**Table D.24 totalBytes and totalFiles Counters**

| Counter | Description |
|---|---|
| totalBytesSentHighWord | The high 32-bits of the total number of bytes that have been sent by the WWW service since the service started. |
| totalBytesSentLowWord | The low 32-bits of the total number of bytes that have been sent by the WWW service since the service started. |
| totalBytesReceivedHighWord | The high 32-bits of the total number of bytes that have been received by the WWW service since the service started. |
| totalBytesReceivedLowWord | The low 32-bits of the total number of bytes that have been received by the WWW service since the service started. |
| totalFilesSent | The total number of files that have been sent by the WWW service since the service started. |
| totalFilesReceived | The total number of files that have been received by the WWW service since the service started. |

Table D.25 describes the AnonymousUsers and NonAnonymousUsers counters that you can use to monitor an SNMP WWW service.

**Table D.25 AnonymousUsers and NonAnonymousUsers Counters**

| Counter | Description |
|---|---|
| currentAnonymousUsers | The number of users who currently have an anonymous connection by using the WWW service. |
| currentNonAnonymousUsers | The number of users who currently have a nonanonymous connection by using the WWW service. |
| totalAnonymousUsers | The total number of users who have made an anonymous connection by using the WWW service since the service started. |
| totalNonAnonymousUsers | The total number of users who have made a nonanonymous connection by using the WWW service since the service started. |
| maxAnonymousUsers | The maximum number of users who have made concurrent anonymous connections by using the WWW service since the service started. |
| maxNonAnonymousUsers | The maximum number of users who have made concurrent nonanonymous connections to the WWW service since the service started up. |

Table D.26 describes the Connections and Attempts counters that you can use to monitor an SNMP WWW service.

**Table D.26 Connections and Attempts Counters**

| Counter | Description |
|---|---|
| currentConnections | The current number of connections made with the WWW service. |
| maxConnections | The maximum number of concurrent connections that have been made with the WWW service since the service started. |
| connectionAttempts | The number of connections that have been attempted by using the WWW service since the service started. |

| | |
|---|---|
| logonAttempts | The number of attempts to log on to the WWW service that have been made since the service started. |

Table D.27 describes the total counters (totalOptions, totalGets, and others) that you can use to monitor an SNMP WWW service.

**Table D.27 total Counters**

| Counter | Description |
|---|---|
| totalOptions | The number of HTTP requests that have been made using the **OPTIONS** method since the service started. |
| totalGets | The number of HTTP requests that have been made using the **GET** method since the service started. |
| totalPosts | The number of HTTP requests that have been made using the **POST** method since the service started. |
| totalHeads | The number of HTTP requests that have been made using the **HEAD** method since the service started. Head requests generally indicate that a client is querying the state of a document it already has to see if it needs to be refreshed. |
| totalPuts | The number of HTTP requests that have been made using the **PUT** method since the service started. |
| totalDeletes | The number of HTTP requests that have been made using the **DELETE** method since the service started. Delete requests are typically used for file removal. |
| totalTraces | The number of HTTP requests that have been made using the **TRACE** method since the service started. Trace requests allow the client to see what is being received at the end of the request chain and to use this information for diagnostic purposes. |
| totalMove | The number of HTTP requests that have been made using the **MOVE** method since the service started. Move requests move files and directories. |
| totalCopy | The number of HTTP requests that have been made using the **COPY** method since the service started. Copy requests copy files and directories. |
| totalMkcol | The number of HTTP requests that have been made using the **MKCOL** method since the service started. Mkcol requests create directories on the server. |
| totalPropfind | The number of HTTP requests that have been made using the **PROPFIND** method since the service started. Propfind requests retrieve property values for files and directories. |
| totalProppatch | The number of HTTP requests that have been made using the **PROPPATCH** method since the service started. Proppatch requests set property values for files and directories. |
| totalSearch | The number of HTTP requests that have been made using the **SEARCH** method since the service started. Search requests query the server to find resources that match a set of conditions provided by the client. |
| totalLock | The number of HTTP requests that have been made using the **LOCK** method since the service started. Lock requests lock a file so that only the user who locked it can modify the file. |
| totalUnlock | The number of HTTP requests that have been made using the **UNLOCK** method since the service started. Unlock requests remove locks from files. |
| totalOthers | The number of HTTP requests that have been made by methods other than **OPTIONS**, **GET**, **HEAD**, **POST**, **PUT**, **DELETE**, **TRACE**, **MOVE**, **COPY**, **MKCOL**, **PROPFIND**, **PROPPATCH**, **SEARCH**, **LOCK**, or **UNLOCK** methods since the service started. |

Table D.28 describes the CGIRequests and BGIRequests counters that you can use to monitor an SNMP WWW service.

**Table D.28 CGIRequests and BGIRequests Counters**

| Counter | Description |
|---|---|
| currentCGIRequests | The current number of CGI requests being processed simultaneously by the WWW service. |
| currentBGIRequests | The current number of ISAPI requests being processed simultaneously by the WWW service. |
| totalCGIRequests | The total number of CGI requests that have been made since the service started. |

| | |
|---|---|
| totalBGIRequests | The total number of ISAPI requests that have been received since the service started. |
| maxCGIRequests | The maximum number of CGI requests that have been processed simultaneously by the WWW service since the service started. |
| maxBGIRequests | The maximum number of ISAPI requests that have been processed simultaneously by the WWW service since the service started. |

Table D.29 lists the Requests counters (Blocked, Allowed, and Rejected), which are no longer valid in IIS 6.0. The value for these counters is always zero.

**Table D.29 Requests Counters (Blocked, Allowed, and Rejected)**

| Counter |
|---|
| currentBlockedRequests |
| totalBlockedRequests |
| totalAllowedRequests |
| totalRejectedRequests |

Table D.30 describes the Errors and Bandwidth counters that you can use to monitor an SNMP WWW service.

**Table D.30 Errors and Bandwidth Counters**

| Counter | Description |
|---|---|
| totalNotFoundErrors | The number of requests made since the service started that the server did not satisfy because the requested document was not found. This type of request is usually reported to the client as an HTTP 404 error message. |
| totalLockedErrors | The number of requests made since the service started that the server did not satisfy because the requested document was locked. This type of request is usually reported to the client as an HTTP 423 error message. |
| measuredBandwidth | The I/O bandwidth that the WWW service used, averaged over a minute. |

Table D.31 lists the CAL-related counters that are no longer valid for the SNMP WWW service. The value of these counters is always zero.

**Table D.31 CAL-related Counters**

| Counter |
|---|
| currentCALsforAuthenticatedUsers |
| maxCALsforAuthenticatedUsers |
| totalCALFailedAuthenticatedUser |
| currentCALsforSecureConnections |
| maxCALsforSecureConnections |
| totalCALFailedSecureConnection |

# Active Server Pages Performance Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

If you are running Active Server Pages (ASP) on your server, the ASP counters can help you determine how well the server or site is responding to ASP requests. The ASP counters are designed to monitor server performance; you cannot monitor individual ASP applications because ASP counters collect global data across the entire WWW service.

Table D.32 describes the ASP Debugging and Errors counters for the Active Server Pages performance object.

**Table D.32 ASP Debugging and Errors Counters**

| Counter | Description |
|---|---|
| ASP Debugging Requests | The number of requests for debugging documents that have been made since the WWW service started. |
| Errors During Script Runtime | The number of requests that failed because run-time errors occurred. |
| Errors From ASP Preprocessor | The number of requests that failed because preprocessor errors occurred. |
| Errors From Script Compilers | The number of requests that failed because script compilation errors occurred. |
| Errors/sec | The average number of errors that occurred per second. |

Table D.33 describes the Requests counters for the Active Server Pages performance object.

**Table D.33 Requests Counters for ASP Pages**

| Counter | Description |
|---|---|
| Request Bytes In Total | The total size, in bytes, of all requests. |
| Request Bytes Out Total | The total size, in bytes, of responses sent to clients. This total does not include standard HTTP response headers. |
| Request Execution Time | The number of milliseconds that it took to execute the most recent request. |
| Request Wait Time | The number of milliseconds that the most recent request waited in the queue. |
| Requests Disconnected | The number of requests that were disconnected because communication failed. |
| Requests Executing | The number of requests that are currently executing. |
| Requests Failed Total | The number of requests that failed due to errors, authorization failure, and rejections. |
| Requests Not Authorized | The number of requests that failed because access rights were insufficient. |
| Requests Not Found | The number of requests that were made for files that were not found. |
| Requests Queued | The number of requests that are waiting in the queue for service. |

| | |
|---|---|
| Requests Rejected | The number of requests that were not executed because there were insufficient resources to process them. |
| Requests Succeeded | The number of requests that executed successfully. |
| Requests Timed Out | The number of requests that timed out. |
| Requests Total | The number of requests that have been made since the service was started. |
| Requests/sec | The average number of requests that were executed per second. |

Table D.34 describes miscellaneous counters for the Active Server Pages performance object.

**Table D.34 Script Engines, Sessions, Templates, and Transactions Counters**

| Counter | Description |
|---|---|
| Script Engines Cached | The number of script engines in the cache. |
| Script Engine Cache Hit Rate | The percentage of requests that were found in the script engine cache. |
| Engine Flush Notifications | The number of engines invalidated in the cache because change notification occurred. |
| Session Duration | The length of time that the most recent session lasted, in milliseconds. |
| Sessions Current | The number of sessions currently being serviced. |
| Sessions Timed Out | The number of sessions that have timed out. |
| Sessions Total | The number of sessions that have run since the service was started. |
| Templates Cached | The number of templates that are currently cached. |
| Template Cache Hit Rate | The percentage of requests that have been found in the template cache. |
| Template Notifications | The number of templates that have been invalidated in the cache because change notification occurred. |
| In Memory Templates Cached | The number of compiled templates that are cached in memory. |
| In Memory Template Cache Hit Rate | The percentage of requests that have been found in the memory cache. |
| Transactions Aborted | The number of transactions that have been aborted. |
| Transactions Committed | The number of transactions that have been committed. This counter increments after page execution if the transaction does not abort. |
| Transactions Pending | The number of transactions that are in progress. |
| Transactions Total | The number of transactions that have occurred since the service was started. |
| Transactions/sec | The average number of transactions that have been started, per second. |

| Note |
| --- |
| The Templates Cached counter, Template Cache Hit Rate counter, and Template Notifications counter provide information about the total number of templates cached on disk and in memory. To determine the number of requests cached on disk only, subtract the value of the In Memory Templates Cached counter from the value of the Templates Cached counter. |

# ASP.NET Performance Counters

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

ASP.NET supports the following ASP.NET system performance counters, which aggregate information for all ASP.NET applications on a Web server computer, or, alternatively, apply generally to a system of ASP.NET servers running the same applications.

**ASP.NET Counters**

Use the ASP.NET counters in Table D.35 through Table D.38 to monitor ASP.NET system performance.

Table D.35 describes the Application Restarts and Applications Running counters for the ASP.NET performance object.

**Table D.35 Application Restarts and Applications Running Counters**

| Counter | Description |
|---|---|
| Application Restarts | The number of times that an application has been restarted since the Web service started. Application restarts are incremented with each **Application_OnEnd** event. An application restart can occur because changes were made to the Web.config file or to assemblies stored in the application's \Bin directory, or because too many changes occurred in Web Forms pages. Sudden increases in this counter can mean that your Web application is shutting down. If an unexpected increase occurs, be sure to investigate it promptly. This value resets every time IIS is restarted. |
| Applications Running | The number of applications that are running on the server computer. |

Table D.36 describes the Requests counters for the ASP.NET performance object.

**Table D.36 Requests Counters**

| Counter | Description |
|---|---|
| Requests Disconnected | The number of requests that were disconnected because a communication failure occurred. |
| Requests Queued | The number of requests in the queue waiting to be serviced. If this number increases as the number of client requests increases, the Web server has reached the limit of concurrent requests that it can process. The default maximum for this counter is 5,000 requests. You can change this setting in the computer's Machine.config file. |
| Requests Rejected | The total number of requests that were not executed because insufficient server resources existed to process them. This counter represents the number of requests that return a 503 HTTP status code, which indicates that the server is too busy. |
| Request Wait Time | The number of milliseconds that the most recent request waited in the queue for processing. |

Table D.37 describes the State Server Sessions counters for the ASP.NET performance object. These counter are available only on a computer on which the state server service (aspnet_state) is running.

**Table D.37 State Server Sessions Counters**

| Counter | Description |
|---|---|
| State Server Sessions Abandoned | The number of user sessions that were explicitly abandoned. These are sessions that have been ended by specific user actions, such as closing the browser or navigating to another site. |
| State Server Sessions Active | The number of active user sessions. |
| State Server Sessions Timed Out | The number of user sessions that are now inactive. In this case, the user is inactive, not the server. |

| | |
|---|---|
| State Server Sessions Total | The number of sessions created during the lifetime of the process. This counter represents the cumulative value of State Server Sessions Active, State Server Sessions Abandoned, and State Server Sessions Timed Out counters. |

Table D.38 describes the worker process counters for the ASP.NET performance object.

**Table D.38 Worker Process Counters**

| Counter | Description |
|---|---|
| Worker Process Restarts | The number of times that a worker process restarted on the server computer. A worker process can be restarted if it fails unexpectedly or when it is intentionally recycled. If worker process restarts increase unexpectedly, investigate immediately. |
| Worker Processes Running | The number of worker processes that are running on the server computer. |

**ASP.NET Applications Performance Counters**

ASP.NET supports the following application performance counters, which you can use to monitor the performance of a single instance of an ASP.NET application. A unique instance of these counters, named __Total__, aggregates counters for all applications on a Web server. The __Total__ instance is always available. When no applications are running on the server, the counters display zero.

Table D.39 describes the Anonymous Requests counters for the ASP.NET Applications performance object.

**Table D.39 Anonymous Requests Counters**

| Counter | Description |
|---|---|
| Anonymous Requests | The number of requests that use anonymous authentication. |
| Anonymous Requests/sec | The average number of requests that have been made per second that use anonymous authentication. |

Table D.40 describes the Cache Total counters for the ASP.NET Applications performance object.

**Table D.40 Cache Total Counters**

| Counter | Description |
|---|---|
| Cache Total Entries | The total number of entries in the cache. This counter includes both internal use of the cache by the ASP.NET framework and external use of the cache through exposed APIs. |
| Cache Total Hits | The total number of responses served from the cache. This counter includes both internal use of the cache by the ASP.NET framework and external use of the cache through exposed APIs. |
| Cache Total Misses | The number of failed cache requests. This counter includes both internal use of the cache by ASP.NET and external use of the cache through exposed APIs. |
| Cache Total Hit Ratio | The ratio of cache hits to cache misses. This counter includes both internal use of the cache by ASP.NET and external use of the cache through exposed APIs. |
| Cache Total Turnover Rate | The number of additions to and removals from the cache per second. Use this counter to help determine how efficiently the cache is being used. If the turnover rate is high, the cache is not being used efficiently. |

Table D.41 describes the Cache API counters for the ASP.NET Applications performance object.

**Table D.41 Cache API Counters**

| Counter | Description |
|---|---|
| Cache API Entries | The total number of entries in the application cache. |

| | |
|---|---|
| Cache API Hits | The total number of requests served from the cache when it was accessed only through the external cache APIs. This counter does not track use of the cache internally by ASP.NET. |
| Cache API Misses | The total number of requests to the cache that failed when the cache was accessed through the external cache APIs. This counter does not track use of the cache internally by ASP.NET. |
| Cache API Hit Ratio | The cache hit-to-miss ratio when the cache was accessed through external cache APIs. This counter does not track use of the cache internally by ASP.NET. |
| Cache API Turnover Rate | The number of additions to and removals from the cache per second, when it is used through the external APIs (excluding internal use by the ASP.NET framework). This counter is useful for determining how effectively the cache is being used. If the turnover is great, then the cache is not being used effectively. |

Table D.42 describes the Errors counters for the ASP.NET Applications performance object.

**Table D.42 Errors Counters**

| Counter | Description |
|---|---|
| Errors During Preprocessing | The number of errors that occurred during parsing. Excludes compilation and run-time errors. |
| Errors During Compilation | The number of errors that occurred during dynamic compilation. Excludes parser and run-time errors. |
| Errors During Execution | The total number of errors that occurred during the execution of an HTTP request. Excludes parser and compilation errors. |
| Errors Unhandled During Execution | The total number of unhandled errors that occurred during the execution of HTTP requests.<br><br>An *unhandled error* is any uncaught run-time exception that escapes user code on the page and enters the ASP.NET internal error-handling logic. Exceptions occur in the following circumstances:<br><br>• When custom errors are enabled, an error page is defined, or both.<br><br>• When the **Page_Error** event is defined in user code and either the error is cleared (by using the **HttpServerUtility.ClearError** method) or a redirect is performed. |
| Errors Unhandled During Execution/sec | The number of unhandled exceptions that occurred per second during the execution of HTTP requests. |
| Errors Total | The total number of errors that occurred during the execution of HTTP requests. Includes parser, compilation, or run-time errors. This counter represents the sum of the Errors During Compilation, Errors During Preprocessing, and Errors During Execution counters. A well-functioning Web server should not generate errors. |
| Errors Total/sec | The average number of errors that occurred per second during the execution of HTTP requests. Includes any parser, compilation, or run-time errors. |

Table D.43 describes the Output Cache counters for the ASP.NET Applications performance object.

**Table D.43 Output Cache Counters**

| Counter | Description |
|---|---|
| Output Cache Entries | The total number of entries in the output cache. |
| Output Cache Hits | The total number of requests serviced from the output cache. |

| | |
|---|---|
| Output Cache Misses | The number of output-cache requests that failed per application. |
| Output Cache Hit Ratio | The percentage of total requests that were serviced from the output cache. |
| Output Cache Turnover Rate | The average number of additions to and removals from the output cache per second. If the turnover is great, the cache is not being used effectively. |

Table D.44 describes the Request Bytes counters for the ASP.NET Applications performance object.

**Table D.44 Request Bytes Counters**

| Counter | Description |
|---|---|
| Request Bytes In Total | The total size, in bytes, of all requests. |
| Request Bytes Out Total | The total size, in bytes, of responses sent to a client. This does not include standard HTTP response headers. |

Table D.45 describes the Requests counters for the ASP.NET Applications performance object.

**Table D.45 Requests Counters**

| Counter | Description |
|---|---|
| Requests Executing | The number of requests that are currently executing. |
| Requests Failed | The total number of failed requests. All status codes greater than or equal to 400 increment this counter.<br><br>**Note:** Requests that cause a 401 status code increment this counter and the Requests Not Authorized counter. Requests that cause a 404 or 414 status code increment this counter and the Requests Not Found counter. Requests that cause a 500 status code increment this counter and the Requests Timed Out counter. |
| Requests In Application Queue | The number of requests in the application request queue. |
| Requests Not Found | The number of requests that failed because resources were not found (status code 404, 414). |
| Requests Not Authorized | The number of requests that failed because of lack of authorization (status code 401). |
| Requests Succeeded | The number of requests that executed successfully (status code 200). |
| Requests Timed Out | The number of requests that timed out (status code 500). |
| Requests Total | The total number of requests that have been made since the service started. |
| Requests/sec | The average number of requests that have been executed per second. This counter represents the current throughput of the application. |

Table D.46 describes the Session State and SQL Server Connections counters for the ASP.NET Applications performance object.

**Table D.46 Session State and SQL Server Connections Counters**

| Counter | Description |
|---|---|
| Session State Server Connections Total | The total number of session-state connections that were made to a computer on which out-of-process session-state data is stored. |

| | |
|---|---|
| Session SQL Server Connections Total | The total number of session-state connections that were made to the Microsoft® SQL Server™ database in which session-state data is stored. |

Table D.47 describes the Sessions counters for the ASP.NET Applications performance object. These counters are supported only with in-memory session state.

**Table D.47 Sessions Counters**

| Counter | Description |
|---|---|
| Sessions Active | The number of sessions that are active. |
| Sessions Abandoned | The number of sessions that have been explicitly abandoned. |
| Sessions Timed Out | The number of sessions that timed out. |
| Sessions Total | The total number of sessions. |

Table D.48 describes the Transactions counters for the ASP.NET Applications performance object.

