message sent to the client will only include the number "220", not the "Microsoft FTP Service" part of the banner name.

| **Important** |
| --- |
| Configurable banner messages which follow this banner are not affected. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_SHOW_4_DIGIT_YEAR |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlags | CASEINSENSITIVE |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5017 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/MSFTPSVC/*n* | IIsFtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# TraceUriPrefix Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **TraceUriPrefix** metabase property defines a specific URL or set of URLs to trace for IIS 6.0 request-based tracing (available in Windows Server 2003 Service Pack 1 or later). When setting this property specify either a physical to a file or a relative path with a wild card.

For example: To trace a specific URL, you would type the following at a command prompt:

**adsutil.vbs set w3svc/** *n* **/TraceUriPrefix=** *path to URL*

and press ENTER. *N* is the number of the site as it is listed in the metabase, e.g. w3svc/1 is the default Web site (by default). Path to URL is the physical path to the file you want to trace, e.g. /Inetpub/wwwroot/asp/default.asp

To trace a set of URLs, for example all .asp pages or .aspx pages, you would type the following at a command prompt:

**adsutil.vbs set w3svc/** *n* **/TraceUriPrefix**=*path to URL*extension*

and press ENTER. *N* is the number of the site as it is listed in the metabase, e.g. w3svc/1 is the default Web site (by default). *Path to URL*extension* is the physical path to the group of files you want to trace, e.g. /Inetpub/wwwroot/asp/*.asp or /Inetpub/wwwroot/aspnet/*.aspx

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# UNCUserName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **UNCUserName** property specifies the user name for Universal Naming Convention (UNC) virtual roots. Use this property only as a flag for authentication schemes that support delegation.

| **Note** |
| --- |
| Integrated Windows authentication (NTLM) does not support delegation. |

When a request comes in to the IIS server, IIS looks at the **UNCUserName** property on the virtual directory. If the property exists and it is not an empty string, then the UNC user name and password are used for authentication. If authentication fails, a 401.2 error is returned to the client. If authentication passes, then the client's original credentials are passed through to the resources that were requested.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_VR_USERNAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 3002 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/MSFTPSVC/*n*/ROOT /LM/MSFTPSVC/*n*/ROOT/*virtual_directory_name* | IIsFtpVirtualDir |
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |
| /LM/SMTPSVC/*n*/ROOT /LM/SMTPSVC/*n*/ROOT/*virtual_directory_name* | IIsSmtpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# UpdatedDefaultDomain Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **UpdatedDefaultDomain** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 36937 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# UpdatedFQDN Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **UpdatedFQDN** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **true** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 36936 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/SMTPSVC | IIsSmtpService |
| /LM/SMTPSVC/*n* | IIsSmtpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# UploadReadAheadSize Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **UploadReadAheadSize** property establishes the number of bytes a Web server will read into a buffer and pass to an ISAPI extension. This occurs once per client request. The ISAPI extension receives any additional data directly from the client. The range is 0 to &HFFFFFFFF (4 GB).

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_UPLOAD_READAHEAD_SIZE |
| Attributes | INHERIT |
| Default Value | 49152 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6045 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name*<br>/LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# UseDigestSSP Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Advanced Digest authentication uses the **UseDigestSSP** metabase property to switch between Digest and Advanced Digest security support provider interface (SSPI) code. If this property is set to **false**, Digest authentication is used. In all other cases (**true**, empty, or not set), IIS uses Advanced Digest authentication. If you configure UseDigestSSP at the W3SVC level of the metabase, all child keys inherit their configuration from that level.

| **Important** |
| --- |
| If Digest SSPI code is used and dedicated application mode is selected, the Local System account must be used as the identity. |

The World Wide Web Publishing Service (WWW service) must be restarted before changes to this property take effect.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | MD_USE_DIGEST_SSP |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 6047 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n*/ROOT/*file_name* /LM/W3SVC/*n*/ROOT/*virtual_directory_name/file_name* | IIsWebFile |
| /LM/W3SVC/*n*/ROOT/*physical_directory_name* /LM/W3SVC/*n/virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# UserIsolationMode Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **UserIsolationMode** property defines the isolation type for the corresponding FTP site.

If **UserIsolationMode** is set to **0**, there is no user isolation. This setting is the default and is backward-compatible.

If the property is set to **1**, a client authenticates using local or domain accounts and is then sent to a folder under the root that matches the user name. This setting is called "Isolated (Locally)," and it supports users who do not want to use Active Directory.

If the property is set to **2**, user isolation is dependent on Active Directory. This setting is called "Isolated (Active Directory)," and it is primarily used by Internet service providers (ISPs) and other customers who want to set up large numbers of FTP accounts.

If you set this property to **2**, you should also set the DefaultLogonDomain Metabase Property, ADConnectionsPassword Metabase Property, and ADConnectionsUserName Metabase Property properties.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_USER_ISOLATION |
| Attributes | INHERIT |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 5012 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC | IIsFtpService |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# VrDoExpire Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **VrDoExpire** property controls whether the virtual root uses its own expiration policy.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **false** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46161 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# VrDriverClsid Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **VrDriverClsid** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46156 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# VrDriverProgid Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **VrDriverProgid** Metabase Property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46157 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# VrOwnModerator Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **VrOwnModerator** property is used by Microsoft Exchange.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | Boolean |
| WMI Data Type | Boolean |
| ADSI Data Type | Boolean |
| ABO Data Type | Boolean |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46163 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# VrUseAccount Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **VrUseAccount** property controls wither the virtual root account is used to log on.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 46160 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# WAMUserName Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **WAMUserName** property specifies the account user name that IIS uses by default as the COM+ application identity for newly created IIS out-of-process applications. The values of this property and its companion property, WAMUserPass Metabase Property, are set when IIS is installed, and match the user name and password values in the Microsoft Windows user account, which is established at the same time. Changing the value of this property is not recommended. If you do, change it to a valid Windows user account, and change **WAMUserPass** to the corresponding password for the new account.

| **Important** |
| --- |
| Changes to **WAMUserName** and **WAMUserPass** may disrupt the operation of existing IIS out-of-process applications. You can synchronize application identities using Component Services to edit the user name and password values, found on the **Identity** tab of the property sheet for each package. |

In-process applications are not affected by these property values.

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_WAM_USER_NAME |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 7501 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

WAMUserPass Metabase Property

# WAMUserPass Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **WAMUserPass** property specifies the password for the account that IIS uses by default as the COM+ application identity for newly created IIS out-of-process applications. The values of this property and its companion property, **WAMUserName**, are set when IIS is installed, and match the password and user name values in the Microsoft Windows user account (IWAM_*MachineName*, where *MachineName* is the name of the machine on which IIS is installed) established at the same time.

| **Important** |
| --- |
| Changing the value of this property is not recommended. If you do, you must change the Windows account password to the identical value. You must also synchronize existing IIS out-of-process application identities, using Component Services to edit the user name and password values, which are found on the **Identity** tab of the property sheet for each package. |

In-process applications are not affected by these property values.

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | MD_VR_PATH_DELIMITER_string |
| Attributes | INHERIT \| SECURE |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_FILE |
| ID | 7502 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

**Related Information**

WAMUserName Metabase Property

# WebDAVMaxAttributesPerElement Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003 with SP1

The **WebDAVMaxAttributesPerElement** metabase property specifies the maximum number of attributes allowed per XML element, including namespaces.

| **Note** |
| --- |
| For Windows Server 2003 with Service Pack 1 (SP1), this property will be added to the IIS schema, but it must be set manually. |

| **Attribute Name** | **Attribute Value** |
| --- | --- |
| **XML Data Type** | DWORD |
| **WMI Data Type** | DWORD |
| **ADSI Data Type** | DWORD |
| **ABO Data Type** | DWORD_METADATA |
| **ABO Metabase Identifier** | MD_WEBDAV_MAX_ATTRIBUTES_PER_ELEMENT |
| **Attributes** | INHERIT |
| **Default Value** | 32 |
| **MetaFlagsEx** | CACHE_PROPERTY_MODIFIED |
| **User Type** | IIS_MD_UT_SERVER |
| **ID** | 8501 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| **Metabase Path** | **IIS Admin Object Type** |
| --- | --- |
| /LM/W3SVC | IIsWebService |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/W3SVC/*n*/ROOT | IIsWebVirtualDir |
| /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n*/ROOT/*virtual_directory_name/physical_directory_name* | IIsWebDirectory |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# WebSvcExtRestrictionList Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **WebSvcExtRestrictionList** property contains a multi-string list of ISAPIs and CGIs used by applications on the Web server, including their location, descriptive information, and a flag for determining whether the Web service extension is enabled or disabled. The **WebSvcExtRestrictionList** property is used by the Web server to determine whether an ISAPI extension is permitted to run.

Each string element is written as:

```
AllowDenyFlag,ExtensionPhysicalPath,UIDeletableFlag,GroupID,Description
```

- AllowDenyFlag is "0" if the extension is not allowed or "1" if the extension is allowed.
- ExtensionPhysicalPath is the full path to the extension. If the last four characters of the physical path are ".dll" (case insensitive), then the extension is an ISAPI, otherwise it is a CGI. In the case of CGI script mappings, the physical path must contain the physical path from the mapping (i.e. "c:\windows\system32\cmd.exe %s %s").
- UIDeletableFlag is "1" if the UI is allowed to delete the extension from the list or "0" if the UI is not allowed to delete it.
- GroupID is a non-localizable string used to identify groups of extensions.
- Description is a localizable description of the extension.

**Example**

Some examples of elements in this property are shown below. The first two entries, for *.dll and *.exe are special cases, referring to "All Unlisted ISAPIs" and "All Unlisted CGIs," respectively. The Web server core enables or disables all ISAPIs or all CGIs depending on the setting, if these entries are present:

```
"0,*.dll"
"0,*.exe"
"0,c:\windows\system32\inetsrv\asp.dll,0,ASP,Active Server Pages"
"0,c:\windows\system32\inetsrv\httpodbc.dll,0,HTTPODBC,Internet Data Connector"
"0,c:\windows\system32\inetsrv\ssinc.dll,1,SSINC,Server Side Includes"
```

Configuring the **WebSvcExtRestrictionList** property using Admin Base Object (ABO) can be risky because the format of the property must be perfect. The property is represented as a buffer of strings that are delimited by \0 and composed of five fields separated by commas. A safer way to configure this property is by using the extension-related ADSI and WMI methods of the **IIsWebService** object. For a brief comparison of ADSI and WMI, see Administering IIS Programmatically.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | MULTISZ |
| WMI Data Type | MULTISZ |
| ADSI Data Type | MULTISZ |
| ABO Data Type | MULTISZ |
| ABO Metabase Identifier | MD_WEB_SVC_EXT_RESTRICTION_LIST |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |

| | |
|---|---|
| ID | 2168 |

**Configurable Locations**
You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC | IIsWebService |

**Code Example**
For general code examples, see Code Examples to Configure Metabase Properties.

# Win32Error Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **Win32Error** property indicates the Microsoft Win32 error status code. For more information about Microsoft Win32 error codes, see "Win32 Error Codes" on MSDN.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | DWORD |
| WMI Data Type | SINT32 |
| ADSI Data Type | DWORD |
| ABO Data Type | DWORD |
| ABO Metabase Identifier | MD_WIN32_ERROR |
| Attributes | VOLATILE |
| Default Value | 0 |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 1099 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/W3SVC/*n*/ROOT /LM/W3SVC/*n*/ROOT/*virtual_directory_name* | IIsWebVirtualDir |
| /LM/W3SVC/*n* | IIsWebServer |
| /LM/MSFTPSVC/*n* | IIsFtpServer |
| /LM/MSFTPSVC/*n*/ROOT /LM/MSFTPSVC/*n*/ROOT/*virtual_directory_name* | IIsFtpVirtualDir |
| /LM/NNTPSVC/*n* | IIsNntpServer |
| /LM/NNTPSVC/*n*/ROOT /LM/NNTPSVC/*n*/ROOT/*virtual_directory_name* | IIsNntpVirtualDir |
| /LM/SMTPSVC/*n* | IIsSmtpServer |
| /LM/SMTPSVC/*n*/ROOT /LM/SMTPSVC/*n*/ROOT/*virtual_directory_name* | IIsSmtpVirtualDir |
| /LM/W3SVC/AppPools/DefaultAppPool<br>/LM/W3SVC/AppPools/DefaultAppPool/*application_pool_name* | IIsApplicationPool |
| /LM/W3SVC/AppPools | IIsApplicationPools |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# XMLSchemaTimeStamp Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **XMLSchemaTimeStamp** property keeps the MBSchema.xml file in sync with the binary schema file.

| **Important** |
| --- |
| Because this property is internally configured by IIS, you should consider it to be read-only. Do not configure this property. |

| Attribute Name | Attribute Value |
| --- | --- |
| XML Data Type | binary |
| WMI Data Type | binary |
| ADSI Data Type | binary |
| ABO Data Type | binary |
| ABO Metabase Identifier | MD_GLOBAL_XMLSCHEMATIMESTAMP |
| Attributes | NO_ATTRIBUTES |
| Default Value | **null** |
| MetaFlagsEx | Not applicable |
| User Type | IIS_MD_UT_SERVER |
| ID | 9992 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
| --- | --- |
| . | IIS_Global |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# XoverTableFile Metabase Property

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The **XoverTableFile** property specifies the Xover hash file.

| Attribute Name | Attribute Value |
|---|---|
| XML Data Type | String |
| WMI Data Type | String |
| ADSI Data Type | String |
| ABO Data Type | String |
| ABO Metabase Identifier | No friendly name is defined for this identifier in iiscnfg.h. Search the *systemroot*\System32\Inetsrv\MBSchema.xml file for this property and use the integer from its ID attribute. |
| Attributes | INHERIT |
| Default Value | **null** |
| MetaFlagsEx | CACHE_PROPERTY_MODIFIED |
| User Type | IIS_MD_UT_SERVER |
| ID | 45161 |

**Configurable Locations**

You can configure this property at the following locations in the IIS metabase.

| Metabase Path | IIS Admin Object Type |
|---|---|
| /LM/NNTPSVC/*n* | IIsNntpServer |

**Code Example**

For general code examples, see Code Examples to Configure Metabase Properties.

# IIS 6.0 Registry Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The configuration registry stores entries that define the working environment for the Microsoft® Windows® operating system and any services that are installed on a computer running Windows. You can use graphical tools (such as Control Panel or Setup) to change these values, or you can use the Registry Editor (Regedit.exe) utility that is included in Windows to modify the configuration registry directly.

This section includes the following information:

- About the Registry: Provides conceptual topics related to the registry.
- Global Registry Entries: Specifies entries used for global control of Internet services.
- Service-Specific Registry Entries: Specifies entries stored in the registry by Internet services for service-specific behavior.
- ASP Registry Entries: Specifies entries for Active Server Pages (ASP).
- WWW Service Registry Entries: Specifies entries for the World Wide Web Publishing Service (WWW service) only.
- FTP Service Registry Entries: Specifies entries for FTP services only.

**Related Information**

- For information about the metabase, see IIS Metabase.
- For information about routine server administration tasks, see Server Administration Guide.

# About the Registry

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The registry is a repository for information about a computer's configuration, such as profiles for each user and the programs that are installed. The registry is organized hierarchically and is made up of keys and their subkeys, hives, and entries.

Many entries that existed in the registry for previous versions of Internet Information Services (IIS) were migrated to a fast-access, hierarchical database, called the *metabase*. Entries that were migrated to the metabase are known as *metabase properties*. Most of the remaining registry keys are used to initiate Internet services and enable backward compatibility with previous versions of IIS, are specific to a service, or are global to IIS and all services. Any new configuration for IIS should be written to the metabase.

Windows includes Registry Editor, which can be used to configure the registry. For information about using Registry Editor, see "Registry Editor" in Help and Support Center for Windows Server 2003.

| **Important** |
| --- |
| For a registry change to take effect, you must restart the service that is affected by the change. For global changes to take effect, you must restart all services. |

**Related Information**

- For more information about the registry, see "Registry structure" in Help and Support Center for Windows Server 2003.
- For information about how to restart IIS, see Restarting IIS.
- For more information about the IIS metabase, see IIS Metabase.

# Global Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following registry entries affect all of the IIS services, without having to be set for each individual service. On a default installation of IIS, you might not see some of these registry entries, which indicates that the default values are being used. To set these entries to values other than the default values, you must manually create the keys and set them.

| **Important** |
| --- |
| For a registry change to take effect, you must restart the service that is affected by the change. For global changes to take effect, you must restart all services. |

| **CacheSecurityDescriptor** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 1 (enabled) |
| Range: 0 - 1 |
| Specifies whether security descriptors are cached for file objects. When **CacheSecurityDescriptor** is enabled, IIS retrieves security permissions when caching a file object and does not need to gain access to the file object to check access rights for new users. The feature is useful only if you have more than one user account (Web server does not use only Anonymous authentication). |

| **CheckCertRevocation** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 - 1 |
| Specifies whether client certificates are checked for revocation by IIS. **CheckCertRevocation** is disabled by default because checking for common certificate issuers is typically done over the Internet and has severe performance impact. However, enabling **CheckCertRevocation** may be useful if you issue your own certificates and the revocation process is local. |

| **DataSetCacheSize** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 50 |

| |
|---|
| Each IIS worker process (w3wp.exe) contains a local metabase data cache of up to 50 entries. For each request, the required dataset is obtained from the local metabase cache if possible. If the dataset is not found in the cache, then an expensive LPC request is made to the Inetinfo.exe process for the dataset residing in the metabase. When there are more than 50 virtual directories, IIS disables the metabase data cache, forcing all requests to go via the expensive path (which negatively impacts throughput).<br><br>This registry entry allows administrators or IT managers to set the maximum number of dataset entries in the cache if the number of total installed virtual directories exceeds the default (50). This key is not created by default. |

| **DigestContextCacheTTL** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 300 (seconds) |
| Range: 0 - 4,294,967 |
| When using Advanced Digest Authentication, this value overrides the Time To Live (TTL) setting for fully formed security contexts after the first authentication request succeeds. |

| **DigestPartialContextCacheTTL** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 30 (seconds) |
| Range: 0 - 4,294,967 |
| When using Advanced Digest Authentication, this value overrides the Time To Live (TTL) setting for partially formed security contexts for the first authentication challenge request. |

| **DisableLazyContentPropagation** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (lazy propagation enabled) |
| Range: 0 - 1 |

| |
|---|
| Lazy propagation refers to the action that IIS takes when a large amount of content is updated at one time.<br><br>IIS has an internal limit of how much content can be updated in the in-memory template cache. If the size of the updated content exceeds that limit, IIS marks each of the files in the in-memory template cache as invalid. On the first request to an invalid file, IIS begins to compile a new template but the expired template is served and is continued to be served until the new template is compiled.<br><br>If you set **DisableLazyContentPropagation** to 1, IIS behaves as it does for IIS 5.0 and IIS 5.1 when a large amount of content is updated at one time. IIS flushes the in-memory template cache, and performance can slow to a standstill as each new request to the server forces IIS to compile new templates.<br><br>If you are developing Web pages and making changes to a few files at a time, you do not have to refresh your pages twice to see new changes because lazy propagation only applies when a large amount of content is updated at one time. |

| **DisableMemoryCache** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 - 1 |
| Disables server caching. |

| **DoDirMonitoringForUNC** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Inetinfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 (disabled) - 1 (enabled) |
| This setting determines whether static files rely on the Change Notification mechanism for UNC to determine whether or not content is stale. The File Change Notification mechanism is not considered robust enough for tracking changes over UNC, and for this reason this setting is disabled. IIS and ASP use the Last Modified mechanism to track files instead. |

| **ErrorLoggingDir** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\HTTP\Parameters |
| Data Type: REG_STRING |
| Default Value: *systemroot*\system32\logfiles |
| Range: N/A |
| Specifies the location of the Httperr.log file. Httperr.log is a new feature in IIS 6.0. If HTTP.sys is unable to write an error to a Web site log because the request did not reach user mode, the error will be entered in Httperr.log. Errors that are written to Httperr.log include the following: 503 errors, idle connection time-outs, URL parsing errors, and the last 10 requests to a failed application pool. |

| **FileAttributeCheckThreshold** |
|---|

| |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 5 (seconds) |
| Range: 0 - 4,294,967 |
| When the Last Modified mechanism is used to track files, this key enables caching of static content from an UNC share in the HTTP.sys cache and specifies the amount of time for the content to remain in the cache. |

| **IncrementalSiteIDCreation** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\InetMgr\Parameters |
| Data Type: REG_DWORD |
| Default Value: Key is not created by default, and therefore site identifiers are large, unique, randomly generated numbers. |
| Range: 0 - 1 |
| When a new site is created on IIS 6.0, a site identification number is randomly generated using the name of the Web site. This ensures that all IIS 6.0 servers in a Web farm have a good chance of generating the same site identification number for sites of the same name. With IIS 5.1 and previous versions, site identification numbers were incremental. For example, because the default Web site is created first, its site identification number is 1, and the next site to be created is identified as 2.<br><br>If you have administration scripts that depend upon the IIS 5.1 method of generating site identification numbers, you can create the **IncrementalSiteIDCreation** key at the path specified above, and set it to 1 to force IIS to use incremental site identification numbers.<br><br>**Note**<br>When you remotely administer another IIS server, the value of the registry key of the local server is used to determine the generation of site identification numbers on the remote server.<br><br>To choose the identification number of your Web site, create the site programmatically using the IIsWebService.CreateNewSite or IIsFtpService.CreateNewSite WMI method, whose optional fourth parameter holds a user-chosen site identification number. |

| **LogBufferSize** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\Http\Parameters\LogBufferSize |
| Data Type: REG_DWORD |
| Default Value: N/A |
| Range: 12,288 - 65,536 (12K - 64K) |
| Overrides the default logging buffer (per site) of 64K. Using this key, administrators can prevent excessive memory usage when running many thousands of sites on a server. This registry key does not exist by default and must be added to the registry. |

| **MaxCachedFileSize** |
|---|

| |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 256 KB (262,144 bytes) |
| Controls the maximum size of cache files. The default is 256 KB if no value is present. |

| **MaxConcurrency** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 |
| Range: 0 - 4,294,967,295 (unlimited) |
| Specifies the amount of concurrency that a system should provide. IIS uses completion ports to handle input-output (I/O). In general, have more than one thread running and conflicting on shared memory or locks. This key specifies how many threads per processor should be allowed to run simultaneously, if there is a pending I/O operation. A value of 0 allows the system to make the intelligent choice of the number of threads to use. Any nonzero value specifies that the system should allow that many threads per processor to run simultaneously. |

| **MaxPoolThreads** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 4 |
| Range: 0 - 4,294,967,295 (unlimited) |
| Specifies the number of pool threads to create per processor. Pool threads watch for the network for requests and process incoming requests. The **MaxPoolThreads** count does not include threads that are consumed by ISAPI applications. Generally, you should not create more than 20 threads per processor. |

| **MemCacheSize** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: approximately one half the available physical memory and calibrated in megabytes |
| Range: 0 - 2500MB |
| Controls the size of the cache. The default value dynamically adjusts every 60 seconds. |

| **MinFileBytesPerSec** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |

| |
|---|
| Data Type: REG_DWORD |
| Default Value: 240 |
| Range: 1 - 8192 |
| When a Web server sends a file to a client, a time-out is established for how long the server will allow the transfer to continue before ending the connection. The time-out chosen is the maximum of the connection time-out specified in IIS Manager plus the size of the file, and divided by the value specified for **MinFileBytesPerSec**. For example, a file size of 100 KB is given a time-out of 100 seconds, or the connection time-out if the latter is greater. |

| **ObjectCacheTTL** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 30 (seconds) |
| Range: 0 - 4,294,967,295 (unlimited) |
| Controls the Time To Live (TTL) setting, which defines the length of time that objects are held in cached memory. If an object in the memory cache has not been referenced for the defined period, that object will be phased out of the cache. If system memory is limited, or the server's contents are dynamic, you can use a lower TTL to prevent system memory from being used to cache a large number of volatile objects. Setting **ObjectCacheTTL** to 0xFFFFFFFF disables the object-cache scavenger and allows cached objects to remain in the cache until they are overwritten. Disabling the cache scavenger is useful if your server has ample system memory and your data is relatively static. |

| **PoolThreadLimit** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 2 * # MB |
| Range: 0 - 4,294,967,295 (unlimited) |
| Specifies the maximum number of pool threads that can be created in the system. Pool threads watch the network for requests and process incoming requests. **PoolThreadLimit** is a hard limit that includes all IIS threads and is always greater than or equal to **MaxPoolThreads**. |

| **ThreadPoolMaxCPU** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: -1 (CPU metric is turned off) |
| Range: 0 - 100 |
| ThreadPoolMaxCPU is the maximum CPU that the thread pool should throttle back at. |

| **ThreadPoolStartDelay** |
|---|

| |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 1000 ms |
| Range: 1000 - 10,000 |
| ThreadPoolStartDelay is how long the thread pool should set the timer for when zero threads are waiting on the completion port. |

| **ThreadTimeout** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 24 * 60 * 60 (24 hours, expressed in seconds) |
| Range: 0 - 4,294,967,295 (unlimited) |
| Specifies the amount of time an input-output (I/O) processing thread should be maintained, even if there is no I/O activity on the system. In general, when there is no I/O activity and no requests outstanding, the server remains idle and does not consume memory. But if the server continues and exceeds the **ThreadTimeout** interval, the I/O processing thread is stopped. Units are in seconds. |

| **UserTokenTTL** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\InetInfo\Parameters |
| Data Type: REG_DWORD |
| Default Value: 15 * 60 (15 Minutes, expressed in seconds) |
| Range: 0 - 0x7FFFFFFF |
| When a request is made to the server, the security credentials for the request (or the configured anonymous user) are used to create a user token on the server. The server impersonates this user token when accessing files or other system resources (see **CacheSecurityDescriptor**). The token is cached so that the Windows log on takes place only the first time the user accesses the system or after the user's token has fallen out of the cache. Integrated Windows authentication tokens are not cached. Units are in seconds. |

# Service-Specific Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

**Service-Specific Registry Entries**

The following registry key, LanguageEngines, is not installed by default. You must create this key in the following location in order to use it.