**Table D.48 COM+ Transactions Counters**

| Counter | Description |
|---|---|
| Transactions Aborted | The number of COM+ transactions that were aborted. |
| Transactions Committed | The number of COM+ transactions that were committed. This counter increments after page execution if the transaction does not abort. |
| Transactions Pending | The number of COM+ transactions that are in progress. |
| Transactions Total | The total number of COM+ transactions that have occurred since the service was started. |
| Transactions/sec | The average number of COM+ transactions that were started per second. |

Table D.49 describes a few miscellaneous counters for ASP.NET Applications.

**Table D.49 Miscellaneous Counters for ASP.NET Applications**

| Counter | Description |
|---|---|
| Compilations Total | The total number of times that the Web server process dynamically compiled requests for files with .aspx, .asmx, .ascx, or .ashx extensions (or a code-behind source file).<br><br>**Note:** This number initially climbs to a peak value as requests are made to all parts of an application. After compilation occurs, however, the resulting binary compilation is saved on disk, where it is reused until its source file changes. This means that, even when a process restarts, the counter can remain at zero (be inactive) until the application is modified or redeployed. |
| Debugging Requests | The number of requests that occurred while debugging was enabled. |
| Pipeline Instance Count | The number of active request pipeline instances for the specified ASP.NET application. Because only one execution thread can run within a pipeline instance, this number represents the maximum number of concurrent requests that are being processed for a specific application. In most circumstances, it is better for this number be low when the server is busy, because this means that the CPU is well used. |

# Timeouts Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Internet Information Services (IIS) has several time-out values that are set by default when you install a member of the Microsoft Windows Server-TM- 2003 family of operating systems. Time-out values allow the server to specify how long server resources are allocated to specific tasks or clients.

Time-out settings are configurable from IIS Manager as well. For more information about setting the various time-out values, see Setting Connection Timeouts.

The following table lists the time-out values in IIS and where you can set them.

| Property Name | Metabase Identifier | Available in IIS Manager |
|---|---|---|
| AspScriptTimeout Metabase Property | MD_ASP_SCRIPTTIMEOUT | Yes |
| AspSessionTimeout Metabase Property | MD_ASP_SESSIONTIMEOUT | Yes |
| ConnectionTimeout Metabase Property | MD_CONNECTION_TIMEOUT | Yes |
| CGITimeout Metabase Property | MD_SCRIPT_TIMEOUT | No |
| ServerListenTimeout Metabase Property | MD_SERVER_LISTEN_TIMEOUT | No |
| PoolIdcTimeout Metabase Property | MD_POOL_IDC_TIMEOUT | No |
| AspQueueTimeout Metabase Property | MD_ASP_QUEUETIMEOUT | No |
| HeaderWaitTimeout Metabase Property | MD_HEADER_WAIT_TIMEOUT | No |
| MinFileBytesPerSec Metabase Property | MD_MIN_FILE_BYTES_PER_SEC | No |

# Redirect Reference

Updated: June 29, 2009

Applies To: Windows Server 2003, Windows Server 2003 with SP1

Redirecting a client request is one way to ensure that users get the correct page, if your site is under construction or has changed identity. You can redirect client requests to a directory on the same Web server or to a different URL.

**Configuring URL and Wildcard Redirection**

You can configure redirection to a URL and wildcard redirection programmatically. Redirection variables and flags allow you to specify targets and behavior by changing the **HttpRedirect** metabase property.

The following example shows the format of a simple redirection string.

`http://` *DestinationURL* `[,` *Flag[s]* `]`

Where *DestinationURL* can include the following redirect variables to pass portions of the original URL with the destination URL. You can use more than one variable in a single redirection string.

| Variable | Description | Example |
|---|---|---|
| $S | Passes the suffix of the requested URL to the new URL. The suffix is the portion of the original URL that remains after the redirected URL is substituted.<br><br>If the EXACT_DESTINATION flag is not set, the resulting destination URL will have the name of the requested file appended as a folder name, as well as the file name itself. | If the virtual directory that is mapped to the following Web site:<br><br>`http://fabrikam/Scripts`<br><br>is configured to be redirected to the following exact URL:<br><br>`http://fabrikam/NewScripts$S`<br><br>A new request for the following URL:<br><br>`http://fabrikam/Scripts/Program.exe`<br><br>Would be redirected automatically to the following URL:<br><br>`http://fabrikam/NewScripts/Program.exe` |
| $P | Passes parameters (such as querystring parameters) in the original URL to the new URL, without the question mark (?). | If the virtual directory that is mapped to the following Web site:<br><br>`http://fabrikam/Scripts`<br><br>is configured to be redirected to the following URL:<br><br>`http://fabrikam/NewScripts$P`<br><br>A new request for the following URL:<br><br>`http://fabrikam/Scripts/File.asp?var1=5&var2=6`<br><br>Would be redirected automatically to the following URL:<br><br>`http://fabrikam/NewScriptsvar1=5&var2=6` |

| | | |
|---|---|---|
| $Q | Passes parameters (such as querystring parameters) in the original URL to the new URL, including the question mark (?). | If the virtual directory that is mapped to the following Web site:<br>`http://fabrikam/Scripts`<br>is configured to be redirected to the following exact URL:<br>`http://fabrikam/NewScripts$S$Q`<br>A new request for the following URL:<br>`http://fabrikam/Scripts/File.asp?var1=5&var2=6`<br>Would be redirected automatically to the following URL:<br>`http://fabrikam/NewScripts/File.asp?var1=5&var2=6` |
| $V | Passes the requested URL, without the server name and without any parameters. To include parameters, use the $P or $Q variable with the $V variable.<br>If the EXACT_DESTINATION flag is not set, the resulting destination URL will have the name of the requested file appended as a folder name, as well as the file name itself. | If the virtual directory that is mapped to the following Web site:<br>`http://fabrikam/Scripts`<br>is configured to be redirected to the following exact URL:<br>`http://contoso$V`<br>A new request for the following URL:<br>`http://fabrikam/Scripts/File.asp`<br>Would be redirected automatically to the following URL:<br>`http://contoso/Scripts/File.asp` |

**Redirection Using Wildcards**

You can use redirect wildcards to match any number of characters in the original URL. Begin the destination URL with an asterisk (*) and a semicolon (;), and separate pairs of wildcard characters and destination URLs with a semicolon. The following example shows the format of a redirection string that uses wildcards.

```
*; Wildcard1; Destination1[; Wildcard2; Destination2][, Flags]
```

Where *WildcardN* can include an asterisk (*) to match any number of characters in the original URL and pass them to *DestinationN* by using the $0 through $9 variables defined in the following table.

| "Variable" | "Description" | "Example" |
|---|---|---|

| | | |
|---|---|---|
| $0 through $9 | Passes the portion of the requested URL that matches the indicted wildcard character. Wildcards must start at $0 for each *Wildcard*;*Destination* set. The EXACT_DESTINATION flag must be appended to the redirection string. | If the virtual directory that is mapped to the following Web site:<br>`http://fabrikam/Scripts`<br>is configured with the following redirection string:<br>`*; /Scripts/*_in.asp; /NewScripts/$0.dll; /Scripts/*_out.asp; http://contoso/NewScripts/$0.dll`<br>A new request for the following URLs:<br>`http://fabrikam/Scripts/data_in.asp`<br>`http://fabrikam/Scripts/data_out.asp`<br>Would be redirected automatically to the following respective URLs:<br>`http://fabrikam/NewScripts/data.dll`<br>`http://contoso/NewScripts/data.dll` |
| ! | Does not allow a redirect.<br>This variable is useful when you want to exempt files or subdirectories from redirection when a parent directory is configured to be redirected. | If the virtual directory that is mapped to the following Web site:<br>`http://fabrikam/Scripts`<br>is configured to be redirected, but the following Web site:<br>`http://fabrikam/Scripts/Commerce/Accounts`<br>needs to be exempt, programmatically set the redirection string for the exempted folder to the following<br>`*;!` |

For example, to redirect all requests for /Scripts/Filename.stm to a single file called Default.stm, and to redirect all requests for /Scripts /Filename.htm to a single file called Default.htm, use the following redirect request for the /Scripts virtual directory:

```
*;Filename.stm;/Default.stm/Filename.htm;/Default.htm
```

**Using Redirection Flags**

The following flags augment redirect strings of either URL or wildcard format. More than one flag is allowed. Flags are appended programmatically to the redirection string in HttpRedirect, or configured by selecting check boxes in IIS Manager.

| Flag | User Interface Check Box | Description |
|---|---|---|
| EXACT_DESTINATION | **The exact URL entered above** | Indicates that the value provided for the destination should be considered an absolute target location. |
| CHILD_ONLY | **A directory below this one** | Alerts IIS that redirection should occur only once because the destination is in a subdirectory of the original URL. This flag avoids loops. Also, this flag instructs IIS to redirect requests only if they are to subfolders or files of the original URL. |
| PERMANENT | **A permanent redirection for this resource** | Indicates that this redirection is permanent for this resource. |
| TEMPORARY | Clear the **A permanent redirection for this resource** check box" | Indicates that this redirection is temporary for this resource. |

**Related Information**

- For information about how to use IIS Manager to configure URL redirection, see Redirecting Requests to Files, Directories, or Programs.

- For information about how to use the URL Rewrite module to configure URL redirection in IIS 7, see Using the URL Rewrite Module.

# Tracing Events Reference

Updated: August 22, 2005

Applies To: Windows Server 2003, Windows Server 2003 with SP1

This reference describes the events that can be recorded in the trace log when using request-based tracing or IIS Admin tracing. When applicable, an event description may include troubleshooting steps. The events listed here are organized by tracing provider:

- Active Server Pages (ASP)
- IIS Admin Service
- IIS:SSL Filter
- World Wide Web Service Global Tracing Events
- IIS: WWW ISAPI Extensions
- IIS: WWW Server
    - IIS: CGI
    - IIS: Cache
    - IIS: Compression
    - IIS: Filter
    - IIS: General
    - IIS: ISAPI
    - IIS: Security

If you are searching for information on a specific event, press CTRL+F and search for the desired event description.

**Active Server Pages (ASP)**

| Event | Description |
|---|---|
| ASP_DEQUEUE_REQUEST | The ASP request was removed from the ASP request queue for processing/execution. |
| ASP_DONE_PROCESSING | The ASP engine finished executing the request, but ASP may still have to send request data back to the client. ASP is done with the request when the ASP_END_REQUEST event is triggered. |
| ASP_END_REQUEST | ASP finished processing the request and has sent all associated response data. |
| ASP_START_REQUEST | ASP received a new request from IIS. |
| ASP_APPLICATION_ONSTART_ERROR | ASP encountered an error when trying to execute the **Application_OnStart** function in the Global.asa file. The ASP execution was aborted. Look at the error response sent back to the client to help determine the source of the error. |
| ASP_CLIENT_DISCONNECTED | The client disconnected while the request was on the ASP queue. |

| | |
|---|---|
| ASP_COMPILE_FAILED | ASP could not compile the ASP file successfully. Look at other events between ASP_START_COMPILE and ASP_END_COMPILE in the trace log to determine why the compile failed. Or look at the error response sent back to the client to help determine why the compile failed. |
| ASP_FILE_ACCESS_DENIED | ASP tried to read the file but failed because of insufficient permissions. The user may not have the appropriate permissions. Check the NTFS permissions on the file. Enable the IIS authentication tracing provider, request the file, and check the trace log for more information about the problem. |
| ASP_FILE_NOT_FOUND | The requested ASP file does not exist at the specified location. Verify the URL of the path. Also look at the data in the ASP_READ_FILE event to determine the file that ASP is trying to read. You may need to run the trace again with verbosity set to level four. |
| ASP_GLOBAL_ASA_ACCESS_DENIED | ASP tried to read the Global.asa file but failed because of insufficient permissions. The user does have the appropriate permissions. Check the NTFS permissions on the Global.asa file for the specified application. Check the ASP_START_GLOBAL_ASA_CHECK event which specifies the location of the Global.asa file it is trying to access. If you do not see the ASP_START_GLOBAL_ASA_CHECK event run the trace again with verbosity set to level four. |
| ASP_INIT_FAILURE | ASP failed to initialize. There are four possible reasons why ASP failed to initialize:<br><br>1. IIS could not read the MetaBase.xml configuration file. This is a fatal error meaning IIS will not be able to process requests. This error may be the result of invalid metabase configuration or an invalid access control list (ACL) on the MetaBase.xml file. This is a level two error.<br><br>To remedy this problem:<br><br>1. Verify that the MetaBase.xml file exists in the %windir%\system32\inetsrv directory.<br><br>2. Check the permissions on the MetaBase.xml file and ensure that System has Full Control.<br><br>3. If necessary, restart IIS and all associated services using the **IISReset** command. From a command prompt, type **iisreset** and press ENTER.<br><br>4. If ASP fails to initialize after restarting all IIS services, contact Microsoft Product Support Services.<br><br>1. ASP could not initialize the ASP disk cache. This is not a fatal error meaning IIS and ASP will continue to process requests, but you may see significant performance degradation because ASP will not be able to use the disk cache.<br><br>To remedy this problem:<br><br>1. Ensure that the ASP Templates Cache directory exists. It is located in the %windir%\system32 directory by default.<br><br>2. Check access control lists (ACLs) on the directory and ensure that the IIS_WPG group is listed. The IIS_WPG group must have Read and Write permissions on the ASP Templates Cache directory. |

| | |
|---|---|
| | 3. Ensure that the user identity that the process is running as is a member of the IIS_WPG group. In the Computer Management console, expand **Local Users and Groups**, right-click the **IIS_WPG group**, and select **Properties**.<br><br>1. ASP could not initialize the Component Object Model (COM). This is a fatal error meaning IIS will not be able to process requests.<br><br>To remedy this problem, look at the Windows NT Event Log for COM errors. Debug any COM errors.<br><br>1. ASP could not initialize the metabase change notification listener. This is a fatal error meaning IIS will not be able to process requests.<br><br>To remedy this problem:<br><br>1. Recycle the application pool. Right-click the application pool and click **Recycle**.<br><br>2. If the problem persists, restart IIS and all associated services using the **IISReset** command. From a command prompt, type **iisreset** and press ENTER.<br><br>3. If the problem persists, contact Microsoft Product Support Services. |
| ASP_QUEUE_REQUEST_FAILED | ASP failed to put a request in the request queue. The queue may be full or another request may be blocking further queue processing. If this failure was preceded by the ASP_SERVER_TOO_BUSY_TOO_QUEUE event, then the queue is full.<br><br>In this situation, ASP should report itself as not healthy and the Windows NT Application Event log should contain an event from W3svc_WP. If Worker Processes Health Monitoring is enabled, the ping to the worker process should fail and the application pool should recycle once IIS detects that the ping failed.<br><br>To remedy this problem<br><br>1. Ensure that the AspRequestQueueMax Metabase Property was not changed from its default value (500). If **AspRequestQueueMax** was not changed, use Currently Executing Requests Tracing to determine which requests were executing when the failure occurred.<br><br>2. Once you have found which requests are executing, trace the requests to the indicated URL to find where the blockage is occurring. |

| | |
|---|---|
| ASP_REQUEST_TIMEOUT | The ASP request spent too much time on the queue. The queue may be full or another request may be blocking further queue processing. Recycle the application pool or use Currently Executing Requests Tracing to understand which requests were executing when the failure occurred.<br><br>To remedy this problem<br><br>1. Ensure that the AspQueueTimeout Metabase Property was not changed from its default value. The default value is an unlimited number, represented by 4294967295.<br><br>2. If **AspQueueTimeout** was not changed, use Currently-Executing Requests Tracing to determine which requests were executing when the failure occurred.<br><br>3. Once you have determined which requests were executing, trace the requests to the indicated URL to find where the blockage is occurring. |
| ASP_SERVER_TOO_BUSY_TO_QUEUE | ASP cannot queue the request. The server may be running out of memory.<br><br>To remedy this problem<br><br>1. Recycle the application pool. Right-click the application pool and click **Recycle**.<br><br>2. If the problem persists, restart IIS and all associated services using the **IISReset** command. From a command prompt, type **iisreset** and press ENTER.<br><br>3. If the problem persists, contact Microsoft Product Support Services. |
| ASP_SESSION_ONSTART_ERROR | ASP encountered an error when trying to execute the **Session_OnStart** function in the Global.asa file. Look at the error response sent back to the client to help determine the source of the error. The ASP execution was aborted. |
| ASP_TRANSACTION_ABORTED | The ASP transaction aborted. Transactions in this case are Microsoft Transaction System (MTS) transactions. Work with the developer of the ASP file to debug the application. |

| | |
|---|---|
| ASP_UNHEALTHY_FAILURE | ASP is not healthy and could not continue to execute requests. The **Reason** field for this event shows either DEADLOCK_DETECTED or OUT_OF_MEMORY. If you are running IIS 6.0 in worker process isolation mode and you see this event, the application pool hosting the application will be recycled if Worker Process Health Monitoring is enabled. If this failure happens repeatedly, your application may have a memory leak. If you are running IIS 6.0 in IIS 5.0 isolation mode, you will see an ASP error in the Windows NT Event Log, but no action will be taken. With IIS 6.0 running in IIS 5.0 isolation mode, you must restart the World Wide Web Publishing Service and then look at the Web site logs for all executed requests to understand why ASP is not healthy. Trace a request using Currently Executing Requests Tracing to understand which requests where executing when the failure occurred.<br><br>**Note**<br>If IIS 6.0 is running in worker process isolation mode and a worker process does not shut down within the time limit configured by the ShutdownTimeLimit Metabase Property, IIS will forcefully shut down the process. If IIS forcefully shuts down the process, all requests executing in that process are logged in the HTTPERR log. |
| ASP_GLOBAL_ASA_DOES_NOT_EXIST | ASP could not find the Global.asa file. If your application uses a Global.asa file, determine why the file does not exist in the specified location. If your application does not use a Global.asa file, then you can ignore this event. |
| ASP_APPLICATION_ONSTART_SUCCESS | ASP successfully executed the **Application_Onstart** function. |
| ASP_CURRENT_SESSION | This event tells you the session ID for the current session. |
| ASP_END_APPLICATION_ONSTART | ASP finished executing the **Application_Onstart** function. |
| ASP_END_CACHE_ACCESS | ASP finished checking the cache. Check the **Reason** field in the trace log for one of the following:<br><br>NOT_SERVED: The file was not found or not served. The file may not have been served because of improper permissions on the file. The file may not exist or there could be a larger problem with the server, for example, a hard disk crash.<br><br>SERVED_CACHE_MISS: The file did not exist in the cache. ASP retrieved the file from disk and tried to load it into the cache.<br><br>SERVED_CACHE_HIT_CHANGENOTIF: The file was found in the cache and served from the cache. Change notification was used to maintain cache consistency.<br><br>SERVED_CACHE_HIT_LASTMOD: The file was found in the cache and served from the cache. ASP polled the last-modified timestamp on the file to maintain cache consistency.<br><br>SERVED_CACHE_HIT_LASTMOD_NOACCESS: The connection between the IIS server and a Universal Naming Connection (UNC) file share is down. ASP cannot check the timestamp on the requested file. However, the requested file exists in the cache so it was served from the cache. The content may be stale. |
| ASP_END_COMPILE | ASP finished generating the ASP template. |
| ASP_END_GLOBAL_ASA_CHECK | ASP finished checking for the Global.asa file. |

| | |
|---|---|
| ASP_END_SCRIPTLESS_SEND | The requested ASP page did not contain any script tags. ASP did not need to compile the page before sending it.<br>**Note**<br>ASP files that do not contain scripts should be renamed with the .htm or .html extension. Script-less .asp files are not processed as efficiently as static .htm or .html files. Responses for static files can be returned by the HTTP.sys kernel cache, which can significantly increase performance. |
| ASP_END_SCRIPT_EXECUTION | ASP finished executing the script code. ASP may not be finished processing the request. |
| ASP_END_SESSION_ONSTART | ASP finished executing the **Session_Onstart** function. |
| ASP_FIRST_REQUEST_FOR_APPLICATION | ASP received the first request for this application. ASP_APPLICATION_ONSTART and GLOBAL.ASA_CHECK events should follow. |
| ASP_FIRST_REQUEST_FOR_ASP | The ASP.dll received its first request. Part of ASP initialization takes place on the first request. |
| ASP_GLOBAL_ASA_ACCESS_SUCCESS | ASP successfully read the Global.asa file. |
| ASP_NEW_SESSION_CREATED | ASP accepted the first request for a new session and created a session ID for this session. |
| ASP_QUEUE_REQUEST | ASP put the request on the queue. This event should be followed by the ASP_DEQUEUE_REQUEST event when the request is pulled off the queue for execution. |
| ASP_READ_FILE | ASP is trying to read the file. The trace log will show one of these events for each included file. |
| ASP_SECURE_SESSION_ID_SET | ASP made a transition to a secure state. This event marks the session ID of the secure session. |
| ASP_SESSION_ONSTART_SUCCESS | ASP successfully executed the **Session_Onstart** function. |
| ASP_START_APPLICATION_ONSTART | ASP is about to call the **Application_Onstart** function. |
| ASP_START_CACHE_ACCESS | ASP is about to check for the file template in the ASP File Template Cache. |
| ASP_START_COMPILE | ASP is about to compile the specified file. |
| ASP_START_GLOBAL_ASA_CHECK | ASP is about to check for the existence of a Global.asa at the specified location. |
| ASP_START_SCRIPTLESS_SEND | The requested page does not contain any script tags. ASP will not need to compile the page before sending it. |
| ASP_START_SCRIPT_EXECUTION | ASP started executing the script code. |
| ASP_START_SESSION_ONSTART | ASP started executing the **Session_Onstart** function. |
| ASP_TRANSACTION_COMMITTED | The ASP transaction was committed. Transactions in this case are Microsoft Transaction System (MTS) transactions. |
| ASP_SCRIPT_TRACE_COM_CALL_END | The ASP script engine finished calling into a COM object, other than the response object, as indicated by your script. |
| ASP_SCRIPT_TRACE_COM_CALL_START | The ASP script engine is making a call into a COM object other than the response object, as indicated by your script. |
| ASP_SCRIPT_TRACE_CREATE_OBJECT_END | The ASP script engine finished creating a COM object as indicated by your script. |

| | |
|---|---|
| ASP_SCRIPT_TRACE_CREATE_OBJECT_START | The ASP script engine is creating a COM object as indicated by your script. |
| ASP_SCRIPT_TRACE_END | The script engine has finished executing. This event shows where the script engine finished executing. For example, the execution could end in an include file. |
| ASP_SCRIPT_TRACE_GET_OBJECT_END | The script engine finished calling the **GetObject** function. |
| ASP_SCRIPT_TRACE_GET_OBJECT_START | The script engine started calling the **GetObject** function. |
| ASP_SCRIPT_TRACE_START | The script engine started executing. This event shows where the execution is starting. For example, the execution could start in an include file. |

**IIS Admin Service**

| Event | Description |
|---|---|
| IISADMIN_END | The IIS Admin service finished shutting down. |
| START | The IIS Admin service has started shutting down. The service may be shutting down because of administrator action, for example, the administrator may have executed the IISreset.exe command or the net stop IIS Admin command. |
| ABO_DISCONNECT_END | The IIS Admin service finished disconnecting metabase COM client connections (as indicated by the process ID). |
| ABO_DISCONNECT_START | The IIS Admin service is about to disconnect metabase COM client connections (as indicated by the process ID) before shutting down. |
| COUNINITIALIZE_END | The IIS Admin service finished calling the **CoUninitialize** function to shutdown all COM activity in the process. All COM activity in the process was successfully shutdown. |
| COUNINITIALIZE_START | The IIS Admin service is about to call the **CoUninitialize** function to shutdown all COM activity in the process. |
| EWR_SHUTDOWN_END | The IIS Admin service successfully shutdown the Edit-While-Running mechanism, which monitors the MetaBase.xml file for changes. |
| EWR_SHUTDOWN_START | The IIS Admin service is about to shutdown the Edit-While-Running mechanism, which monitors the MetaBase.xml file for changes. |
| LISTENER_SHUTDOWN_END | The IIS Admin service successfully shutdown the listener that monitors change notification in the metabase. This means the IIS Admin service has stopped publishing IIS metabase change notifications.<br>**Note**<br>All processes listening for change notification, as indicated by the process ID (PID), will no longer receive IIS metabase change notification. |
| LISTENER_SHUTDOWN_START | The IIS Admin service is about to shutdown the listener that monitors change notification in the metabase. This means the IIS Admin service will no longer publish IIS metabase change notifications.<br>**Note**<br>All processes listening for change notification, as indicated by the PID, no longer receive IIS metabase change notification. |
| METADATA_SHUTDOWN_END | The IIS Admin service successfully shutdown the in-memory metabase. |
| METADATA_SHUTDOWN_START | The IIS Admin service is about to shutdown the in-memory metabase. |

| | |
|---|---|
| SVCEXT_SHUTDOWN_END | The IIS Admin service successfully shut down the service extensions. |
| SVCEXT_SHUTDOWN_START | The IIS Admin service is about to shutdown the service extensions. |
| END | The IIS Admin service successfully started. |
| IISADMIN_START | The IIS Admin service is starting up. This should be the first published IIS Admin service event. If you do not see this event in the trace log, check the NT System event log for service control manager events with the IIS Admin service. |
| ABO_REGISTER_FAILURE | The IIS Admin service could not register the metabase ABO interface in COM, an indication that there is a problem in COM. Look at the error code published with this event and take the action described by the error code. If the problem persists, call Microsoft Product Support Services. |
| COM_SECURITY_FAILURE | The IIS Admin service could not set the permissions on the ABO interface in COM. Look at the error code published with this event and take the action described by the error code. If the problem persists, call Microsoft Product Support Services. |
| DCPROMO_FAILURE | The IIS Admin service could not register the IIS accounts in Active Directory after the machine was promoted to a domain controller. The problem probably resides in Active Directory. Once Active Directory is back online, stop and restart the IIS Admin service. By its very nature, this failure can only happen one time. Look at the error code published with this event and take the action described by the error code. If the problem persists, call Microsoft Product Support Services.<br><br>**Note**<br>When you see this event in the trace log, the IIS Admin service is still running. However, all IIS accounts may have shut down, including the default anonymous user account. |
| MBSCHEMA_PARSE_FAILURE | The IIS Admin service failed to parse the MBSchema.xml file. Look at the error code published with this event and take the action described by the error code. You can also look in the NT System event log for errors in the IIS Admin service. These errors may provide more information about this failure. If the errors do not provide you with the necessary information, role back to an earlier version of the MBSchema.xml file if you have one. You can also open the MBSchema.xml file in an XML editor to ensure that the file is properly formatted. If the problem persists, call Microsoft Product Support Services. |
| METABASE_PARSE_FAILURE_MB_XML | The IIS Admin service failed to parse the MetaBase.xml file. Look at the error code published with this event and take the action described by the error code. You can also check the NT System event log for errors in the IIS Admin service. If the errors do not provide you with the necessary information, role back to an earlier version of the MetaBase.xml file. If the problem persists, call Microsoft Product Support Services. |
| METABASE_PARSE_FAILURE_SESSION_KEY | The IIS Admin Service failed to decrypt the encrypted session key in the metabase, which means IIS cannot read the metabase. The machine key IIS has stored does not match the machine key used to encrypt the session key. This is a critical failure. As a result, IIS will not run. Stop and restart the IIS Admin service. If the problem persists, rollback to an earlier version of the MetaBase.xml file and MBSchema.xml file from the History folder and restart the IIS Admin service. If the problem persists, uninstall IIS, reinstall IIS, and restore a known-good backup from an IIS 6.0 server that was backed up with a password (the password is used in the encryption process). If the problem persists, contact Microsoft Product Support Services. |
| SVCEXT_STARTUP_FAILURE | The IIS Admin service attempted to start a service extension and the startup failed. Restart the IIS Admin service. If the problem persists, contact Microsoft Product Support Services. |

| | |
|---|---|
| COM_CATALOG_FAILURE | The IIS Admin service attempted to start the COM catalog and failed. There is probably an error in the COM catalog. |
| VSS_FAILURE | The IIS Admin service attempted to register with the Volume Snapshot Service (VSS), but failed. The IIS Admin service will continue to run, but if any system-wide backups are performed using the Windows Server backup utility, then IIS may not be able to get the MetaBase.xml file ready for backup. |
| DCPROMO_END | The IIS Admin service finished updating the user accounts in the case where the IIS server was promoted to a domain controller. |
| DCPROMO_START | The IIS Admin service is about to check if the machine has been promoted to a domain controller. If the machine has been updated to a domain controller, the IIS Admin service will begin updating the user accounts. |
| METABASE_PARSE_FAILURE_SETTING | The IIS Admin service failed to read one or more of the property settings in the metabase. The IIS Admin service will still run, but will ignore the settings that failed. Check the Windows NT System Event log to determine which properties were ignored. |
| ABO_REGISTER_END | The IIS Admin service finished registering the ABO interface with COM. |
| ABO_REGISTER_START | The IIS Admin service is about to register the ABO interface with COM. |
| COM_CATALOG_START | The IIS Admin service is about to start using the COM catalog. |
| COM_CATALOG_END | The IIS Admin service successfully started and is using the COM catalog. |
| COM_SECURITY_END | The IIS Admin service successfully setup the permissions in COM on the ABO interface. |
| COM_SECURITY_START | The IIS Admin service is about to setup the permissions in COM on the ABO interface. |
| MBSCHEMA_PARSE_END | The IIS Admin service successfully parsed the MBSchema.xml file. |
| MBSCHEMA_PARSE_START | The IIS admin service is about to parse the MBSchema.xml file. |
| METABASE_PARSE_END | The IIS Admin service successfully parsed the MetaBase.xml file. |
| METABASE_PARSE_START | The IIS Admin service is about to parse the MetaBase.xml file. |
| SVCEXT_STARTUP_END | The IIS Admin service successfully started a service extension. |
| SVCEXT_STARTUP_START | The IIS Admin service is about to start a service extension. |
| VSS_END | The IIS Admin service successfully registered with the Volume Snapshot Service (VSS). |
| VSS_START | The IIS Admin service is about to register with the Volume Snapshot Service (VSS). |

**IIS: SSL Filter**

| Event | Description |
|---|---|
| SSLERROR_DECRYPT | The HTTP Filter service failed while decrypting Secure Sockets Layer (SSL) data. This is a fatal error. The request was rejected as a result of this error. This error may be the result of a change in the encrypted data on the client side or on the transport layer. Because this error is the result of a change on the client side, this error does not require any action on the part of the administrator |

| | |
|---|---|
| SSLERROR_ENCRYPT | The HTTP Filter service failed while encrypting SSL data. This is a fatal error. This error could be the result of a low-memory condition on the server. The Windows NT Event logs should contain more information about this error. If the problem persists, contact Microsoft Product Support Services. |
| SSLERROR_HANDSHAKE | The HTTP Filter service failed during the SSL handshake. This is a fatal error. The request was rejected. This error could be the result of a low-memory condition on the server. Also, the server may not support the SSL protocol and/or cipher requested by the client. This error most likely resides with the client computer. The client computer may be using the SSL 2.0 protocol and the server may be configured to use client certificates, as indicated by following error in the trace log: SEC_E_ALGORITHM_MISMATCH. This error does not require any action on the part of the administrator. |
| SSLERROR_INTERNALINCONSISTENCY | The HTTP Filter service failed because the SSL filter detected an internal error. This is a fatal error. The request was rejected. This error can happen during the SSL handshake. This error does not require any action on the part of the administrator. |
| SSLERROR_INVALIDCONTEXT | The HTTP Filter service failed because the SSL filter detected an internal error. This is a fatal error. The request was rejected. This error can happen during the SSL handshake. This error does not require any action on the part of the administrator. |
| SSLERROR_RENEGOTIATION | The HTTP Filter service failed while the client certificate was being renegotiated. This is a fatal error. The request was rejected. The source of this problem may be in the secure channel (Schannel) call or an internal error. This error can happen during the SSL handshake. This error does not require any action on the part of the administrator. |
| SSLERROR_USERDATADURINGRENEGOTIATION | The HTTP Filter service failed during the SSL renegotiation handshake. This is a fatal error. The request was rejected. This is an internal error. This error does not require any action on the part of the administrator. |
| ENDCONNECTION | The HTTP Filter service closed the connection and all data has been sent. |
| SSLCLIENTCERTINFO | This event tells you the details of the client certificate that was negotiated during the SSL handshake. |
| SSLCREDENTIALINFO | This event tells you the credentials that will be used during the SSL handshake. |
| SSLDECRYPTEDDATA | The HTTP Filter service successfully decrypted the client data and wrote the data as clear text into the ETW log. The HTTP Filter service may limit the amount of decrypted data going into the ETW log to 32K. |
| SSLENDHANDSHAKE | The HTTP Filter service successfully completed the SSL handshake. |
| SSLSCHANNELCALL | The HTTP Filter service is monitoring calls into the Schannel, which implements the SSL protocol handling. |
| SSLSTARTHANDSHAKE | The HTTP Filter service started an SSL handshake on a secure connection. This event can be triggered in two situations:<br>• This is a new connection to the secure port.<br>• This is a renegotiation when client-certificate authentication is requested, but the initial SSL handshake did not include the request for client authentication. |

| | |
|---|---|
| SSLTOBEENCRYPTEDDATA | The HTTP Filter service received the clear-text data and is preparing to encrypt that data. |
| STARTCLOSECONNECTION | The HTTP Filter service has started to shut down the client connection. The connection may still contain data. |
| STARTCONNECTION | The HTTP Filter service was notified by HTTP.sys that a client has connected to a secure port. |

**World Wide Web Service Global Tracing Events**

These events describe WWW service actions but exclude request-processing events.

| Event | Description |
|---|---|
| FILTER_UNLOAD_END | A worker process finished unloading an Internet Server API (ISAPI) filter. A worker process will unload an ISAPI filter during normal shutdown. The name of the unloaded filter is identified by the **Filter Name** property in the trace log. |
| FILTER_UNLOAD_START | A worker process started unloading an ISAPI filter. A worker process will unload an ISAPI filter during normal shutdown. The name of the unloaded filter is identified by the **Filter Name** property in the trace log. |
| GLOBAL_PROCESS_SHUTDOWN_MODE | A worker process was told by the WWW Service to stop listening for new requests and to shutdown. This can happen for a variety of reasons, including a process recycle. This is not a crash. If a worker process was instructed to shutdown immediately, then the worker process also shutdown all Common Gateway Interface (CGI) scripts. This event is followed by the GLOBAL_W3_SERVER_SHUTDOWN_START event. |
| GLOBAL_W3_SERVER_SHUTDOWN_END | A worker process finished shutting down and finished cleaning up after its objects. |
| GLOBAL_W3_SERVER_SHUTDOWN_START | A worker process is preparing to shutdown and preparing to clean up after its objects. |
| GLOBAL_W3_SERVER_INIT_ERROR | This is an internal error. A worker process failed one of its initialization routines. The INITSTATUS event indicates how far the worker process got in its initialization routine. The ERROR CODE event indicates the Win32 error received when trying to execute the initialization routine. Recycle the application pool. If the problem persists, contact Microsoft Product Support Services. Tell the support engineer the value of the INITSTATUS and ERROR CODE properties. |
| FILTER_LOAD_END | A worker process finished loading an ISAPI filter. If the ERROR CODE event for this event is zero, the filter loaded successfully. If the ERROR CODE event is a numeric value other than zero, the filter did not load. The Windows NT Event log will contain more information explaining why the filter did not load. If the problem persists, contact Microsoft Product Support Services. |
| FILTER_LOAD_START | A worker process is attempting to load an ISAPI filter. The **Filter Name** property indicates the name of the filter the worker process is attempting to load. |
| GLOBAL_PROCESS_START_INFO | A worker process is starting up. This event records the parameters passed to the worker process during startup, including command-line arguments, which mode the worker process is running in, the identity under which the process is running, and the processor affinity mask for that process. |
| GLOBAL_ULATQ_START_LISTENING | A worker process started listening for requests from HTTP.sys. |
| GLOBAL_W3_SERVER_END | A worker process finished initializing. The worker process is ready to process requests. |
| GLOBAL_W3_SERVER_START | A worker process has started up and is beginning initialization. |

| | |
|---|---|
| GLOBAL_CACHE_START | The worker process caches are about to be initialized. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_CERTIFICATE_START | A worker process is about to initialize the certificate object wrapper. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_CGI_RESTRICTION_LIST_START | A worker process is about to initialize the CGI restriction list. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_COMPRESSION_START | A worker process is about to initialize HTTP compression. Failure to initialize HTTP compression does not result in a failure to initialize the worker process. The worker process will continue to run, but will not be able to compress files. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_FILTER_START | A worker process is about to initialize global ISAPI filters. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_IISUTIL_START | A worker process is about to initialize the IISUTIL (a set of common utility routines). If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_ISAPI_RESTRICTION_LIST_START | A worker process is about to initialize the ISAPI restriction list. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_LOGGING_START | A worker process is about to initialize logging. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_METABASE_LISTENER_START | A worker process is about to initialize the metabase listener, which monitors the metabase for changes. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_METABASE_START | A worker process is about to initialize the metabase. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_MIME_MAP_START | A worker process is about to initialize the Multipurpose Internet Mail Extensions (MIME) map. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_RAW_CONNECTION_START | A worker process running in IIS 5.0 isolation mode is about to initialize stream filter support. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_RESOURCE_DLL_START | A worker process is about to load its resource DLL. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_SERVER_VARIABLE_START | A worker process is about to initialize the global server variables. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_SITE_LIST_START | A worker process is about to initialize the site list. This means the objects that will store the list of sites have been initialized by the worker process. This does not mean the list of sites have been completely loaded into the worker process. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_ULATQ_START | A worker process is about to initialize communication to HTTP.sys and the World Wide Web Publishing Service (WWW service). If the worker process initializes communication, this event will be followed with a GLOBAL_FILTER_START event. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_W3_CONNECTION_START | A worker process is about to initialize the connection table. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |

| | |
|---|---|
| GLOBAL_W3_CONTEXT_START | A worker process is about to initialize its World Wide Web context. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_W3_REQUEST_START | A worker process is about to initialize the request object. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_W3_RESPONSE_START | A worker process is about to initialize the response object. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_W3_SITE_START | A worker process is about to initialize the World Wide Web site object. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |
| GLOBAL_W3_WINSOCK_START | A worker process is about to initialize Winsock for network address translation. In IIS 6.0, Winsock is not used as the transport layer. The kernel-mode driver, HTTP.sys, is the request/response transport layer. If the action fails, the GLOBAL_W3_SERVER_INIT_ERROR will be written to the trace log. |

**IIS: WWW ISAPI Extensions**

| Event | Description |
|---|---|
| CALL_ISAPI_EXTENSION | A worker process is about to pass a request to the ISAPI extension. |
| ISAPI_EXTENSION_DONE | The client computer received the final response from the ISAPI extension or disconnected. The ISAPI context for this request has been reclaimed. When tracing for capacity planning purposes, calculate the delta between the NOTIFY_ISAPI_COMPLETION event and this event to determine how long it took to send the last bit of the response. |
| NOTIFY_ISAPI_COMPLETION | The ISAPI extension sent the last segment of the response. The ISAPI extension is done with the request. |