HKEY_LOCAL_MACHINE\SYSTEM

\CurrentControlSet

\Services

\W3SVC

\ASP

\LanguageEngines

\LanguageName

Value: Write REG_SZ: Response.WriteEquiv |

Value: WriteBlock REG_SZ: Response.WriteBlockEquiv |

| **Important** |
| --- |
| For a registry change to take effect, you must restart the service that is affected by the change. For global changes to take effect, you must restart all services. |

**LanguageEngines**

| | |
| --- | --- |
| Registry Path | (See above) |
| Data Type | REG_STRING |
| Default Value | Not applicable |
| Description | Specifies a scripting language that does not support the **Object.Method** syntax as the Active Server Pages (ASP) primary scripting language (the language used within the ASP script delimiters <% ... %>). *LanguageName* is the name of the chosen language. `Response.WriteEquiv` is the language's equivalent of **Response.Write**; and `Response.WriteBlockEquiv` is the language's equivalent of **Response.WriteBlock**. The pipe symbol (\|) is an insertion used by ASP to send expressions and HTML blocks that are normally processed with **Response.Write** and **Response.WriteBlock** methods. This can be done automatically when installing additional scripting languages. If your scripting language is sensitive to white space or newline characters, you may not be able to use it as the primary scripting language even when this registry value is set. As an alternative, you can manually write HTML blocks to the browser or write that language's functions within tagged script blocks (<SCRIPT> ... </SCRIPT> ) and call them from any other language. |

# ASP Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The following registry entries affect the behavior and performance of ASP on IIS. On a default installation of IIS, you will not see these registry entries, which means the default values are being used. To set these entries to their non-default values, you must manually create the keys and set them.

| **DisableLazyContentPropagation** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 0 (lazy propagation enabled) |
| Range: 0 - 1 |
| Lazy propagation refers to the action that IIS takes when a large amount of content is updated at one time.<br><br>IIS has an internal limit of how much content can be updated in the in-memory template cache. If the size of the updated content exceeds that limit, IIS marks each of the files in the in-memory template cache as invalid. On the first request to an invalid file, IIS begins to compile a new template but the expired template is served and is continued to be served until the new template is compiled.<br><br>If you set **DisableLazyContentPropagation** to 1, IIS behaves as it does for IIS 5.0 and IIS 5.1 when a large amount of content is updated at one time. IIS flushes the in-memory template cache, and performance can slow to a standstill as each new request to the server forces IIS to compile new templates. If you are developing Web pages and making changes to a few files at a time, you do not have to refresh your pages twice to see new changes because lazy propagation only applies when a large amount of content is updated at one time. |

| **ThreadMax** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 100 |
| Range: 0 - PoolThreadLimit |
| This value is a hard limit on the maximum number of ASP worker threads. The number of threads in ASP is generally determined by the number of processors in the system multiplied by the **AspProcessorThreadMax** metabase setting. If the product of the number of processors present and **AspProcessorThreadMax** exceeds the value of **ThreadMax**, the ASP engine will not spawn any additional threads than the value specified by **ThreadMax**.<br><br>**Note**<br>A large number of threads can reduce system performance because of the resulting high context switching rate. |

| **DisableComPlusCpuMetric** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |

| |
|---|
| Default Value: 0 (enabled) |
| Range: 0 (enabled) - 1 (disabled) |
| This setting determines whether COM+ controls the rate at which new threads are spawned. If **DisableComPlusCpuMetric** is set to 1 (disabled), COM+ will not control the rate of spawning of additional threads. If **DisableComPlusCpuMetric** is set to 0(the default), COM+ controls spawning of additional threads based on a number of factors; primarily on the CPU utilization and the Context Switch rate for the system. These values can also be adjusted using the registry. To specify the CPU utilization at which COM+ begins to throttle the thread creation, use the MaxCPU Registry key. To specify the context switch rate at which COM+ should throttle thread creation use the MaxCSR registry key.<br>**Important**<br>Changing these settings from the default value can have a severe impact on performance. It is recommended that you leave these values at their defaults. |

| **AspMaxResponseHeaderLength** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 64 Kilobytes |
| Range: 0 - ffffffff |
| This is a security setting that limits the size of the header generated using the response object by an ASP script file. If the size of the response header exceeds the value of **AspMaxResponseHeaderLength**, the system returns a 500 response to the client. |

| **AspMaxPropertyStringLength** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 16 Kilobytes |
| Range: 0 - ffffffff |
| This is a security setting that limits the string length of a single property name. If the string length of the property name exceeds the value of **AspMaxPropertyStringLength**, the system returns a 500 response to the client. |

| **DisableCachedResponseOnUNCAccessFailure** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 0 (enabled) |
| Range: 0 (enabled) - 1 (disabled) |

This setting determines whether ASP will serve a cached response in the event a network or other communication problem prevents ASP from validating the requested page against the back end system (mapped by way of a UNC path) containing the content to be served. By default, if communication with the back end system is not possible when ASP attempts to validate the requested page, ASP will serve the cached page. Note that the response is still checked against existing credentials stored with the file. An event log message will be logged to let the administrator know that the system took a corrective action. The administrator may want to look at the event log if customers complain of stale content. There might be a problem with the network connection with the back end. If **DisableCachedResponseOnUNCAccessFailure** is set to 1 (disabled), ASP returns a 500 error to the client. This setting can be useful for failure detection systems to kick in (e.g., if a load balancer attached to the system it can direct the request to another system.) This prevents serving stale content, and also notifies the administrator of the error.

**F5AttackDetectionEnabled**

Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\

Data Type: REG_DWORD

Default Value: 1 (enabled)

Range: 0 (disabled) - 1 (enabled)

This is a security setting that determines whether ASP scans the request queue at regular intervals to detect disconnected requests and remove them from the queue. This has the effect of not allowing disconnected requests to fill up the request queue. In addition, cleaning up the queue improves system efficiency.

**Note**

Because disabling this setting can make your system vulnerable to attack, it is strongly recommended that you leave this setting enabled.

**HangDetRequestThreshold**

Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\

Data Type: REG_DWORD

Default Value: 1000

Range: 0 - ffffffff

This setting determines whether the hang detection algorithm should be invoked based on the number of requests in the request queue. A value of 0 means that the hang detection algorithm is never invoked.

**HangDetThreadHungThreshold**

Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\

Data Type: REG_DWORD

Default Value: 50 (%)

Range: 1 - 100

This setting determines what percentage of the total number of ASP application threads must be unresponsive to fulfill one of the criteria for recycling the application.

| **HangDetConsecIllStatesThreshold** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 3 |
| Range: 0 - 3 |
| This setting helps prevent applications from being declared unhealthy and recycled because of transitory bursts in the application's request queue. If the number of times an application is consecutively detected to be in the "ill" state exceeds the **HangDetConsecIllStatesThreshold** value, AND if the application's request queue length has been increasing during the same period of time, ASP reports the application as being unhealthy, and IIS recycles the application. |

| **HangDetEnabled** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 1 (enabled) |
| Range: 0 (disabled) - 1 (enabled) |
| This setting determines whether or not ASP checks for and tracks unresponsive threads.<br><br>Once ASP hands over a page to a COM component for execution, it does not regain control unless the component returns a success or error. If a thread does not return within the timeout period specified on the **AspScriptTimeout** metabase property), it is considered unresponsive. Because there are a limited number of threads that can be executing at any one time on the system, each unresponsive thread means there is 1 less thread available to service a request queue. This results in a build up of the request queue unless the unresponsive threads are closed down.<br><br>ASP invokes the hang detection algorithm based on a combination of ASP registry and metabase request queue length settings. If the hang detection algorithm determines that the ratio of queued requests to the number of available threads high, ASP reports the application(s) with the unresponsive thread(s) as unhealthy, and IIS recycles the application(s). |

| **EnableChangeNotificationForUNC** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 (disabled) - 1 (enabled) |
| This setting determines whether ASP relies on the Change Notification mechanism for UNC to determine whether or not content is stale. The file change notification mechanism is not considered robust for tracking changes over UNC, and for this reason this setting is disabled. IIS and ASP use the Last Modified mechanism to track files instead. |

| **FileMonitoringEnabled** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |

| |
|---|
| Default Value: 1 (enabled) |
| Range: 0 (disabled) - 1 (enabled) |
| This setting determines whether files are registered for change notification. This setting is no longer used as the functionality has been encompassed in system logic and the **FileMonitoringEnabled** setting. Do not use this setting. |

| **FileMonitoringTimeoutSeconds** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 5 |
| Range: 0 - ffffffff |
| The last modified time stamp method of maintaining consistency in cache verifies if last modified time stamp of a file has changed since the file was last checked. This means that the check occurs on every request. This has a serious affect on performance. **FileMonitoringTimeoutSeconds** specfies the number of seconds that the system should return the cached copy since its last timestamp check.<br><br>Increasing the value of this key will improve performance, but can lead to returning stale content for the number of seconds specified in this key. This key applies to cases where the content is stored on a back end UNC or the local disk has had a huge content propagation and the change notification buffer has not been able to capture all the changes, thus pushing the system into a last modified algorithm for all files. You may want to tailor this key to suit your needs. |

| **MaxCSR** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: None. Determined dynamically. |
| Range: 0 - ffffffff |
| If COM+ is managing the CPU metric then this setting can be adjusted to tune COM+'s creation of the number of threads that ASP will use to process requests. COM+ tries to create threads on demand while staggering their creation so as not to put the system into an overloaded state. MaxCSR watches the context switch rate, and if the context switching in the system exceeds the rate specified in this key, COM+ stops spawning threads until the context switch rate falls below the value specified by this key. |

| **MaxCPU** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 100 |
| Range: 0 - 100 |

| |
|---|
| If COM+ is managing the CPU metric then this setting can be adjusted to tune COM+'s creation the number of threads that ASP uses to process requests, while staggering their creation so as not to put the system into an overloaded state. MaxCPU watches CPU utilization, and if the CPU utilization in the system exceeds the rate specified in this key, COM+ will stop spawning threads until CPU usage falls below the value specified by this key. |

| **DisableOOMRecycle** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\ASP\Parameters\ |
| Data Type: REG_DWORD |
| Default Value: 0 (enabled) |
| Range: 0 (enabled) - 1 (disabled) |
| If ASP is not able to allocate memory for its internal processing, it assumes the system is out of memory and requests that the application be recycled, thereby freeing memory possibly held by a misbehaving application.<br><br>Allowing ASP to request recycling based on out of memory conditions must be considered carefully because of unintended consequences, such as loss of session state. |

# WWW Service Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to Service-Specific Registry Entries, the World Wide Web Publishing Service (WWW service) maintains the following entries.

| **Important** |
| --- |
| For a registry change to take effect, you must restart the service that is affected by the change. For global changes to take effect, you must restart all services. |

| **EnableTraceMethod** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 - 1 |
| Determines whether IIS recognizes the **HTTP TRACE** method. The **TRACE** method is used to invoke a remote, application-layer loop-back of a request message. **TRACE** allows a client to see what is being received at the other end of the request chain and use that data for testing and debugging information.<br>**Important**<br>Do not leave **EnableTraceMethod** enabled on a production system, as it can reveal back-end server address information to a malicious user. |

| **LogErrorRequests** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 1 (enabled) |
| Range: 0 - 1 |
| Determines whether to record failed activities in the log file. A value of 1 logs failed activities, and a value of 0 turns it off. |

| **LogSuccessfulRequests** |
| --- |
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 1 (enabled) |
| Range: 0 - 1 |

| |
|---|
| Determines whether to record successful activities in the log file. A value of 1 logs successful activities, and a value of 0 turns it off. |

| **MaxConcurrentCgisExecuting** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 256 |
| Range: 0 - 4294967295 |
| Determines the maximum number of concurrent CGIs allowed to run on the system. Additional CGI requests will be queued and then processed when the number of processing requests falls below the number set in this registry key. |

| **SSIEnableCmdDirective** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 - 1 |
| To execute shell commands, the **#exec cmd** directive of server-side includes is used. Security-conscious sites may want to disable the **#exec cmd** directive when untrusted parties are allowed to place files on the server by setting **SSIEnableCmdDirective** to 0 as an added security precaution. **SSIEnableCmdDirective** does not exist in the registry by default; to allow the **#exec cmd** directive to execute shell commands, you must first create **SSIEnableCmdDirective** and set it to 1. |

| **TryExceptDisable** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 (disabled) |
| Range: 0 - 1 |
| Disables exception caching when calling the **HttpExtensionproc** of an Internet Server API (ISAPI) application. Setting **TryExceptDisable** to 1 results in any exception that is caused by a misbehaving ISAPI application to stop the server, but it allows developers to do just-in-time debugging. Therefore, you should set **TryExceptDisable** to 1 only to debug ISAPI applications. |

| **UploadReadAhead** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 48KB |

| |
|---|
| Range: 0 - 0x80000000 |
| When a client posts data to the server, some data is read by the server and some by the application. **UploadReadAhead** sets the amount of data the server will read before passing control to the application. The application is then responsible for reading the rest of the data. If you increase this size, you should increase the amount of RAM on the server. |

| **UsePoolThreadForCGI** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 1 (enabled) |
| Range: 0 - 1 |
| IIS, by default, uses a server pool thread to do Common Gateway Interface (CGI) processing. This means that CGI requests that take an extended period of time can consume a server pool thread. |

| **UseSharedWPDesktop** |
|---|
| Registry Path: HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\W3SVC\Parameters |
| Data Type: REG_DWORD |
| Default Value: 0 |
| Range: 0 - 1 |
| If you are setting up your application pools with unique identities, then depending on the applications and memory resources on your server, you will reach a limit of about 60 application pools. There are finite limits of some system resources that get allocated with each new logon session. This means that 60 processes can run concurrently as distinct accounts. IIS 6.0 supports running these processes in a single shared workstation and desktop, at a cost of sharing a single encapsulation of a user session among all parties. To scale beyond 60 application pools and to share a single desktop, change the **UseSharedWPDesktop** to a DWORD value of 1. After changing this registry key, you should be able to scale to hundreds of application pools and hundreds of concurrently running worker processes. |

# FTP Service Registry Entries

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In addition to Service-Specific Registry Entries,the FTP service maintains the following value entries.

**Details**

| **Important** |
| --- |
| For a registry change to take effect, you must restart the service that is affected by the change. For global changes to take effect, you must restart all services. |

**AnnotateDirectories**

| | |
| --- | --- |
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters |
| Data Type | REG_DWORD |
| Default Value | 0 (disabled) |
| Range | 0,1 |
| Description | The FTP service supports annotating a directory with custom messages. The annotation text is stored in a file named ~ftpsvc~.ckm in the directory to be annotated. If ~ftpsvc~.ckm exists in the target directory of a Change Directory (CWD - Change Working Directory) FTP operation, the FTP service responds with the contents of this file for the operation. This provides a way for administrators to add custom messages for directories under consideration. By default, the service is configured to not send annotation text. If you choose to add a custom message, you should also create the annotation file. Also, you should make the annotation file a hidden file so that the file does not appear on a directory listing. |

**AnonymousHomeDirInfoGrace**

| | |
| --- | --- |
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters\ |
| Data Type | REG_DWORD |
| Default Value | 1 |
| Range | 0 - 4,294,967,295 |
| Description | This entry specifies the number of seconds (grace period) during which the cached value for anonymous home directory will still be used after the interval in AnonymousHomeDirInfoInterval expires. After the grace period expires, the entries in the cache are updated and the requests will receive the new updated entries. The first request made after that time will update the cached entry. Although the range of values allows up to the maximum for DWORD properties, it is recommended that you keep this value low. |

**AnonymousHomeDirInfoInterval**

| | |
| --- | --- |
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters\ |
| Data Type | REG_DWORD |
| Default Value | 10 |

| | |
|---|---|
| Range | 0 - 4,294,967,295 |
| Description | This entry specifies the number of seconds during which the entry of the anonymous home directory is cached. The first anonymous login made after that time will update the cached entry. Although the range of values allows up to the maximum for DWORD properties, you should consider potential changes in the home directory path when you decide on the value set for this registry key. |

**CacheAnonymousHomeDirInfo**

| | |
|---|---|
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters\ |
| Data Type | REG_DWORD |
| Default Value | 0 (disabled) |
| Range | 0 to 4,294,967,295. Any DWORD value other than 0 will cause the FTP server to cache the anonymous home directory. |
| Description | This entry enables caching of the anonymous home directory. Caching the anonymous home directory helps to avoid having the FTP server refuse anonymous connections when the home directory resides on an UNC share and too many users are already connected. In such cases, you may see FTP event message number 8: "FTP Server could not create a client worker thread for user at host %1. The connection to this user is terminated. The data is the error."<br><br>When this key is enabled, the cache will have a 10 second refresh interval and a 1 second grace period, both of which are configurable--respectively--in the registry keys AnonymousHomeDirInfoInterval and AnonymousHomeDirInfoGrace. |

**EnablePortAttack**

| | |
|---|---|
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters |
| Data Type | REG_DWORD |
| Default Value | 0 (disabled) |
| Range | 0,1 |
| Description | This entry is disabled by default to prevent a security problem in the FTP protocol specification. Because EnablePortAttack is disabled by default, you should enable this flag if you want users to connect by using other ports as specified in the FTP RFC. The FTP service specification allows passive connections to be established based on the port address given by the client. This can allow malicious users to execute destructive commands in the FTP service. The problem occurs when the FTP service makes a connection to a client using a port other than FTP Data port (20) and that port number is less than IP_PORT_RESERVED (1024). EnablePortAttack controls whether or not such an attack should be allowed. By default, the service does not make any connections to port numbers lower than IP_PORT_RESERVED (other than 20). |

**LowercaseFiles**

| | |
|---|---|
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters\ |
| Data Type | REG_DWORD |
| Default Value | 0 (disabled) |
| Range | 0,1 |

| | |
|---|---|
| Description | The FTP service uses uppercase for file names. In order for comparisons with case-sensitive file systems to work, you need to ensure that the exact file names are compared. Administrators can add LowercaseFiles to the registry to ensure that the FTP service also uses lowercase for such comparisons. |

**MaxPassiveAcceptEvents**

| | |
|---|---|
| Registry Path | HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\MSFTPSVC\Parameters\ |
| Data Type | REG_DWORD |
| Default Value | 60 |
| Range | 1 through 300. Any number is rounded up to the nearest multiple of 60 and capped off at 300. |
| Description | This registry value is intended for advanced users. When FTP clients initiate passive file transfer operations, the FTP server uses asynchronous network notification to wait for the actual client connection to a passive data socket. By default, the FTP server allows 60 passive file transfer operations to be queued simultaneously. Once the queue reaches 60, subsequent client requests receive error 451: Too many Passive Users. Client connections remain in this transient state for a short time, between issuing a file transfer command (e.g. RETR, STOR) and connecting the data channel to the passive socket. For this reason, this error can only occur in one of the following scenarios:<br>1. A DoS attack has issued concurrent file transfer commands without actually connecting to the data socket.<br>2. An extremely large number of concurrent users are transferring files in passive mode (which is possible on slow networks).<br>Consistent failure with the above error may indicate a DoS attack. However, sporadic failures at peak usage times may indicate valid usage of this registry value. |

# Events Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS generates events in Event Viewer so that you can verify the performance of IIS. Event Viewer tracks (in order of importance) error events, warning events, and informational events. The logs in Event Viewer provide an audited record of all services and processes in the Microsoft® Windows® Server 2003 operating system, such as logon and connection times.

**In This Section**

- About Events: Provides conceptual topics related to Windows Events.
- ASP Errors: Specifies errors generated by the World Wide Web Publishing Service (WWW service) when processing ASP applications that are configured incorrectly.
- ASP Events: Specifies events generated from Active Server Pages.
- FTP Service Events: Specifies events generated by the FTP service.
- ODBC Driver Errors Returned by IIS: Specifies events caused by Web pages that contain ODBC driver errors.
- Server-Side Includes Events: Specifies events generated by the part of the WWW service that processes server-side include directives in Web pages.
- Core WWW Service Events: Specifies events generated from Web services.
- WWW Performance Counter Events: Specifies events generated by the part of the WWW service that monitors and records performance counter data.
- WWW Service Events: Specifies events generated by the part of the WWW service that handles internal administration of the IIS server.

**Related Information**

- For information about error messages displayed in the browser of a client, see Error Messages in IIS 6.0.
- For information about logging client requests, see Logging Site Activity.
- For information about viewing and interpreting log files, see Analyzing Log Files.
- For information about performance monitoring and tuning, see Optimizing IIS 6.0 Performance.

# About Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Logging begins automatically when Windows is started. There are three types of logs: system, security, and application. For each type of log, you can filter the events to be viewed, designate the number of entries to view, specify how long to save entries, and specify whether to automatically overwrite existing events when the log becomes full.

You can open Event Viewer in any one of the following ways:

- From the **Start** menu, click **Run**. In the **Open** box, type **eventvwr**. Click **OK**.

- or -

- Type **start eventvwr** at the command prompt, and press ENTER.

- or -

- From the **Start** menu, point to **Administrative Tools**, and then click **Event Viewer**.

- or -

- From the **Start** menu, point to **Administrative Tools**, and then click **Computer Management**. **Event Viewer** is listed under the **System Tools** node. The benefit of this display is that IIS Manager is in the same window under the **Services and Applications** node.

**ASP Errors and the Windows Events Log**

For more information, see **AspLogErrorRequests** and **AspErrorsToNTLog**. **AspLogErrorRequests** can be set in IIS Manager, or it can be set programmatically using ADSI, WMI, or ABO. See Code Examples to Configure Metabase Properties for instructions on how to programmatically change metabase properties.

**AspErrorsToNTLog** cannot be set in IIS Manager, and must be set programmatically.

**Related Information**

- For instructions on how to programmatically change metabase properties, see Code Examples to Configure Metabase Properties.

- For descriptions of ASP Event errors, see ASP Events.

- For more information about the metabase and programmatic administration of IIS, see Administering IIS Programmatically.

# ASP-Related Errors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the errors that are generated by the World Wide Web Publishing Service (WWW service) when processing ASP applications that are configured incorrectly or ASP pages that contain errors. These errors are logged to the Windows Event application log only if the AspLogErrorRequests metabase property is set to **true**. If the AspErrorsToNTLog metabase property is also set to **true**, then all of the errors get logged to the Windows Event application log; otherwise, only a subset are logged. The subset includes the error numbers 100, 101, 102, 103, 104, 105, 106, 107, 115, 190, 191, 192, 193, 194, 240, 241, and 242.

**Details**

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!.20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 0100 | Out of memory. Unable to allocate required memory. |
| 0101 | Unexpected error. The function returned \|. |
| 0102 | Expecting string input. The function expects a string as input. |
| 0103 | Expecting numeric input. The function expects a number as input. |
| 0104 | Operation not Allowed. |
| 0105 | Index out of range. An array index is out of range. |
| 0106 | Type Mismatch. An unhandled data type was encountered. |
| 0107 | Data size too large. Size of data being sent in the request is over the allowed limit. |
| 0108 | Create object failed. An error occurred while creating object '%s'. |
| 0109 | Member not found. |
| 0110 | Unknown name. |
| 0111 | Unknown interface. |
| 0112 | Missing parameter. |
| 0113 | Script timed out. The maximum amount of time for a script to execute was exceeded. You can change this limit by specifying a new value for the property Server.ScriptTimeout or by changing the value in the IIS administration tools. |
| 0114 | Object not free threaded. The application object accepts only free threaded objects; object '%s' is not free threaded. |
| 0115 | Unexpected error. A trappable error (%X) occurred in an external object. The script cannot continue running. |
| 0116 | Missing close of script delimiter. The Script block lacks the close of script tag (%>). |
| 0117 | Missing close of script tag. The Script block lacks the close of script tag (</SCRIPT>) or close of tag symbol (>). |
| 0118 | Missing close of object tag. The Object block lacks the close of object tag (</OBJECT>) or close of tag symbol (>). |
| 0119 | Missing Classid or Progid attribute. The object instance '\|' requires a valid Classid or Progid in the object tag. |
| 0120 | Invalid Runat attribute. The Runat attribute of the Script tag or Object tag can only have the value 'Server'. |

| | |
|---|---|
| 0121 | Invalid Scope in object tag. The object instance '\|' cannot have Application or Session scope. To create the object instance with Session or Application scope, place the Object tag in the Global.asa file. |
| 0122 | Invalid Scope in object tag. The object instance '\|' must have Application or Session scope. This applies to all objects created in a Global.asa file. |
| 0123 | Missing Id attribute. The required Id attribute of the Object tag is missing. |
| 0124 | Missing Language attribute. The required Language attribute of the Script tag is missing. |
| 0125 | Missing close of attribute. The value of the '\|' attribute has no closing delimiter. |
| 0126 | Include file not found. The include file '\|' was not found. |
| 0127 | Missing close of HTML comment. The HTML comment or server-side include lacks the close tag (-->). |
| 0128 | Missing File or Virtual attribute. The Include file name must be specified using either the File or Virtual attribute. |
| 0129 | Unknown scripting language. The scripting language '\|' is not found on the server. |
| 0130 | Invalid File attribute. File attribute '\|' cannot start with forward slash or back slash. |
| 0131 | Disallowed Parent Path. The Include file '\|' cannot contain '..' to indicate the parent directory. |
| 0132 | Compilation Error. The Active Server Page '\|' could not be processed. |
| 0133 | Invalid ClassID attribute. The object tag has an invalid ClassID of '\|'. |
| 0134 | Invalid ProgID attribute. The object has an invalid ProgID of '\|'. |
| 0135 | Cyclic Include. The file '\|' is included by itself (perhaps indirectly). Please check include files for other Include statements. |
| 0136 | Invalid object instance name. The object instance '\|' is attempting to use a reserved name. This name is used by Active Server Pages intrinsic objects. |
| 0137 | Invalid Global Script. Script blocks must be one of the allowed Global.asa procedures. Script directives within <% ... %> are not allowed within the Global.asa file. The allowed procedure names are Application_OnStart, Application_OnEnd, Session_OnStart, or Session_OnEnd. |
| 0138 | Nested Script Block. A script block cannot be placed inside another script block. |
| 0139 | Nested Object. An object tag cannot be placed inside another object tag. |
| 0140 | Page Command Out Of Order. The @ command must be the first command within the Active Server Page. |
| 0141 | Page Command Repeated. The @ command can only be used once within the Active Server Page. |
| 0142 | Thread token error. A thread token failed to open. |
| 0143 | Invalid Application Name. A valid application name was not found. |
| 0144 | Initialization Error. The page level objects list failed during initialization. |
| 0145 | New Application Failed. The new Application could not be added. |
| 0146 | New Session Failed. The new Session could not be added |
| 0147 | 500 Server Error. |
| 0148 | Server Too Busy. |
| 0149 | Application Restarting. The request cannot be processed while the application is being restarted. |
| 0150 | Application Directory Error. The Application directory could not be opened. |

| | |
|---|---|
| 0151 | Change Notification Error. The change notification event could not be created. |
| 0152 | Security Error. An error occurred while processing a user's security credentials. |
| 0153 | Thread Error. A new thread request failed. |
| 0154 | Write HTTP Header Error. The HTTP headers could not be written to the client browser. |
| 0155 | Write Page Content Error. The page content could not be written to the client browser. |
| 0156 | Header Error. The HTTP headers are already written to the client browser. Any HTTP header modifications must be made before writing page content. |
| 0157 | Buffering On. Buffering cannot be turned off once it is already turned on. |
| 0158 | Missing URL. A URL is required. |
| 0159 | Buffering Off. Buffering must be on. |
| 0160 | Logging Failure. Failure to write entry to log. |
| 0161 | Data Type Error. The conversion of a Variant to a String variable failed. |
| 0162 | Cannot Modify Cookie. The cookie 'ASPSessionID' cannot be modified. It is a reserved cookie name. |
| 0163 | Invalid Comma Use. Commas cannot be used within a log entry. Please select another delimiter. |
| 0164 | Invalid TimeOut Value. An invalid TimeOut value was specified. |
| 0165 | SessionID Error. A SessionID string cannot be created. |
| 0166 | Uninitialized Object. An attempt was made to access an uninitialized object. |
| 0167 | Session Initialization Error. An error occurred while initializing the Session object. |
| 0168 | Disallowed object use. An intrinsic object cannot be stored within the Session object. |
| 0169 | Missing object information. An object with missing information cannot be stored in the Session object. The threading model information for an object is required. |
| 0170 | Delete Session Error. The Session did not delete properly. |
| 0171 | Missing Path. The Path parameter must be specified for the MapPath method. |
| 0172 | Invalid Path. The Path parameter for the MapPath method must be a virtual path. A physical path was used. |
| 0173 | Invalid Path Character. An invalid character was specified in the Path parameter for the MapPath method. |
| 0174 | Invalid Path Character(s). An invalid '/' or '\\' was found in the Path parameter for the MapPath method. |
| 0175 | Disallowed Path Characters. The '..' characters are not allowed in the Path parameter for the MapPath method. |
| 0176 | Path Not Found. The Path parameter for the MapPath method did not correspond to a known path. |
| 0177 | Server.CreateObject Failed. %s |
| 0178 | Server.CreateObject Access Error. The call to Server.CreateObject failed while checking permissions. Access is denied to this object. |
| 0179 | Application Initialization Error. An error occurred while initializing the Application object. |
| 0180 | Disallowed object use. An intrinsic object cannot be stored within the Application object. |
| 0181 | Invalid threading model. An object using the apartment threading model cannot be stored within the Application object. |

| | |
|---|---|
| 0182 | Missing object information. An object with missing information cannot be stored in the Application object. The threading model information for the object is required. |
| 0183 | Empty Cookie Key. A cookie with an empty key cannot be stored. |
| 0184 | Missing Cookie Name. A name must be specified for a cookie. |
| 0185 | Missing Default Property. A default property was not found for the object. |
| 0186 | Error parsing certificate |
| 0187 | Object addition conflict. Could not add object to application. Application was locked down by another request for adding an object. |
| 0188 | Disallowed object use. Cannot add objects created using object tags to the session intrinsic. |
| 0189 | Disallowed object use. Cannot add objects created using object tags to the application intrinsic. |
| 0190 | Unexpected error. A trappable error occurred while releasing an external object. |
| 0191 | Unexpected error. A trappable error occurred in the OnStartPage method of an external object. |
| 0192 | Unexpected error. A trappable error occurred in the OnEndPage method of an external object. |
| 0193 | OnStartPage Failed. An error occurred in the OnStartPage method of an external object. |
| 0194 | OnEndPage Failed. An error occurred in the OnEndPage method of an external object. |
| 0195 | Invalid Server Method Call. This method of the Server object cannot be called during Session_OnEnd and Application_OnEnd. |
| 0196 | Cannot launch out of process component. Only InProc server components should be used. If you want to use LocalServer components, you must set the AspAllowOutOfProcComponents metabase setting. Please consult the help file for important considerations. |
| 0197 | Disallowed object use. Cannot add object with apartment model behavior to the application intrinsic object. |
| 0198 | Server shutting down. Cannot process request |
| 0199 | Disallowed object use. Cannot add JScript objects to the session. |
| 0200 | Out of Range 'Expires' attribute. The date and time given for 'Expires' precedes Jan 1, 1980 or excedes Jan 19, 2038, 3:14:07 GMT. |
| 0201 | Invalid Default Script Language. The default script language specified for this application is invalid. |
| 0202 | Missing Code Page. The code page attribute is missing. |
| 0203 | Invalid Code Page. The specified code page attribute is invalid. |
| 0204 | Invalid CodePage Value. An invalid CodePage value was specified. |
| 0205 | Change Notification. Failed to create event for change notification. |
| 0206 | Cannot call BinaryRead. Cannot call BinaryRead after using Request.Form collection. |
| 0207 | Cannot use Request.Form. Cannot use Request.Form collection after calling BinaryRead. |
| 0208 | Cannot use generic Request collection. Cannot use the generic Request collection after calling BinaryRead. |
| 0209 | Illegal value for TRANSACTION property. The TRANSACTION property can only be REQUIRED, REQUIRES_new, SUPPORTED or NOT_SUPPORTED. |
| 0210 | Method not implemented. This method has not yet been implemented. |

| | |
|---|---|
| 0211 | Object out of scope. A built-in ASP object has been referenced, which is no longer valid. |
| 0212 | Cannot Clear Buffer. Response.Clear is not allowed after a Response.Flush while Client Debugging is Enabled. |
| 0214 | Invalid Path parameter. The Path parameter excedes the maximum length allowed. |
| 0215 | Illegal value for ENABLESESSIONSTATE property. The ENABLESESSIONSTATE property can only be TRUE or FALSE. |
| 0216 | MSDTC Service not running. Transactional web pages cannot be run if the MSDTC service is not running. |
| 0217 | Invalid Scope in object tag. Object scope must be Page, Session or Application. |
| 0218 | Missing LCID. The LCID attribute is missing. |
| 0219 | Invalid LCID. The specified LCID is not available. |
| 0220 | Requests for GLOBAL.ASA Not Allowed. Requests with the URL pointing to GLOBAL.ASA are not allowed. |
| 0221 | Invalid @ Command directive. The specified '\|' option is unknown or invalid. |
| 0222 | Invalid TypeLib Specification. METADATA tag contains an invalid Type Library specification. |
| 0223 | TypeLib Not Found. METADATA tag contains a Type Library specification that does not match any Registry entry. |
| 0224 | Cannot load TypeLib. Cannot load Type Library specified in the METADATA tag. |
| 0225 | Cannot wrap TypeLibs. Cannot create a Type Library Wrapper object from the Type Libraries specified in METADATA tags. |
| 0226 | Cannot modify StaticObjects. StaticObjects collection cannot be modified at run time. |
| 0227 | Server.Execute Failed. The call to Server.Execute failed |
| 0228 | Server.Execute Error. The call to Server.Execute failed while loading the page. |
| 0229 | Server.Transfer Failed. The call to Server.Transfer failed |
| 0230 | Server.Transfer Error. The call to Server.Transfer failed while loading the page. |
| 0231 | Server.Execute Error. Invalid URL form or fully-qualified absolute URL was used. Use relative URLs. |
| 0232 | Invalid Cookie Specification. METADATA tag contains an invalid cookie specification. |
| 0233 | Cannot load cookie script source. Cannot load cookie script source file specified in the METADATA tag. |
| 0234 | Invalid include directive. Server side include directives may not be present in script blocks. Please use the SRC= attribute of the <SCRIPT> tag. |
| 0235 | Server.Transfer Error. Invalid URL form or fully-qualified absolute URL was used. Use relative URLs. |
| 0236 | Invalid Cookie Specification. METADATA tag contains an invalid or missing SRC parameter. |
| 0237 | Invalid Cookie Specification. METADATA tag contains an invalid or missing NAME parameter. |
| 0238 | Missing attribute value. No value was specified for the '\|' attribute. |
| 0239 | Cannot process file. UNICODE ASP files are not supported. |
| 0240 | Script Engine Exception. A ScriptEngine threw exception '%X' in '%s' from '%s'. |
| 0241 | CreateObject Exception. The CreateObject of '%s' caused exception %X. |
| 0242 | Query OnStartPage Interface Exception. Querying Object '%s''s OnStartPage or OnEndPage methods caused exception %X. |

| | |
|---|---|
| 0243 | Invalid METADATA tag in Global.asa. Only METADATA TYPE="TypeLib" may be used in Global.asa. |
| 0244 | Cannot Enable Session State. Session state cannot be enabled when it has been disabled in the application. |
| 0245 | Mixed usage of Code Page values. The @CODEPAGE value specified differs from that of the including file's CODEPAGE or the file's saved format. |
| 0246 | Too many concurrent users. Please try again later.. |
| 0247 | Bad Argument to BinaryRead. The argument to BinaryRead must be non-negative. |
| 0248 | Script isn't transacted. This ASP file must be transacted in order to use the ObjectContext object. |
| 0249 | Cannot use IStream on Request. Cannot use IStream on Request object after using Request.Form collection or Request.BinaryRead. |
| 0250 | Invalid Default Code Page. The default code page specified for this application is invalid. |
| 0251 | Response Buffer Limit Exceeded. Execution of the ASP page caused the Response Buffer to exceed its configured limit. |

# ASP-Related Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are generated by the World Wide Web Publishing Service (WWW service) when processing ASP applications that are configured incorrectly or ASP pages that contain errors. These events are logged to the Windows Event application log regardless of the value of the AspLogErrorRequests Metabase Property.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!.20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 0x10 | Warning: %1, %2. |
| 0x11 | Warning: %1, %2, %3. |
| 0x12 | Warning: %1, %2, %3, %4. |
| 0x13 | Failed to create an ASP Session due to Access Denied when activating COM+ Partition %1. |
| 0x14 | Failed to create ASP Application %1 due to invalid or missing COM+ Partition ID. |
| 0x15 | Failed to retrieve the Anonymous User Token for ASP Application%1. Global.ASA OnEnd routines will not be executed. |
| 0x16 | Failed to impersonate the Anonymous User for ASP Application%1. Global.ASA OnEnd routines will not be executed. |
| 0x17 | No Default Script Language specified for Application %s. Using default: %s. |
| 0x1f3 | Invalid ProgID. |
| 0x5 | Error: %1. |
| 0x6 | Error: %1, %2. |
| 0x7 | Error: %1, %2, %3. |
| 0x8 | Error: %1, %2, %3, %4. |
| 0x9 | Warning: %1. |

# FTP Service-Related Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are generated by the FTP service.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear in the documentation below (such as \|, %s, %X, %1, %2, %2!. 20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 1 | FTP Server could not initialize its security. The data is the error. |
| 3 | FTP Server could not initialize the socket library. The data is the error. |
| 4 | FTP Server was unable to initialize due to a shortage of available memory. The data is the error. |
| 5 | FTP Server could not locate the FTP/TCP service. The data is the error. |
| 6 | FTP Server could not create the main connection socket. The data is the error. |
| 7 | FTP Server could not create the main connection thread. The data is the error. |
| 8 | FTP Server could not create a client worker thread for user at host %1. The connection to this user is terminated. The data is the error. |
| 9 | A call to a system service failed unexpectedly. The data is the error. |
| 10 | User %1 at host %2 has timed-out after %3 seconds of inactivity. |
| 11 | Anonymous logon request received from %1 at host %2. |
| 12 | User logon request received from %1 at host %2. |
| 13 | User %1 failed to log on, could not access the home directory%2. |
| 14 | User %1 denied access to the current directory %2 due to a security change. |
| 15 | Failed to read metabase property **PassivePortRange** under the FTP Service node %1. |
| 16 | The FTP Service configuration property **PassivePortRange** has invalid value: %1. |
| 14401 | The server failed to create a data channel connection to a client on local interface *ip_address*. The FTP data port *port_number* may be in use by another service or application. |

# ODBC Driver Errors Returned by IIS

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are caused by Web pages that contain ODBC driver errors.

| **Note** |
| --- |
| When errors appear in the IIS error log, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!. 20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 2602 | The form you just filled in requires the %1 entry to be filled in. Please fill in that entry in the form and resubmit the form. |
| 2603 | The query file could not be opened. The file may not exist or you may have insufficient permission to open the file. |
| 2605 | The template file contains an **else** tag without a matching **if** tag. |
| 2606 | The template file contains an **endif** tag without a matching **if** tag. |
| 2607 | The template file contains an expression with parameters that are of different type. For example, an **if** tag comparing a string with a number would cause this error. |
| 2608 | The template file contains an expression using the CONTAINS operator where one or both parameters are not strings. CONTAINS is only valid with string values. |
| 2609 | The template file contains an expression that uses a quoted string but the close quote is missing. |
| 2610 | The template file contains an expression with an unrecognized operator. Valid operators are GT, LT, EQ and CONTAINS. |
| 2611 | The query file contains an unrecognized field %1. |
| 2612 | The query file must contain a valid, non-empty Datasource: field and SQLStatement: field. |
| 2613 | The library odbc32.dll could not be loaded to perform the query. Make sure ODBC has been properly installed on the server. |
| 2615 | Error performing query. %1 |
| 2616 | The maximum number of SQLStatement fields in the IDC file has been exceeded. |

# Server-Side Includes Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are generated by the part of the World Wide Web Publishing Service (WWW service) that processes server-side include directives in Web pages.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!.20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 2501 | Error processing SSI file. |
| 2502 | Invalid SSI tag. |
| 2503 | Cannot perform flastmod(): Win32 Error Code = %2!.20s! |
| 2504 | Cannot perform fsize(): Win32 Error Code = %2!.20s! |
| 2505 | Variable '%1!.40s!' cannot be found. |
| 2506 | Variable '%1!.40s!' cannot be evaluated. |
| 2507 | SSI feature not supported |
| 2508 | Error handling SSI File : Win32 Error Code = %2!.20s! |
| 2509 | Failed to process SSI file. |
| 2510 | Failed to execute CMD : Win32 Error Code = %2!.20s! |
| 2511 | Failed to execute CGI: Win32 Error Code = %2!.20s! |
| 2512 | Failed to execute ISAPI extension: Win32 Error Code =%2!.20s! |
| 2513 | Cannot #EXEC file due to lack of EXECUTE permission. |
| 2514 | Cannot process file due to access denied. |
| 2515 | A server side include file has included itself or the maximum depth of server side includes has been exceeded. |
| 2516 | The CMD option is not enabled for #EXEC calls. |
| 2517 | #EXEC calls have been disabled for this virtual path. |
| 2518 | There is a recursive #INCLUDE chain. |
| 2519 | Failed to execute script: Http Status Code = %2!.20s! |

# Core WWW Service Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are generated by the core processes of the World Wide Web Publishing Service (WWW service) such as authentication and authorization, application problems, memory monitoring, and so on.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!.20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 2201 | HTTP Server could not initialize its security. The data is the error. |
| 2203 | HTTP Server could not initialize the socket library. The data is the error. |
| 2204 | HTTP Server was unable to initialize due to a shortage of available memory. The data is the error. |
| 2206 | HTTP Server could not create the main connection socket. The data is the error. |
| 2208 | HTTP Server could not create a client connection object for user at host %1. The connection to this user is terminated. The data is the error. |
| 2214 | The HTTP Filter DLL %1 failed to load. The data is the error. |
| 2216 | The script started from the URL '%1' with parameters '%2' has not responded within the configured timeout period. The HTTP server is terminating the script. |
| 2218 | The HTTP server encountered an error processing the server side include file '%1'.The error was '%2'. |
| 2219 | The HTTP server encountered an unhandled exception while processing the ISAPI Application '%1'. |
| 2220 | The HTTP server was unable to load the ISAPI Application '%1'.The data is the error. |
| 2221 | A server side include file has included itself or the maximum depth of server side includes has been exceeded. |
| 2222 | An attempt was made to load filter '%1' on a server instance but it requires the SF_NOTIFY_READ_RAW_DATA filter notification so it must be loaded as a global filter. |
| 2223 | For compatibility with previous versions of IIS, the filter'%1' was loaded as a global filter from the registry. To control the filter with the Internet Service Manager, remove the filter from the registry and add it as a global filter with Internet Service Manager. Filters in the registry are stored at "HKLM\System\CurrentControlSet\Services\W3Svc\Parameters\FilterDLLs". |
| 2226 | The server was unable to read the file %1 due to a lack of access permissions. |
| 2227 | The server was unable to acquire a license for a SSL connection. |
| 2228 | The server stop serving requests for application '%1' because the number of Out of Process component crashes exceed a limit. |

| | |
|---|---|
| 2229 | The server failed to shut down application '%1'. The error was'%2'. |
| 2230 | The server was unable to read the file %1. The file does not exist. |
| 2231 | The server was unable to read the file %1. The Windows 32 error returned from the attempt is %2. |
| 2232 | The server was unable to read the file %1. The file exceeds the maximum allowable size of %2. |
| 2233 | The server was unable to allocate a buffer to read the file%1. |
| 2236 | The server failed to load application '%1'. The error was'%2'. |
| 2237 | Out of process application '%1' terminated unexpectedly. |
| 2238 | Job object query failed. The data is the error. |
| 2239 | Job object set limit failed. The data is the error. |
| 2240 | Schedule a work item for CPU Accounting or Limits failed. The data is the error. |
| 2241 | Site '%1' hit its CPU Limit. No action was taken. |
| 2242 | Site '%1' hit its CPU Limit. The priority of all process on that site has been lowered to idle class. |
| 2243 | Site '%1' hit its CPU Limit. All processes on that site have been terminated. |
| 2244 | Site '%1' hit its CPU Limit. The site has been paused. |
| 2245 | The server certificate for instance '%1' has expired or is not yet valid. |
| 2246 | The server certificate for instance '%1' has been revoked. |
| 2247 | The server certificate for instance '%1' does not chain up to a trusted root certificate. |
| 2248 | One of the certificates in the certificate chain of the server certificate for instance '%1' has an invalid signature. |
| 2249 | CPU Limits/Accounting failed to queue work item. The data is the error. |
| 2250 | The server certificate for instance '%1' had invalid metabase data associated with it and could not be retrieved; the error encountered was '%2'. |
| 2251 | A CryptoAPI error was encountered trying to retrieve the server certificate for instance '%1'; the error encountered was '%2'. |
| 2252 | The server certificate for instance '%1' could not be retrieved because it could not be found in a certificate store; the error encountered was '%2' |
| 2253 | The server certificate for instance '%1' could not be retrieved due to an internal error; the error encountered was '%2'. |
| 2254 | The server Certificate Trust List for instance '%1' had invalid metabase data associated with it and could not be retrieved; the error encountered was '%2'. |
| 2255 | A CryptoAPI error was encountered trying to retrieve the server Certificate Trust List for instance '%1'; the error encountered was'%2'. |

| | |
|---|---|
| 2256 | The server Certificate Trust List for instance '%1' could not be retrieved because it could not be found in a certificate store; the error encountered was '%2'. |
| 2257 | The server certificate for instance '%1' could not be retrieved due to an internal error; the error number is '%2'. |
| 2258 | The server failed to close client connections to the following URLs during shutdown: '%1'. |
| 2259 | The COM Application '%1' at '%2' failed to activate out of process. |
| 2261 | An attempt was made to load filter '%1' but it requires the SF_NOTIFY_READ_RAW_DATA filter notification and this notification is not supported in Worker Process Isolation Mode. |
| 2262 | ISAPI '%1' reported itself as unhealthy for the following reason: '%2'. |
| 2263 | ISAPI '%1' reported itself as unhealthy. No reason was given by the ISAPI. |
| 2264 | The directory specified for caching compressed content %1 is invalid. Static compression is being disabled. |
| 2265 | The registry key for IIS subauthenticator is not configured correctly on local machine, the anonymous password sync feature is disabled. |
| 2266 | The account that the current worker process is running under does not have SeTcbPrivilege privilege, the anonymous password sync feature and the Digest authentication feature are disabled. |
| 2267 | Raw ISAPI Filter could not be loaded due to configuration problem. HTTPFilter Service has to be hosted in Inetinfo.exe for Raw ISAPI filters to work correctly. The most likely reason is that IIS5IsolationModeEnabled setting was changed and HTTPFilter service was not restarted. Restart HTTPFilter for configuration changes to be taken into effect. |
| 2268 | Could not load all ISAPI filters for site/service. Therefore startup aborted. |
| 2269 | The worker process failed to initialize the HTTP.sys communication or the w3svc communication layer and therefore could not be started. The data field contains the error number. |
| 2270 | IIS Client certificate mapping configuration for site %1 failed to be loaded. The data field contains the error number. |
| 2271 | Could not initialize the logging module for site %1. The site will therefore be non-functional. |
| 2272 | The registry key for IIS subauthenticator is not configured correctly on domain controller, the Digest feature is disabled. |

# WWW Performance Counter Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are generated by the part of the World Wide Web Publishing Service (WWW service) that monitors and records performance counter data.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!.20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 2000 | Unable to query the W3SVC (HTTP) service performance data. The error code returned by the service is data DWORD 0. |
| 2001 | It has taken too long to refresh the W3SVC counters, the stale counters are being used instead. |
| 2002 | Setting up Web Service counters failed, please make sure your Web Service counters are registered correctly. |
| 2003 | It has taken too long to refresh the W3SVC counters, the stale counters are being used instead. This is the second message within the past %1 (hours, minutes, seconds). No more stale counter messages will be logged for this client session until the time limit expires. %n For additional information specific to this message please visit the Microsoft Help and Support site. |