**IIS: WWW Server**

| Event | Description |
|---|---|

| | |
|---|---|
| AUTH_ANON_PASSWD_CHANGE_NEEDED | The virtual directory is configured for anonymous authentication. The password for the anonymous user ID has expired or needs to be changed per policy. To resolve this issue, reset the anonymous user password in two places:<br>• The IIS metabase<br>• The Local Users and Groups node of the Computer Management MMC snap-in<br><br>To reset the anonymous user password in the IIS metabase:<br>1. Enter the following command at a command prompt: **cscript.exe adsutil.vbs set w3svc/site number/AnonymousUserPass** *new password*<br>2. Press ENTER.<br><br>or<br>1. Open IIS Manager, expand the Local Computer, right-click the Web site or virtual directory where you want to change the Anonymous Authentication password and click **Properties**.<br>2. Click the **Directory Security** tab.<br>3. In the **Authentication and access control** section, click **Edit**.<br>4. Change the password in the **Password** text box.<br>5. Click **OK**.<br><br>To reset the anonymous user password in the Local Users and Groups node of the Computer Management MMC snap-in<br>1. Right-click My Computer and click **Manage**.<br>2. Expand the Local Users and Groups node and click **Users**.<br>3. Right-click the anonymous user account (IUSR_machine name) and click **Set password**.<br>4. Click **OK**. |
| AUTH_INVALID_ANON_ACCOUNT | The virtual directory is configured for anonymous authentication. The anonymous user name for this virtual directory does not exist or is an invalid account. To resolve this issue, ensure that the user name stored in the AnonymousUserName Metabase Property exists on the computer or is available to the computer in the case of a domain account. |
| AUTH_BAD_BASIC_HEADER | The server computer requires Basic authentication to access the requested URL. The client computer supplied an invalid basic header or failed to supply a basic header. The request failed. This server sent an HTTP 401: Unauthorized response. |
| AUTH_BASIC_LOGON_FAILED | The client attempted to authenticate using basic authentication. The client supplied an invalid user name and/or password. The request failed. This server sent an HTTP 401: Unauthorized response. |

| | |
|---|---|
| AUTH_IISDIGEST_LOGON_FAILED | The client attempted to authenticate using digest authentication. The client supplied an invalid user name and/or password. The request failed. This server sent an HTTP 401: Unauthorized response. |
| AUTH_NTLM_NULL_SESSION | The virtual directory is configured for NTLM authentication. The client computer did not provide a user name and/or password during authentication. The request failed. This server sent an HTTP 401: Unauthorized response. |
| AUTH_PASSPORT_LOGON_FAILED | The virtual directory is configured for Passport authentication. The client computer provided an invalid user name and/or password during authentication. The request failed. This server sent an HTTP 401: Unauthorized response. |
| AUTH_PASSWD_CHANGE_DISABLED | The authenticated user's password is about to expire and the server is not configured for password change according to the **PasswordChangeFlags** metabase property. Configure the IIS 6.0 server for password change. For more information, see the PasswordChangeFlags Metabase Property. |
| AUTH_PASSWD_CHANGE_NEEDED | The user's password needs to be changed. IIS is about to change the user's password as configured by the **PasswordChangeFlags** metabase property. For more information, see the PasswordChangeFlags Metabase Property. |
| AUTH_SSPI_LOGON_FAILED | IIS attempted to logon to the user with the credentials supplied in the client request. The logon failed due to invalid credentials. Logon was denied. |
| AUTH_TYPE_NOT SUPPORTED | The client requested an authentication type that is not configured on the IIS server in the metabase. The server is not configured for the authentication type requested by the client. |
| AUTH_WDIGEST_LOGON_FAILED | IIS attempted to logon the user using Windows Digest Authentication (Advanced Digest Authentication). The authorization attempt failed. |
| AUTH_END | IIS finished the logon attempt. Authentication for this request is finished. |
| AUTH_REQUEST_AUTH_TYPE | IIS determined the authentication type requested by the client computer. This authentication type is included in the trace log with this event. |
| AUTH_SSPI_CONTINUE_NEEDED | The server needs to continue the authentication handshake between the client and the server. The server sent an HTTP 401: Bad Logon response. The response included the WWW authenticate header. |
| AUTH_START | IIS started authenticating the request. |
| AUTH_SUCCEEDED | The request was successfully authenticated. This event includes the following information:<br>• The requested authentication type<br>• The remote user's name<br>• The local user name<br>• The impersonation level |

**IIS: CGI**

| Event | Description |
|---|---|
| CGI_END | IIS finished processing the CGI. IIS may still be processing the request. |
| CGI_START | IIS started executing a CGI. |
| CGI_HEADERS_RECIEVED | IIS received the complete set of HTTP response headers generated by the CGI. |

| | |
|---|---|
| CGI_LAUNCH | The CGI executable process has been created and launched. |
| CGI_PREMATURE_TERMINATION | A CGI terminated unexpectedly. The server sent an HTTP 502: Premature Exit error code to the client. Investigate why the CGI failed or debug the CGI executable. |
| CGI_REQUEST_ENTITY_SENT | The CGI sent the complete request-entity body. |
| CGI_TIMEOUT | The CGI timed out. The server sent an HTTP 502: Timeout error to the client. Investigate why the CGI timed out or debug the CGI executable. |

**IIS: CACHE**

| Event | Description |
|---|---|
| FILE_CACHE_ACCESS_END | IIS finished checking the file cache for the requested file. The trace log for this event includes the following information:<br>• Whether the file was found in the cache<br>• Whether the file was added to the cache<br>• Whether the directory where the file resides is being monitored for changes<br>• Whether IIS encountered an error when checking the last-modified date stamp on the file<br>• Whether IIS ignored the error for the last-modified date stamp on the file |
| FILE_CACHE_ACCESS_START | IIS started to check the file cache for the requested file. |
| HTTPSYS_CACHEABLE | IIS checked to see if a response could be cached in the HTTP.sys response cache. For information about the HTTP.sys response cache and why a response was not cached, see Events and Conditions That Disable HTTP.sys Response Caching. |
| URL_CACHE_ACCESS_END | IIS finished checking the URL metadata configuration cache for the requested URL. The trace log details for this event indicate whether or not the URL was added to the cache. |
| URL_CACHE_ACCESS_START | IIS started checking the metadata cache for the URL metadata. |

**IIS: Compression**

| Event | Description |
|---|---|
| DYNAMIC_COMPRESSION_NOT_SUCCESS | IIS could not compress the dynamic response. Ensure that dynamic compression is enabled. |
| DYNAMIC_COMPRESSION_START | IIS attempted to compress a dynamic response (any request that is not static). |
| DYNAMIC_COMPRESSION_SUCCESS | IIS verified various criteria for dynamic compression, including whether the client can accept compressed responses and whether the server is configured for dynamic compression. IIS is ready to start compressing the entity body for the dynamic response. |
| STATIC_COMPRESSION_CREATE_END | IIS attempted to compress a static file and store the compressed response in the IIS Temporary Compressed Files directory (by default). The trace log for this event indicates the error code, if any. If the trace log for this event shows a zero, the response was successfully compressed. The trace log also indicates the original file name and size and the compressed file name and size. Use this information to determine how much the static file was compressed. |
| STATIC_COMPRESSION_CREATE_START | IIS started compressing a static file. IIS will attempt to store the compressed response in the IIS Temporary Compressed Files directory (by default). |

| | |
|---|---|
| STATIC_COMPRESSSION_NOT_SUCCESS | IIS attempted to compress a static file but failed. The trace log for this event contains details about the error. IIS will attempt to compress the file again on the next request. |
| STATIC_COMPRESSION_START | IIS started compressing the static file. |
| STATIC_COMPRESSION_SUCCESS | IIS found the requested file in the IIS Temporary Compressed Files directory (the default directory) and is preparing to send it. |
| DYNAMIC_COMPRESSION_DO | IIS dynamically compressed a portion of the response. |

**IIS: Filter**

| Event | Description |
|---|---|
| FILTER_END | An ISAPI filter finished processing a request. |
| FILTER_START | An ISAPI filter started processing a request. The filter name is indicated in the event. |
| FILTER_ERROR | An ISAPI filter returned an error after processing a request. The error number is indicated in the event. |
| FILTER_ACCESS_DENIED_END | An ISAPI filter that requested SF_NOTIFY_ACCESS_DENIED notification finished processing a request. |
| FILTER_ACCESS_DENIED_START | An ISAPI filter that registered for the SF_NOTIFY_ACCESS_DENIED notification denied access to a request. The trace log for this event contains the name of the requested URL, the physical path, and the reason why the request was denied access. |
| FILTER_ADD_REQ_HEADER | An ISAPI filter that has registered for the PREPROC_HEADER notification added additional headers to the request. This event is triggered each time the filter adds a header to the request. The trace log for this event contains the header name and value. |
| FILTER_ADD_RESP_HEADER | An ISAPI filter that registered for the SEND_RESPONSE notification added additional headers to the response. This event is triggered each time the filter adds a header to the response. The trace log for this event contains the header name and value. |
| FILTER_AUTHENTICATION_END | The SF_NOTIFY_AUTHENTICATION notification completed. The trace log for this event contains the final user name and whether or not the user name changed. |
| FILTER_AUTHENTICATION_START | IIS started the SF_NOTIFY_AUTHENTICATION notification. IIS logs this event only if a filter has registered for this notification The trace log for this event contains the original user name. |
| FILTER_AUTH_COMPLETE_END | The ISAPI filter finished reporting the SF_NOTIFY_AUTHENTICATION event. The trace log for this event includes the final user name (in case the filter changed the user name) and whether or not the password changed. |
| FILTER_AUTH_COMPLETE_START | The ISAPI filter registered for the SF_NOTIFY_AUTHENTICATION filter event notification and is about to be notified. |
| FILTER_END_OF_REQUEST_END | The ISAPI filter finished handling the SF_NOTIFY_END_OF_REQUEST filter event notification. |
| FILTER_END_OF_REQUEST_START | The ISAPI filter is about to handle the SF_NOTIFY_END_OF_REQUEST filter event. |
| FILTER_LOG_END | The ISAPI filter finished handling the SF_NOTIFY_LOG filter event notification. The trace log for this event contains the final log data parameters. |
| FILTER_LOG_START | The ISAPI filter is about to handle the SF_NOTIFY_LOG filter event notification. The event contains the original data to be logged. |

| | |
|---|---|
| FILTER_PREPROC_HEADERS_END | The ISAPI filter finished handling the SF_NOTIFY_PREPROC_HEADERS filter event notification. |
| FILTER_PREPROC_HEADERS_START | The ISAPI filter is about to handle the SF_NOTIFY_PREPROC_HEADERS filter event notification. |
| FILTER_SEND_RAW_DATA_END | The ISAPI filter handled the SF_NOTIFY_SEND_RAW_DATA filter event notification. |
| FILTER_SEND_RAW_DATA_START | The ISAPI filter is about to handle the SF_Nofity_Send_Raw_Data filter event notification. |
| FILTER_SEND_RESPONSE_END | The ISAPI filter handled the SF_NOTIFY_SEND_RESPONSE_START filter event notification. |
| FILTER_SEND_RESPONSE_START | The ISAPI filter is about to handle the SF_NOTIFY_SEND_RESPONSE_START filter event notification. |
| FILTER_SET_REQ_HEADER | An ISAPI filter successfully set an HTTP request header. This event is logged each time a request header is set. The trace log for this event contains the header name and header value. |
| FILTER_SET_RESP_HEADER | An ISAPI filter successfully set an HTTP response header. This event is logged each time a response header that is set. The trace log for this event contains the header name and header value. |
| FILTER_URL_MAP_END | The ISAPI filter handled the SF_NOTIFY_URL_MAP_START filter event notification. The trace log contains the following information for this event:<br>• The original URL<br>• The file path<br>• Access permission for the URL<br>• The number of matching characters in the physical path<br>• The number of matching characters in the URL<br>• The script map entry for this URL |
| FILTER_URL_MAP_START | The ISAPI filter is about to handle the SF_NOTIFY_URL_MAP_START filter event notification. The trace log contains the following information for this event:<br>• The original URL<br>• The file path<br>• Access permission for the URL<br>• The number of matching characters in the physical path<br>• The number of matching characters in the URL<br>• The script map entry for this URL |

**IIS: General**

| **Event** | **Description** |
|---|---|
| GENERAL_CGI_HANDLER | IIS determined that the request was for a CGI and started processing that CGI. |

| | |
|---|---|
| GENERAL_CHILD_REQUEST_END | The child execution completed and the child context was deleted. The trace log for this event contains the response status code, sub-status codes, and the number of bytes sent. |
| GENERAL_CHILD_REQUEST_START | IIS started to execute the child request.<br><br>**Note**<br>An ISAPI extension can call HSE_REQ_EXECUTE_URL to re-execute a request.<br><br>The trace log for this event contains the following:<br>• The site id<br>• The new URL to execute<br>• The new verb to execute<br>• The number of times the verb/URL has been re-executed |
| GENERAL_DAV_HANDLER | IIS determined that the incoming request was a Web Distributed Authoring and Versioning (WebDAV) request. |
| GENERAL_ISAPI_HANDLER | IIS set up the initial context for the ISAPI, but has yet to determine if the ISAPI extension is enabled. |
| GENERAL_MAP_HANDLER | IIS started processing a map file request. |
| GENERAL_OOP_ISAPI_HANDLER | IIS determined that the request was for an ISAPI extension that is Out of Process. This is only applicable in IIS 5.0 Isolation mode. |
| GENERAL_OPTIONS_HANDLER | IIS started processing the Options request. A client request can use an **Options** method to determine the options available once it connects to the server. |
| GENERAL_REDIRECTION_HANDLER | IIS started sending the configured redirect-response to the client. |
| GENERAL_REQUEST_END | IIS completely finished processing the request and the response. The response was sent to the client. |
| GENERAL_REQUEST_START | An IIS worker process picked up a request from HTTP.sys and successfully associated that request with a site on the server. This event is logged before any filter notifications are triggered. This event marks the beginning of the request in the worker process. |
| GENERAL_SEND_CUSTOM_ERROR | The response status and sub-status codes have been generated. The HTTP status code is greater than or equal to 400 (that is, the requested generated an error). The custom error will be sent to the client if one of the following is true:<br>• The request and all of its children allow an error body to be sent back to the client<br>• The response code is greater than 400.<br><br>**Note**<br>This event is logged before IIS checks to see if the customer (if configured as a file) exists. |
| GENERAL_STATIC_FILE_HANDLER | IIS started processing a request for a static file. |
| GENERAL_TRACE_HANDLER | IIS started processing a request whose method is **Trace**. |

| | |
|---|---|
| GENERAL_GET_URL_METADATA | IIS found the URL metadata in the cache, or IIS created a new URL metadata cache object for the request. |

**IIS: ISAPI**

| Event | Description |
|---|---|
| ISAPI_END | IIS started its cleanup routine after a request was processed by an ISAPI. |
| ISAPI_START | IIS is about to call into the ISAPI extension. |

**IIS: Security**

| Event | Description |
|---|---|
| SECURITY_DENIED_BY_CGI_RESTRICTION | A request was either script-mapped to a CGI or called a CGI directly and that CGI was not enabled in the Web Service Extensions. |
| SECURITY_DENIED_BY_ISAPI_RESTRICTION | A request was either script-mapped to an ISAPI or called an ISAPI directly and that ISAPI was not enabled in the Web Service Extensions. |
| SECURITY_DENIED_BY_MIMEMAP | IIS could not locate a MIME map for the requested static file. IIS sent an HTTP 404.3 status code to the client. |
| SECURITY_FILE_ACCESS_DENIED | A request attempted to load the default file for a virtual directory and the file was either not found (the path was not found) or the requested resource had an invalid name. The trace log for this event contains the requested file system path and the user name (including domain) used to access the requested file. Check the file system ACL on the requested resource and verify that the user name has permission to access the file. |
| SECURITY_ILLEGAL_SHORT_FILENAME | A requested resource contains a short file name which expands to something other than the actual resource indicated. For example: */~test expands to /testsite/user/filename* |
| SECURITY_REJECTED_HOSTNAME | The client computer's host name is not allowed. IIS rejected the request. For more information, see Securing Sites with IP Address Restrictions. |
| SECURITY_REJECTED_IP | The originating client IP address is listed in the Web server's IP address restriction list. IIS rejected the request. For more information, see Securing Sites with IP Address Restrictions. |
| SECURITY _REJECTED_REQUIRED_SSL_128 | The requested directory requires 128-bit SSL encryption. IIS rejected the request. For more information, see IIS 6.0 Encryption. |

# Windows Server 2003 Product Help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Welcome**

- Roadmap to Help and Information
- Choosing the features that are most useful for your server
- Common Administrative Tasks
- Troubleshooting Strategies
- New ways to do familiar Windows tasks
- Checklists Provided in Windows Server 2003 Help
- Best practices: pointers to recommendations and tips
- Submit product feedback to Microsoft

# Viewing Help for the Windows Server 2003 family from another computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing Help for the Windows Server 2003 family from another computer**

You can view Help for the Windows Server 2003 family from another computer by using Help and Support Center. For more information about how to do this, see To install Help content from another Windows computer, CD, or disk image.

You can also use Remote Desktop for Administration. For more information about how to do this, see Connect to another computer using Remote Desktop Web Connection. For more information about Remote Desktop for Administration, see Remote Desktop for Administration.

# Viewing Help using Remote Desktop

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing Help using Remote Desktop**

You can view Help for Windows XP and the Windows Server 2003 family from any computer running Windows XP by using Remote Desktop for Administration. For more information about how to do this, see Connect to another computer using Remote Desktop Web Connection. For more information about Remote Desktop for Administration, see Remote Desktop for Administration.

# Viewing classic Help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing classic Help**
Classic Help is Help in the format that shipped with Windows 2000. This is the same content that appears in Help and Support Center, but in a different format.

To access classic Help, open Windows Help.

### Notes

- To open the Windows Help file, click **Start**, click **Run**, and then type **hh windows.chm**.
- If you install Help content from another Windows computer, CD, or disk image, the Help file contains the Help content for the local computer, not the Help content from the other source.

# Viewing Help for Windows 2000

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing Help for Windows 2000**

You can access Help for all Windows 2000 Server operating systems at the Microsoft Web site:

- To access Help for Windows 2000 Server, see Windows 2000 Server Documentation at the Microsoft Web site.
- To access Help for Windows 2000 Advanced Server, see Windows 2000 Advanced Server Documentation at the Microsoft Web site.
- To access Help for Windows 2000 Datacenter Server, see Windows 2000 Datacenter Server Documentation at the Microsoft Web site.

# Viewing Help on the Web

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

You can find product Help for the Microsoft® Windows Server™ 2003 operating systems on the Microsoft Web site. However, the site does not offer a separate set of topics for each version and each edition in that set of products. To reduce duplication and improve search efficiency, each topic in the product Help contains information about how a feature works across all versions and editions. In addition, each topic specifies any differences between versions and editions. If a topic does not specify any differences, the functionality that it describes is the same across all Windows Server 2003 operating systems.

In addition to differences between versions and editions, other differences can affect whether your server appears and functions exactly as the topics describe. For example, the steps to open an item in Control Panel vary slightly based on how a server is configured. The following list explains in more detail why Help topics on the Web might differ from what you see on a particular server:

- **Versions of Windows Server 2003**

  Different versions of Windows Server 2003 are available for installation on computers with different microprocessors, and not all features are available on all versions. For example, the x64-based versions of Windows Server 2003 have different sets of features than do the 32-bit and Itanium-based versions of Windows Server 2003. You can find out whether a particular feature is available on a particular version by reading the topics about that feature. For more information, see Accessing information about compatibility and Considerations for 64-bit drivers and software.

- **Editions of Windows Server 2003**

  Windows Server 2003 comprises multiple editions so that you can choose which sets of features best address your needs. For example, the feature set of Windows Server 2003, Web Edition, is optimized for a particular purpose, and several features that do not relate to that purpose are not available in that edition. Procedure topics state when the functionality that they describe are not available on all editions. For more information about feature availability on specific editions of Windows Server 2003, see the Microsoft Web site.

- **Service packs**

  Service packs also affect how a server appears and functions, and topics describe the changes that result from installing Windows Server 2003 Service Pack 1 (SP1). For more information about SP1, see Technical Overview of Windows Server 2003 Service Pack 1 (SP1) and Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1.

- **Account permissions**

  You might not be able to perform certain tasks based on the permissions that have been granted to the account that you used to log on. For more information about account permissions, see User and computer accounts and Local user accounts.

- **User preference settings**

  Product Help for Windows Server 2003 documents functionality based on default settings for options such as menu styles and file locations. If these settings have been changed, you might need to follow a slightly different set of steps than those presented in Help topics. For more information about user preference settings, see Settings saved in a user profile and Setting environment variables.

# Using the Windows Deployment and Resource Kits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the Microsoft Windows Deployment and Resource Kits**
The Microsoft® Windows® Deployment and Resource Kits provide IT professionals with the technical information and tools they need to successfully deploy and operate Windows.

See the topics in this Help and Support site for the content in the Microsoft® Windows® Server 2003 Deployment Kit, the Microsoft® Windows® Server 2003 Resource Kit, and Microsoft® Windows® XP Professional Resource Kit Documentation. For more information about purchasing the kits, or to browse the documentation on the Web, go to the Windows Deployment and Resource Kits Web site. This Web site also contains other important documentation developed by the Windows Resource Kit teams, including the Windows Server 2003 System Administration Scripting Guide and Windows 2000 documentation.