# WWW Service-Related Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This topic lists the events that are generated by the part of the World Wide Web Publishing Service (WWW service) that handles internal administration of the IIS server.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear below (such as \|, %s, %X, %1, %2, %2!. 20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

| Event ID | Description |
| --- | --- |
| 1001 | The World Wide Web Publishing Service's Inetinfo.exe process monitor encountered an error and has shut down. This condition prevents the World Wide Web Publishing Service from detecting an unexpected termination of the Inetinfo.exe process and, therefore, may not detect changes to the metabase as expected. It is recommended that you restart the World Wide Web Publishing Service. |
| 1002 | Application pool '%1' is being automatically disabled due to a series of failures in the process (es) serving that application pool. |
| 1003 | Cannot register the URL prefix '%1' for site '%2'. The URL maybe invalid. The site has been deactivated. The data field contains the error number. |
| 1004 | Cannot register the URL prefix '%1' for site '%2'. The site has been deactivated. The data field contains the error number. |
| 1005 | The World Wide Web Publishing Service is exiting due to an error. The data field contains the error number. |
| 1006 | Not Used. |
| 1007 | Cannot register the URL prefix '%1' for site '%2'. The necessary network binding may already be in use. The site has been deactivated. The data field contains the error number. |
| 1008 | Not Used. |
| 1009 | A process serving application pool '%1' terminated unexpectedly. The process id was '%2'. The process exit code was'0x%3'. |
| 1010 | A process serving application pool '%1' failed to respond to aping. The process id was '%2'. |
| 1011 | A process serving application pool '%1' suffered a fatal communication error with the World Wide Web Publishing Service. The process id was '%2'. The data field contains the error number. |
| 1012 | A process serving application pool '%1' exceeded time limits during start up. The process id was '%2'. |
| 1013 | A process serving application pool '%1' exceeded time limits during shut down. The process id was '%2'. |
| 1014 | The World Wide Web Publishing Service encountered an internal error in its process management of worker process '%2' serving application pool '%1'. The data field contains the error number. |

| | |
|---|---|
| 1015 | A process serving application pool '%1' was orphaned but the specified orphan action %2 could not be executed. The data field contains the error number. |
| 1016 | Unable to configure logging for site '%1'. The data field contains the error number. |
| 1017 | The World Wide Web Publishing Service has terminated due to a Worker process failure. |
| 1018 | The World Wide Web Publishing Service was not able to initialize performance counters. The service will run without the performance counters. Please restart the World Wide Web Publishing Service to reinitialize the performance counters. The data field contains the error number. |
| 1019 | The World Wide Web Publishing Service encountered difficulty initializing performance counters. Performance counters will function, however, not all counter data may be accurate. The data field contains the error number. |
| 1020 | The World Wide Web Publishing Service encountered difficulty configuring the HTTP.sys control channel property '%1'. The data field contains the error number. |
| 1021 | The identity of application pool, '%1' is invalid. If it remains invalid when the first request for the application pool is processed, the application pool will be disabled. The data field contains the error number. |
| 1022 | The World Wide Web Publishing Service failed to create a worker process for the application pool '%1'. The data field contains the error number. |
| 1023 | Not Used. |
| 1024 | Virtual site '%1' is configured to truncate its log every '%2'bytes. Since this value must be at least 1048576 bytes (1 megabyte), 1048576 bytes will be used. |
| 1025 | Application pool '%1' exceeded its job limit settings. |
| 1026 | An error occurred securing the handle of application pool '%1'.Therefore, the application pool was not secured as expected. Change the identification information to cause the World Wide Web Publishing Service to secure the handle of the application pool again. The data field contains the error number. |
| 1027 | The World Wide Web Publishing Service's request of HTTP.sys tenable the application pool '%1' failed. The data field contains the error number. |
| 1028 | The World Wide Web Publishing Service failed to add the worker process '%1' to the job object representing application pool '%2'.The data field contains the error number. |
| 1029 | A failure occurred while configuring an application's bindings for site '%1'. The site has been deactivated. The data field contains the error number. |
| 1030 | Inetinfo.exe terminated unexpectedly and the system was not configured to restart IIS Admin. The World Wide Web Publishing Service has shut down. |
| 1031 | Not Used. |
| 1032 | A failure occurred while configuring the logging properties for the site '%1'. Probable cause: A mapped network path is being used for the site's log file directory path, which is not supported by IIS. Please use a UNC path instead. |
| 1033 | A failure occurred while configuring the logging properties for the site '%1'. Probable cause: The site's log file directory contains an invalid machine or share name. |
| 1034 | A failure occurred while configuring the logging properties for the site '%1'. The server does not have access permissions to the site's log file directory. |

| | |
|---|---|
| 1035 | A failure occurred while configuring the logging properties for the site '%1'. The site's log file directory is not fully qualified. Probable cause: It is missing the drive letter or other crucial information. |
| 1036 | A failure occurred while initializing the configuration manager for the World Wide Web Publishing Service. The data field contains the error number. |
| 1037 | A failure occurred while opening the HTTP control channel for the World Wide Web Publishing Service. The data field contains the error number. |
| 1038 | Not Used. |
| 1039 | A process serving application pool '%1' reported a failure. The process id was '%2'. The data field contains the error number. |
| 1040 | Not Used. |
| 1041 | The '%1' '%2' failed range validation for property '%3'. The configured value '%4' is outside of the range '%5' to '%6'. The value will default to '%7'. |
| 1042 | The AppPoolCommand property set on the application pool '%1' is not a valid value. It is '%2'. It must be eitherMD_APPPOOL_COMMAND_START = 1 or MD_APPPOOL_COMMAND_STOP = 2. |
| 1043 | The virtual site '%1' has been invalidated and will be ignored because valid site bindings could not be constructed, or no site bindings exist. |
| 1044 | The virtual site '%1' has been invalidated and will be ignored because the site's AppPoolId is null. |
| 1045 | Not Used. |
| 1046 | The server command property for virtual site '%1' is not a valid value. It is set to '%2'. It must be one of the following:MD_SERVER_COMMAND_START = 1 or MD_SERVER_COMMAND_STOP = 2 orMD_SERVER_COMMAND_PAUSE = 3 or MD_SERVER_COMMAND_CONTINUE = 4. |
| 1047 | The application '%2' belonging to site '%1' has an AppPoolIdset, but the property is empty. Therefore, the application will be ignored. |
| 1048 | The application '%2' belonging to site '%1' has an invalidAppPoolId '%3' set. Therefore, the application will be ignored. |
| 1049 | The application pool '%1' has an IdleTimeout '%2' greater than the PeriodicRestartTime '%3'. The defaults ( IdleTimeout = '%4'& PeriodicRestartTime '%5' ) will be used. |
| 1050 | The application pool id '%1' exceeds length limits. It is '%2'characters and can not be more than '%3' characters. The application pool will therefore be ignored. |
| 1051 | An application pool id was defined as a zero length string. An application pool id must not be a zero length string. The application pool will therefore be ignored. |
| 1052 | "The application '%2' belongs to an invalid site '%1'.Therefore, the application will be ignored." |
| 1053 | The World Wide Web Publishing Service received a change notification, but was unable to process it correctly. The data field contains the error number. |
| 1054 | The World Wide Web Publishing Service failed to run the auto stop action %2 for application pool '%1'. The data field contains the error number. |

| | |
|---|---|
| 1055 | The site '%1' was disabled because the application pool defined for the site '%2' is not a valid application pool. |
| 1056 | The site '%1' was disabled because the application pool '%2'defined for the site's root application is not a valid application pool. |
| 1057 | The identity of application pool '%1' is invalid, so the Worldwide Web Publishing Service can not create a worker process to serve the application pool. Therefore, the application pool has been disabled. |
| 1058 | The World Wide Web Publishing Service encountered a failure while setting the affinity mask of application pool '%1'. Probable cause: The mask does not contain any processors available on this machine. The data field contains the error number. |
| 1059 | A failure was encountered while launching the process serving application pool '%1'. The application pool has been disabled. |
| 1060 | The job object associated with application pool '%1'encountered an error during configuration. CPU monitoring may not function as expected. The data field contains the error number. |
| 1061 | The job object attached to application pool '%1' failed to start its timer. The application pool's CPU usage is being monitored and will eventually reach the limit and report a failure. The data field contains the error number. |
| 1062 | The World Wide Web Publishing Service encountered a failure configuring the logging properties on the HTTP Control Channel.Logging Enabled is '%1'. Log File Directory is '%2'. Log Period is'%3'. Log Truncate Size is '%4'. The data field contains the error number. |
| 1063 | The World Wide Web Publishing Service encountered a failure requesting metabase change notifications. The data field contains the error number. |
| 1064 | The World Wide Web Publishing Service encountered a failure requesting metabase change notifications during recovery fromInetinfo.exe terminating unexpectedly. While the World Wide Web Publishing Service will continue to run, it is highly probable that it is no longer using current metabase data. Please restart the World Wide Web Publishing Service to correct this condition. The data field contains the error number. |
| 1065 | Centralized logging is configured to truncate its log every'%1' bytes. Since this value must be at least 1048576 bytes ( 1megabyte ), 1048576 bytes will be used. |
| 1066 | The World Wide Web Publishing Service encountered an error attempting to configure centralized logging. It is not configured as expected. The data field contains the error number. |
| 1067 | The World Wide Web Publishing Service property '%1' failed range validation. The configured value, '%2' is outside of the range '%3' to '%4'. The default value, '%5', will be used. |
| 1068 | The World Wide Web Publishing Service failed to record the proper state '%2' and win32error '%3' of site '%1'in the metabase. To correct, start/stop the site or restart the World Wide Web Publishing Service. The data field contains the error number. |
| 1069 | The World Wide Web Publishing Service failed to record the proper state '%2' and win32error '%3' of application pool '%1' in the metabase. To correct, start/stop the application pool or restart the World Wide Web Publishing Service. The data field contains the error number. |
| 1070 | The World Wide Web Publishing Service failed to issue recycle requests to all worker processes of application pool '%1'. The data field contains the error number. |
| 1071 | The World Wide Web Publishing Service failed to enable bandwidth throttling on site '%1' because QoS Packet Scheduler is not installed. |

| | |
|---|---|
| 1072 | The World Wide Web Publishing Service failed to enable bandwidth throttling on site '%1'. The data field contains the error number. |
| 1073 | The World Wide Web Publishing Service failed to enable global bandwidth throttling because QoS Packet Scheduler is not installed. |
| 1074 | A worker process with process id of '%1' serving application pool '%2' has requested a recycle because the worker process reached its allowed processing time limit. |
| 1075 | A worker process with process id of '%1' serving application pool '%2' has requested a recycle because it reached its allowed request limit. |
| 1076 | A worker process with process id of '%1' serving application pool '%2' has requested a recycle because it reached its scheduled recycle time. |
| 1077 | A worker process with process id of '%1' serving application pool '%2' has requested a recycle because it reached its virtual memory limit. |
| 1078 | An ISAPI reported an unhealthy condition to its worker process. Therefore, the worker process with process id of '%1' serving application pool '%2' has requested a recycle. |
| 1079 | An administrator has requested a recycle of all worker processes in application pool '%1'. |
| 1080 | The worker processes serving application pool '%1' are being recycled due to 1 or more configuration changes in the application pool properties which necessitate a restart of the processes. |
| 1081 | The worker processes serving application pool '%1' are being recycled due to detected problems with the metabase that may make current cached metadata invalid. |
| 1082 | A worker process with pid '%2' that serves application pool'%1' has been determined to be unhealthy (see previous event log message), but because a debugger is attached to it, the World Wide Web Publishing Service will ignore the error. |
| 1083 | HTTP.sys provided inconsistent site performance counter data tithe World Wide Web Publishing Service. Therefore, the World Wide Web Publishing Service will ignore the data provided. |
| 1084 | The World Wide Web Publishing Service's request of HTTP.sys to disable the application pool '%1' failed. The data field contains the error number. |
| 1085 | The World Wide Web Publishing Service failed to apply a new configuration for application pool '%1'. The data field contains the error number. |
| 1086 | The World Wide Web Publishing Service failed to properly configure the load balancer capabilities on application pool '%1'.The data field contains the error number. |
| 1087 | The World Wide Web Publishing Service failed to properly configure the application pool queue length on app pool '%1'. The data field contains the error number. |
| 1088 | The World Wide Web Publishing Service failed to properly configure the job object for application pool '%1'. The data field contains the error number. |
| 1089 | The World Wide Web Publishing Service failed to issue a demand start to HTTP.sys for application pool '%1'. The data field contains the error number. |

| | |
|---|---|
| 1090 | The World Wide Web Publishing Service failed to update the AutoStart property for application pool '%1'. The data field contains the error number. |
| 1091 | The World Wide Web Publishing Service failed to run the auto stop action for application pool '%1'. The data field contains the error number. |
| 1092 | The World Wide Web Publishing Service failed to issue a request for the worker process '%2' of application pool '%1' to supply its performance counters. The data field contains the error number. |
| 1093 | The World Wide Web Publishing Service failed to overlap recycle for application pool '%1' worker process '%2'. The data field contains the error number. |
| 1094 | The World Wide Web Publishing Service failed to disassociate the application '%1' from the virtual site '%2'. The data field contains the error number. |
| 1095 | The World Wide Web Publishing Service failed to delete the config group for the application '%1' in site '%2'. The data field contains the error number. |
| 1096 | The World Wide Web Publishing Service failed to remove the urls for the virtual site '%1'. The data field contains the error number. |
| 1097 | The World Wide Web Publishing Service failed to set the application pool for the application '%1' in site '%2'. The data field contains the error number. |
| 1098 | The World Wide Web Publishing Service failed to set the max connections for the virtual site '%1'. The data field contains the error number. |
| 1099 | The World Wide Web Publishing Service failed to set the connection timeout for the virtual site '%1'. The data field contains the error number. |
| 1100 | The World Wide Web Publishing Service failed to create the application '%2' in site '%1'. The data field contains the error number. |
| 1101 | The World Wide Web Publishing Service failed to create app pool'%1'. The data field contains the error number. |
| 1102 | The World Wide Web Publishing Service failed to create site'%1'. The data field contains the error number. |
| 1103 | The World Wide Web Publishing Service failed to delete the application '%2' in site '%1'. The data field contains the error number. |
| 1104 | The World Wide Web Publishing Service failed to delete app pool'%1'. The data field contains the error number. |
| 1105 | The World Wide Web Publishing Service failed to delete site'%1'. The data field contains the error number. |
| 1106 | The World Wide Web Publishing Service failed to modify the application '%2' in site '%1'. The data field contains the error number. |
| 1107 | The World Wide Web Publishing Service failed to modify app pool'%1'. The data field contains the error number. |
| 1108 | The World Wide Web Publishing Service failed to modify site'%1'. The data field contains the error number. |
| 1109 | The World Wide Web Publishing Service failed to set the control channel's filter config. The data field contains the error number." |

| | |
|---|---|
| 1110 | The World Wide Web Publishing Service failed to write the AutoStart Property for site '%1'. The data field contains the error number. |
| 1111 | The World Wide Web Publishing Service failed to delete all IIS owned SSL configuration data. The data field contains the error number. |
| 1112 | The World Wide Web Publishing Service failed to query SSL configuration data for site '%1'. The data field contains the error number. |
| 1113 | One of the IP/Port combinations for site '%1' has already be configured to be used by another site. The other site's SSL configuration will be used. |
| 1114 | One of the IP/Port combinations for site '%1' has already been configured to be used by another program. The other program's SSL configuration will be used. |
| 1115 | The World Wide Web Publishing Service failed to set SSL configuration data for site '%1'. The data field contains the error number. |
| 1116 | The World Wide Web Publishing Service failed to delete SSL configuration data for site '%1'. The data field contains the error number. |
| 1117 | A worker process with process id of '%1' serving application pool '%2' has requested a recycle because it reached its private bytes memory limit. |
| 1118 | During recovery from an unexpected termination of theInetinfo.exe process, the World Wide Web Publishing Service failed to identify the appropriate records requiring deletion from its metadata cache. The data field contains the error number. |
| 1119 | During recovery from an unexpected termination of theInetinfo.exe process, the World Wide Web Publishing Service failed to queue action items necessary to handle the recovery. It is recommended that you restart the World Wide Web Publishing Service. The data field contains the error number. |
| 1120 | The World Wide Web Publishing Service failed to obtain cache counters from HTTP.sys. The reported performance counters do not include performance counters from HTTP.sys for this gathering. The data field contains the error number. |
| 1121 | The World Wide Web Publishing Service failed to obtain site performance counters from HTTP.sys. The reported performance counters do not include counters from HTTP.sys for this gathering. The data field contains the error number. |
| 1122 | The World Wide Web Publishing Service failed to publish the performance counters it gathered. The data field contains the error number. |
| 1123 | The World Wide Web Publishing Service failed to cancel the performance counter gathering timer. The data field contains the error number. |
| 1124 | The World Wide Web Publishing Service failed to cancel the performance counter timer. The data field contains the error number. |
| 1125 | The World Wide Web Publishing Service failed to start the performance counter gathering timer. The data field contains the error number. |
| 1126 | The World Wide Web Publishing Service failed to copy a change notification for processing. Therefore, the service may not be in sync with the current data in the metabase. The data field contains the error number. |

| | |
|---|---|
| 1127 | A worker process '%2' serving application pool '%1' is no longer trusted by the World Wide Web Publishing Service, based on ill-formed data the worker process sent to the service. |
| 1128 | The World Wide Web Publishing Service was not able to initialize asp performance counters. The service will therefore run without asp performance counters. Restart the World Wide Web Publishing Service to start asp performance counter gathering. The data field contains the error number. |
| 1129 | Cannot register the URL prefix '%1' for site '%2'. Either the network endpoint for the site's IP address could not be created, or the IP listen list for HTTP.sys did not contain any usable IP addresses. The site has been deactivated. The data field contains the error number. |
| 1130 | Cannot register the URL prefix '%1' for site '%2'. The IP address for the site is not in the HTTP.sys IP listen list. The site has been deactivated. The data field contains the error number. |
| 1131 | Cannot register the URL prefix '%1' for site '%2'. Too many listening ports have been configured in HTTP.sys. The site has been deactivated. The data field contains the error number. |

# IIS 6.0 Event Messages

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) 6.0 generates events in Event Viewer so that you can verify the performance of IIS. Event Viewer tracks the following: error events, warning events, and informational events. The logs in Event Viewer provide an audited record of all services and processes in the Microsoft® Windows® Server 2003 operating system, such as logon and connection times.

**In This Section**

Event Logging Overview

WWW Service Events

WWW Service Worker Process Events

ASP Events and Errors

FTP Service Events

WWW Service Performance Counter Events

**Related Sections**

- For information about viewing and interpreting log files, see Analyzing Log Files in this reference.
- For information about performance monitoring and tuning, see Optimizing IIS 6.0 Performance in this reference.

# Event Logging Overview

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

By default, a computer running the Microsoft® Windows® Server 2003, Standard Edition; Windows® Server 2003, Enterprise Edition; Windows® Server 2003, Web Edition; or Windows® Server 2003, Datacenter Edition operating system records events in three kinds of logs:

- **Application**. Contains events logged by applications or programs.
- **Security**. Records events such as valid and invalid logon attempts, as well as events related to resource use.
- **System**. Contains events logged by Windows system components.

Logging begins automatically when Windows is started. For each type of log, you can filter the events to be viewed, designate the number of entries to view, specify how long to save entries, and specify whether to automatically overwrite existing events when the log becomes full.

You view Windows event logs through Event Viewer. You can open Event Viewer by using any one of the following methods:

- From the **Start** menu, click **Run**. In the **Open** box, type **eventvwr**, and then click **OK**.
- At the command prompt, type **start eventvwr**, and then press ENTER.
- From the **Start** menu, point to **Administrative Tools**, and then click **Event Viewer**.
- From the **Start** menu, point to **Administrative Tools**, and then click **Computer Management**. Event Viewer is listed under the **System Tools** node. The benefit of this display is that IIS Manager is in the same window under the **Services and Applications** node.

For more information about event logs and Event Viewer, see "Event Log Overview" in Help and Support Center for Windows Server 2003.

Operating system events related to IIS are logged in the event logs. These logs are not the same as the IIS logs that record specific information about Web site usage and activity. For more information about IIS logs, see Analyzing Log Files in this reference.

| **Note** |
| --- |
| When messages appear in the event log or Web browser, the symbols that appear in the tables in this chapter (such as \|, %s, %X, %1, %2, %2!.20s!, and so on) are replaced with details about the error at the time that the error actually occurs. |

# WWW Service Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table E.1 lists the events that are generated by the part of the World Wide Web Publishing Service (WWW service) that handles internal administration of the W3SVC. The WWW service events are listed in the System log, with the source name W3SVC. For information about troubleshooting IIS, see Troubleshooting IIS 6.0

**Table E.1 WWW Service Events**

| Event ID | Description |
|---|---|
| 1001 | The WWW services InetInfo process monitor encountered an error and has shut down. This condition prevents the WWW service from detecting an unexpected termination of the InetInfo process and, therefore, it might not detect changes to the metabase as expected. Restart the WWW service. |
| 1002 | Application pool %1 is being automatically disabled because of a series of failures in the processes serving that application pool. |
| 1003 | Cannot register the URL prefix %1 for site %2. The URL might be invalid. The site has been deactivated. The data field contains the error number. |
| 1004 | Cannot register the URL prefix %1 for site %2. The site has been deactivated. The data field contains the error number. |
| 1005 | The WWW service is exiting because an error occurred. The data field contains the error number. |
| 1007 | Cannot register the URL prefix %1 for site %2. The necessary network binding might already be in use. The site has been deactivated. The data field contains the error number. |
| 1009 | A process serving application pool %1 was terminated unexpectedly. The process ID was %2. The process exit code was '0x%3. |
| 1010 | A process serving application pool %1 failed to respond to a ping. The process ID was %2. |
| 1011 | A process serving application pool %1 suffered a fatal communication error with the WWW service. The process ID was %2. The data field contains the error number. |
| 1012 | A process serving application pool %1 exceeded time limits during start up. The process ID was %2. |
| 1013 | A process serving application pool %1 exceeded time limits during shut down. The process ID was %2. |
| 1014 | The WWW service encountered an internal error in its process management of worker process %2 serving application pool %1. The data field contains the error number. |
| 1015 | A process serving application pool %1 was orphaned, but the specified orphan action %2 could not be executed. The data field contains the error number. |
| 1016 | Unable to configure logging for site %1. The data field contains the error number. |
| 1017 | The WWW service has terminated because of a worker process failure. |
| 1018 | The WWW service was not able to initialize performance counters. The service will run without the performance counters. Restart the WWW service to reinitialize the performance counters. The data field contains the error number. |

| | |
|---|---|
| 1019 | The WWW service encountered difficulty initializing performance counters. Performance counters will function; however, some counter data might be inaccurate. The data field contains the error number. |
| 1020 | The WWW service encountered difficulty configuring the HTTP.sys control channel property %1. The data field contains the error number. |
| 1021 | The identity of application pool %1 is invalid. If it remains invalid when the first request for the application pool is processed, the application pool will be disabled. The data field contains the error number. |
| 1022 | The WWW service failed to create a worker process for the application pool %1. The data field contains the error number. |
| 1024 | Virtual site %1 is configured to truncate its log every %2 bytes. Because this value must be at least 1,048,576 bytes (1 megabyte), 1,048,576 bytes will be used. |
| 1025 | Application pool %1 exceeded its job limit settings. |
| 1026 | An error occurred securing the handle of application pool %1'; therefore, the application pool was not secured as expected. Change the identification information to cause the WWW service to secure the handle of the application pool again. The data field contains the error number. |
| 1027 | The WWW service's request of HTTP.sys to enable the application pool %1 failed. The data field contains the error number. |
| 1028 | The WWW service failed to add the worker process %1 to the job object representing application pool %2. The data field contains the error number. |
| 1029 | A failure occurred while configuring an application's bindings for site %1. The site has been deactivated. The data field contains the error number. |
| 1030 | InetInfo was terminated unexpectedly, and the system was not configured to restart the IIS Admin service. The WWW service has shut down. |
| 1032 | A failure occurred while configuring the logging properties for the site %1. Probable cause: A mapped network path is being used for the site's log file directory path, which is not supported by IIS. Use a UNC path instead. |
| 1033 | A failure occurred while configuring the logging properties for the site %1. Probable cause: The site's log file directory contains an invalid machine or share name. |
| 1034 | A failure occurred while configuring the logging properties for the site %1. The server does not have access permissions to the site's log file directory. |
| 1035 | A failure occurred while configuring the logging properties for the site %1. The site's log file directory is not fully qualified. Probable cause: It is missing the drive letter or other crucial information. |
| 1036 | A failure occurred while initializing the configuration manager for the WWW service. The data field contains the error number. |
| 1037 | A failure occurred while opening the HTTP control channel for the WWW service. The data field contains the error number. |
| 1039 | A process serving application pool %1 reported a failure. The process ID was %2. The data field contains the error number. |

| | |
|---|---|
| 1041 | The %1 %2 failed range validation for property %3. The configured value %4 is outside of the range %5 to %6. The value will default to %7. |
| 1042 | The **AppPoolCommand** property set on the application pool %1 is not a valid value. It is %2. It must be either MD_APPPOOL_COMMAND_START = 1 or MD_APPPOOL_COMMAND_STOP = 2. |
| 1043 | The virtual site %1 has been invalidated and will be ignored because valid site bindings could not be constructed, or no site bindings exist. |
| 1044 | The virtual site %1 has been invalidated and will be ignored because the site's **AppPoolID** is null. |
| 1046 | The server command property for virtual site %1 is not a valid value. It is set to %2. It must be one of the following: MD_SERVER_COMMAND_START = 1, MD_SERVER_COMMAND_STOP = 2, MD_SERVER_COMMAND_PAUSE = 3, or MD_SERVER_COMMAND_CONTINUE = 4. |
| 1047 | The application %2 belonging to site %1 has an **AppPoolId** set, but the property is empty; therefore, the application will be ignored. |
| 1048 | The application %2 belonging to site %1 has an invalid **AppPoolId** %3 set; therefore, the application will be ignored. |
| 1049 | The application pool %1 has an **IdleTimeout** %2 greater than the **PeriodicRestartTime** %3. The defaults ( **IdleTimeout** = %4 & PeriodicRestartTime %5 ) will be used. |
| 1050 | The application pool ID %1 exceeds length limits. It is %2 characters and cannot be more than %3 characters. The application pool will, therefore, be ignored. |
| 1051 | An application pool ID was defined as a zero-length string. An application pool ID must not be a zero-length string. The application pool will, therefore, be ignored. |
| 1052 | The application %2 belongs to an invalid site %1'; therefore, the application will be ignored. |
| 1053 | The WWW service received a change notification, but was unable to process it correctly. The data field contains the error number. |
| 1054 | The WWW service failed to run the auto-stop action %2 for application pool %1. The data field contains the error number. |
| 1055 | The site %1 was disabled because the application pool defined for the site %2 is not a valid application pool. |
| 1056 | The site %1 was disabled because the application pool %2 defined for the site's root application is not a valid application pool. |
| 1057 | The identity of application pool %1 is invalid, so the WWW service cannot create a worker process to serve the application pool; therefore, the application pool has been disabled. |
| 1058 | The WWW service encountered a failure while setting the affinity mask of application pool %1. Probable cause: The mask does not contain any processors available on this machine. The data field contains the error number. |
| 1059 | A failure was encountered while launching the process serving application pool %1. The application pool has been disabled. |
| 1060 | The job object associated with application pool %1 encountered an error during configuration. CPU monitoring might not function as expected. The data field contains the error number. |

| | |
|---|---|
| 1061 | The job object attached to application pool %1 failed to start its timer. The application pool's CPU usage is being monitored and will eventually reach the limit and report a failure. The data field contains the error number. |
| 1062 | The WWW service encountered a failure configuring the logging properties on the HTTP Control Channel. **Logging Enabled** is %1. **Log File Directory** is %2. **Log Period** is %3. **Log Truncate Size** is %4. The data field contains the error number. |
| 1063 | The WWW service encountered a failure requesting metabase change notifications. The data field contains the error number. |
| 1064 | During recovery from an unexpected termination of the InetInfo process, the WWW service encountered a failure requesting metabase change notifications. Although the WWW service will continue to run, it is highly probable that it is no longer using current metabase data. Restart the WWW service to correct this condition. The data field contains the error number. |
| 1065 | Centralized logging is configured to truncate its log every %1 bytes. Because this value must be at least 1,048,576 bytes (1 megabyte), 1,048,576 bytes will be used. |
| 1066 | The WWW service encountered an error attempting to configure centralized logging. It is not configured as expected. The data field contains the error number. |
| 1067 | The WWW service property %1 failed range validation. The configured value %2 is outside of the range %3 to %4. The default value, %5, will be used. |
| 1068 | The WWW service failed to record the proper state %2 and **Win32Error** %3 of site %1 in the metabase. To correct, start/stop the site, or restart the WWW service. The data field contains the error number. |
| 1069 | The WWW service failed to record the proper state %2 and **Win32Error** %3 of application pool %1 in the metabase. To correct, start/stop the application pool, or restart the WWW service. The data field contains the error number. |
| 1070 | The WWW service failed to issue recycle requests to all worker processes of application pool %1. The data field contains the error number. |
| 1071 | The WWW service failed to enable bandwidth throttling on site %1 because QoS Packet Scheduler is not installed. |
| 1072 | The WWW service failed to enable bandwidth throttling on site %1. The data field contains the error number. |
| 1073 | The WWW service failed to enable global bandwidth throttling because QoS Packet Scheduler is not installed. |
| 1074 | A worker process with process ID of %1 serving application pool %2 has requested a recycle because the worker process reached its allowed processing time limit. |
| 1075 | A worker process with process ID of %1 serving application pool %2 has requested a recycle because it reached its allowed request limit. |
| 1076 | A worker process with process ID of %1 serving application pool %2 has requested a recycle because it reached its scheduled recycle time. |
| 1077 | A worker process with process ID of %1 serving application pool %2 has requested a recycle because it reached its virtual memory limit. |
| 1078 | An ISAPI reported an unhealthy condition to its worker process; therefore, the worker process with process ID of %1 serving application pool %2 has requested a recycle. |
| 1079 | An administrator has requested a recycle of all worker processes in application pool %1. |

| | |
|---|---|
| 1080 | The worker processes serving application pool %1 are being recycled, because one or more configuration changes in the properties of the application pool necessitated a restart of the processes. |
| 1081 | The worker processes serving application pool %1 are being recycled because of detected problems with the metabase that might make current cached metadata invalid. |
| 1082 | A worker process with process ID %2 that serves application pool %1 has been determined to be unhealthy (see previous event log message), but — because a debugger is attached to it — the WWW service will ignore the error. |
| 1083 | HTTP.sys provided inconsistent site performance counter data to the WWW service. Therefore, the WWW service will ignore the data provided. |
| 1084 | The WWW service's request of HTTP.sys to disable the application pool %1 failed. The data field contains the error number. |
| 1085 | The WWW service failed to apply a new configuration for application pool %1. The data field contains the error number. |
| 1086 | The WWW service failed to properly configure the load balancer capabilities on application pool %1. The data field contains the error number. |
| 1087 | The WWW service failed to properly configure the application pool queue length on application pool %1. The data field contains the error number. |
| 1088 | The WWW service failed to properly configure the job object for application pool %1. The data field contains the error number. |
| 1089 | The WWW service failed to issue a demand start to HTTP.sys for application pool %1. The data field contains the error number. |
| 1090 | The WWW service failed to update the **AutoStart** property for application pool %1. The data field contains the error number. |
| 1091 | The WWW service failed to run the auto-stop action for application pool %1. The data field contains the error number. |
| 1092 | The WWW service failed to issue a request for the worker process %2 of application pool %1 to supply its performance counters. The data field contains the error number. |
| 1093 | The WWW service failed to overlap recycle for application pool %1 worker process %2. The data field contains the error number. |
| 1094 | The WWW service failed to disassociate the application %1 from the virtual site %2. The data field contains the error number. |
| 1095 | The WWW service failed to delete the configuration group for the application %1 in site %2. The data field contains the error number. |
| 1096 | The WWW service failed to remove the URLs for the virtual site %1. The data field contains the error number. |
| 1097 | The WWW service failed to set the application pool for the application %1 in site %2. The data field contains the error number. |
| 1098 | The WWW service failed to set the maximum connections for the virtual site %1. The data field contains the error number. |
| 1099 | The WWW service failed to set the connection time-out for the virtual site %1. The data field contains the error number. |

| | |
|---|---|
| 1100 | The WWW service failed to create the application %2 in site %1. The data field contains the error number. |
| 1101 | The WWW service failed to create application pool %1. The data field contains the error number. |
| 1102 | The WWW service failed to create site %1. The data field contains the error number. |
| 1103 | The WWW service failed to delete the application %2 in site %1. The data field contains the error number. |
| 1104 | The WWW service failed to delete application pool %1. The data field contains the error number. |
| 1105 | The WWW service failed to delete site %1. The data field contains the error number. |
| 1106 | The WWW service failed to modify the application %2 in site %1. The data field contains the error number. |
| 1107 | The WWW service failed to modify application pool %1. The data field contains the error number. |
| 1108 | The WWW service failed to modify site %1. The data field contains the error number. |
| 1109 | The WWW service failed to set the control channel's filter configuration. The data field contains the error number. |
| 1110 | The WWW service failed to write the **AutoStart** property for site %1. The data field contains the error number. |
| 1111 | The WWW service failed to delete all IIS-owned Secure Sockets Layer (SSL) configuration data. The data field contains the error number. |
| 1112 | The WWW service failed to query SSL configuration data for site %1. The data field contains the error number. |
| 1113 | One of the IP/Port combinations for site %1 has already been configured to be used by another site. The other site's SSL configuration will be used. |
| 1114 | One of the IP/Port combinations for site %1 has already been configured to be used by another program. The other program's SSL configuration will be used. |
| 1115 | The WWW service failed to set SSL configuration data for site %1. The data field contains the error number. |
| 1116 | The WWW service failed to delete SSL configuration data for site %1. The data field contains the error number. |
| 1117 | A worker process with process ID of %1 serving application pool %2 has requested a recycle because it reached its private-bytes-memory limit. |
| 1118 | During recovery from an unexpected termination of the InetInfo process, the WWW service failed to identify the appropriate records requiring deletion from its metadata cache. The data field contains the error number. |
| 1119 | During recovery from an unexpected termination of the InetInfo process, the WWW service failed to queue action items necessary to handle the recovery. Restart the WWW service. The data field contains the error number. |
| 1120 | The WWW service failed to obtain cache counters from HTTP.sys. The reported performance counters do not include performance counters from HTTP.sys for this gathering. The data field contains the error number. |
| 1121 | The WWW service failed to obtain site performance counters from HTTP.sys. The reported performance counters do not include counters from HTTP.sys for this gathering. The data field contains the error number. |
| 1122 | The WWW service failed to publish the performance counters it gathered. The data field contains the error number. |

| | |
|---|---|
| 1123 | The WWW service failed to cancel the performance counter gathering timer. The data field contains the error number. |
| 1124 | The WWW service failed to cancel the performance counter timer. The data field contains the error number. |
| 1125 | The WWW service failed to start the performance counter gathering timer. The data field contains the error number. |
| 1126 | The WWW service failed to copy a change notification for processing. Therefore, the service might not be in sync with the current data in the metabase. The data field contains the error number. |
| 1127 | A worker process %2 serving application pool %1 is no longer trusted by the WWW service, based on ill-formed data the worker process sent to the service. |
| 1128 | The WWW service was not able to initialize Active Server Pages (ASP) performance counters. The service will, therefore, run without ASP performance counters. Restart the WWW service to start ASP performance-counter gathering. The data field contains the error number. |
| 1129 | Cannot register the URL prefix %1 for site %2. Either the network endpoint for the site's IP address could not be created or the IP listen list for HTTP.sys did not contain any usable IP addresses. The site has been deactivated. The data field contains the error number. |
| 1130 | Cannot register the URL prefix %1 for site %2. The IP address for the site is not in the HTTP.sys IP listen list. The site has been deactivated. The data field contains the error number. |
| 1131 | Cannot register the URL prefix %1 for site %2. Too many listening ports have been configured in HTTP.sys. The site has been deactivated. The data field contains the error number. |

# WWW Service Worker Process Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table E.2 lists the events that the WWW service worker process generates, such as authentication and authorization, application problems, memory monitoring, and so on. These events are listed in the Application log with the source name W3SVC-WP.

**Table E.2 Worker Process Events for the WWW Service**

| Event ID | Description |
|---|---|
| 2201 | The HTTP server could not initialize its security. The data is the error. |
| 2203 | The HTTP server could not initialize the socket library. The data is the error. |
| 2204 | The HTTP server was unable to initialize because of a shortage of available memory. The data is the error. |
| 2206 | The HTTP server could not create the main connection socket. The data is the error. |
| 2208 | The HTTP server could not create a client connection object for the user at host %1. The connection to this user is terminated. The data is the error. |
| 2214 | The HTTP filter DLL %1 failed to load. The data is the error. |
| 2216 | The script that was started from the URL %1 with parameters %2 has not responded within the configured time-out period. The HTTP server is terminating the script. |
| 2218 | The HTTP server encountered an error processing the server-side include file %1. The error was %2. |
| 2219 | The HTTP server encountered an unhandled exception while processing the ISAPI application %1. |
| 2220 | The HTTP server was unable to load the ISAPI application %1. The data is the error. |
| 2221 | A server-side include file has included itself, or the maximum depth of server-side includes has been exceeded. |
| 2222 | An attempt was made to load filter %1 on a server instance, but it requires the SF_NOTIFY_READ_RAW_DATA filter notification so it must be loaded as a global filter. |
| 2223 | For compatibility with previous versions of IIS, the filter %1 was loaded as a global filter from the registry. To control the filter with IIS Manager, remove the filter from the registry and add it as a global filter with IIS Manager. Filters in the registry are stored at HKLM\System\CurrentControlSet\Services\W3Svc\Parameters\Filter DLLs. |
| 2226 | The server was unable to read the file %1 because of a lack of access permissions. |
| 2227 | The server was unable to acquire a license for an SSL connection. |
| 2228 | The server stopped serving requests for application %1 because the number of crashes of out-of-process components exceeded a limit. |
| 2229 | The server failed to shut down application %1. The error was %2. |
| 2230 | The server was unable to read the file %1. The file does not exist. |

| | |
|---|---|
| 2231 | The server was unable to read the file %1. The Windows 32 error returned from the attempt is %2. |
| 2232 | The server was unable to read the file %1. The file exceeds the maximum allowable size of %2. |
| 2233 | The server was unable to allocate a buffer to read the file %1. |
| 2236 | The server failed to load application %1. The error was %2. |
| 2237 | Out-of-process application %1 terminated unexpectedly. |
| 2238 | The job object query failed. The data is the error. |
| 2239 | The job object set limit failed. The data is the error. |
| 2240 | Schedule a work item for CPU Accounting or Limits failed. The data is the error. |
| 2241 | Site %1 hit its CPU Limit. No action was taken. |
| 2242 | Site %1 hit its CPU Limit. The priority of all process on that site has been lowered to idle class. |
| 2243 | Site %1 hit its CPU Limit. All processes on that site have been terminated. |
| 2244 | Site %1 hit its CPU Limit. The site has been paused. |
| 2245 | The server certificate for instance %1 has expired or is not yet valid. |
| 2246 | The server certificate for instance %1 has been revoked. |
| 2247 | The server certificate for instance %1 does not chain up to a trusted root certificate. |
| 2248 | One of the certificates in the certificate chain of the server certificate for instance %1 has an invalid signature. |
| 2249 | CPU Limits/Accounting failed to queue work item. The data is the error. |
| 2250 | The server certificate for instance %1 had invalid metabase data associated with it and could not be retrieved. The error encountered was %2. |
| 2251 | A CryptoAPI error was encountered trying to retrieve the server certificate for instance %1. The error encountered was %2. |
| 2252 | The server certificate for instance %1 could not be retrieved because it could not be found in a certificate store. The error encountered was %2'. |
| 2253 | The server certificate for instance %1 could not be retrieved because of an internal error. The error encountered was %2. |
| 2254 | The server Certificate Trust List for instance %1 had invalid metabase data associated with it and could not be retrieved. The error encountered was %2. |
| 2255 | A CryptoAPI error was encountered trying to retrieve the server Certificate Trust List for instance %1. The error encountered was %2. |
| 2256 | The server Certificate Trust List for instance %1 could not be retrieved because it could not be found in a certificate store. The error encountered was %2. |

| | |
|---|---|
| 2257 | The server certificate for instance %1 could not be retrieved because of an internal error. The error number is %2. |
| 2258 | The server failed to close client connections to the following URLs during shutdown: %1. |
| 2259 | The COM application %1 at %2 failed to activate out of process. |
| 2261 | An attempt was made to load filter %1, but it requires the SF_NOTIFY_READ_RAW_DATA filter notification, which is not supported in worker process isolation mode. |
| 2262 | ISAPI %1 reported itself as unhealthy for the following reason: %2. |
| 2263 | ISAPI %1 reported itself as unhealthy. No reason was given by the ISAPI. |
| 2264 | The directory specified for caching compressed content %1 is invalid. Static compression is being disabled. |
| 2265 | The registry key for IIS subauthenticator is not configured correctly on the local machine; the anonymous password sync feature is disabled. |
| 2266 | The account that the current worker process is running under does not have SeTcbPrivilege privilege; the anonymous password sync feature and the Digest authentication feature are disabled. |
| 2267 | A raw ISAPI filter could not be loaded because of a configuration problem. HTTPFilter Service has to be hosted in InetInfo.exe for raw ISAPI filters to work correctly. The most likely reason is that the **IIS5IsolationModeEnabled** setting was changed and HTTPFilter service was not restarted. Restart HTTPFilter for configuration changes to be taken into effect. |
| 2268 | Could not load all ISAPI filters for site/service. Therefore, startup was aborted. |
| 2269 | The worker process failed to initialize the HTTP.sys communication or the W3svc.exe communication layer and, therefore, could not be started. The data field contains the error number. |
| 2270 | IIS client certificate mapping configuration for site %1 failed to be loaded. The data field contains the error number. |
| 2271 | Could not initialize the logging module for site %1. The site will, therefore, be nonfunctional. |
| 2272 | The registry key for IIS subauthenticator is not configured correctly on the domain controller; the Digest authentication feature is disabled. |
| 2273 | The worker process could not access the metabase because a disconnection error occurred. Marking process as unhealthy. |

# ASP Events and Errors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

In Event Viewer, you can open the property pages for each type of log and configure the filter options that generally apply to all events.

IIS increases the degree of control by providing two metabase keys that enable you to specify what is sent to the Windows Events log when ASP events and errors occur: **AspLogErrorRequests** and **AspErrorsToNTLog**.

**AspLogErrorRequests**
The **AspLogErrorRequests** property controls whether the Web server writes unsuccessful client requests to the Windows event log file. If **AspLogErrorRequests** is set to TRUE, a standard set of ASP error requests are logged.

If **AspLogErrorRequests** is set to TRUE and **AspErrorsToNTLog** is set to FALSE, then the ASP errors are sent to the IIS log. If these errors are serious or logging to the IIS log previously failed, then each error is also sent to the Windows event log.

If **AspLogErrorRequests** is set to FALSE, these errors are sent only to the IIS log and not to the Windows Event Log. If **AspLogErrorRequests** is set to TRUE and **AspErrorsToNTLog** is set to TRUE, then all ASP-related errors go to the Windows event log and the IIS log. For more information about setting the **AspLogErrorRequests** property, see About Events.

To completely prevent ASP errors from being logged in the IIS log file, you must disable logging altogether. For more information about disabling logging, see Analyzing Log Files.

**AspErrorsToNTLog**
If the **AspErrorsToNTLog** key is set to TRUE, all possible ASP errors are sent to the application event log. If this key is set to FALSE, only a subset of all ASP errors is sent. The subset includes the error numbers 100, 101, 102, 103, 104, 105, 106, 107, 115, 190, 191, 192, 193, 194, 240, 241, and 242. This key cannot be set in IIS Manager. It must be set programmatically, using scripts, for example.

# ASP Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table E.3 lists the events that the WWW service generates when processing ASP applications that are configured incorrectly or ASP pages that contain errors. These events are listed in the Application log regardless of the value of the **ASPLogErrorRequests** metabase property.

**Table E.3 ASP Events**

| Event ID | Description |
|---|---|
| 0x5 | Error: %1. |
| 0x6 | Error: %1, %2. |
| 0x7 | Error: %1, %2, %3. |
| 0x8 | Error: %1, %2, %3, %4. |
| 0x9 | Warning: %1. |
| 0x10 | Warning: %1, %2. |
| 0x11 | Warning: %1, %2, %3. |
| 0x12 | Warning: %1, %2, %3, %4. |
| 0x13 | Failed to create an ASP session because access was denied when activating COM+ partition %1. |
| 0x14 | Failed to create ASP application %1 because of invalid or missing COM+ partition ID. |
| 0x15 | Failed to retrieve the anonymous user token for ASP application %1. Global.asa OnEnd routines will not be executed. |
| 0x16 | Failed to impersonate the anonymous user for ASP application %1. Global.asa OnEnd routines will not be executed. |
| 0x17 | No default script language was specified for application %s. Using default: %s. |
| 0x1f3 | Invalid progID. |

# ASP Errors

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table E.4 lists the errors that the WWW service generates when processing ASP applications that are configured incorrectly or ASP pages that contain errors. These errors are listed in the Application log only if the **ASPLogErrorRequests** metabase property is set to TRUE. If the **ASPErrorsToNTLog** metabase property is also set to TRUE, all the errors get logged to the Windows event application log; otherwise, only a subset is logged. The subset includes the error numbers 100, 101, 102, 103, 104, 105, 106, 107, 115, 190, 191, 192, 193, 194, 240, 241, and 242. These error messages are listed in the Application log with the source name Active Server Pages.

**Table E.4 ASP Errors**

| Error ID | Description |
|---|---|
| 0100 | Out of memory. Unable to allocate required memory. |
| 0101 | Unexpected error. The function returned \|. |
| 0102 | Expecting string input. The function expects a string as input. |
| 0103 | Expecting numeric input. The function expects a number as input. |
| 0104 | Operation not allowed. |
| 0105 | Index out of range. An array index is out of range. |
| 0106 | Type mismatch. An unhandled data type was encountered. |
| 0107 | Data size too large. The size of the data being sent in the request is over the allowed limit. |
| 0108 | Create object failed. An error occurred while creating object %s. |
| 0109 | Member not found. |
| 0110 | Unknown name. |
| 0111 | Unknown interface. |
| 0112 | Missing parameter. |
| 0113 | Script timed out. The maximum amount of time for a script to be executed was exceeded. You can change this limit by specifying a new value for the property **Server.ScriptTimeout** or by changing the value in the IIS administration tools. |
| 0114 | Object not free-threaded. The application object accepts only free-threaded objects; object %s is not free-threaded. |
| 0115 | Unexpected error. A trappable error (%X) occurred in an external object. The script cannot continue running. |
| 0116 | Missing close of script delimiter. The script block lacks the close of the <script> tag (%>). |
| 0117 | Missing close of <script> tag. The script block lacks the close of the <script> tag (</SCRIPT>) or the close-of-tag symbol (>). |

| | |
|---|---|
| 0118 | Missing close of <object> tag. The object block lacks the close of the <object> tag (</OBJECT>) or the close-of-tag symbol (>). |
| 0119 | Missing **Classid** or **Progid** attribute. The object instance '\|' requires a valid **Classid** or **Progid** in the <object> tag. |
| 0120 | Invalid **Runat** attribute. The **Runat** attribute of the <script> tag or <object> tag can have only the value 'Server. |
| 0121 | Invalid scope in <object> tag. The object instance '\|' cannot have Application or Session scope. To create the object instance with Session or Application scope, place the <object> tag in the Global.asa file. |
| 0122 | Invalid scope in <object> tag. The object instance '\|' must have Application or Session scope. This applies to all objects created in a Global.asa file. |
| 0123 | Missing **ID** attribute. The required **ID** attribute of the <object> tag is missing. |
| 0124 | Missing **Language** attribute. The required **Language** attribute of the <script> tag is missing. |
| 0125 | Missing close of attribute. The value of the '\|' attribute has no closing delimiter. |
| 0126 | Include file not found. The include file '\|' was not found. |
| 0127 | Missing close of HTML comment. The HTML comment or server-side include lacks the close tag (-->). |
| 0128 | Missing **File** or **Virtual** attribute. The include file name must be specified by using either the **File** or **Virtual** attribute. |
| 0129 | Unknown scripting language. The scripting language '\|' is not found on the server. |
| 0130 | Invalid **File** attribute. **File** attribute '\|' cannot start with a forward slash or a backward slash. |
| 0131 | Disallowed parent path. The include file '\|' cannot contain '..' to indicate the parent directory. |
| 0132 | Compilation error. The ASP page '\|' could not be processed. |
| 0133 | Invalid **ClassID** attribute. The <object> tag has an invalid **ClassID** of '\|. |
| 0134 | Invalid **ProgID** attribute. The object has an invalid **ProgID** of '\|. |
| 0135 | Cyclic include. The file '\|' is included by itself (perhaps indirectly). Select the **Include files for other include statements** box. |
| 0136 | Invalid object instance name. The object instance '\|' is attempting to use a reserved name. This name is used by ASP pages intrinsic objects. |
| 0137 | Invalid global script. Script blocks must be one of the allowed Global.asa procedures. Script directives within <% ... %> are not allowed within the Global.asa file. The allowed procedure names are **Application_OnStart**, **Application_OnEnd**, **Session_OnStart**, and **Session_OnEnd**. |
| 0138 | Nested script block. A script block cannot be placed inside another script block. |
| 0139 | Nested object. An <object> tag cannot be placed inside another <object> tag. |
| 0140 | Page command out of order. The @ command must be the first command within the ASP page. |
| 0141 | Page command repeated. The @ command can be used only once within the ASP page. |

| | |
|---|---|
| 0142 | Thread token error. A thread token failed to open. |
| 0143 | Invalid application name. A valid application name was not found. |
| 0144 | Initialization error. The page-level objects list failed during initialization. |
| 0145 | New application failed. The new application could not be added. |
| 0146 | New session failed. The new session could not be added. |
| 0147 | 500 server error. |
| 0148 | Server too busy. |
| 0149 | Application restarting. The request cannot be processed while the application is being restarted. |
| 0150 | Application directory error. The application directory could not be opened. |
| 0151 | Change notification error. The change notification event could not be created. |
| 0152 | Security error. An error occurred while processing a user's security credentials. |
| 0153 | Thread error. A new thread request failed. |
| 0154 | Write HTTP header error. The HTTP headers could not be written to the client browser. |
| 0155 | Write page content error. The page content could not be written to the client browser. |
| 0156 | Header error. The HTTP headers are already written to the client browser. Any HTTP header modifications must be made before writing page content. |
| 0157 | Buffering on. Buffering cannot be turned off once it is turned on. |
| 0158 | Missing URL. A URL is required. |
| 0159 | Buffering off. Buffering must be on. |
| 0160 | Logging failure. Failure to write entry to the log. |
| 0161 | Data type error. The conversion of a **Variant** to a **String** variable failed. |
| 0162 | Cannot modify cookie. The cookie 'ASPSessionID' cannot be modified. It is a reserved cookie name. |
| 0163 | Invalid comma use. Commas cannot be used within a log entry. Select another delimiter. |
| 0164 | Invalid **TimeOut** value. An invalid **TimeOut** value was specified. |
| 0165 | **SessionID** error. A **SessionID** string cannot be created. |
| 0166 | Uninitialized object. An attempt was made to access an uninitialized object. |
| 0167 | Session initialization error. An error occurred while initializing the **Session** object. |