**Important**

- Some of the links on this page are to English-only content on the Web, regardless of the language of your operating system. In addition, if you install a Windows Deployment or Resource Kit on a non-English operating system, you will see English content mixed with non-English content in the Help and Support Center table of contents.

**Using Windows Server 2003 Help and Support Center from Windows XP Professional**
Windows Server 2003 Help and Support Center contains technical content for the IT professional that you won't find in Windows XP Professional. If you administer servers running Windows Server 2003 from a computer running Windows XP Professional, you should install Windows Server 2003 Help and Support Center. When you do this, your installed Windows Deployment and Resource Kits can be viewed and searched from within the Windows Server 2003 Help and Support Center. This way you have easy access to a more complete documentation set for server deployment and administration.

To install Windows Server 2003 Help and Support Center on a computer running Windows XP Professional, follow the steps in the Help topic Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional. Windows Server 2003 family Help content is available on the Windows Server 2003 Deployment Kit companion CD, the Windows Server 2003 Resource Kit companion CD, and the Windows Server 2003 operating system CD.

# Updated technical information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Updated technical information**

The Microsoft Product Support Services Web site contains an extensive collection of articles, troubleshooting wizards, files you can download, and other useful product information. The articles can help you understand more about the features included in the Windows Server 2003 family.

In addition, Microsoft Product Support Services contains other information you may find useful, such as frequently asked questions (FAQs), troubleshooting information, and information from newsgroups.

For more information, see Microsoft Product Support Services at the Microsoft Web site.

# Using TechNet

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using TechNet**

TechNet is a service that contains resources for information technology (IT) professionals. This includes access to white papers and articles written by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software. For more information, see Microsoft Technet at the Microsoft Web site.

# Using MSDN

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using MSDN**

The Microsoft Developer Network (MSDN) is a complete resource for developers. You can find downloads, guidelines for hardware and driver compatibility testing, and how-to guides to help you build device drivers for Windows operating systems. For more information, see MSDN at the Microsoft Web site.

# Accessing documentation on the Web

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing documentation on the Web**

To download the latest product documentation, see Windows Update at the Microsoft Web site. Windows Update is a catalog of items, such as drivers, patches, the latest Help files, and Internet products, that you can download to keep your computer up to date.

# Accessing Microsoft white papers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing Microsoft white papers**

Microsoft white papers, many of which are written by Microsoft system engineers and network specialists, provide in-depth information on a variety of subjects. For more information, see Technical White Papers at the Microsoft Web site.

# Accessing information about training and certification

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing information about training and certification**

The Training and Certification Web site provides information about Microsoft training, certification, and technical careers. For more information, see Microsoft Training and Certification at the Microsoft Web site.

# Accessing information about compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing information about compatibility**

There are several ways to assess the readiness of your system and to make sure that your hardware and software will run properly.

**Compatible Hardware and Software**

You can search the Compatible Hardware and Software area in Help and Support Center to find compatibility information about specific products. You can search by manufacturer or by product, or your can browse through the list of hardware and software devices to see if your device is compatible or if it needs an update. For more information, see Compatible Hardware and Software overview.

**Program Compatibility Wizard**

This wizard prompts you to test a program in different modes (environments) and with various settings. For example, if the program was originally designed to run on Windows 95, set the compatibility mode to Windows 95 and try running the program again. If this is successful, the program will start in that mode every time. You can also run the Program Compatibility Wizard on the setup file for a program.

**Compatibility Mode**

Compatibility Mode provides an environment for running applications that more closely reflects the behavior of Windows 95, Windows 98, Windows NT 4.0, or Windows 2000 operating systems. These modes resolve several of the most common issues that prohibit older applications from working correctly on the Windows Server 2003 family of products. Applications that experience problems after migration may benefit from being started in one of these compatibility environments. You can also use Compatibility Mode to provide solutions for your own applications.

**Microsoft Web site**

You can search for compatible computers, hardware devices, and software applications at the Microsoft Web site. For more information, see Hardware compatibility information in the Windows Catalog (search page) at the Microsoft Web site.

**Notes**

- To get the most current compatibility information when using Compatible Hardware and Software in Help and Support Center, you must be connected to the Internet.

- Compatible Hardware and Software in Help and Support Center is not necessarily a complete list of programs and devices that are compatible with this release. It is a collection of products for which test data has been submitted to Microsoft. If you do not find a specific product, you can contact the manufacturer and ask the manufacturer about registering its product in the Windows Logo Program.

# Accessing information about accessibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing information about accessibility**

The Windows Server 2003 family contains features to help people with disabilities use the product. In addition, Microsoft offers other products and services for people with disabilities. For more information, and for information about products and services offered by other organizations, see Accessibility for People with Disabilities.

# Copyright

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Copyright**

This software is supplied as is without expressed or implied warranties of any kind.

# Getting Started

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Getting Started**
The Getting Started topics provide information about new features as well as information designed to help you install or upgrade a network with one to five servers and 100 or fewer clients. If you are an administrator of a larger collection of servers, also see the Windows Server 2003 Deployment Kit at the Microsoft Windows Server System Web site. For information about obtaining the Windows Deployment and Resource Kits, see Using the Windows Deployment and Resource Kits.

For additional information, see:

- Step-by-step guides for deployment
- New Features
- Installing and Upgrading the Operating System
- Installing and Upgrading on Cluster Nodes
- Configuring Roles for Your Server
- Windows Product Activation

# Step-by-step guides for deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Step-by-step guides for deployment**
The Microsoft Web site provides tutorials that you can use to learn about and deploy the operating system. These technical walkthroughs provide step-by-step instructions and illustrations for installing and configuring key features.

You can access the Step-by-Step Guides at the Microsoft Web site.

The following list includes some of the topics that you can find in these guides:

**Infrastructure**

- Building a common network infrastructure

**Active Directory**

- Setting up additional domain controllers
- Delegating control of objects
- Managing Active Directory
- Managing replication topology
- Using LDAP and VBScript to manage Active Directory
- Extending Active Directory using the Schema and display specifiers

**Management services**

- Understanding Group Policy
- Managing remote installation of the operating system
- Managing application deployments for groups of users and computers
- Managing user data and user settings

**Security services**

**Setting up and configuring certificates**

- Setting up a certification authority
- Configuring a domain to trust an external certification authority
- Managing Certificate Services
- Obtaining and managing certificates
- Configuring automatic certificate requests

**Using certificates**

- Requesting certificates using Web pages
- Mapping certificates to user accounts to be used on a Web site

**Additional security features**

- Configuring local security policy on individual computers
- Managing security in an enterprise network
- Encrypting files
- Using Kerberos V5
- Encrypting IP network traffic using Internet Protocol security (IPSec)

**File and print services**

- Creating logical views of directories and files

**Clustering**

- Installing a typical two-node cluster on Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition

# Considerations for 64-bit drivers and software

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Considerations for 64-bit drivers and software**

Device drivers that are 32-bit do not work on computers running 64-bit versions of the Windows operating systems. If you are attempting to install hardware that only has 32-bit drivers available, that hardware will not work correctly on 64-bit versions of Windows. Additionally, applications that attempt to install 32-bit device drivers on 64-bit versions of Windows will encounter errors.

For information about updating drivers and troubleshooting issues with device drivers for 64-bit versions of Windows, contact the manufacturer of the hardware or software.

# New Features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features**

Windows Server 2003, Standard Edition, gives you a high level of reliability and scalability, lowers your cost of computing with flexible management services, and provides the best foundation for running business applications.

Windows Server 2003, Web Edition, is an easy-to-deploy, easy-to-manage server operating system that is optimized to be a complete Web hosting package.

Windows Server 2003, Enterprise Edition, includes the full feature set of Windows Server 2003, Standard Edition, and it also offers support for greater than 4 GB of memory and multiple processors, as well as for clustering. For more information about clustering, see Windows Clustering.

Windows Server 2003, Datacenter Edition, includes the full feature set of Windows Server 2003, Standard Edition, and it adds the high availability, reliability, and scalability required for enterprise and larger departmental solutions.

For information about feature changes in Windows Server 2003 with Service Pack 1, see topics in Features for Management, Security, and Best Performance, Features for Directory, File, Print, and Collaboration Services, and

Features for Internet, Application, and Networking Services.

- For information about features and components that have changed names or locations, see New ways to do familiar Windows tasks.
- To view a table that compares features in this release with features in previous releases, see Feature comparison: Windows NT, Windows 2000, and the Windows Server 2003 family. This table is especially useful if you upgrade from Windows NT 4.0 or Windows 2000 and you want to examine the differences between features.
- To learn more about the features that are useful for a specific function or administrative task, see Choosing the features that are most useful for your server.
- For a concise list of features in alphabetical order, see Alphabetical list of features.
- For an overview of the features in these topics, see Overview of Features.

# New ways to do familiar Windows tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

Many components have changed names or locations since Windows NT 4.0 and Windows 2000. To find the new way to do a task, click the letter that the name of the component starts with, and then click the name of the component.

# Feature comparison: Windows NT, Windows 2000, and the Windows Server 2003 family

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Feature comparison: Windows NT, Windows 2000, and the Windows Server 2003 family**
The following tables provide a feature comparison based on your upgrade path. For example, if you upgrade from Windows NT 4.0, select the "Windows NT 4.0 to the Windows Server 2003 family" option below. For links to more information about the features in this release, see New Features.

The tables, which are categorized by feature area, display information about improved features that were introduced in earlier operating systems, as well as features that are new to this release.

Some features are not available on some of the products in the Windows Server 2003 family. For more information, click the links in the following tables. For information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

Click the option that describes your upgrade path:

- Windows NT 4.0 to the Windows Server 2003 family
- Windows 2000 to the Windows Server 2003 family

**Windows NT 4.0 to the Windows Server 2003 family**

| Feature area | Features that were added since Windows NT 4.0 and are updated in this release | Features that are new to the Windows Server 2003 family |
|---|---|---|
| Server reliability | • Improved memory management<br>• Robust system architecture<br>• Diagnostic tools<br>• Safe Mode start<br>• Recovery Console<br>• Windows File Protection<br>• Enhanced Backup utility | • Automated System Recovery (ASR)<br>• Compatibility Mode |
| Server availability | • Server clusters<br>• Network Load Balancing clusters<br>• Fewer server restarts<br>• Plug and Play<br>• Start from mirrored volumes | • User State Migration Tool<br>• Emergency Management Services |

| | | |
|---|---|---|
| Server scalability | • Hardware scalability<br>• I2O support<br>• Symmetric multiprocessing enhancements<br>• Network Load Balancing<br>• Server clusters<br>• Enterprise Memory Architecture | • Internet Information Services (IIS) 6.0 |
| Server manageability | • IntelliMirror<br>• Windows Management Instrumentation (WMI)<br>• Remote Installation Services (RIS)<br>• Manage Your Server | • Remote Desktop for Administration<br>• Remotely administered server support<br>• User State Migration Tool<br>• Emergency Management Services<br>• Resultant Set of Policy (RSOP)<br>• Authorization Manager |
| Performance and tuning features | • Winsock Direct<br>• I2O support<br>• CPU throttling for Web applications or sites<br>• Process Accounting for Web applications or sites<br>• Predictable, end-to-end Quality of Service (QoS)<br>• Network Load Balancing<br>• New performance tools<br>• Disk Defragmenter<br>• Event Tracing enhancements | • Performance Options<br>• New command-line utilities for System Monitor |

| | | |
|---|---|---|
| Authentication and smart card support | • Full support for the Kerberos V5 protocol<br>• Public key infrastructure (PKI), Certificate Services, and smart cards<br>• Virtual private networking<br>• Flexible, secure authentication and authorization<br>• Internet Authentication Service (IAS)<br>• Routing and Remote Access | • Stored User Names and Passwords<br>• Smart card access through Terminal Server |
| Additional security features | • Encrypting File System (EFS)<br>• Internet Protocol Security (IPSec) | • TCP/UDP port ownership<br>• Software restriction policies |
| Remote management | • Microsoft Management Console (MMC)<br>• Scripting with Windows Script Host<br>• Remote Installation Services (RIS) | • Remote Desktop for Administration<br>• Remote assistance<br>• Web Interface for Remote Administration (Windows Server 2003, Web Edition only) |
| Maintenance and product updates | • Windows Update | • Does not apply |
| Internationalization features | • Multilingual support<br>• Multiregional support | • New Phonetic Input Method Editor (IME) for Traditional Chinese |

| | | |
|---|---|---|
| Active Directory | • Simplified user and network-resource management<br>• Flexible, secure authentication and authorization<br>• Directory consolidation<br>• Directory-enabled applications and infrastructure<br>• Scalability without complexity<br>• Use of Internet standards<br>• A powerful development environment<br>• Replication and trust monitoring<br>• Message Queuing distribution lists | • For a list of the Active Directory features that are new in this release, see New features for Active Directory. |
| Disk and file management features | • Disk Management<br>• Disk quota support<br>• Distributed File System<br>• Distributed Link Tracking<br>• Distributed Authoring and Versioning (DAV)<br>• High-performance content indexing<br>• Encrypting File System (EFS)<br>• Removable Storage and Remote Storage | • Remote document sharing<br>• Command-line support for disk management<br>• GUID partition table (GPT). Available on all versions of Windows Server 2003 with Service Pack 1 (SP1) and on all versions of Windows Server 2003, x64 Edition.<br>• Shadow copies of shared folders |

| | | |
|---|---|---|
| Printer and protocol support | • Printers published in Active Directory<br>• Broad device and protocol support<br>• Plug and Play<br>• Internet Printing Protocol<br>• Printer management features<br>• Network printing features | • New command-line support for printing<br>• Easier printer driver installation on server clusters |
| Internet and e-mail services and features | • Active Server Pages (ASP)<br>• Windows Media Services<br>• Web Distributed Authoring and Versioning (WebDAV)<br>• Application recycling | • Microsoft .NET Framework components<br>• Internet Information Services (IIS) 6.0<br>• Universal Description, Discovery, and Integration (UDDI) Services<br>• E-mail services (POP3, SMTP)<br>• Windows Management Instrumentation (WMI) Provider |
| Features for collaboration | • Windows Media Services<br>• Predictable, end-to-end Quality of Service (QoS)<br>• Asynchronous transfer mode (ATM) | • Microsoft .NET Framework<br>• Audio Acceleration on the remote access server |
| Support for existing systems(see also Application support) | • Industry standards<br>• Support for existing server applications<br>• Integration with existing operating systems | • Compatibility Mode<br>• Program Compatibility Wizard |

| | | |
|---|---|---|
| Application support | • Widest range of turnkey applications<br>• Comprehensive Internet application services<br>• Microsoft Active Accessibility<br>• TAPI 3.1<br>• Transaction services<br>• Message Queuing<br>• Component Services<br>• Job objects<br>• Host data integration | • Compatibility Mode<br>• Web gardens in Internet Information Services (IIS) |
| Management and deployment | • Change and configuration management with Group Policy<br>• Directory consolidation in Active Directory<br>• IntelliMirror<br>• Remote Installation Services (RIS)<br>• Windows Management Instrumentation (WMI)<br>• Side-by-side component sharing<br>• Add or Remove Programs<br>• Windows Installer<br>• Application management | • Remotely administered server support<br>• Resultant Set of Policy (RSOP) |

| | | |
|---|---|---|
| Terminal Server features | • Centralized deployment of programs<br>• Remote access to applications<br>• Single application access<br>• Terminal Services Manager<br>• Remote control | • Audio redirection |
| Development support | • Visual Studio .NET<br>• Multilingual technology | • Automatic generation of link IDs<br>• Background Intelligent Transfer Service (BITS) |

# Choosing the features that are most useful for your server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Choosing the features that are most useful for your server**

To learn more about the features that are most useful for your server according to its function, see the following table. For links to more information about the features in this release, see New Features.

| Server type | Description of the feature or type of support | Information on how to use the feature |
|---|---|---|
| File server | • Features for Active Directory<br>• Disk and file management features | • Administering Active Directory<br>• Disks and Data<br>• Client Computers |
| Print server | • Features for Active Directory<br>• Printer and protocol support | • Administering Active Directory<br>• Printing<br>• Printers and Faxes |
| Web server | • Overview of Windows Server 2003, Web Edition<br>• Internet and e-mail services and features<br>• Application support<br>**Related areas:**<br>Application server<br>Networking/communications<br>Server security | • Internet and E-mail Services<br>• Internet Information Services (IIS) 6.0<br>• Technologies for Application and Development Support |
| Multimedia server | • Features for collaboration | • Using Windows Media Services<br>• Quality of Service (QoS)<br>• Windows ATM Services |

| | | |
|---|---|---|
| Application server | • Microsoft .NET Framework<br>• Support for existing systems<br>• Terminal Server features<br>• Application support<br>• Management and deployment<br>• Performance and tuning features<br>• Development support | • Remote Desktop for Administration<br>• Group Policy (pre-GPMC)<br>• IntelliMirror<br>• Monitoring and Status Tools<br>• Quality of Service (QoS)<br>• Windows ATM Services<br>• Enterprise Memory Architecture (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, not including 64-bit versions)<br>• Network Load Balancing Clusters<br>• Windows Clustering (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition only)<br>• Technologies for Application and Development Support<br><br>See also the Microsoft Platform SDK. You can download the SDK at the Platform SDK Update Web site. |
| Networking/ communications | • Network protocols and technologies<br>• Support for existing systems<br>• Performance and tuning features | • Network Services<br>• Configuring Communication Links<br>• Monitoring and Status Tools<br>• Quality of Service (QoS)<br>• Windows ATM Services |

# Alphabetical list of features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Alphabetical list of features**
This is a partial list of the extensive set of features included in the Windows Server 2003 family. For links to more information about the features in this release, see New Features.

- Active Directory
- Asynchronous transfer mode
- Automated System Recovery
- Certificate Services
- Clustering
- Compatibility Mode
- Component Services
- Connection Manager
- DHCP with DNS and Active Directory
- Disk Management
- Disk quota support
- E-mail services (POP3, SMTP)
- Encrypting File System
- Group Policy (part of Active Directory)
- Indexing Service
- Internet Authentication Service
- Internet Connection Sharing
- Internet Information Services 6.0
- Internet protocol security support
- Kerberos V5 protocol support
- Layer Two Tunneling protocol support
- Lightweight Directory Access protocol support
- Message Queuing

- Microsoft Management Console
- Network address translation
- Network Load Balancing clusters
- Operating system migration, support, and integration
- Plug and Play
- Public key infrastructure and smart card infrastructure
- Quality of Service
- Recovery Console
- Remote Assistance
- Remote Desktop for Administration
- Remote Installation Services
- Remote Storage
- Removable Storage
- Routing and Remote Access
- Safe Mode
- Security Configuration Wizard
- Server clusters (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition only)
- Smart card infrastructure
- Software restriction policies
- TAPI 3.1
- Terminal Server
- Universal Description, Discovery, and Integration Services
- Virtual private networking
- Windows Firewall
- Windows Media Services
- Windows Script Host
- Windows Update
- Winsock Direct

**Active Directory**
Active Directory is the directory service for Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. It stores information about objects on the network and makes this information easy for administrators and users to find and use. Active Directory uses a structured data store as the basis for a logical, hierarchical organization of directory information. For more information, see Active Directory.

**Asynchronous transfer mode**
Asynchronous transfer mode (ATM) is a high-speed, connection-oriented protocol designed to transport multiple types of traffic across a network. It is applicable to both local area networks (LANs) and wide area networks (WANs). Using ATM, your network can simultaneously transport a wide variety of network traffic: voice, data, image, and video.

**Automated System Recovery**
Automated System Recovery (ASR) helps you recover your system in the event that your hard disk fails or your system is seriously damaged. You can easily prepare the necessary backup materials for ASR through wizards that are part of Backup. By using ASR in combination with standard backups (data and application backups), you can restore a system to the state it was in when you backed it up. For more information about ASR, see Automated System Recovery (ASR) overview. For more information about other system recovery options, see Disaster Recovery.

**Certificate Services**
Using Certificate Services and certificate management tools, you can deploy your own public key infrastructure (PKI). With a PKI, you can implement standards-based technologies, such as smart card logon capabilities, client authentication (through Secure Sockets Layer (SSL) and Transport Layer Security (TLS)), secure e-mail, digital signatures, and secure connectivity (using Internet protocol security (IPSec)). Using Certificate Services, you can set up and manage certification authorities (CAs) that issue and revoke X.509 v3 certificates. This means that you do not have to depend on commercial client authentication services, although you can integrate commercial client authentication into your PKI if you choose. For more information, see Certificate Services.

**Clustering**
A cluster is a group of independent computers that work together to run a common set of applications and provide the image of a single system to the client and application. For more information, see "Network Load Balancing clusters" or "server clusters" in this list.

Server clusters are available only on Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition.

**Compatibility Mode**
A new Compatibility Mode feature ensures out-of-box compatibility for many popular applications. Compatibility Mode technology provides an environment that more closely reflects the behavior of Windows 95, Windows 98, Windows NT 4.0, or Windows 2000 operating systems. These modes resolve several of the most common issues that prevent older applications from working correctly. Applications that experience problems after migration might benefit from being started in one of these compatibility environments. Advanced users can also take advantage of this technology to create solutions for their own applications.

**Component Services**
Component Services is a set of services based on extensions of Component Object Model (COM) and on Microsoft Transaction Server (an earlier release of a component-based transaction processing system). Component Services provides threading and security, transaction management, object pooling, queued components, and application administration and packaging.

To see the complete Help documentation for COM+ applications and Component Services, click **Start**, point to **All programs**, point to **Administrative Tools**, and then click **Component Services**. In Component Services, click **Help**, and then click **Help Topics**.

**Connection Manager**
Connection Manager provides support for local and remote connections to your service by using a network of access points, such as those available worldwide through Internet service providers (ISP). For more information, see Connection Manager Administration Kit.

**DHCP with DNS and Active Directory**
Dynamic Host Configuration protocol (DHCP) works with DNS and Active Directory on Internet protocol (IP) networks, helping to free you from assigning and tracking static IP addresses. DHCP dynamically assigns IP addresses to computers or other resources that are connected to an IP network. For more information, see Network Services.

**Disk Management**
Disk Management is a graphical tool for managing disk storage that includes such features as:

- Support for dynamic volumes, working outside the restriction of four partitions per disk.
- Online disk management (fewer restarts).
- Local and remote drive management.
- Volume Mount Points, which you can use to connect, or mount, a local drive at any empty folder on a local NTFS-formatted volume.

For more information, see Disk Management.

**Disk quota support**
You can use disk quotas on volumes that are formatted with the NTFS file system to monitor and limit the amount of disk space that is available to individual users. You can define the responses that result when users exceed your specified thresholds. For more information, see Disk Quotas.

**E-mail services (POP3, SMTP)**
The POP3 (Post Office protocol 3) service provides e-mail transfer and retrieval services. Administrators can use the POP3 service to store and manage e-mail accounts on the mail server. Simple Mail Transfer protocol (SMTP) supports the transfer of e-mail between servers. For more information, see POP3 Service and Simple Mail Transfer Protocol (SMTP) service.

**Encrypting File System**
Encrypting File System (EFS) complements other access controls and provides an additional level of protection for your data. EFS runs as an integrated system service, making it easy to manage, difficult to attack, and transparent to the user. For more information, see Encrypting File System.

**Group Policy (part of Active Directory)**
You can use policy to define the settings and allowed actions for users and computers. In contrast with local policy, you can use Group Policy to set policies that apply across a given site, domain, or organizational unit in Active Directory. Policy-based management simplifies such tasks as system update operation, application installation, user profiles, and desktop-system lockdown. For more information, see Group Policy (pre-GPMC).

**Indexing Service**
Indexing Service provides a fast, easy, and secure way for users to search for information locally or on the network. Users can search in files in different formats and languages, either through the **Search** command on the **Start** menu or through Hypertext Markup Language (HTML) pages that they view in a browser.

**Internet Authentication Service**
Internet Authentication Service (IAS) provides a central point for managing authentication, authorization, accounting, and auditing of dial-up or virtual private network (VPN) users. IAS uses the Internet Engineering Task Force (IETF) protocol called Remote Authentication Dial-In User Service (RADIUS). For more information, see Internet Authentication Service.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition. In Windows Server 2003, Standard Edition, you can configure IAS with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. For more information about these limits, see Internet Authentication Service.

**Internet Connection Sharing**
With the Internet Connection Sharing (ICS) feature of Network Connections, you can connect your home network or small office network to the Internet. For example, you might have a home network that connects to the Internet through a dial-up connection. By enabling Internet Connection Sharing on the computer that uses the dial-up connection, you can provide network address translation, addressing, and name resolution services for all the computers on your network. For more information, see Internet Connection Sharing and network address translation.

Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Internet Information Services 6.0**
Internet Information Services (IIS) 6.0 is a full-featured Web server that provides the foundation for the Windows Server 2003 family and existing Web applications and Web services. IIS 6.0 offers dedicated application mode, which runs all application code in an isolated environment. IIS 6.0 also supports Web gardens, in which a set of equivalent processes on a computer each receive a share of the requests that are normally served by a single process, achieving better multiprocessor scalability.

**Note**

- By default, IIS is not installed with new installations of Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. You can add it by using the Configure Your Server Wizard or by using Add or Remove programs.

**Internet protocol security support**
You can use Internet protocol security (IPSec) to secure communications within an intranet and to create secure virtual private network (VPN) solutions across the Internet. IPSec was designed by the Internet Engineering Task Force (IETF), and it is an industry standard for encrypting TCP/IP traffic. For more information, see Internet Protocol Security (IPSec).

**Kerberos V5 protocol support**
Kerberos V5 is a mature, industry-standard network authentication protocol. With Kerberos V5 support, a fast, single logon process gives users the access they need to enterprise resources, as well as to other environments that support this protocol. Support for Kerberos V5 includes additional benefits, such as mutual authentication (client and server must both provide authentication) and delegated authentication (the user's credentials are tracked end to end). For more information, see Kerberos V5 authentication.

**Layer Two Tunneling protocol support**
Layer Two Tunneling protocol (L2TP) is a more secure version of Point-to-Point Tunneling protocol (PPTP), and it is used for tunneling, address assignment, and authentication. For more information, see Layer Two Tunneling Protocol.

**Lightweight Directory Access protocol support**
Lightweight Directory Access protocol (LDAP), an industry standard, is the primary access protocol for Active Directory. LDAP version 3 was defined by the Internet Engineering Task Force (IETF). For more information, see Directory access protocol.

**Message Queuing**
The Message Queuing feature helps developers build and deploy applications that run more reliably over networks, including the Internet. These applications can interoperate with applications running on different platforms, such as mainframe computers and UNIX-based systems. For more information, see Using Message Queuing.

**Microsoft Management Console**
You can use Microsoft Management Console (MMC) to arrange administrative tools and processes within a single interface. You can also delegate tasks to specific users by creating preconfigured MMC consoles for them. The consoles provide the users with the tools that you select. For more information, see Microsoft Management Console.

**Network address translation**
Network address translation (NAT) hides internally managed IP addresses from external networks by translating private internal addresses to public external addresses. This reduces IP address registration costs by letting you use private IP addresses internally, with translation to a small number of registered IP addresses externally. It also hides the internal network structure, reducing the risk of attacks against internal systems. For more information, see Understanding Network Address Translation.

**Network Load Balancing clusters**
Previously known as Windows NT Load Balancing Service (WLBS), Network Load Balancing distributes incoming TCP/IP traffic among multiple servers. Your clustered applications, especially Web server applications, can handle more traffic and provide higher availability and faster response times. For more information, see Network Load Balancing Clusters.

**Operating system migration, support, and integration**
The Windows Server 2003 family of products integrates seamlessly with existing systems, and it contains support for earlier Windows operating systems, as well as other popular operating systems. The following support is included:

- Interoperability with Windows NT Server 3.51 and 4.0.

- Support for clients that run a variety of operating systems, including Windows 3.*x*, Windows 95, Windows 98, Windows 2000, and Windows NT Workstation 4.0.

- UNIX interoperability, provided through an add-on pack called Windows Services for UNIX. Telnet services (for remote access and administration) are included in the Windows Server 2003 family, as well as in the add-on pack.

- Mainframe and midrange connectivity, using S/390 and AS/400 transaction and queuing gateways through Host Integration Server 2000.

- File Server for Macintosh, which allows Macintosh clients to use the TCP/IP protocol (AFP over IP) to share files and to access shares on a server running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. For more information, see Services for Macintosh.

  This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Plug and Play**
With Plug and Play, a combination of hardware and software support, the server can recognize and adapt to hardware configuration changes automatically, without your intervention and without restarting. For more information, see Plug and Play overview.

**Public key infrastructure and smart card infrastructure**
Using Certificate Services and certificate management tools, you can deploy your own public key infrastructure (PKI). With a PKI, you can implement standards-based technologies, such as smart card logon capabilities, client authentication (through Secure Sockets Layer (SSL) and Transport Layer Security (TLS)), secure e-mail, digital signatures, and secure connectivity (using Internet protocol security (IPSec)). Using Certificate Services, you can set up and manage certification authorities (CAs) that issue and revoke X.509 v3 certificates. This means that you do not have to depend on commercial client authentication services, although you can integrate commercial client authentication into your PKI if you choose. For more information, see Certificate Services and Smart Cards.

**Quality of Service**
Quality of Service (QoS)-based services and protocols provide a guaranteed, end-to-end, express delivery system for information across the network. For more information, see Quality of Service (QoS).

**Recovery Console**
With Recovery Console, you can start a command-line console on a system on which a software problem (such as a problem with drivers or files) is preventing the system from starting. From Recovery Console, you can use basic commands to try to recover the system. For more information, see Recovery Console overview.

**Remote Assistance**
You can use Remote Assistance to remotely administer a computer. If you have an invitation, Remote Assistance is a convenient way for you to connect to a remote computer from a computer running Windows XP or any product in the Windows Server 2003 family. After you are connected, you can view the remote computer's screen and chat in real time. If the person requesting assistance allows you to, you can even use the mouse and keyboard to work on the remote computer. For more information, see Windows interface administrative tool reference A-Z: Remote Assistance.

This feature is not available on the Itanium-based versions of the Windows operating systems.

**Remote Desktop for Administration**
With Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode), you can administer a computer from virtually any computer on your network. Based on Terminal Services technology, Remote Desktop for Administration is specifically designed for server management. For more information about this feature, see Remote Desktop for Administration.

**Remote Installation Services**
With Remote Installation Services (RIS), you can create installation images of operating systems or even of complete computer configurations, including desktop settings and applications. You can then make these images available to users at client computers. The client computers must support remote booting with the Pre-Boot eXecution Environment (PXE) ROM, or else they must be started with a remote-startup floppy disk. For more information, see Remote Installation Services.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Remote Storage**
Remote Storage uses criteria that you specify to automatically copy little-used files to removable media. If hard-disk space drops below specified levels, Remote Storage removes the (cached) file content from the disk. If the file is needed later, the content is automatically recalled from storage. For more information, see Remote Storage.

Remote Storage is not available on Windows Server 2003, Web Edition or on Windows Server 2003, Standard Edition. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

**Removable Storage**
Removable Storage makes it easy to track your removable storage media (tapes and optical discs) and to manage the hardware libraries, such as changers and jukeboxes, that contain them. Because removable optical discs and tapes are less

expensive per megabyte (MB) than hard disks, Removable Storage and Remote Storage can decrease your costs. For more information, see Removable Storage.

**Routing and Remote Access**
Routing and Remote Access replaces the Routing and Remote Access Service (RRAS) and Remote Access Service (RAS) features from Windows NT 4.0. Routing and Remote Access is a single, integrated service that terminates connections from either dial-up or virtual private network (VPN) clients or that provides routing (IP, IPX, and Services for Macintosh), or both. With Routing and Remote Access, your server can function as a remote access server, a VPN server, a gateway, or a branch-office router. For more information, see Routing and Remote Access.

**Safe Mode**
With Safe Mode, you can start the Windows operating system with a minimal set of drivers and services and then view a log showing the sequence of events at startup. By using Safe Mode, you can diagnose problems with drivers and other components that might be preventing normal startup. For more information, see Startup options.

**Security Configuration Wizard**
The Security Configuration Wizard reduces the attack surface of computers that are running Windows Server 2003 with Service Pack 1 (SP1). The wizard asks the user a series of questions designed to determine the functional requirements of the server. Any functionality that is not required by the roles being performed by the server is then disabled. In addition to being a fundamental security best practice, reducing the attack surface increases the diversity of your Windows landscape, and reduces the number of systems that need to be immediately updated if a security issue arises. For more information, see Windows Server TechCenter.

**Server clusters (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition only)**
Server clusters provide high availability, scalability, and manageability for important resources and applications. Multiple servers (nodes) in a cluster remain in constant communication. If one of the nodes in a cluster is unavailable as a result of failure or maintenance, another node immediately begins providing service (a process known as failover). Users who access the cluster are constantly connected to server-based resources.

With Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, you can configure server clusters in one of three available cluster models, depending on your requirements. For more information, see Server Clusters.

**Smart card infrastructure**
Using Certificate Services and certificate management tools, you can deploy your own public key infrastructure (PKI). With a PKI, you can implement standards-based technologies, such as smart card logon capabilities, client authentication (through Secure Sockets Layer (SSL) and Transport Layer Security (TLS)), secure e-mail, digital signatures, and secure connectivity (using Internet protocol security (IPSec)). For more information, see Certificate Services and Smart Cards.

**Software restriction policies**
With software restriction policies, you can protect your computer environment from untrusted code by identifying and specifying which applications are allowed to run. For more information, see Software Restriction Policies.

**TAPI 3.1**
TAPI 3.1 unifies Internet protocol (IP) and traditional telephony to enable developers to create computer telephony applications that work as effectively over the Internet or an intranet as they do over the traditional telephone network. For more information, see Telephony.

**Terminal Server**
By using Terminal Server, a user can access programs running on the server from a variety of older devices. For example, a user can access a virtual Windows XP Professional desktop and x86-based Windows applications from hardware that cannot run the software locally. Terminal Server provides this capability for both Windows client devices and other client devices. (Other devices require add-on software by Citrix Systems.) For a more detailed description, see Terminal Server features.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition. Note that Remote Desktop for Administration is available on Windows Server 2003, Web Edition.

**Universal Description, Discovery, and Integration Services**
Universal Description, Discovery, and Integration (UDDI) is an industry specification for publishing and locating information about Web services. Some products in the Windows Server 2003 family include UDDI Services, a Web service that provides UDDI capabilities for use within an enterprise or across organizations. For more information, see UDDI Services overview.

UDDI Services is not included with Windows Server 2003, Web Edition. In addition, Windows Server 2003, Standard Edition, supports only stand-alone installations of UDDI Services. Distributed installation support is available with Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. In a stand-alone installation of UDDI Services, both the UDDI Web server component and the UDDI database component are installed onto a single server. In a distributed

installation, UDDI components are distributed across multiple servers.

For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

**Virtual private networking**
You can give users ready access to your organization's network even when they are out of the office--and reduce the cost of this access--by implementing a virtual private network (VPN). The VPN connection creates a secure tunnel across the Internet into the private network.

There are two types of VPN technology in the Windows Server 2003 family:

- Point-to-Point Tunneling protocol (PPTP), which employs user-level Point-to-Point protocol (PPP) authentication methods and Microsoft Point-to-Point Encryption (MPPE) for data encryption.

- Layer Two Tunneling protocol (L2TP) with Internet protocol security (IPSec). L2TP employs user-level PPP authentication methods and computer-level certificates with IPSec for data encryption.

On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

For more information about virtual private networking, see Virtual Private Networks.

**Windows Firewall**
Windows Firewall is a host firewall technology. As a host firewall, Windows Firewall runs on each of your clients and servers. It provides protection from network attacks that pass through your perimeter network or originate inside your organization, such as Trojan horse attacks, port scanning attacks, and worms. Like many firewall technologies, Windows Firewall is a stateful firewall. As such, Windows Firewall inspects and filters all Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) traffic. Unsolicited incoming traffic is dropped unless it is a response to a request by the host (solicited traffic), or it is specifically allowed (excepted traffic). You can specify excepted traffic according to port number, application name, or service name by configuring Windows Firewall settings. With the exception of some Internet Control Message Protocol (ICMP) messages, Windows Firewall allows all outgoing traffic.

Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

For more information, see Windows Server TechCenter.

**Windows Media Services**
Windows Media Services provides support for the distribution of streaming audio and video over corporate intranets and the internet. In Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition, Windows Media Services delivers advanced streaming functionality, such as multicasting, wireless network support, internet authentication, server plug-ins, and Cache/proxy APIs.

Windows Media Services is not included with Windows Server 2003, Web Edition, or the Itanium-based versions of Windows Server 2003.

**Windows Script Host**
By using Windows Script Host (WSH), you can automate such actions as creating a shortcut and connecting to and disconnecting from a network server. WSH is language independent: you can write scripts in common scripting languages, such as Microsoft Visual Basic, Scripting Edition, and JScript. For more information, see Windows Script Host.

**Windows Update**
Windows Update is an online extension of Windows that detects and replaces outdated Windows system files with the most recent versions. Windows Update can significantly increase computer system stability over a long period. It can also reduce the load on administrators and support staff charged with maintaining a productive operating environment. Windows Update requires an internet connection. For more information, see Windows Update.

**Winsock Direct**
Winsock Direct, now available on all server editions, enables applications that use Winsock to perform faster and with less overhead when they communicate across a system area network (SAN). If there is a SAN in place, Winsock Direct has the effect of streamlining communications between distributed components.

# Overview of Features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Overview of features**
This section provides information about new and improved features in Microsoft® Windows Server 2003 family operating systems. For links to more information about the features in this release, see New Features.

This section covers:

- Features for Management, Security, and Best Performance
- Features for Directory, File, Print, and Collaboration Services
- Features for Internet, Application, and Networking Services

# Features for Management, Security, and Best Performance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Features for management, security, and best performance**
The features in the Windows Server 2003 family ensure that data access, storage, and exchange comply with your needs while providing strong security and performance.

For links to more information about the features in this release, see New Features.

This section covers:

- Server reliability
- Server availability
- Server scalability
- Server manageability
- Performance and tuning features
- Authentication and smart card support
- Additional security features
- Remote management
- Maintenance and product updates
- Internationalization features

# Server reliability

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Server reliability**

This topic contains a brief overview of the features that support server reliability. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

Reliability is the likelihood of a computer system or device continuing to function over a given period of time and under specified conditions. For descriptions of features that are related to availability, which is closely related to reliability, see Server availability.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT) that help provide increased levels of server reliability:

**Improved memory management**

Improvements to memory management in both Windows 2000 and the Windows Server 2003 family mean greater speed, reliability, and flexibility for your servers.

**Robust system architecture**

A robust system provides you with greater reliability, even if one application or service encounters problems. For example, with better handling of nonresponsive applications, you can move, resize, minimize, and close the window of a nonresponsive application. Also, in the event that an updated driver does not function properly, you can restore the previous drivers. The system's support infrastructure ensures that applications that worked on previous Windows operating systems will continue to work on the Windows Server 2003 family of products.

**Diagnostic tools**

You can monitor system states and prevent problems by using the improved diagnostic tools that are included with this release. For more information, see Monitoring and Status Tools.

**Safe Mode start**

With Safe Mode, you can start the operating system with a minimal set of drivers and services and then view a log showing the sequence of events at startup. By using Safe Mode, you can diagnose problems with drivers and other components that might be preventing normal startup. For more information, see Disaster Recovery.

**Recovery Console**

With Recovery Console, you can start a command-line console on a system on which a software problem (such as a problem with drivers or files) is preventing the system from starting. From Recovery Console, you can use basic commands to help recover the system. For more information, see Recovery Console overview.

**Windows File Protection**

Windows File Protection prevents the replacement of protected system files, such as .sys, .dll, .ocx, .ttf, .fon, and .exe files. Windows File Protection runs in the background and prevents other programs from changing these files, which are needed by the operating system. For more information, see Windows File Protection.

**Enhanced Backup utility**

You can back up data to a wide variety of storage media, such as tape drives, external hard disks, and Zip disks. For more information, see Backup.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of server reliability:

**Automated System Recovery**

Automated System Recovery (ASR) helps you recover your system in the event that a hard disk fails or the system is seriously damaged. You can easily prepare the necessary backup materials for ASR through wizards that are part of Backup. By using ASR in combination with standard backups (data and application backups), you can restore a system to the state it was in when you backed it up. For more information about ASR, see Automated System Recovery (ASR) overview. For more information about other system recovery options, see Disaster Recovery.