| | |
|---|---|
| 0168 | Disallowed object use. An intrinsic object cannot be stored within the **Session** object. |
| 0169 | Missing object information. An object with missing information cannot be stored in the **Session** object. The threading model information for an object is required. |
| 0170 | Delete session error. The session was not deleted properly. |
| 0171 | Missing path. The *Path* parameter must be specified for the **MapPath** method. |
| 0172 | Invalid path. The *Path* parameter for the **MapPath** method must be a virtual path. A physical path was used. |
| 0173 | Invalid path character. An invalid character was specified in the *Path* parameter for the **MapPath** method. |
| 0174 | Invalid path characters. An invalid '/' or '\\' was found in the *Path* parameter for the **MapPath** method. |
| 0175 | Disallowed path characters. The '..' characters are not allowed in the *Path* parameter for the **MapPath** method. |
| 0176 | Path not found. The *Path* parameter for the **MapPath** method did not correspond to a known path. |
| 0177 | **Server.CreateObject** failed. %s' |
| 0178 | **Server.CreateObject** access error. The call to **Server.CreateObject** failed while checking permissions. Access is denied to this object. |
| 0179 | Application initialization error. An error occurred while initializing the **Application** object. |
| 0180 | Disallowed object use. An intrinsic object cannot be stored within the **Application** object. |
| 0181 | Invalid threading model. An object using the apartment threading model cannot be stored within the **Application** object. |
| 0182 | Missing object information. An object with missing information cannot be stored in the **Application** object. The threading model information for the object is required. |
| 0183 | Empty cookie key. A cookie with an empty key cannot be stored. |
| 0184 | Missing cookie name. A name must be specified for a cookie. |
| 0185 | Missing default property. A default property was not found for the object. |
| 0186 | Error parsing certificate. |
| 0187 | Object addition conflict. Could not add object to application. Application was locked down by another request for adding an object. |
| 0188 | Disallowed object use. Cannot add objects created by using <object> tags to the session intrinsic. |
| 0189 | Disallowed object use. Cannot add objects created by using <object> tags to the application intrinsic. |
| 0190 | Unexpected error. A trappable error occurred while releasing an external object. |
| 0191 | Unexpected error. A trappable error occurred in the **OnStartPage** method of an external object. |
| 0192 | Unexpected error. A trappable error occurred in the **OnEndPage** method of an external object. |

| | |
|---|---|
| 0193 | **OnStartPage** failed. An error occurred in the **OnStartPage** method of an external object. |
| 0194 | **OnEndPage** failed. An error occurred in the **OnEndPage** method of an external object. |
| 0195 | Invalid server method call. This method of the **Server** object cannot be called during **Session_OnEnd** and **Application_OnEnd**. |
| 0196 | Cannot launch out-of-process component. Only InProc server components should be used. If you want to use LocalServer components, you must set the **AspAllowOutOfProcComponents** metabase setting. |
| 0197 | Disallowed object use. Cannot add object with apartment model behavior to the application intrinsic object. |
| 0198 | Server shutting down. Cannot process request. |
| 0199 | Disallowed object use. Cannot add **JScript** objects to the session. |
| 0200 | Out-of-range **Expires** attribute. The date and time given for the **Expires** attribute is earlier than Jan 1, 1980 or later than Jan 19, 2038, 3:14:07 GMT. |
| 0201 | Invalid default script language. The default script language specified for this application is invalid. |
| 0202 | Missing code page. The **CodePage** attribute is missing. |
| 0203 | Invalid code page. The specified **CodePage** attribute is invalid. |
| 0204 | Invalid **CodePage** value. An invalid **CodePage** value was specified. |
| 0205 | Change notification. Failed to create event for change notification. |
| 0206 | Cannot call BinaryRead. Cannot call BinaryRead after using Request.Form collection. |
| 0207 | Cannot use Request.Form. Cannot use Request.Form collection after calling BinaryRead. |
| 0208 | Cannot use generic Request collection. Cannot use the generic Request collection after calling BinaryRead. |
| 0209 | Illegal value for **Transaction** property. The **Transaction** property can only be REQUIRED, REQUIRES_NEW, SUPPORTED, or NOT_SUPPORTED. |
| 0210 | Method not implemented. This method has not yet been implemented. |
| 0211 | Object out of scope. A built-in ASP object, which is no longer valid, has been referenced. |
| 0212 | Cannot clear buffer. Response.Clear is not allowed after a Response.Flush while client debugging is enabled. |
| 0214 | Invalid *Path* parameter. The *Path* parameter exceeds the maximum length allowed. |
| 0215 | Illegal value for **EnableSessionState** property. The **EnableSessionState** property can be only TRUE or FALSE. |
| 0216 | MSDTC Service not running. Transactional Web pages cannot be run if the MSDTC service is not running. |
| 0217 | Invalid scope in <object> tag. Object scope must be Page, Session, or Application. |
| 0218 | Missing LCID. The LCID attribute is missing. |

| | |
|---|---|
| 0219 | Invalid LCID. The specified LCID is not available. |
| 0220 | Requests for Global.asa not allowed. Requests with the URL pointing to Global.asa are not allowed. |
| 0221 | Invalid @ Command directive. The specified '\|' option is unknown or invalid. |
| 0222 | Invalid TypeLib Specification. The <metadata> tag contains an invalid type library specification. |
| 0223 | TypeLib not found. The <metadata> tag contains a type library specification that does not match any registry entry. |
| 0224 | Cannot load TypeLib. Cannot load the type library specified in the <metadata> tag. |
| 0225 | Cannot wrap TypeLibs. Cannot create a type library wrapper object from the type libraries specified in <metadata> tags. |
| 0226 | Cannot modify StaticObjects. StaticObjects collection cannot be modified at run time. |
| 0227 | Server.Execute failed. The call to Server.Execute failed. |
| 0228 | Server.Execute error. The call to Server.Execute failed while loading the page. |
| 0229 | Server.Transfer failed. The call to Server.Transfer failed |
| 0230 | Server.Transfer error. The call to Server.Transfer failed while loading the page. |
| 0231 | Server.Execute error. Invalid URL form or fully qualified absolute URL was used. Use relative URLs. |
| 0232 | Invalid cookie specification. The <metadata> tag contains an invalid cookie specification. |
| 0233 | Cannot load cookie script source. Cannot load cookie script source file specified in the <metadata> tag. |
| 0234 | Invalid include directive. Server-side include directives cannot be present in script blocks. Use the **SRC=** attribute of the <script> tag. |
| 0235 | Server.Transfer error. Invalid URL form or fully qualified absolute URL was used. Use relative URLs. |
| 0236 | Invalid cookie specification. The <metadata> tag contains an invalid or missing *SRC* parameter. |
| 0237 | Invalid cookie specification. The <metadata> tag contains an invalid or missing *Name* parameter. |
| 0238 | Missing attribute value. No value was specified for the '\|' attribute. |
| 0239 | Cannot process file. Unicode ASP files are not supported. |
| 0240 | Script engine exception. A script engine threw exception %X in %s from %s. |
| 0241 | **CreateObject** exception. The **CreateObject** of %s caused exception %X. |
| 0242 | Query **OnStartPage** interface exception. Querying the **OnStartPage** or **OnEndPage** methods of object %s caused exception %X. |
| 0243 | Invalid <metadata> tag in Global.asa. Only <metadata> TYPE="TypeLib" can be used in Global.asa. |
| 0244 | Cannot enable session state. Session state cannot be enabled when it has been disabled in the application. |

| | |
|---|---|
| 0245 | Mixed usage of code page values. The **@CODEPAGE** value specified differs from that of the including file's code page or the file's saved format. |
| 0246 | Too many concurrent users. Try again later. |
| 0247 | Bad argument to **BinaryRead**. The argument to **BinaryRead** must be nonnegative. |
| 0248 | Script is not transacted. This ASP file must be transacted to use the **ObjectContext** object. |
| 0249 | Cannot use IStream on **Request**. Cannot use IStream on **Request** object after using Request.Form collection or Request.BinaryRead. |
| 0250 | Invalid default code page. The default code page specified for this application is invalid. |
| 0251 | Response buffer limit exceeded. Execution of the ASP page caused the response buffer to exceed its configured limit. |

# FTP Service Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table E.5 lists the events that are generated by the FTP service. The FTP service events are listed in the System log with the source name MSFTPSVC.

**Table E.5 FTP Service Events**

| Event ID | Description |
|---|---|
| 1 | FTP server could not initialize its security. The data is the error. |
| 3 | FTP server could not initialize the socket library. The data is the error. |
| 4 | FTP server was unable to be initialized because of a shortage of available memory. The data is the error. |
| 5 | FTP server could not locate the FTP/TCP service. The data is the error. |
| 6 | FTP server could not create the main connection socket. The data is the error. |
| 7 | FTP server could not create the main connection thread. The data is the error. |
| 8 | FTP server could not create a client worker thread for the user at host %1. The connection to this user is terminated. The data is the error. |
| 9 | A call to a system service failed unexpectedly. The data is the error. |
| 10 | User %1 at host %2 has timed out after %3 seconds of inactivity. |
| 11 | An anonymous logon request was received from %1 at host %2. |
| 12 | A user logon request was received from %1 at host %2. |
| 13 | User %1 failed to log on, could not access the home directory %2. |
| 14 | User %1 denied access to the current directory %2 because of a security change. |
| 15 | Failed to read metabase property **PassivePortRange** under the FTP service node %1. |
| 16 | The FTP service configuration property **PassivePortRange** has the invalid value: %1. |

# WWW Service Performance Counter Events

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Table E.6 lists the events that are generated by the part of the WWW service that monitors and records performance counter data. These events are listed in the Application log with the source name W3Ctrs.

**Table E.6 WWW Service Performance Counter Events**

| Event ID | Description |
|---|---|
| 2000 | Unable to query the WWW service performance data. The error code returned by the service is data DWORD 0. |
| 2001 | It has taken too long to refresh the WWW service counters; the stale counters are being used instead. |
| 2002 | Setting up Web service counters failed; make sure your Web service counters are registered correctly. |
| 2003 | It has taken too long to refresh the WWW service counters; the stale counters are being used instead. This is the second message within the past %1 (hours, minutes, seconds). No more stale counter messages will be logged for this client session until the time limit expires. |

# Metabase Auditing Event Messages

Applies To: Windows Server 2003 with SP1

When metabase auditing is enabled, IIS tracks and logs each change to the metabase keys or properties using event messages in the Security log. Each change type is associated with an event message ID in the Security log. Metabase auditing records similar information for each event message.

For information about the common output produced for metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

The Metabase Auditing Event Messages table shows the event IDs, names, and descriptions for IIS 6.0 metabase auditing event messages.

**Metabase Auditing Event Messages**

| Event ID | Event Name | Description | Event Message Output |
|---|---|---|---|
| 4500 | IISADMIN_AUDIT_ADD_KEY | Shows information about a change to add a metabase key | See Metabase Audit Add Key |
| 4501 | IISADMIN_AUDIT_DELETE_KEY | Shows information about a change to delete a metabase key | See Metabase Audit Delete Key |
| 4502 | IISADMIN_AUDIT_DELETE_CHILD_KEYS | Shows information about a change to delete child keys from a metabase property | See Metabase Audit Delete Child Keys |
| 4503 | IISADMIN_AUDIT_COPY_KEY | Shows information about a change to copy a metabase key | See Metabase Audit Copy Key |
| 4504 | IISADMIN_AUDIT_RENAME_KEY | Shows information about a change to rename a metabase key | See Metabase Audit Rename Key |
| 4505 | IISADMIN_AUDIT_SET_DATA | Shows information about a change to add or change data in a metabase property | See Metabase Audit Set Data |
| 4506 | IISADMIN_AUDIT_DELETE_DATA | Shows information about a change to delete data from a metabase property | See Metabase Audit Delete Data |
| 4507 | IISADMIN_AUDIT_DELETE_ALL_DATA | Shows information about a change to delete all data from the metabase properties | See Metabase Audit Delete All Data |
| 4508 | IISADMIN_AUDIT_COPY_DATA | Shows information about a change to copy data from the metabase properties | See Metabase Audit Copy Data |
| 4509 | IISADMIN_AUDIT_SET_LAST_CHANGETIME | Shows the last time a change was made to the metabase | See Metabase Audit Set Last Change Time |
| 4510 | IISADMIN_AUDIT_RESTORE | Shows information about a change to restore the metabase | See Metabase Audit Restore |
| 4511 | IIADMIN_AUDIT_DELETE_BACKUP | Shows information about a change to delete the metabase backup | See Metabase Audit Delete Backup |
| 4512 | IISADMIN_AUDIT_IMPORT | Shows information about a change to import data into the metabase | See Metabase Audit Import |

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Common Output in Metabase Auditing Event Messages

Applies To: Windows Server 2003 with SP1

All event messages produced when metabase auditing is enabled provide information specific to the event with content that is common to every event message. For example, the specific event message for a metabase audit set data event differs from the specific event message provided for a metabase audit copy data event. The set data event message includes the common output and information about the change to a specific property ID and property name, the old value and new value. While the event log message for a copy data metabase auditing event provides the common output and the destination and the source path of the copy action.

The Event Viewer details pane provides the following information about the metabase auditing event:

- Event type - Success or Failure
- When the event occurred - Date and time
- Source - IIS Metabase
- Event ID - specific to the metabase auditing event
- User - the user account
- Computer - short name for the computer

The metabase auditing event log message common output appears in the event properties view. The following table describes the event information common to each metabase auditing event log message.

**Message Output - Common**

| Log Output Name | Description |
|---|---|
| Primary User Name | The name of the user account that tried to change the metabase file manually when this information is possible to obtain, or System when a local system account was used. |
| Primary User Domain | The user domain when that information is possible to obtain. |
| Primary Logon ID | The ID used to log on to and change the metabase, when this information is possible to obtain. |
| Caller PID | The process ID of the application pool. |
| Caller Image Path | The absolute path of the resource. |
| Result | The variable representing the result. |

For information about using metabase auditing, see Metabase Auditing.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Add Key

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_ADD_KEY table shows the information about the attempt to add a metabase key, the name of the metabase key, and whether the attempt was successful.

**IISADMIN_AUDIT_ADD_KEY**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4500 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_ADD_KEY |
| Metabase Add Key | %n%n |
| Path | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about using metabase auditing, see Metabase Auditing.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Delete Key

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_DELETE_KEY table shows information about the attempt to delete a metabase key, the name of the metabase key, and whether the attempt was successful.

**IISADMIN_AUDIT_DELETE_KEY**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4501 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_DELETE_KEY |
| Metabase Delete Key | %n%n |
| Path | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Delete Child Keys

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_DELETE_CHILD_KEYS table shows information about the attempt to delete child metabase keys, the name of the keys, and whether the attempt was successful.

**IISADMIN_AUDIT_DELETE_CHILD_KEYS**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4502 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_DELETE_CHILD_KEYS |
| Metabase Delete Child Keys | %n%n |
| Path | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Copy Key

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_COPY_KEYS table shows information about the attempt to copy data from a metabase key, the name of the key, and whether the attempt was successful.

**IISADMIN_AUDIT_COPY_KEYS**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4503 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_COPY_KEY |
| Metabase Copy Key | %n%n |
| Source Path | %4%n |
| Destination Path | %5%n |
| Result | %8%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Rename Key

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_RENAME_KEY table shows information about the attempt to rename a metabase key, the name of the metabase key, and whether the attempt was successful.

**IISADMIN_AUDIT_RENAME_KEYS**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4504 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_RENAME_KEY |
| Metabase Rename Key | %n%n |
| Source Path | %4%n |
| New Key Name | %5%n |
| Result | %8%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Set Data

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_SET_DATA_KEY table shows information about the attempt to add or change data in a metabase key, the name of the key, and whether the attempt was successful.

**IISADMIN_AUDIT_SET_DATA_KEY**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4505 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_SET_DATA_KEY |
| Metabase Set Data | %n%n |
| Path | %4%n |
| Property ID | %5%n |
| Property Name | %6%n |
| Old Value | %7%n |
| New Value | %8%n |
| Result | %11%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Delete Data

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_DELETE_DATA table shows information about the attempt to delete data from a property in a metabase key, the name of the key, and whether the attempt was successful.

**IISADMIN_AUDIT_DELETE_DATA**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4506 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_DELETE_DATA |
| Metabase Delete Data | %n%n |
| Path | %4%n |
| Property ID | %5%n |
| Property Name | %6%n |
| Old Value | %7%n |
| Result | %10%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Delete All Data

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_DELETE_ALL_DATA table shows information about the attempt to delete all data from the metabase, and whether the attempt was successful.

**IISADMIN_AUDIT_DELETE_ALL_DATA**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4507 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_DELETE_ALL_DATA |
| Metabase Delete All Data | %n%n |
| Path | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Copy Data

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_COPY_DATA table shows information about the attempt to copy data from the metabase and whether the attempt was successful.

**IISADMIN_AUDIT_COPY_DATA**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4508 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_COPY_DATA |
| Metabase Copy Data | %n%n |
| Source Path | %4%n |
| Destination Path | %5%n |
| Result | %8%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Set Last Change Time

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_SET_LAST_CHANGETIME table shows information about the attempt to set the last change timestamp for the metabase and whether the attempt was successful.

**IISADMIN_AUDIT_SET_LAST_CHANGETIME**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4509 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_SET_LAST_CHANGETIME |
| Metabase Set Last Change Time | %n%n |
| Path | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Restore

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_RESTORE table shows information about the attempt to restore a backup file to the metabase and whether the attempt was successful.

**IISADMIN_AUDIT_RESTORE**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4510 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_RESTORE |
| Metabase Restore | %n%n |
| Name of Backup | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Delete Backup

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_DELETE_BACKUP table shows information about the attempt to delete the metabase backup and whether the attempt was successful.

**IISADMIN_AUDIT_DELETE_BACKUP**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4511 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_DELETE_BACKUP |
| Metabase Delete Backup | %n%n |
| Name of Backup | %4%n |
| Result | %7%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Metabase Audit Import

Applies To: Windows Server 2003 with SP1

The IISADMIN_AUDIT_IMPORT table shows information about the attempt to import a file into the metabase, and whether the attempt was successful.

**IISADMIN_AUDIT_IMPORT**

| Output | Description or Placeholder |
|---|---|
| Message ID | 4512 |
| Severity | Success |
| Symbolic Name | IISADMIN_AUDIT_IMPORT |
| Metabase Import | %n%n |
| Source Path | %4%n |
| Destination Path | %5%n |
| Filename | %6%n |
| Result | %9%n |

**Note**

The placeholders designated by percent sign, n or a number, and a following percent sign, such as in the metabase key, path, and result fields are replaced by the actual values when the metabase auditing event occurs.

For information about the common output produced for all metabase auditing event messages, see Common Output in Metabase Auditing Event Messages.

To view sample output for one metabase auditing event message, see Sample Metabase Auditing Event Log.

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Sample Metabase Auditing Event Log

Applies To: Windows Server 2003 with SP1

The Security log shows Metabase Audit Log Message Event ID 4505 indicating a set data metabase auditing event that changed the MaxConnections property ID 1014 from the old value of 4294967295 to a new value of 2. The Security log event header information is repeated in the detailed view of the event.

```
Event Type:Success Audit
Event Source:IIS-METABASE
Event Category:Object Access
Event ID:4505
Date:8/22/2006
Time:1:49:42 PM
User:NT AUTHORITY\SYSTEM
Computer:ATestMachine
Description:
Metabase Set Data
 Primary User Name: SYSTEM
 Primary User Domain: NT AUTHORITY
 Primary Logon ID: (0x0,0x3E7)
 Path: /LM/W3SVC
 Property ID: 1014
 Property Name: MaxConnections
 Old Value: 4294967295
 New Value: 2
 Caller PID: 2588
 Caller Image Path: \Device\HarddiskVolume1\WINNT\system32\inetsrv\inetinfo.exe - EWR
 Result: 0x0
```

For information about using metabase auditing, see Metabase Auditing.

For information about enabling metabase auditing, see Auditing the Metabase.

# Performance Counters Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Performance counters measure quantities of information or data, according to the number, size, duration, and rate of data being requested or received. You should not expect to get a list of details from a counter, such as a list of error messages. Instead, use performance counters to get quantities, such as the number of error message since startup or the rate at which error messages are being generated.

You can access counter data through the System Monitor (formerly known as Performance Monitor) or through the "Simple Network Management Protocol" (SNMP) service in the Help and Support for Windows 2003.

The names and descriptions of the following counters are included in this reference:

System Monitor Counters

- WWW Service Counters
- ASP System Monitor Counters
- WWW Service Cache Counters
- IIS Global Counters
- FTP Service Counters

SNMP Counters

- SNMP FTP Service Counters
- SNMP HTTP Service Counters

You must be a member of the Administrators group on the IIS server or a member of the Performance Logging group to retrieve valid data from the following counters. If you are not a member of one of these groups, or if the service you are monitoring is not running, the performance counters return a zero value.

**WWW Service Counters**
These counters help you determine how well the World Wide Web Publishing Service (WWW service) processes requests. These counters can be configured to monitor performance for all sites on a server (using the _Total instance) or for individual Web sites. Note that a few counters included with IIS 5.*x* are now obsolete and are marked as such. Obsolete counters return a zero value.

| Counter | Description |
|---|---|
| Total Bytes Sent | Number of data bytes that have been sent by the WWW service (since service startup). This counter is new in IIS 6.0. |
| Bytes Sent/Sec | Rate that data bytes are sent by the WWW service, per second. This counter was called Bytes Sent in IIS 5.*x*. |
| Total Bytes Received | Total bytes of data received by the WWW service since service startup. This counter is new in IIS 6.0. |
| Bytes Received/Sec | Rate at which data bytes are received by the WWW service, per second. This counter was called Bytes Received in IIS 5.*x*. |
| Total Bytes Transferred | Total bytes of data that were sent and received by the WWW service since service startup. This counter is new in IIS 6.0. |

| | |
|---|---|
| Bytes Total/Sec | Sum of bytes sent/sec and bytes received/sec. This counter was called Bytes Total in IIS 5.*x*. |
| Total Files Sent | Number of user-mode files that were sent by the WWW service since service startup (not including cache hits). Note that this counter does not increment when files are being served from the kernel-mode cache. For more information, see Kernel: URI Cache Hits under "WWW Service Cache Counters". Also note that in IIS 5.0, when a 404 error (File not found) was returned to the client, this counter was not incremented, even if a file was sent with a custom error message. In IIS 6.0, the counter is incremented whether a custom or standard error is returned to the browser. |
| Files Sent/Sec | Rate that files are sent, per second. |
| Total Files Received | Number of files received by the WWW service since service startup. |
| Files Received/Sec | Rate at which files are received by the WWW service, per second. |
| Total Files Transferred | Sum of files sent and received by the WWW service since service startup. Note that this counter does not increment when files are being served from the kernel-mode cache. For more information, see Kernel: URI Cache Hits under "WWW Service Cache Counters". |
| Files/Sec | Rate at which files are sent and received by the WWW service, per second. |
| Current Anonymous Users | Number of users who currently have an anonymous request using the WWW service. Note that IIS 6.0 counts each request as a new user. This is a change from IIS 5.*x*, which counted each connection as a new user. Current Users (Anonymous or Non Anonymous) are now the number of requests currently being worked on by the server. |
| Current Non Anonymous Users | Number of users who currently have a non anonymous request using the WWW service. Note that IIS 6.0 counts each request as a unique user. This is a change from IIS 5.*x*, which counted each connection as a new user. Current Users (Anonymous or Non Anonymous) are now the number of requests currently being worked on by the server. |
| Total Anonymous Users | Number of users who established an anonymous request since the WWW service started. Note that IIS 6.0 counts each request as a unique user. This counter does not increment when files are being served from the kernel cache. For more information, see Kernel: URI Cache Hits under "WWW Service Cache Counters". |
| Anonymous Users/Sec | Rate at which users are making anonymous requests to the WWW service. Note that IIS 6.0 counts each request as a new user. |
| Total NonAnonymous Users | Number of users who had nonanonymous requests to the WWW service since service startup. Note that IIS 6.0 counts each request as a unique user. This counter does not increment when files are being served from the kernel cache. For more information, see Kernel: URI Cache Hits under "WWW Service Cache Counters". |
| NonAnonymous Users/Sec | Rate at which users are making nonanonymous requests to the WWW service, per second. Note that IIS 6.0 counts each request as a new user. |
| Maximum NonAnonymous Users | Maximum number of users who made concurrent nonanonymous requests to the WWW service since service startup. Note that IIS 6.0 counts each request as a new user. |
| Current Connections | Current number of active connections to the WWW service. The behavior of this counter is unchanged from IIS 5.*x*. |
| Maximum Connections | Maximum number of simultaneous connections to the WWW service since service startup. |
| Total Connection Attempts | Number of attempted connections to the WWW service since service startup. |
| Connection Attempts/Sec | Rate of attempted connections to the WWW service since service startup, per second. |