**Compatibility Mode**

A new Compatibility Mode feature ensures out-of-box compatibility for many popular applications. Compatibility Mode technology provides an environment that more closely reflects the behavior of Windows 95, Windows 98, Windows NT 4.0, or Windows 2000 operating systems. These modes resolve several of the most common issues that prevent older applications from working correctly. Applications that experience problems after migration may benefit from being started in one of these compatibility environments. Advanced users can also take advantage of this technology to create solutions for their own applications.

# Server availability

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Server availability**

This topic contains a brief overview of the features that support server availability. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

Availability is a level of service provided by applications, services, or systems. Highly available systems have minimal downtime, whether planned or unplanned. The Windows Server 2003 family supports high levels of server availability for your critical business solutions. This operating system also gives you clustering, advanced fault tolerance, and file system recoverability features.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT) that help provide increased levels of server availability:

**Server clusters (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition only)**

Server clusters provide high availability, scalability, and manageability for important resources and applications. Multiple servers (nodes) in a cluster remain in constant communication. If one of the nodes in a cluster is unavailable as a result of failure or maintenance, another node immediately begins providing service (a process known as failover). Users who access the cluster are constantly connected to server-based resources. For more information, see Windows Clustering.

**Network Load Balancing**

Network Load Balancing enhances the availability and scalability of Internet server programs on mission-critical servers. The two principal functions of Network Load Balancing are to provide high availability for Web server programs and to scale server performance. By combining the resources of two or more computers into a single cluster, Network Load Balancing delivers reliability and performance by distributing the incoming network traffic. For more information, see Network Load Balancing Overview.

**Fewer server restarts**

Configuring hardware and software is easier, because you can perform many activities without restarting the server. These activities include, but are not limited to:

- Extending a storage volume
- Configuring network protocols
- Managing storage dynamically (Dynamic Volume Management)
- Reconfiguring settings on Peripheral Component Interconnect (PCI) and other Plug and Play hardware

**Plug and Play**

With Plug and Play, a combination of hardware and software support, the server can recognize and adapt to hardware configuration changes automatically, without your intervention and without restarting. With Plug and Play, planned system restarts are reduced by more than 90 percent.

**Start from mirrored volumes**

With appropriate preparation, you can start your server from a redundant copy of data on a mirrored volume, which increases system availability during server recovery or planned maintenance. For more information, see Using mirrored volumes.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of server availability:

**User State Migration Tool**

The User State Migration Tool (USMT) aids deployment by capturing and restoring user settings, files, and documents. Users

do not have to reconfigure desktop settings for such things as e-mail servers, proxy servers, desktop color schemes, and desktop wallpaper.

**Emergency Management Services**

With Emergency Management Services, combined with the appropriate hardware, you can perform remote management and system recovery tasks, even when the server is not available through the standard remote administration tools and mechanisms. For more information, see Emergency Management Services.

**Storage area network and network-attached storage support**

Storage area network (SAN) and network-attached storage (NAS) support in the Windows Server 2003 family has a number of new system enhancements to increase server availability. These improvements include fault tolerant, network-attached scenarios, such as connecting to SAN and NAS servers. When connecting to SANs, the Windows Server 2003 family supports multipath failover, which enables redundant paths from the host server (running Windows 2000 Server, Windows 2000 Advanced Server, Windows 2000 Datacenter Server, or any product in the Windows Server 2003 family) to the SAN volume. The Windows Server 2003 family also supports connecting to NAS and being used as a NAS.

**Network Load Balancing enhancements**

Several improvements have been made to Network Load Balancing in this release:

- Network Load Balancing can now be bound to multiple network adapters, so that you can configure multiple independent clusters on each host. For more information about virtual clusters, see Virtual clusters.

- Network Load Balancing uses Internet Group Management Protocol (IGMP) support for limiting switch flooding, so that traffic intended for a Network Load Balancing cluster passes through only those ports that serve the cluster hosts and not through all switch ports.

- With Network Load Balancing Manager, you can create new Network Load Balancing clusters, and you can configure and manage clusters and all the cluster's hosts from a single remote or local computer.

# Server scalability

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Server scalability**

This topic contains a brief overview of the features that support server scalability. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

Scalability is the measure of how well a computer, service, or application can grow to meet increasing performance demands. For server clusters, it is the ability to incrementally add one or more systems to an existing cluster when the overall load of the cluster exceeds its capabilities. Products in the Windows Server 2003 family scale from small workgroups to enterprise data center deployments, and they support up to 64 processors and advanced I/O. The Windows Server 2003 family also integrates network load balancing and multiprocessor optimizations for your business applications.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of server scalability:

**Physical Address Extension (PAE)**

To support the addition of Data Execution Prevention (DEP), which is also known as no-execute page protection, the following changes have been made:

- PAE is automatically enabled on computers running Windows Server 2003 with Service Pack 1 and Windows XP with Service Pack 2 when DEP is also enabled on a computer with a processor that supports the no-execute page protection feature.

- When PAE mode is enabled on computers running Windows Server 2003, Standard Edition with Service Pack 1 and Windows XP with Service Pack 2, physical address space is limited to 4 gigabytes (GB). Limiting physical address space to 4 GB helps prevent driver compatibility issues with PAE mode.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT) that help provide increased levels of server scalability:

**Hardware scalability**

By choosing from products in the Windows Server 2003 family, you can take advantage of the growing number of competitively priced multiprocessor computers.

**I2O support**

I2O (also called Intelligent Input/Output) architecture provides for higher I/O performance on your servers by offloading certain I/O operations to a secondary processor. I2O improves I/O performance in high-bandwidth applications, such as networked video, groupware, and client/server processing.

**Symmetric multiprocessing enhancements**

The Windows Server 2003 family supports single or multiple CPUs that conform to the symmetric multiprocessing (SMP) standard. Using SMP, the operating system can run threads on any available processor, which makes it possible for applications to use multiple processors when additional processing power is required to increase the capability of a system. New features include SMP locking performance, improved registry performance, and increased Terminal server sessions.

**Network Load Balancing**

Previously known as Windows NT Load Balancing Service (WLBS), Network Load Balancing distributes incoming TCP/IP traffic between multiple servers. Your clustered applications, especially Web server applications, can handle more traffic and provide higher availability and faster response times.

**Server clusters (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition only)**

Server clusters provide high availability, scalability, and manageability for important resources and applications. Multiple servers (nodes) in a cluster remain in constant communication. If one of the nodes in the cluster is unavailable due to failure

or maintenance, another node immediately begins providing service (a process known as failover). Users who access the cluster are constantly connected to server-based resources. For more information, see Windows Clustering.

**Enterprise Memory Architecture (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, not including 64-bit versions)**

With Enterprise Memory Architecture, you can run applications that take advantage of large amounts of physical memory on Windows Server 2003, Enterprise Edition. Using applications that are written with the Address Windowing Extensions (AWE) API, you can map more physical memory into the applications' virtual address memory space for improved performance. For systems with 2 GB to 4 GB of memory, you can also use application memory tuning, also known as 4-gigabyte tuning (4GT). This enables you to provide up to 3 GB of your virtual address memory space to applications (by providing less memory to the operating system).

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of server scalability:

**Internet Information Services 6.0**

Internet Information Services (IIS) 6.0 is a full-featured Web server that provides the foundation for the Windows Server 2003 family and existing Web applications and Web services. IIS 6.0 offers dedicated application mode, which runs all application code in an isolated environment. IIS 6.0 also supports Web gardens, in which equivalent processes on a computer each receive a share of the requests that are normally served by a single process, achieving better multiprocessor scalability.

**Note**

- By default, IIS is not installed with new installations of Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. You can add it by using the Configure Your server Wizard or by using Add or Remove Programs.

**Network Load Balancing enhancements**

Several improvements have been made to Network Load Balancing in this release:

- Network Load Balancing can now be bound to multiple network adapters, so that you can configure multiple independent clusters on each host. For more information about virtual clusters, see Virtual clusters.

- Network Load Balancing uses Internet Group Management Protocol (IGMP) support for limiting switch flooding, so that traffic intended for a Network Load Balancing cluster passes through only those ports that serve the cluster hosts and not through all switch ports.

- With Network Load Balancing Manager, you can create new Network Load Balancing clusters, and you can configure and manage clusters and all the cluster's hosts from a single remote or local computer.

# Server manageability

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Server manageability**

This topic contains a brief overview of the features that support server manageability. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

Improved manageability in the Windows Server 2003 family makes it easy to deploy and maintain Windows applications and systems.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT) that help provide increased levels of server manageability:

### IntelliMirror

To help reduce costs, administrators need the highest levels of control over portable and desktop systems. IntelliMirror provides this control on client systems running Windows 2000 Professional or Windows XP Professional. You can use IntelliMirror to define policy settings based on business roles, group memberships, and locations. With these policy settings, Windows 2000 Professional desktops and Windows XP Professional desktops are automatically reconfigured to meet a specific user's requirements each time that user logs on to the network, regardless of where the user logs on. For more information about IntelliMirror, see IntelliMirror.

### Windows Management Instrumentation

Windows Management Instrumentation (WMI) is a scalable management infrastructure that is based on the Web-Based Enterprise Management (WBEM) initiative. Using WMI, which includes command-line and scripting capabilities, you can monitor, track, and control system events that are related to software applications, hardware components, and networks. WMI includes a uniform scripting application programming interface (API) that defines all managed objects under a common object framework based on the Common Information Model (CIM). WMI makes it possible for applications and scripts to discover what information is available for a system by enumerating the classes that are available. WMI can submit queries that filter requests for very specific information, and it can subscribe to WMI events based on your particular interests, rather than being limited to events that are predefined by the original developers. For more information about WMI, see WMI Overview.

### Active Directory Migration Tool

The Active Directory Migration Tool (ADMT) can help you migrate user accounts, groups, and computer accounts from Windows NT 4.0 domains to Active Directory domains (that is, domains in which the domain controllers run Windows 2000 or Windows Server 2003). For more information, see Active Directory support tools and *Designing and Deploying Directory and Security Services* at the Microsoft Windows Server System Web site.

### Remote Installation Services

With Remote Installation Services (RIS), you can create installation images of operating systems or even of complete computer configurations, including desktop settings and applications. You can then make these images available to users at client computers. The client computers must support remote booting with the Pre-Boot eXecution Environment (PXE) ROM, or else they must be started with a remote-startup floppy disk. For more information, see Remote Installation Services.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

### Manage Your Server

Manage Your Server provides a central location for you to set up various server roles and perform daily administrative tasks. For more information, see Configuring Roles for Your Server.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of server manageability:

### Remote Desktop for Administration

With Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode), you can administer a computer from virtually any computer on your network. Based on Terminal Services technology, Remote

Desktop for Administration is specifically designed for server management. For more information about this feature, see Remote Desktop for Administration.

**Remotely administered server support**

Remotely administered server support provides the ability to install and manage a computer that does not have a monitor, VGA display adaptor, keyboard, or mouse. This feature also includes Emergency Management Services, which provides a mechanism to manage the remotely administered server when the operating system is not functional, such as when the computer is restarted, when the server is unavailable on a network, or during use of Remote Installation Services (RIS).

**User State Migration Tool**

The User State Migration Tool (USMT) aids deployment by capturing and restoring user settings, files, and documents. Users do not have to reconfigure desktop settings for such things as e-mail servers, proxy servers, desktop color schemes, and desktop wallpaper.

**Emergency Management Services**

With Emergency Management Services, combined with the appropriate hardware, you can perform remote management and system recovery tasks, even when the server is not available through the standard remote administration tools and mechanisms. For more information, see Emergency Management Services.

**Resultant Set of Policy**

You can use Resultant Set of Policy (RSoP) to simulate and test policy settings that are applied to computers or users through Group Policy. RSoP is a query engine that polls existing policies--and also planned policies--and then reports the results of those queries. It polls existing policies based on site, domain, domain controller, and organizational unit. RSoP gathers this information from Windows Management Instrumentation (WMI). For more information, see Resultant Set of Policy.

**Windows Management Instrumentation improvements**

Windows Management Instrumentation (WMI) filtering enhances the Group Policy infrastructure by helping you to determine the effect of a Group Policy object (GPO).

**Remote Installation Services improvements**

Enhancements to Remote Installation Services (RIS) include support for both Windows Server 2003 family and Windows XP product installations, more control over answer file processing for an RIS installation, and access to network files in recovery modes.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Authorization Manager**

Authorization Manager is a new tool for authorization-related tasks. It is helpful for application developers who use authorization services in their applications, as well as for administrators who define groups and assign security principals to perform roles and tasks requiring appropriate user rights and permissions. For more information, see Authorization Manager.

# Performance and tuning features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance and tuning features**

This topic contains a brief overview of the performance and tuning features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

New features in the Windows Server 2003 family provide for better performance and the ability to tune your server to your needs and environment.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of server performance:

**Winsock Direct**

Winsock Direct enables applications that use Winsock to perform faster and with less CPU overhead when they communicate across a system area network (SAN). Winsock Direct has the effect of streamlining communications between distributed components, if there is a SAN in place.

**I2O support**

I2O (also called Intelligent Input/Output) architecture allows for higher I/O performance on your servers by offloading certain I/O operations to a secondary processor. I2O improves I/O performance in high-bandwidth applications, such as networked video, groupware, and client/server processing.

**CPU throttling for Web applications or sites**

CPU throttling limits the amount of CPU time a Web application or site can use, which ensures that processor time is available to other Web sites or to non-Web applications.

**Process Accounting for Web applications or sites**

With Process Accounting, you can obtain information about how Web sites use CPU resources. This information can be crucial for making decisions about changing or improving hardware or applications. It can also be important when monitoring or diagnosing problems with scripts or applications.

**Predictable, end-to-end Quality of Service**

Quality of Service (QoS)-based services and protocols provide a guaranteed, end-to-end, express delivery system for traffic that is generated by QoS-enabled programs across a network or across multiple disparate networks. For more information, see Quality of Service (QoS).

**Network Load Balancing**

Previously known as Windows NT Load Balancing Service (WLBS), Network Load Balancing distributes incoming TCP/IP traffic between multiple servers. Your clustered applications, especially Web server applications, can handle more traffic and provide higher availability and faster response times.

**New performance tools**

Several new performance tools are available to help you diagnose and resolve memory, registry, driver, and other system problems.

**Disk Defragmenter**

Disk Defragmenter enhancements include Defrag.exe, a new command-line tool. Both Disk Defragmenter and Defrag.exe can now defragment the master file table (MFT) on NTFS volumes. For more information, see Disk Defragmenter.

**Event tracing enhancements**

Event tracing provides a mechanism for managing data that is useful to performance monitors, capacity planning tools, and other applications that analyze information relating to system resource utilization. New command-line tools control event trace log scheduling, collection, and analysis on local and remote computers.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of server performance:

**Performance Options**

Performance Options is a tool that consolidates processor, memory, and virtual memory settings, so that you can quickly and easily configure a computer for best performance.

**New command-line utilities for System Monitor**

New command-line tools are provided to control performance counter and event trace log scheduling, as well as collection and analysis on local and remote computers without using System Monitor (Sysmon). These command-line tools include **logman**, **relog**, **tracerpt**, and **typeperf**. For more information, see Logman, Relog, Tracerpt, and Typeperf.

**System Monitor enhancements**

The Windows Server 2003 family supports viewing data from multiple log files simultaneously and from data stored in a SQL database that has been collected using the Performance Logs and Alerts service. Selected data from a performance log file or SQL database can be saved to a new file for analysis at a later time. Display enhancements make it easy to select multiple counter objects and to display the data properties page for a selected counter directly from the list window.

**Performance Logs and Alerts improvements**

The Windows Server 2003 family supports log files greater than 1 GB in size and, with the new log file format, performance data can now be appended to an existing log file. You can log data directly to a SQL database through Open Database Connectivity (ODBC) data connections.

# Authentication and smart card support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication and smart card support**

This topic contains a brief overview of the authentication and smart card support features in this release. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family provides a wide variety of authentication technologies, including technologies for using smart cards. For more information about new security features, see New features in security.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for authentication and use of smart cards:

**Full support for the Kerberos V5 protocol**

With Kerberos V5 support, a fast, single logon process gives users the access they need to enterprise resources running on Windows 2000 or the Windows Server 2003 family of products. Support for Kerberos V5 includes additional benefits, such as mutual authentication (the client and server must both provide authentication) and delegated authentication (the user's credentials are tracked end to end). For more information, see Kerberos V5 authentication.

**Public key infrastructure, Certificate Services, and smart cards**

By using Certificate Services and certificate management tools, you can deploy your own public key infrastructure (PKI). With a PKI, you can implement standards-based technologies, such as smart card logon capabilities, client authentication (through Secure Sockets Layer (SSL) and Transport Layer Security (TSL)), secure e-mail, digital signatures, and secure connectivity (through Internet Protocol security (IPSec)). Using Certificate Services, you can set up and manage certification authorities (CAs) that issue and revoke X.509 v3 certificates. This means that you do not have to depend on commercial client authentication services, although you can integrate commercial client authentication into your public key infrastructure if you choose.

**Virtual private networking**

You can give users ready access to your organization's network even when they are out of the office, and reduce the cost of such access, by implementing a virtual private network (VPN). The VPN connection creates a secure tunnel across the Internet into the private network.

There are two types of VPN technology in the Windows Server 2003 family:

- Point-to-Point Tunneling Protocol (PPTP), which employs user-level Point-to-Point Protocol (PPP) authentication methods and Microsoft Point-to-Point Encryption (MPPE) for data encryption.
- Layer Two Tunneling Protocol (L2TP) with Internet Protocol security (IPSec). L2TP employs user-level PPP authentication methods and computer-level certificates with IPSec for data encryption.

On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

**Flexible, secure authentication and authorization**

Flexible and secure authentication and authorization services provide protection for data while minimizing barriers to doing business over the Internet. Active Directory supports multiple authentication protocols, such as Kerberos V5, Secure Sockets Layer (SSL) v3, and Transport Layer Security (TSL) using X.509 v3 certificates, and security groups that span domains efficiently.

**Internet Authentication Service**

Internet Authentication Service (IAS) provides you with a central point for managing authentication, authorization, accounting, and auditing of dial-up or virtual private network (VPN) users. IAS uses the Internet Engineering Task Force (IETF) protocol called Remote Authentication Dial-In User Service (RADIUS).

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition. In Windows Server 2003, Standard Edition, you can configure IAS with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. For more information about these limits, see Internet Authentication Service.

**Routing and Remote Access**

Routing and Remote Access replaces the Routing and Remote Access Service (RRAS) and Remote Access Service (RAS) features in Windows NT 4.0. Routing and Remote Access is a single, integrated service that terminates connections from either dial-up or virtual private network (VPN) clients or that provides routing (IP, IPX, and AppleTalk), or both. With Routing and Remote Access, your server can function as a remote access server, a VPN server, a gateway, or a branch-office router. For more information, see Routing and Remote Access.

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for authentication and use of smart cards:

**Stored User Names and Passwords**

Stored User Names and Passwords stores user credentials, including passwords and X.509 v3 certificates, so that they can be associated with remote computers and automatically reused. This provides a consistent, single sign-on experience for users, including roaming users.

**Smart card access through Terminal Server**

With Terminal Server, you can log on from a Remote Desktop Connection to a Windows Server 2003 domain by using trusted X.509 v3 certificates that are stored on a smart card. For example, you can use a smart card to log on to Active Directory on a terminal server.

**Subordinate certification authority improvements**

Subordinate certification authorities (CA) now support qualified subordination, which allows public key infrastructure (PKI) administrators to use qualified subordinate CAs for more precise security and administrative purposes than standard CAs, such as having a qualified subordinate CA only issue certificates to subjects in certain domains that can only be used by specific software applications. For more information, see Qualified subordination.

# Additional security features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Additional security features**

This topic contains a brief overview of the additional security features in the Windows Server 2003 family. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0, and New and updated features since Windows 2000.

For information about authentication and smart card support features, see Authentication and smart card support. For more information about new security features, see New features in security. For links to more information about the features in this release, see New Features.