| | |
|---|---|
| Total Logon Attempts | Number of logons attempted on the WWW service since service startup. |
| Logon Attempts/Sec | Rate at which logons to the WWW service are being attempted, per second. |
| Total Options Requests | Number of HTTP requests that were using the **OPTIONS** method since WWW service startup. |
| Options Requests/Sec | Rate at which HTTP requests using the **OPTIONS** method are made. |
| Total Get Requests | Number of HTTP requests that were using the **GET** method since WWW service startup. |
| Get Requests/Sec | Rate at which HTTP requests using the **GET** method are made to the WWW service, per second. |
| Total Post Requests | Number of HTTP requests that were using the **POST** method since WWW service startup. |
| Post Requests/Sec | Rate at which requests using the **POST** method are made to the WWW service, per second. |
| Total Head Requests | Number of HTTP requests that were made using the **HEAD** method since WWW service startup. |
| Head Requests/Sec | Rate at which HTTP requests using the **HEAD** method are made to the WWW service, per second. |
| Total Put Requests | Number of HTTP requests that were using the **PUT** method since WWW service startup. |
| Put Requests/Sec | Rate at which HTTP requests using the **PUT** method are made to the WWW service, per second. |
| Total Delete Requests | Number of HTTP requests that were using the **DELETE** method since WWW service startup. |
| Delete Requests/Sec | Rate at which HTTP requests using the **DELETE** method are made to the WWW service, per second. |
| Total Trace Requests | Number of HTTP requests that were using the **TRACE** method since WWW service startup. |
| Trace Requests/Sec | Rate at which HTTP requests using the **TRACE** method are made to the WWW service, per second. |
| Total Move Requests | Number of HTTP requests that were using the **MOVE** method since WWW service startup. |
| Move Requests/Sec | Rate at which HTTP requests using the **MOVE** method are made to the WWW service, per second. |
| Total Copy Requests | Number of HTTP requests that were using the **COPY** method since WWW service startup. |
| Copy Requests/Sec | Rate at which HTTP requests using the **COPY** method are made to the WWW service, per second. |
| Total Mkcol Requests | Number of HTTP requests that were using the **MKCOL** method since WWW service startup. |

| | |
|---|---|
| Mkcol Requests/Sec | Rate at which HTTP requests using the **MKCOL** method are made to the WWW service, per second. |
| Total Propfind Requests | Number of HTTP requests that were using the **PROPFIND** method since WWW service startup. |
| Propfind Requests/Sec | Rate at which HTTP requests using the **PROPFIND** method are made to the WWW service, per second. |
| Total Proppatch Requests | Number of HTTP requests that were using the **PROPPATCH** method since WWW service startup. |
| Proppatch Requests/Sec | Rate at which HTTP requests using the **PROPPATCH** method are made to the WWW service, per second. |
| Total Search Requests | Number of HTTP requests that were using the **SEARCH** method since WWW service startup. |
| Search Requests/Sec | Rate at which HTTP requests using the **SEARCH** method are made to the WWW service, per second. |
| Total Lock Requests | Number of HTTP requests that were using the **LOCK** method since WWW service startup. |
| Lock Requests/Sec | Rate at which HTTP requests using the **LOCK** method are made to the WWW service, per second. |
| Total Unlock Requests | Number of HTTP requests that were using the **UNLOCK** method since WWW service startup. |
| Unlock Requests/Sec | Rate at which HTTP requests using the **UNLOCK** method are made to the WWW service, per second. |
| Total Other Requests Methods | Number of HTTP requests that do not use the **OPTIONS**, **GET**, **HEAD**, **POST**, **PUT**, **DELETE**, **TRACE**, **MOVE**, **COPY**, **MKCOL**, **PROPFIND**,**PROPPATCH**, **SEARCH**, **LOCK**, or **UNLOCK** methods since WWW service startup. May include **LINK** or other methods supported by gateway applications. |
| Other Requests Methods/Sec | Rate at which HTTP requests are made to the WWW service that do not use the methods listed for Total Other Requests, per second. |
| Total Method Requests | Number of HTTP requests since WWW service startup. |
| Total Method Requests/Sec | Rate at which all HTTP requests are received, per second. |
| Total Not Found Errors | Number of requests that could not be satisfied by the server because the requested document could not be found (since service startup). Generally reported as HTTP error 404. |
| Not Found Errors/Sec | Rate of errors due to requests that couldn't be satisfied by the server because the requested document couldn't be found, per second. |
| Total Locked Errors | Number of requests that could not be satisfied by the server because the requested document was locked (since service startup).Generally reported as HTTP error 423. |
| Locked Errors/Sec | Rate at which requests couldn't be satisfied because the document requested was locked, per second. |
| Current CGI Requests | Current number of CGI requests that are being processed simultaneously by the WWW service. |
| Total CGI Requests | Number of all CGI requests that have been made since WWW service startup. |

| | |
|---|---|
| CGI Requests/Sec | Rate at which CGI requests are being processed simultaneously by the WWW service, per second. |
| Maximum CGI Requests | Maximum number of CGI requests simultaneously processed by the WWW service since service startup. |
| Current ISAPI Extension Requests | Current number of ISAPI extension requests that are being processed simultaneously by the WWW service. |
| Total ISAPI Extension Requests | Number of all ISAPI extension requests that have been made since WWW service startup. |
| ISAPI Extension Requests/Sec | Rate of ISAPI extension requests that are processed simultaneously by the WWW service, per second. |
| Maximum ISAPI Extension Requests | Maximum number of ISAPI extension requests that have been processed simultaneously by the WWW service. |
| Current CAL count for authenticated users | This counter is no longer valid. The value will always be zero. |
| Maximum CAL count for authenticated users | This counter is no longer valid. The value will always be zero. |
| Total count of failed CAL requests for authenticated users | This counter is no longer valid. The value will always be zero. |
| Current CAL count for SSL connections | This counter is no longer valid. The value will always be zero. |
| Maximum CAL count for SSL connections | This counter is no longer valid. The value will always be zero. |
| Total count of failed CAL requests for SSL connections | This counter is no longer valid. The value will always be zero. |
| Total Allowed Async I/O Requests | This counter is no longer valid. The value will always be zero. |
| Total Blocked Async I/O Requests | This counter is no longer valid. The value will always be zero. |
| Total Rejected Async I/O Requests | This counter is no longer valid. The value will always be zero. |

| | |
|---|---|
| Current Blocked Async I/O Requests | This counter is no longer valid. The value will always be zero. |
| Measured Async I/O Bandwidth Usage | This counter is no longer valid. The value will always be zero. |
| Total blocked bandwidth bytes | Total bytes blocked due to bandwidth throttling settings (since service startup). This counter is new in IIS 6.0. |
| Current blocked bandwidth bytes | Current bytes temporarily blocked due to bandwidth throttling settings (since service startup). This counter is new in IIS6.0. |
| Service Uptime | Uptime for WWW service or Web site. |
| MaxCalSsl | This counter is no longer valid. The value will always be zero. |

**ASP System Monitor Counters**

If you are running Active Server Pages (ASP) on your server, these counters can help you determine how well the pages are performing. The counters are designed to monitor server performance and cannot be configured for individual sites.

| Counter | Description |
|---|---|
| ASP Debugging Requests | Number of requests for debugging documents since WWW service startup. |
| Errors During Script Runtime | Number of requests failed due to runtime errors. |
| Errors From ASP Preprocessor | Number of requests failed due to preprocessor errors. |
| Errors From Script Compilers | Number of requests failed due to script compilation errors. |
| Errors/Sec | Number of errors per second. |
| Request Bytes In Total | Total size, in bytes, of all requests. |
| Request Bytes Out Total | Total size, in bytes, of responses sent to clients. This does not include standard HTTP response headers. |
| Request Execution Time | Number of milliseconds that it took to execute the most recent request. |
| Request Wait Time | Number of milliseconds the most recent request was waiting in the queue. |
| Requests Disconnected | Number of requests that were disconnected due to communication failure. |
| Requests Executing | Number of requests currently executing. |
| Requests Failed Total | Number of requests failed due to errors, authorization failure, and rejections. |
| Requests Not Authorized | Number of requests failed due to insufficient access rights. |
| Requests Not Found | Number of requests for files that were not found. |
| Requests Queued | Number of requests waiting for service from the queue. |
| Requests Rejected | Number of requests not executed because there were insufficient resources to process them. |
| Requests Succeeded | Number of requests that executed successfully. |
| Requests Timed Out | Number of requests that timed out. |

| | |
|---|---|
| Requests Total | Number of requests since the service was started. |
| Requests/Sec | Number of requests executed per second. |
| Script Engines Cached | Number of script engines in cache. |
| Session Duration | Number of milliseconds that the most recent session persisted. |
| Sessions Current | The current number of sessions being serviced. |
| Sessions Timed Out | Number of sessions timed out. |
| Sessions Total | Number of sessions since the service was started. |
| Templates Cached | Number of templates currently cached. |
| Template Cache Hit Rate | Percent of requests found in template cache. |
| Template Notifications | Number of templates invalidated in the cache due to change notification. |
| Transactions Aborted | Number of transactions aborted. |
| Transactions Committed | Number of transactions committed. |
| Transactions Pending | Number of transactions in progress. |
| Transactions Total | Number of transactions since the service was started. |
| Transactions/Sec | Transactions started per second. |
| In Memory Templates Cached | Number of compiled templates cached in memory. |
| In Memory Template Cache Hit Rate | Percent of requests found in cache in memory |
| Script Engine Cache Hit Rate | Percent of requests found in script engine cache. |
| Engine Flush Notifications | Number of engines invalidated in the cache due to change notification. |

**WWW Service Cache Counters**

The WWW service and FTP service do not share a common cache. The caches are split into two separate performance objects: one for FTP service (IIS global counters) and one for the WWW service (WWW service cache counters).

WWW service cache counters are designed to monitor server performance and cannot be configured to monitor individual sites.

| **Counter** | **Description** |
|---|---|
| Active Flushed Entries | Active Flushed Entries are file handlers cached in user mode that will be closed when all current transfers complete. This counter is new in IIS 6.0. |
| Current File Cache Memory Usage | Current number of bytes used for the user-mode file cache. This counter is new in IIS 6.0. |
| Current Files Cached | Current number of files whose content is in the user-mode cache. This counter is new in IIS 6.0. |
| Total Files Cached | Number of files whose content was ever added to the user-mode cache since WWW service startup. This counter is new in IIS 6.0. |
| File Cache Hits | Number of successful lookups in the user-mode file cache since WWW service startup. This counter is new in IIS 6.0. |

| | |
|---|---|
| File Cache Hits % | Ratio of user-mode file cache hits to total cache requests since WWW service startup. This counter is new in IIS 6.0. |
| File Cache Misses | Number of unsuccessful look ups in the user-mode file cache since WWW service startup. This counter is new in IIS 6.0. |
| File Cache Flushes | Number of files removed from the user-mode cache since WWW service startup. This counter is new in IIS 6.0. |
| Maximum File Cache Memory Usage | Maximum number of bytes used for user-mode file cache since service startup. This counter is new in IIS 6.0. |
| Total Flushed Files | Number of file handles that have been removed from the user-mode cache since WWW service startup. This counter is new in IIS 6.0. |
| Current URIs Cached | Number of URI information blocks that are currently in the user-mode cache. This counter is new in IIS 6.0. |
| Total URIs Cached | Number of URI information blocks that have been added to the user-mode cache since WWW service startup. This counter is new in IIS 6.0. |
| URI Cache Hits | Number of successful look ups in the user-mode URI cache since WWW service startup. This counter is new in IIS 6.0. |
| URI Cache Misses | Number of unsuccessful lookups in the user-mode URI cache since WWW service startup. This counter is new in IIS 6.0. |
| URI Cache Hit % | Ratio of URI Cache Hits to total cache requests since WWW service startup. This counter is new in IIS 6.0. |
| URI Cache Flushes | Total URI cache flushes since WWW service startup. This counter is new in IIS 6.0. |
| Total Flushed URIs | Number of URI information blocks that have been removed from the user-mode cache since WWW service startup. This counter is new in IIS 6.0. |
| Current Metadata Cached | Current number of metadata information blocks in the user-mode cache. This counter is new in IIS 6.0. |
| Total Metadata Cached | Number of metadata information blocks that have been added to the user-mode cache since service startup. This counter is new in IIS 6.0. |
| Metadata Cache Hits | Number of successful lookups in the user-mode metadata cache since WWW service startup. This counter is new in IIS 6.0. |
| Metadata Cache Misses | Number of unsuccessful look ups in the user-mode metadata cache since WWW service startup. This counter is new in IIS 6.0. |
| Metadata Cache Hits % | Ratio of successful lookups to total metadata cache requests. This counter is new in IIS 6.0. |
| Metadata Cache Flushes | Number of user-mode metadata cache flushes since WWW service startup. This counter is new in IIS 6.0. |
| Total Flushed Metadata | Number of metadata information blocks that have been removed from the user-mode cache since WWW service startup. This counter is new in IIS 6.0. |
| Kernel: Current URIs Cached | URI information blocks currently cached by the kernel. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |
| Kernel: Total URIs Cached | Number of URI information blocks added to the kernel URI cache since WWW service startup. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |
| Kernel: URI Cache Hits | Number of successful look ups in the kernel URI cache since WWW service startup. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |

| | |
|---|---|
| Kernel: URI Cache Hits% | The ratio of kernel URI cache hits to total cache requests since WWW service startup. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |
| Kernel: URI Cache Hits/Sec | Number of kernel URI cache hits, per second. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |
| Kernel URI Cache Misses | Number of unsuccessful lookups in the kernel URI cache since WWW service startup. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |
| Kernel: URI Cache Flushes | Number of kernel URI cache flushes since WWW service startup. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |
| Kernel: Total Flushed URIs | Number of URI information blocks that have been removed from the kernel cache since WWW service startup. Kernel counters reflect all HTTP.sys activity, not just IIS activity. This counter is new in IIS 6.0. |

**IIS Global Counters**

These counters monitor FTP, SMTP, and NNTP services as a whole and cannot be configured to monitor individual sites. This is a change from IIS 5.x, in which global counters monitored WWW and FTP services. Additionally, some IIS 5.x counters are now obsolete and return a zero value.

| **Note** |
|---|
| If the service you wish to monitor (FTP, SMTP, or NNTP) is not installed or is not running, the counters return a zero value. |

| **Counter** | **Description** |
|---|---|
| Measured Async I/O Bandwidth Usage | This counter is no longer valid. The value will always be zero. |
| Total Blocked Async I/O Requests | This counter is no longer valid. The value will always be zero. |
| Total Rejected Async I/O Requests | This counter is no longer valid. The value will always be zero. |
| Current Blocked Async I/O Requests | This counter is no longer valid. The value will always be zero. |
| Measured Async I/O Bandwidth Usage | This counter is no longer valid. The value will always be zero. |
| Current Files Cached | Current number of files whose content is in the cache. |
| Total Files Cached | Number of files whose content was ever added to the cache. |
| File Cache Hits | Number of successful lookups in the file cache. |
| File Cache Misses | Number of unsuccessful lookups in the file cache. |
| File Cache Hits % | Ratio of File Cache Hits to total cache requests. |
| File Cache Flushes | Number of file cache flushes since server startup. |
| Current File Cache Memory Usage | Current number of bytes used for file cache. |
| Maximum File Cache Memory Usage | Maximum number of bytes used for file cache. |
| Active Flushed Entries | Number of cached file handles that will be closed when all current transfers complete. |
| Total Flushed Files | Number of file handles that have been removed from the cache since service start up. |
| Current URIs Cached | URI information blocks currently in the cache. |
| Total URIs Cached | Number of URI information blocks ever added to the cache. |

| | |
|---|---|
| URI Cache Hits | Number of successful lookups in the URI cache. |
| Uri Cache Misses | Number of unsuccessful lookups in the URI cache. |
| URI Cache Hit % | The ratio of URI Cache Hits to total cache requests. |
| URI Cache Flushes | URI Cache Flushes since server startup. |
| Total Flushed URIs | Number of URI information blocks that have been removed from the cache since service start up. |
| Current Blobs Cached | BLOB information blocks currently in the cache. |
| Total Blobs Cached | Number of BLOB information blocks ever added to the cache. |
| Blob Cache Hits | Number of successful lookups in the BLOB cache. |
| Blob Cache Misses | Number of unsuccessful lookups in the BLOB cache. |
| Blob Cache HitRatio | The ratio of BLOB Cache Hits to total cache requests. |
| Blob Cache Flushes | BLOB Cache Flushes since server startup. |
| Total Flushed Blobs | Number of BLOB information blocks that have been removed from the cache since service start up. |

**FTP Service Counters**

These counters are designed to monitor FTP service performance. They can be configured to monitor a server or individual FTP sites.

| **Counter** | **Description** |
|---|---|
| Bytes Sent/Sec | Rate that data bytes are sent by the FTP service. |
| Bytes Received/Sec | Rate that data bytes are received by the FTP service. |
| Bytes Total/Sec | Sum of Bytes Sent/sec and Bytes Received/sec. This is the total rate of bytes transferred by the FTP service. |
| Total Files Sent | Total number of files sent by the FTP service since service startup. |
| Total Files Received | Total number of files received by the FTP service since service startup. |
| Total Files Transferred | Sum of Files Sent and Files Received. This is the total number of files transferred by the FTP service since service startup. |
| Current Anonymous Users | Number of users who currently have an anonymous connection using the FTP service. |
| Current NonAnonymous Users | Number of users who currently have a nonanonymous connection using the FTP service. |
| Total Anonymous Users | Number of users who established an anonymous connection withthe FTP service (since service startup). |
| Total NonAnonymous Users | Number of users who had nonanonymous connections to the FTP service since FTP service startup. |
| Maximum Anonymous Users | Maximum number of users who established concurrent anonymous connections using the FTP service (since service startup). |
| Maximum NonAnonymous Users | Maximum number of users who established concurrent nonanonymous connections using the FTP service (since service startup). |

| | |
|---|---|
| Current Connections | Current number of connections established with the FTP service. |
| Maximum Connections | Maximum number of simultaneous connections established with the FTP service. |
| Total Connection Attempts (all instances) | Number of connections that have been attempted using the FTP service (since service startup). This counter is for all instances listed. |
| Total Logon Attempts | Number of logons that have been attempted using the FTP service (since service startup). |
| FTP Service Uptime | FTP Service and FTP site uptime, in seconds. |

**SNMP Counters**

If you prefer to use Simple Network Management Protocol (SNMP) services to monitor your Web servers, IIS exposes a set of counters via SNMP. These counters are defined in 3 .mib files in the %windir%\system32 folder. These files are named inetsrv.mib, http.mib and ftp.mib. Inetsrv.mib is a container object for the other two and does not contain any counters.

For information about installing and using the SNMP service see "SNMP" in Help and Support Center for Windows Server 2003.

**SNMP FTP Service Counters**

These SNMP counters are designed to monitor FTP service performance.

| Counter | Description |
|---|---|
| totalBytesSentHighWord | This is the high 32-bits of the total number of bytes sent by the FTP server. |
| totalBytesSentLowWord | This is the low 32-bits of the total number of bytes sent by the FTP server. |
| totalBytesReceivedHighWord | This is the high 32-bits of the total number of bytes received by the FTP server. |
| totalBytesReceivedLowWord | This is the low 32-bits of the total number of bytes received by the FTP server. |
| totalFilesSent | This is the total number of files sent by this FTP server. |
| totalFilesReceived | This is the total number of files received by this FTP server. |
| currentAnonymousUsers | This is the number of anonymous users currently connected to the FTP server. |
| currentNonAnonymousUsers | This is the number of nonanonymous users currently connected to the FTP server. |
| totalAnonymousUsers | This is the total number of anonymous users that have ever connected to the FTP server. |
| totalNonAnonymousUsers | This is the total number of nonanonymous users that have ever connected to the FTP server. |
| maxAnonymousUsers | This is the maximum number of anonymous users simultaneously connected to the FTP server. |
| maxNonAnonymousUsers | This is the maximum number of nonanonymous users simultaneously connected to the FTP server. |
| currentConnections | This is the current number of connections to the FTP server. |
| maxConnections | This is the maximum number of simultaneous connections to the FTP server. |
| connectionAttempts | This is the number of connection attempts that have been made to the FTP server. |
| logonAttempts | This is the number of logon attempts that have been made to the FTP server. |

**SNMP HTTP Service Counters**

These counters are designed to monitor World Wide Web Publishing (WWW) service performance.

| Counter | Description |
|---|---|

| | |
|---|---|
| totalBytesSentHighWord | This is the high 32-bits of the total number of bytes sent by the WWW service (since service startup). |
| totalBytesSentLowWord | This is the low 32-bits of the total number of bytes sent by the WWW service (since service startup). |
| totalBytesReceivedHighWord | This is the high 32-bits of the total number of bytes received by the WWW service (since service startup). |
| totalBytesReceivedLowWord | This is the low 32-bits of the total number of bytes received by the WWW service (since service startup). |
| totalFilesSent | This is the total number of files sent by this WWW service (since service startup). |
| totalFilesReceived | This is the total number of files received by the WWW service (since service startup). |
| currentAnonymousUsers | This is the number of users who currently have an anonymous connection using the WWW service. |
| currentNonAnonymousUsers | This is the number of users who currently have a nonanonymous connection using the WWW service. |
| totalAnonymousUsers | This is the total number of users who established an anonymous connection with the WWW service (since service startup). |
| totalNonAnonymousUsers | This is the total number of users who established a nonanonymous connection with the WWW service (since service startup). |
| maxAnonymousUsers | This is the maximum number of users who established concurrent anonymous connections using the WWW service (since service startup). |
| maxNonAnonymousUsers | This is the maximum number of concurrent nonanonymous connections to the WWW service (since service startup). |
| currentConnections | This is the current number of connections established with the WWW service. |
| maxConnections | This is the maximum number of concurrent connections established with the WWW service (since service startup). |
| connectionAttempts | This is the number of connections that have been attempted using the WWW service (since service startup). |
| logonAttempts | This is the number of logons attempts to the WWW service (since service startup). |
| totalOptions | This is the number of HTTP requests using the OPTIONS method (since service startup). |
| totalGets | This is the number of HTTP requests using the GET method (since service startup). Get requests are the most common HTTP request. |
| totalPosts | This is the number of HTTP requests using the POST method (since service startup). |
| totalHeads | This is the number of HTTP requests using the HEAD method (since service startup). Head requests generally indicate a client is querying the state of a document they already have to see if it needs to be refreshed. |
| totalPuts | This is the number of HTTP requests using the PUT method (since service startup). |
| totalDeletes | This is the number of HTTP requests using the DELETE method (since service startup). Delete requests are generally used for file removals. |
| totalTraces | This is the number of HTTP requests using the TRACE method (since service startup). Trace requests allow the client to see what is being received at the end of the request chain and use the information for diagnostic purposes. |

| | |
|---|---|
| totalMove | This is the number of HTTP requests using the MOVE method (since service startup). Move requests are used for moving files and directories. |
| totalCopy | This is the number of HTTP requests using the COPY method (since service startup). Copy requests are used for copying files and directories. |
| totalMkcol | This is the number of HTTP requests using the MKCOL method (since service startup). Mkcol requests are used to create directories on the server. |
| totalPropfind | This is the number of HTTP requests using the PROPFIND method (since service startup). Propfind requests retrieve property values on files and directories. |
| totalProppatch | This is the number of HTTP requests using the PROPPATCH method (since service startup). Proppatch requests set property values on files and directories. |
| totalSearch | This is the number of HTTP requests using the SEARCH method (since service startup). Search requests are used to query the server to find resources that match a set of conditions provided by the client. |
| totalLock | This is the number of HTTP requests using the LOCK method (since service startup). Lock requests are used to lock a file for one user so that only that user can modify the file. |
| totalUnlock | This is the number of HTTP requests using the UNLOCK method (since service startup). Unlock requests are used to remove locks from files. |
| totalOthers | This is the number of HTTP requests that are not OPTIONS, GET,HEAD, POST, PUT, DELETE, TRACE, MOVE, COPY, MKCOL, PROPFIND,PROPPATCH, SEARCH, LOCK or UNLOCK methods (since service startup). |
| currentCGIRequests | This is the current number of CGI requests being simultaneously processed by the WWW service. |
| currentBGIRequests | This is the current number of ISAPI requests being simultaneously processed by the WWW service. |
| totalCGIRequests | This is the total number of CGI requests (since service startup). |
| totalBGIRequests | This is the total ISAPI requests received (since service startup). |
| maxCGIRequests | This is the maximum number of CGI requests simultaneously processed by the WWW service (since service startup). |
| maxBGIRequests | This is the maximum number of ISAPI requests simultaneously processed by the WWW service (since service startup). |
| currentBlockedRequests | This is the current number of requests that have been temporarily blocked by the WWW service due to bandwidth throttling settings. |
| totalBlockedRequests | This is the total number of requests that have been temporarily blocked by the WWW service due to bandwidth throttling settings. |
| totalAllowedRequests | This is the total number of requests that the WWW service has allowed when the bandwidth throttling settings on the server have been enabled (since service startup). |
| totalRejectedRequests | This is the total number of requests rejected due to bandwidth throttling settings (since service startup). |
| totalNotFoundErrors | This is the number of requests that couldn't be satisfied by the server because the requested document could not be found (since service startup). These are generally reported as an HTTP 404 error code to the client. |
| totalLockedErrors | This is the number of requests that couldn't be satisfied by the server because the requested was locked (since service startup). These are generally reported as an HTTP 423 error code to the client. |

| | |
|---|---|
| measuredBandwidth | This is the I/O bandwidth used by the WWW service, averaged over a minute. |
| currentCALsforAuthenticatedUsers | This counter is no longer valid. Value will always be zero. |
| maxCALsforAuthenticatedUsers | This counter is no longer valid. Value will always be zero. |
| totalCALFailedAuthenticatedUser | This counter is no longer valid. Value will always be zero. |
| currentCALsforSecureConnections | This counter is no longer valid. Value will always be zero. |
| maxCALsforSecureConnections | This counter is no longer valid. Value will always be zero. |
| totalCALFailedSecureConnection | This counter is no longer valid. Value will always be zero. |

# IIS 6.0 Performance Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Microsoft® Windows® Server 2003 operating system obtains performance data from components in your computer as those components are utilized. This data is described as a performance object and is typically named for the component that is generating the data. For example, the Web Service performance object is a collection of performance data about Internet Information Services (IIS) 6.0. Each performance object provides performance counters that represent data on specific aspects of a system or service. When you install IIS 6.0, all of the IIS performance counters, with the exception of the SNMP counters, appear in System Monitor and in Performance Logs and Alerts. You can also use Windows Instrumentation Management (WMI) to view and use these counters and the SNMP counters.

**In This Section**

Web Service Counters for the WWW Service

Web Service Cache Counters for the WWW Service

FTP Service Counters

Internet Information Services Global Counters

SNMP Counters

Active Server Pages Performance Counters

ASP.NET Performance Counters

**Related Sections**

# Web Service Counters for the WWW Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The Web Service counters help you determine how well the World Wide Web Publishing Service (WWW service) processes requests. The WWW service is a user-mode service. These counters also reflect the processing that occurs in the kernel-mode driver, HTTP.sys.

Configure these counters to monitor performance for individual Web sites or for all sites on a server (by using the _Total instance). Note that some counters that were included with IIS 5.*x* are now obsolete and, therefore, return a zero value. Obsolete counters are listed in Table D.8 and Table D.9.

Table D.1 describes the Bytes counters for the Web Service performance object.

**Table D.1 Bytes (Sent, Received, and Transferred) Counters**

| Counter | Description |
|---|---|
| Total Bytes Sent | The number of data bytes that have been sent by the WWW service since the service started. This counter is new in IIS 6.0. |
| Bytes Sent/sec | The rate, in seconds, at which data bytes have been sent by the WWW service. |
| Total Bytes Received | The total bytes of data that have been received by the WWW service since the service started. This counter is new in IIS 6.0. |
| Bytes Received/sec | The rate, in seconds, at which data bytes have been received by the WWW service. |
| Total Bytes Transferred | The total number of bytes of data that have been sent and received by the WWW service since the service started. This counter is new in IIS 6.0. |
| Bytes Total/sec | The sum of Bytes Sent/sec and Bytes Received/sec. |

Table D.2 describes the Files counters for the Web Service performance object.

**Table D.2 Files (Sent, Received, and Transferred) Counters**

| Counter | Description |
|---|---|
| Total Files Sent | The number of user-mode files that have been sent by the WWW service since the service started. This counter does not include cache hits. Note that this counter does not increment when files are being served from the kernel-mode cache. For more information, see Kernel: URI Cache Hits in Table D.13. |
| Files Sent/sec | The rate, in seconds, at which files have been sent. |
| Total Files Received | The number of files that have been received by the WWW service since the service started. |
| Files Received/sec | The rate, in seconds, at which files have been received by the WWW service. |
| Total Files Transferred | The sum of Total Files Sent and Total Files Received by the WWW service since the service started. Note that this counter does not increment when files are being served from the kernel-mode cache. For more information, see Kernel: URI Cache Hits in Table D.13. |
| Files/sec | The rate, in seconds, at which files have been sent and received by the WWW service. |

Table D.3 describes the Anonymous Users and NonAnonymous Users counters for the Web Service performance object. In this

context, nonanonymous users are authenticated users.

| Note |
| --- |
| With Anonymous and NonAnonymous Users counters, IIS6.0 counts each request as a new user. This behavior differs from IIS5.*x*, which counted each connection as a new user. |

**Table D.3 Anonymous Users and NonAnonymous Users Counters**

| Counter | Description |
| --- | --- |
| Current Anonymous Users | The number of users who currently have an anonymous request pending with the WWW service. In IIS 6.0, Current Users (Anonymous or NonAnonymous) is the number of requests currently being worked on by the server. |
| Current NonAnonymous Users | The number of users who currently have a nonanonymous request pending with the WWW service. In IIS 6.0, Current Users (Anonymous or NonAnonymous) is the number of requests currently being worked on by the server. |
| Total Anonymous Users | The number of users who have established an anonymous request since the WWW service started. This counter does not increment when files are being served from the kernel cache. For more information, see Kernel: URI Cache Hits in Table D.13. |
| Anonymous Users/sec | The rate, in seconds, at which users have made anonymous requests to the WWW service. |
| Total NonAnonymous Users | The number of users who have made nonanonymous requests to the WWW service since the service started. For more information, see Kernel: URI Cache Hits in Table D.13. |
| NonAnonymous Users/sec | The rate, in seconds, at which users have made nonanonymous requests to the WWW service. |
| Maximum NonAnonymous Users | The maximum number of users who have made concurrent nonanonymous requests to the WWW service since the service started. |

Table D.4 describes the Connections and Attempts counters for the Web Service performance object.

**Table D.4 Connections and Attempts Counters**

| Counter | Description |
| --- | --- |
| Current Connections | The number of active connections to the WWW service. |
| Maximum Connections | The maximum number of simultaneous connections made to the WWW service since the service started. |
| Total Connection Attempts | The number of connections to the WWW service that have been attempted since the service started. |
| Connection Attempts/sec | The rate, in seconds, at which connections to the WWW service have been attempted since the service started. |
| Total Logon Attempts | The number of attempts to log on to the WWW service that have occurred since the service started. |
| Logon Attempts/sec | The rate, in seconds, at which attempts to log on to the WWW service have occurred. |

Table D.5 describes the Requests counters for the Web Service performance object.

**Table D.5 Requests Counters**

| Counter | Description |
| --- | --- |

| | |
|---|---|
| Total Options Requests | The number of HTTP requests that have used the **OPTIONS** method since the WWW service started. |
| Options Requests/sec | The rate, in seconds, at which HTTP requests that use the **OPTIONS** method have been made. |
| Total Get Requests | The number of HTTP requests that have used the **GET** method since the WWW service started. |
| Get Requests/sec | The rate, in seconds, at which HTTP requests that use the **GET** method have been made to the WWW service. |
| Total Post Requests | The number of HTTP requests that have used the **POST** method since the WWW service started. |
| Post Requests/sec | The rate, in seconds, at which requests that use the **POST** method have been made to the WWW service. |
| Total Head Requests | The number of HTTP requests that have used the **HEAD** method since the WWW service started. |
| Head Requests/sec | The rate, in seconds, at which HTTP requests that use the **HEAD** method have been made to the WWW service. |
| Total Put Requests | The number of HTTP requests that have used the **PUT** method since the WWW service started. |
| Put Requests/sec | The rate, in seconds, at which HTTP requests that use the **PUT** method have been made to the WWW service. |
| Total Delete Requests | The number of HTTP requests that have used the **DELETE** method since the WWW service started. |
| Delete Requests/sec | The rate, in seconds, at which HTTP requests that use the **DELETE** method have been made to the WWW service. |
| Total Trace Requests | The number of HTTP requests that have used the **TRACE** method since the WWW service started. |
| Trace Requests/sec | The rate, in seconds, at which HTTP requests that use the **TRACE** method have been made to the WWW service. |
| Total Move Requests | The number of HTTP requests that have used the **MOVE** method since the WWW service started. |
| Move Requests/sec | The rate, in seconds, at which HTTP requests that use the **MOVE** method have been made to the WWW service. |
| Total Copy Requests | The number of HTTP requests that have used the **COPY** method since the WWW service started. |
| Copy Requests/sec | The rate, in seconds, at which HTTP requests that use the **COPY** method have been made to the WWW service. |

| | |
|---|---|
| Total Mkcol Requests | The number of HTTP requests that have used the **MKCOL** method since the WWW service started. |
| Mkcol Requests/sec | The rate, in seconds, at which HTTP requests that use the **MKCOL** method have been made to the WWW service. |
| Total Propfind Requests | The number of HTTP requests that have used the **PROPFIND** method since the WWW service started. |
| Propfind Requests/sec | The rate, in seconds, at which HTTP requests that use the **PROPFIND** method have been made to the WWW service. |
| Total Proppatch Requests | The number of HTTP requests that have used the **PROPPATCH** method since the WWW service started. |
| Proppatch Requests/sec | The rate, in seconds, at which HTTP requests that use the **PROPPATCH** method have been made to the WWW service. |
| Total Search Requests | The number of HTTP requests that have used the **SEARCH** method since the WWW service started. |
| Search Requests/sec | The rate, in seconds, at which HTTP requests that use the **SEARCH** method have been made to the WWW service. |
| Total Lock Requests | The number of HTTP requests that have used the **LOCK** method since the WWW service started. |
| Lock Requests/sec | The rate, in seconds, at which HTTP requests that use the **LOCK** method have been made to the WWW service. |
| Total Unlock Requests | The number of HTTP requests that have used the **UNLOCK** method since the WWW service started. |
| Unlock Requests/sec | The rate, in seconds, at which HTTP requests that use the **UNLOCK** method have been made to the WWW service. |
| Total Other Request Methods | The number of HTTP requests that did not use the **OPTIONS**, **GET**, **HEAD**, **POST**, **PUT**, **DELETE**, **TRACE**, **MOVE**, **COPY**, **MKCOL**, **PROPFIND**, **PROPPATCH**, **SEARCH**, **LOCK**, or **UNLOCK** methods since the WWW service started. Can include **LINK** or other methods supported by gateway applications. |
| Other Request Methods/sec | The rate, in seconds, at which HTTP requests that do not use the methods listed for the Total Other Requests Methods counter have been made to the WWW service. |
| Total Method Requests | The number of HTTP requests that have been made since the WWW service started. |
| Total Method Requests/sec | The rate, in seconds, at which all HTTP requests have been received. |

Table D.6 describes the Errors counters for the Web Service performance object.

**Table D.6 Errors (Not Found and Locked) Counters**

| Counter | Description |
| --- | --- |
| Total Not Found Errors | The number of requests that have been made since the service started that were not satisfied by the server because the requested document was not found. Usually reported as HTTP error 404. |
| Not Found Errors/sec | The rate, in seconds, at which requests were not satisfied by the server because the requested document was not found. |
| Total Locked Errors | The number of requests that have been made since the service started that could not be satisfied by the server because the requested document was locked. Usually reported as HTTP error 423. |
| Locked Errors/sec | The rate, in seconds, at which requests were not satisfied because the requested document was locked. |

Table D.7 describes the Common Gateway Interface (CGI) Requests and ISAPI Extension Requests counters for the Web Service performance object.

**Table D.7 CGI Requests and ISAPI Extension Requests Counters**

| Counter | Description |
| --- | --- |
| Current CGI Requests | The number of CGI requests that are being processed simultaneously by the WWW service. |
| Total CGI Requests | The number of all CGI requests that have been made since the WWW service started. |
| CGI Requests/sec | The rate, in seconds, at which CGI requests are being processed simultaneously by the WWW service. |
| Maximum CGI Requests | The maximum number of CGI requests that have been processed simultaneously by the WWW service since the service started. |
| Current ISAPI Extension Requests | The number of ISAPI extension requests that are being processed simultaneously by the WWW service. |
| Total ISAPI Extension Requests | The number of ISAPI extension requests that have been made since the WWW service started. |
| ISAPI Extension Requests/sec | The rate, in seconds, at which ISAPI extension requests are being processed by the WWW service. |
| Maximum ISAPI Extension Requests | The maximum number of ISAPI extension requests that were processed simultaneously by the WWW service. |

Table D.8 lists the CAL (client access license) Count counters for the Web Service performance object, which are not valid in IIS 6.0. The value of these counters is always zero.

**Table D.8 CAL Count Counters**

| Counter |
| --- |
| Current CAL count for authenticated users |
| Maximum CAL count for authenticated users |
| Total count of failed CAL requests for authenticated users |
| Current CAL count for SSL connections |
| Maximum CAL count for SSL connections |

| |
|---|
| Total count of failed CAL requests for SSL connections |

Table D.9 describes other miscellaneous counters, some of which are no longer valid, for the Web Service performance object.

**Table D.9 Async I/O Requests, Bandwidth Bytes, and Miscellaneous Counters**

| Counter | Description |
|---|---|
| Total Allowed Async I/O Requests | This counter is no longer valid; its value is always zero. |
| Total Blocked Async I/O Requests | This counter is no longer valid; its value is always zero. |
| Total Rejected Async I/O Requests | This counter is no longer valid; its value is always zero. |
| Current Blocked Async I/O Requests | This counter is no longer valid; its value is always zero. |
| Measured Async I/O Bandwidth Usage | This counter is no longer valid; its value is always zero. |
| Total Blocked Bandwidth Bytes | This counter is no longer valid; its value is always zero. |
| Current Blocked Bandwidth Bytes | This counter is no longer valid; its value is always zero. |
| Service Uptime | The uptime for the WWW service or a Web site. |
| MaxCalSsl | This counter is no longer valid; its value is always zero. |

# Web Service Cache Counters for the WWW Service

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

The WWW service and FTP service do not share a common cache. Instead, the caches are split into two separate performance objects: one for FTP service and one for the WWW service. WWW service cache counters are designed to monitor server performance only; therefore, you cannot configure them to monitor individual sites.

For information about FTP service counters, see Internet Information Services Global Counters later in this appendix.

Table D.10 describes the File counters for the Web Service Cache performance object. These counters are new in IIS 6.0.

**Table D.10 File Counters for the Web Service Cache Object**

| Counter | Description |
|---|---|
| Active Flushed Entries | The number of user-mode cache entries that have been flushed, though memory is still allocated for these entries. The allocated memory will be released after all current transfers complete. |
| Current File Cache Memory Usage | The number of bytes currently used for the user-mode file cache. |
| Current Files Cached | The number of files whose content is currently in the user-mode cache. |
| Total Files Cached | The number of files whose content has been added to the user-mode cache since the WWW service started. |
| File Cache Hits | The number of successful lookups in the user-mode file cache that have occurred since the WWW service started. |
| File Cache Hits % | The ratio of user-mode file cache hits to total cache requests that have been made since the WWW service started up. |
| File Cache Misses | The number of unsuccessful lookups in the user-mode file cache that have been made since the WWW service started. |
| File Cache Flushes | The number of files that have been removed from the user-mode cache since the WWW service started. |
| Maximum File Cache Memory Usage | The maximum number of bytes that have been used for the user-mode file cache since the WWW service started. |
| Total Flushed Files | The number of file handles that have been removed from the user-mode cache since the WWW service started. |

Table D.11 describes the URI counters for the Web Service Cache performance object. These counters are new in IIS 6.0.

**Table D.11 URI Counters for the Web Service Cache Object**

| Counter | Description |
|---|---|
| Current URIs Cached | The number of URI information blocks that are currently stored in the user-mode cache. |
| Total URIs Cached | The number of URI information blocks that have been added to the user-mode cache since the WWW service started. |

| | |
|---|---|
| URI Cache Hits | The number of successful lookups that have been made in the user-mode URI cache since the WWW service started. |
| URI Cache Misses | The number of unsuccessful lookups that have been made in the user-mode URI cache since the WWW service started. |
| URI Cache Hits % | The ratio of URI Cache Hits to total cache requests that have occurred since the WWW service started. |
| URI Cache Flushes | The total number of URI cache flushes that have occurred since the WWW service started. |
| Total Flushed URIs | The number of URI information blocks that have been removed from the user-mode cache since the WWW service started. |

Table D.12 describes the Metadata counters for the Web Service Cache performance object. These counters are new in IIS 6.0.

**Table D.12 Metadata Counters for the Web Service Cache Object**

| Counter | Description |
|---|---|
| Current Metadata Cached | The current number of metadata information blocks in the user-mode cache. |
| Total Metadata Cached | The number of metadata information blocks that have been added to the user-mode cache since the WWW service started. |
| Metadata Cache Hits | The number of successful lookups in the user-mode metadata cache that have occurred since the WWW service started. |
| Metadata Cache Misses | The number of unsuccessful lookups in the user-mode metadata cache that have occurred since the WWW service started. |
| Metadata Cache Hits % | The ratio of successful lookups to total metadata cache requests. |
| Metadata Cache Flushes | The number of user-mode metadata cache flushes that have occurred since the WWW service started. |
| Total Flushed Metadata | The number of metadata information blocks that have been removed from the user-mode cache since the WWW service started. |

Table D.13 describes the Kernel counters for the Web Service Cache performance object. These counters are new in IIS 6.0.

| **Note** |
|---|
| Kernel counters reflect all HTTP.sys activity, not just IIS activity. |

**Table D.13 Kernel Counters for the Web Service Cache Object**

| Counter | Description |
|---|---|
| Kernel: Current URIs Cached | The number of URI information blocks currently cached by the kernel. |
| Kernel: Total URIs Cached | The number of URI information blocks that have been added to the kernel URI cache since the WWW service started. |
| Kernel: URI Cache Hits | The number of successful lookups in the kernel URI cache that have occurred since the WWW service started. |

| | |
|---|---|
| Kernel: URI Cache Hits% | The ratio of Kernel: URI Cache Hits to total cache requests since the WWW service started. |
| Kernel: URI Cache Hits/sec | The average number of kernel URI cache hits that are being made per second. |
| Kernel URI Cache Misses | The number of unsuccessful lookups in the kernel URI cache that have occurred since the WWW service started. |
| Kernel: URI Cache Flushes | The number of kernel URI cache flushes that have occurred since the WWW service started. |
| Kernel: Total Flushed URIs | The number of URI information blocks that have been removed from the kernel cache since the WWW service started. |

# FTP Service Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the counters in the following tables to monitor FTP service performance. You can configure the counters to monitor a server or an individual FTP site.

Table D.14 describes Bytes and Total Files counters for the FTP Service performance object.

**Table D.14 Bytes and Total Files Counters**

| Counter | Description |
|---|---|
| Bytes Sent/sec | The rate at which data bytes are being sent by the FTP service. |
| Bytes Received/sec | The rate at which data bytes are being received by the FTP service. |
| Bytes Total/sec | The sum of Bytes Sent/sec and Bytes Received/sec. |
| Total Files Sent | The total number of files that have been sent by the FTP service since the service started. |
| Total Files Received | The total number of files that have been received by the FTP service since the service started. |
| Total Files Transferred | The sum of Total Files Sent and Total Files Received. This is the total number of files transferred by the FTP service since the service started. |

Table D.15 describes Anonymous and NonAnonymous Users counters for the FTP Service performance object.

**Table D.15 Anonymous and NonAnonymous Users Counters**

| Counter | Description |
|---|---|
| Current Anonymous Users | The number of users who currently have an anonymous connection that was made by using the FTP service. |
| Current NonAnonymous Users | The number of users who currently have a nonanonymous connection that was made by using the FTP service. |
| Total Anonymous Users | The number of users who have established an anonymous connection with the FTP service since the service started. |
| Total NonAnonymous Users | The number of users who have established nonanonymous connections with the FTP service since the service started. |
| Maximum Anonymous Users | The maximum number of users who have established concurrent anonymous connections using the FTP service since the service started. |
| Maximum NonAnonymous Users | The maximum number of users who have established concurrent nonanonymous connections using the FTP service since the service started. |

Table D.16 describes Connections, Attempts, and Uptime counters for the FTP Service performance object.

**Table D.16 Connections, Attempts, and Uptime Counters**

| Counter | Description |
|---|---|
| Current Connections | The current number of connections that have been established with the FTP service. |

| | |
|---|---|
| Maximum Connections | The maximum number of simultaneous connections that have been established with the FTP service. |
| Total Connection Attempts (all instances) | The number of connections that have been attempted by using the FTP service since the service started. This counter applies to all instances listed. |
| Total Logon Attempts | The number of logons that have been attempted by using the FTP service since the service started. |
| FTP Service Uptime | The amount of time, in seconds, that the FTP service has been running. |

# Internet Information Services Global Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Use the Internet Information Services Global counters described in Table D.17 through Table D.20 to monitor FTP, SMTP, and NNTP services as a whole. You cannot configure these counters to monitor individual sites. This differs from IIS 5.*x*, in which global counters monitored the WWW and FTP services.

If the service that you want to monitor (FTP, SMTP, or NNTP) is not installed or is not running, the counters return a zero value.

Table D.17 lists the Async I/O counters that are no longer valid for the Internet Information Services Global performance object. The value of these counters is always zero.

**Table D.17 Async I/O Counters**

| Counter |
|---|
| Measured Async I/O Bandwidth Usage |
| Total Blocked Async I/O Requests |
| Total Rejected Async I/O Requests |
| Current Blocked Async I/O Requests |
| Measured Async I/O Bandwidth Usage |

Table D.18 describes File Cache counters for the Internet Information Services Global performance object.

**Table D.18 File Cache Counters**

| Counter | Description |
|---|---|
| Current Files Cached | The number of files whose content is currently in the cache. |
| Total Files Cached | The number of files whose content has been added to the cache since the service started. |
| File Cache Hits | The number of successful lookups in the file cache. |
| File Cache Misses | The number of unsuccessful lookups in the file cache. |
| File Cache Hits % | The ratio of File Cache Hits to the total number of cache requests. |
| File Cache Flushes | The number of file cache flushes that have occurred since the service started. |
| Current File Cache Memory Usage | The current number of bytes used for the file cache. |
| Maximum File Cache Memory Usage | The maximum number of bytes used for the file cache. |

Table D.19 describes Flushed and URI Cached counters for the Internet Information Services Global performance object.

**Table D.19 Flushed and URI Cached Counters**

| Counter | Description |
|---|---|
| Active Flushed Entries | The number of cached file handles that will close when all current transfers are complete. |
| Total Flushed Files | The number of file handles that have been removed from the cache since the service started. |
| Current URIs Cached | The number of URI information blocks that are currently in the cache. |

| | |
|---|---|
| Total URIs Cached | The number of URI information blocks that have been added to the cache. |
| URI Cache Hits | The number of successful lookups in the URI cache. |
| Uri Cache Misses | The number of unsuccessful lookups in the URI cache. |
| URI Cache Hits % | The ratio of URI Cache Hits to the total number of cache requests. |
| URI Cache Flushes | The number of URI cache flushes that have occurred since the server started. |
| Total Flushed URIs | The number of URI information blocks that have been removed from the cache since the service started. |

Table D.20 describes the BLOBs counters for the Internet Information Services Global performance object. A *BLOB* is a binary large object.

**Table D.20 BLOBs Counters**

| Counter | Description |
|---|---|
| Current BLOBs Cached | The BLOB information blocks currently in the cache. |
| Total BLOBs Cached | The number of BLOB information blocks that have been added to the cache. |
| BLOB Cache Hits | The number of successful lookups in the BLOB cache. |
| BLOB Cache Misses | The number of unsuccessful lookups in the BLOB cache. |
| BLOB Cache Hit % | The ratio of BLOB Cache Hits to the total number of cache requests. |
| BLOB Cache Flushes | The number of BLOB cache flushes that have occurred since the service started. |
| Total Flushed BLOBs | The number of BLOB information blocks that have been removed from the cache since the service started. |

# SNMP Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

IIS exposes the following counters for Simple Network Management Protocol (SNMP) services. These counters are defined in more detail in three .mib files — Inetsrv.mib, Http.mib and Ftp.mib — which you can find in the *Windir*\System32 folder. Inetsrv.mib is a container object for the other two files and, therefore, does not contain counters. To view the contents of the .mib files, open the files by using Notepad.

You cannot view the SNMP counters in System Monitor or Performance Logs and Alerts. Use WMI or a management information base (MIB) Browser tool instead.

For information about installing and using the SNMP service, see Checklist: Implementing the SNMP service in Help and Support Center for Microsoft® Windows® Server 2003.

**SNMP FTP Service Counters**

Use the SNMP counters in Table D.21 through Table D.23 to monitor FTP service performance.

Table D.21 describes the totalBytes and totalFiles counters that you can use to monitor an SMTP FTP service.

**Table D.21 totalBytes and totalFiles Counters**

| Counter | Description |
|---|---|
| totalBytesSentHighWord | The high 32-bits of the total number of bytes sent by the FTP server. |
| totalBytesSentLowWord | The low 32-bits of the total number of bytes sent by the FTP server. |
| totalBytesReceivedHighWord | The high 32-bits of the total number of bytes received by the FTP server. |
| totalBytesReceivedLowWord | The low 32-bits of the total number of bytes received by the FTP server. |
| totalFilesSent | The total number of files sent by this FTP server. |
| totalFilesReceived | The total number of files received by this FTP server. |

Table D.22 describes the AnonymousUsers and NonAnonymousUsers counters that you can use to monitor an SNMP FTP service.

**Table D.22 AnonymousUsers and NonAnonymousUsers Counters**

| Counter | Description |
|---|---|
| currentAnonymousUsers | The number of anonymous users currently connected to the FTP server. |
| currentNonAnonymousUsers | The number of nonanonymous users currently connected to the FTP server. |
| totalAnonymousUsers | The total number of anonymous users that have been connected to the FTP server. |
| totalNonAnonymousUsers | The total number of nonanonymous users that have been connected to the FTP server. |
| maxAnonymousUsers | The maximum number of anonymous users that have been simultaneously connected to the FTP server. |
| maxNonAnonymousUsers | The maximum number of nonanonymous users that have been simultaneously connected to the FTP server. |

Table D.23 describes the Connections and Attempts counters that you can use to monitor an SNMP FTP service.

**Table D.23 Connections and Attempts Counters**

| Counter | Description |
|---|---|
| currentConnections | The current number of connections to the FTP server. |
| maxConnections | The maximum number of simultaneous connections that have been made to the FTP server. |

| | |
|---|---|
| connectionAttempts | The number of attempts that were made to connect to the FTP server. |
| logonAttempts | The number of attempts that were made to log on to the FTP server. |

**SNMP HTTP Service Counters**

Use the SNMP HTTP counters in Table D.24 through Table D.31 to monitor WWW service performance.

Table D.24 describes the totalBytes and totalFiles counters that you can use to monitor an SNMP WWW service.