The Windows Server 2003 family includes a variety of features for the creation of a strong, flexible security system, including file encryption and the security features that are built into Active Directory. For information about the kinds of authentication that are available, see Authentication and smart card support.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of support for security:

**Security Configuration Wizard**

The Security Configuration Wizard reduces the attack surface of computers that are running Windows Server 2003 with SP1. The wizard asks the user a series of questions designed to determine the functional requirements of the server. Any functionality that is not required by the roles being performed by the server is then disabled. In addition to being a fundamental security best practice, reducing the attack surface increases the diversity of your Windows landscape, and reduces the number of systems that need to be immediately updated if a security issue arises. For more information, see Windows Server TechCenter.

**Windows Firewall**

Windows Firewall is a host firewall technology. As a host firewall, Windows Firewall runs on each of your clients and servers. It provides protection from network attacks that pass through your perimeter network or originate inside your organization, such as Trojan horse attacks, port scanning attacks, and worms. Like many firewall technologies, Windows Firewall is a stateful firewall. As such, Windows Firewall inspects and filters all Internet Protocol version 4 (IPv4) and Internet Protocol version 6 (IPv6) traffic. Unsolicited incoming traffic is dropped unless it is a response to a request by the host (solicited traffic), or it is specifically allowed (excepted traffic). You can specify excepted traffic according to port number, application name, or service name by configuring Windows Firewall settings. With the exception of some Internet Control Message Protocol (ICMP) messages, Windows Firewall allows all outgoing traffic.

Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

For more information, see Windows Server TechCenter.

**Digital Identity Management Service (DIMS) and Credential Roaming**

DIMS and credential roaming make it possible for users who log onto any domain-joined computer running Windows Server 2003 with SP1 to seamlessly and silently have all of their certificates and private keys available for applications and services. Administrators can use Group Policy to enable credential roaming, thereby automatically synchronizing and replicating user certificates and private keys with the Active Directory user object. For more information, see Windows Server TechCenter.

**Windows Server 2003 Privacy Information**

Windows Server 2003 with SP1 includes Group Policy settings that were not available in the original release of Windows Server 2003. You can find new settings designed to help protect your privacy in Group Policy under a key called Internet Communication Management. The settings under the Internet Communication Management key are designed to help you control the way Windows components communicate with the Internet. One of the settings new to Windows Server 2003 with SP1 is Restrict Internet communication, which you can use to control multiple privacy-related settings simultaneously. For more information about privacy, see *Using Windows Server 2003 in a Managed Environment* at the Microsoft TechNet Web site.

**Enabling Authentication for Terminal Services connections**

With Windows Server 2003 with SP1, you can configure Terminal Services connections to use Transport Layer Security (TLS) for server authentication and encryption. TLS is often referred to as Secure Sockets Layer/Transport Layer Security (SSL/TLS).

By default, TLS is not enabled when SP1 is installed. For more information, see *Terminal Services Security* at the Microsoft Web site.

#### New and updated features since Windows NT 4.0

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for security:

**Encrypting File System**

Encrypting File System (EFS) complements other access controls and provides an added level of protection for your data. EFS runs as an integrated system service, making it easy for you to manage, difficult to attack, and transparent to the user. For more information, see Encrypting File System.

**Internet Protocol security**

You can use Internet Protocol security (IPSec) to secure communications within an intranet and to create secure virtual private network (VPN) solutions across the Internet. IPSec was designed by the Internet Engineering Task Force (IETF), and it is an industry standard for encrypting TCP/IP traffic. For more information, see Internet Protocol Security (IPSec).

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for security:

**TCP/UDP port ownership**

A new **netstat** command option displays the process that owns the Transmission Control Protocol/User Datagram Protocol (TCP/UDP) port. You can use this feature to configure secure servers, security audits, and performance improvements.

**Encrypting File System improvements**

Encrypting File System (EFS) has been improved in several ways. Stronger encryption algorithms are available with larger keys. Multiple users can be authorized to share encrypted files. Offline files can be encrypted through EFS, so that you can protect locally cached documents. For more information, see Encrypting File System.

**Software restriction policies**

With software restriction policies, you can protect your computer environment from untrusted code by identifying and specifying which applications are allowed to run. For more information, see Software Restriction Policies.

**Internet Protocol security monitoring improvements**

Internet Protocol security (IPSec) monitoring improvements include a Microsoft Management Console (MMC) snap-in that provides detailed information about IPSec policy configuration and active security states. This feature replaces the Ipsecmon.exe monitor program in Windows 2000. For more information, see Internet Protocol Security (IPSec).

# Remote management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote management**

This topic contains a brief overview of the remote management features available in the Windows Server 2003 family. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0, and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family includes a variety of remote management features. For detailed information on how to use these features, see Remote Administration.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of support for remote management:

### Remote Installation Services

Users can now use the Remote Installation Preparation (RIPrep) Wizard to install an x64-based server image.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for remote management:

### Microsoft Management Console

You can use Microsoft Management Console (MMC) to arrange the administrative tools and processes that you need within a single interface. You can also delegate tasks to specific users by creating preconfigured MMCs that contain the tools you select. For more information, see Microsoft Management Console.

### Scripting with Windows Script Host

By using Windows Script Host (WSH), you can automate such actions as creating a shortcut and connecting to and disconnecting from a network server. WSH is language independent. You can write scripts in common scripting languages, such as Microsoft Visual Basic®, Scripting Edition, (VBScript) and JScript. For more information, see Windows Script Host.

### Remote Installation Services

With Remote Installation Services (RIS), you can create installation images of operating systems or even of complete computer configurations, including desktop settings and applications. You can then make these images available to users at client computers. The client computers must support remote booting with the Pre-Boot eXecution Environment (PXE) ROM, or else they must be started with a remote-startup floppy disk. For more information, see Remote Installation Services.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for remote management:

### Remote Desktop for Administration

With Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode), you can administer a computer from virtually any computer on your network. Based on Terminal Services technology, Remote Desktop for Administration is specifically designed for server management. You can use Remote Desktop for Administration to log on to the server remotely as though you were logged on to it locally. Additionally, Remote Desktop for Administration now supports greater color depth and screen resolution. For more information about this feature, see Remote Desktop for Administration.

### Remote Assistance

You can use Remote Assistance to remotely administer a computer. If you have an invitation, Remote Assistance is a convenient way for you to connect to a remote computer from a computer running Windows XP or any product in the Windows Server 2003 family. After you are connected, you can view the remote computer's screen and chat in real time. If the person requesting assistance allows you to, you can even use the mouse and keyboard to work on the remote computer. For more information, see Windows interface administrative tool reference A-Z: Remote Assistance.

This feature is not available on the Itanium-based versions of the Windows operating systems.

**Web Interface for Remote Administration (Windows Server 2003, Web Edition only)**

On Windows Server 2003, Web Edition, the Web Interface for Remote Administration is a Hypertext Markup Language (HTML)-based application that is used to configure and manage the server from a remote client. Individual servers, entire server farms, and multiple sites per server can be managed from a single remote workstation.

The Web Interface for Remote Administration provides a simple means of performing common Web server configuration tasks, including:

- Creating and deleting Web sites
- Configuring network settings
- Managing local user accounts
- Restarting the Web server

**Remote Installation Services improvements**

Enhancements to Remote Installation Services (RIS) include support for both Windows Server 2003 family and Windows XP product installations, more control over answer file processing for an RIS installation, and access to network files in recovery modes.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Maintenance and product updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maintenance and product updates**

This topic contains a brief overview of the maintenance and product updates features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family offers several features that can help keep your system current with the latest system files and product updates.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help keep your system updated with the latest system files:

### Windows Update

Windows Update is an online extension of Windows that detects outdated Windows system files and replaces them with the most recent versions. Windows Update can significantly increase computer system stability over a long period. It can also reduce the workload on administrators and support staff who must maintain a productive operating environment. Windows Update requires an Internet connection. For more information, see Windows Update at the Microsoft Web site.

Windows Update includes Dynamic Update, which is available during Setup. If you have a working Internet connection on the computer on which you run Setup, you can use Dynamic Update to obtain the most up-to-date Setup files, including drivers and other files. For more information, see Using Dynamic Update for updated drivers and other setup files.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help keep your system updated with the latest system files:

### Windows Update enhancements

Windows Update now provides additional choices:

- With Windows Update Catalog, you can select updates that you plan to deploy later, which means you can control how and when the updates are deployed. For more information, see Windows Update Catalog at the Microsoft Web site.

- With Automatic Updates, which is built into Windows XP and products in the Windows Server 2003 family, the operating system can automatically download and install critical updates from the Windows Update site. For more information, see Automatic Updates.

- With Microsoft Windows Update Services, you can deploy a limited version of the Windows Update site inside your firewall. You can control how and when updates are deployed, and you can deliver updates to users through your intranet rather than having updates occur directly from the Internet. For more information, see Windows Update Services at the Microsoft Web site.

# Internationalization features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### Internationalization features

This topic contains a brief overview of the internationalization features in the Windows Server 2003 family of products. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

#### New and updated features since Windows NT 4.0

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for internationalization:

**Multilingual support**

The Windows Server 2003 family provides support for multiple languages on a single system. As a result of the system architecture, the operating system, utilities, and properly written applications can be translated and modified into local versions for hundreds of languages. Local administrators therefore do not need to be fluent in technical English.

**Multiregional support**

Support for additional locales and regional and language options is also included in this release, which makes it even easier to access relevant content.

#### New and updated features since Windows 2000

Many products in the Windows Server 2003 family offer the following improvements (in comparison to Windows 2000) that help provide increased support for internationalization. Some of these languages may not be available on certain products:

**New Phonetic Input Method Editor for Traditional Chinese**

The new Phonetic Input Method Editor (IME) is a new design, based on the latest state-of-the-art Chinese keyboard input technology. It is an update of the Microsoft Phonetic IME 98a CHT edition.

**Improved Japanese Input Method Editor**

The Japanese IME Version 8 receives alphabetical keyboard characters, converts them to Japanese characters, and then enters the result in the application. This new feature also supports the use of Japanese IME dictionaries over a network. IME saves user-defined words and conversion rules in a user dictionary, which can be edited on the user's local computer. (This dictionary was read-only in Windows 2000).

**Improved Korean Input Method Editor**

The Korean IME maps key sequences to Korean Jamo and then converts them into Korean syllables. The new Korean IME supports handwriting input for Hangul and Hanja.

**Improved Simplified Chinese Input Method Editor**

The MSPY3.0 IME provides an enlarged IME lexicon (approximately 100,000 words and phrases) and updated IME rules, an improved language model with higher IME accuracy and performance, and modeless typing (Chinese/English mixed input).

# Features for Directory, File, Print, and Collaboration Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Features for directory, file, print, and collaboration services**
The Windows Server 2003 family contains improved support for directory, file, print, and collaboration services. The topics in this section describe the features that support these server types.

Windows Server 2003, Web Edition, is not intended for use as a file or print server. Support for file and print services is limited on the Windows Server 2003, Web Edition, operating system.

For links to more information about the features in this release, see New Features.

This section covers:

- Features for Active Directory
- Features for collaboration
- Disk and file management features
- Printer and protocol support

# Features for Active Directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Features for Active Directory**

This topic contains a brief overview of the features of the Active Directory directory service in the Windows Server 2003 family. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0, and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features. For more information about Active Directory, see Active Directory. For a more detailed list of new Active Directory features, see New features for Active Directory.

Active Directory is an enterprise-class directory service that is scalable, built from the ground up using Internet-standard technologies, and fully integrated at the operating-system level. Active Directory simplifies administration and makes it easier for users to find resources. Active Directory provides a wide range of features and capabilities.

### Note

- Computers running the Windows Server 2003, Web Edition operating system cannot function as domain controllers. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of support for Active Directory:

### Improved replication and DNS diagnostic testing capabilities

Active Directory® has been updated to provide automatic directory service backup reminders, improved protection against replication errors, improvements to Install from Media (to facilitate adding new domain controllers that are DNS servers), improved DNS diagnostic testing capabilities, and access to a new platform for running domain controllers in virtual machines under Microsoft® Virtual Server 2005. For more information about these and other new Active Directory features and enhancements, see New features for Active Directory.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for Active Directory:

### Simplified user and network-resource management

Using Active Directory, you can build hierarchical information structures that make it easier for you to control administrative credentials and other security settings and that make it easier for your users to locate network resources, such as files and printers.

### Flexible, secure authentication and authorization

Flexible and secure authentication and authorization services provide protection for data while minimizing barriers to doing business over the Internet. Active Directory supports multiple authentication protocols, such as the Kerberos V5 protocol, Secure Sockets Layer (SSL) v3, and Transport Layer Security (TLS) using X.509 v3 certificates, and security groups that span domains efficiently.

### Directory consolidation

You can organize and simplify the management of users, computers, applications, and devices, and make it easier for users to find the information they need. You can take advantage of synchronization support through Lightweight Directory Access Protocol (LDAP)-based interfaces, and you can work with directory consolidation requirements specific to your applications.

### Directory-enabled applications and infrastructure

Active Directory features make it easier for you to configure and manage applications and other directory-enabled network components.

### Scalability without complexity

Active Directory scales to millions of objects per domain and uses indexing technology and advanced replication techniques to speed performance.

### Use of Internet standards

Active Directory provides access through LDAP and uses a Domain Name System (DNS)-based namespace.

**A powerful development environment**

Active Directory provides a powerful development environment through Active Directory Service Interfaces (ADSI), which provides an object-oriented interface to Active Directory. ADSI makes it easy for programmers and administrators to create directory programs by using high-level tools such as Microsoft Visual Basic, Java, C, or Visual C++, without having to worry about the underlying differences between the different namespaces. For more information, see Programming interfaces.

**Replication and trust monitoring**

Active Directory provides Windows Management Instrumentation (WMI) classes to monitor whether domain controllers are successfully replicating Active Directory information and whether trusts are functioning properly.

**Message Queuing distribution lists**

Message Queuing (also known as MSMQ) enables you to send messages to distribution lists that are hosted in Active Directory.

#### New and updated features since Windows 2000

The Windows Server 2003 family offers several improvements (in comparison to Windows 2000) that help provide increased levels of support for and better management of Active Directory. For a list of the Active Directory features that are new in this release, see New features for Active Directory.

# Features for collaboration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Features for collaboration**

This topic contains a brief overview of the collaboration features, including multimedia support, in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family improves employee communication and collaboration with team collaboration tools, as well as secure real-time communications, mobile data, and streaming media on a wide range of connected devices. Because servers are continuously available, employees can access information anywhere, anytime, and on any device, improving productivity across your organization.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for collaboration:

### Windows Media Services

Windows Media Services provides support for the distribution of streaming audio and video over corporate intranets and the Internet. In Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, Windows Media Services delivers advanced streaming functionality, such as multicasting, wireless network support, internet authentication, server plug-ins, and Cache/Proxy APIs.

The core components of Windows Media Services were developed using Component Object Model (COM), creating a flexible architecture that is easily customized for specific applications. Many features are implemented through the use of plug-ins. With this platform, developers can easily extend Windows Media Services functionality and integrate with existing systems and solutions, such as storage systems, billing applications, and logging applications.

Windows Media Services is not included with Windows Server 2003, Web Edition or the Itanium-based versions of the Windows Server 2003 family.

### Predictable, end-to-end Quality of Service

Quality of Service (QoS)-based services and protocols provide a guaranteed, end-to-end, express delivery system for traffic that is generated by QoS-enabled programs across a network or across multiple disparate networks. For more information, see Quality of Service (QoS).

### Asynchronous transfer mode

Asynchronous transfer mode (ATM) is a high-speed, connection-oriented protocol designed to transport multiple types of traffic across a network. It is applicable to both local area networks (LANs) and wide area networks (WANs). Using ATM, your network can simultaneously transport a wide variety of network traffic: voice, data, image, and video.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for collaboration:

### Microsoft .NET Framework

Microsoft .NET Framework provides the most comprehensive and powerful means to build, deploy, and manage XML Web services. XML Web services allow applications to communicate and share data over the Internet, regardless of operating system or programming language. The Windows Server 2003 family is the foundation of the Microsoft .NET vision, delivering an unprecedented .NET computing foundation to organizations of all sizes. For more information, see Microsoft .NET Framework.

### Audio Acceleration on the remote access server

The Audio Acceleration feature prioritizes multimedia traffic over other data streams, which provides better performance, especially for lower-speed networks. Audio Acceleration on the remote access server ensures the quality of streaming audio and video communication.

### NetMeeting enhancements

You can use NetMeeting to communicate with another person by using Microsoft Exchange multicast conferencing, which

allows you to communicate and collaborate in real time over intranets and the Internet. NetMeeting also offers a platform for real-time communication, so that software vendors can integrate Internet conferencing into their applications and services. For more information, see Using NetMeeting.

This feature is not available on the Itanium-based versions of the Windows operating systems.

# Disk and file management features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Disk and file management features**

This topic contains a brief overview of the disk and file management features in the Windows Server 2003 family. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0, and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The disk, volume, and file management features in this release make it a flexible platform for file servers and make it easier for users to locate and access information.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of support for disk and file management:

**Distributed File System (DFS)**

You can use the /move parameter in Dfscmd.exe to rename a DFS link.

**GUID partition table (GPT) disks**

The GUID partition table (GPT) disk partitioning style supports volumes up to 18 exabytes in size and up to 128 partitions per disk. In comparison, the master boot record (MBR) disk partitioning style supports volumes up to 2 terabytes in size and up to four primary partitions per disk (or three primary partitions, one extended partition, and unlimited logical drives). Unlike MBR partitioned disks, data that is critical to platform operation is located in partitions instead of unpartitioned or hidden sectors. In addition, GPT partitioned disks have redundant primary and backup partition tables for improved partition data structure integrity.

For more information about using GPT and MBR disks on Itanium-based computers, on x64-based computers, and on x86-based computers running Windows Server 2003 Service Pack 1 (SP1), see GUID partition table.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for disk and file management:

**Disk Management**

Disk Management is a system utility for managing hard disks and the volumes, or partitions, that they contain. With Disk Management, you can initialize disks; create volumes; format volumes with FAT, FAT32, or NTFS file systems; and create fault-tolerant disk systems. Disk Management enables you to perform most disk-related tasks without shutting down the system or interrupting users; most configuration changes take effect immediately. For more information, see Disk Management.

**Disk quota support**

You can use disk quotas on volumes formatted with the NTFS file system to monitor and limit the amount of disk space available to individual users. You can define the responses that result when users exceed your specified thresholds. For more information, see Disk Quotas.

**Distributed File System**

With Distributed File System (DFS), you can create a single directory tree that includes multiple file servers and file shares in a group, division, or enterprise. This allows users to easily find files or folders distributed across the network. DFS shares can also be published as Volume Objects in Active Directory. For more information, see Distributed File System (DFS).

**Distributed Link Tracking**

Using Distributed Link Tracking and NTFS, you can enable client applications to track linked sources that have been moved. For example, a client application will always be able to access a linked database, even if the database location changes.

**Distributed Authoring and Versioning**

Using Distributed Authoring and Versioning, remote authors can edit, move, or delete files, file properties, directories, and directory properties on your server over a Hypertext Transfer Protocol (HTTP) connection.

**High-performance content indexing**

You can use Indexing Service to provide a fast, easy, and secure way for users to search for information locally or on the

network. Users can search in files in different formats and languages, either through the **Search** command on the **Start** menu or through Hypertext Markup Language (HTML) pages that they view in a browser.

**Encrypting File System**

Encrypting File System (EFS) complements other access controls and provides an added level of protection for your data. EFS runs as an integrated system service, making it easy to manage, difficult to attack, and transparent to the user. For more information, see Encrypting File System.

**Removable Storage and Remote Storage**

Removable Storage makes it easy to track your removable storage media (tapes and optical discs) and to manage the hardware libraries, such as changers and jukeboxes, that contain them. Remote Storage uses criteria that you specify to automatically copy little-used files to removable media. If hard-disk space drops below specified levels, Remote Storage removes the (cached) file content from the disk. If the file is needed later, the content is automatically recalled from storage. Because removable optical discs and tapes are less expensive per megabyte (MB) than hard disks, Removable Storage and Remote Storage can decrease your costs. For more information about Removable Storage, see Removable Storage. For more information about Remote Storage, see Remote Storage.

Remote Storage is not available on Windows Server 2003, Web Edition or on Windows Server 2003, Standard Edition. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for disk and file management:

**Remote document sharing**

A new Web Distributed Authoring and Versioning (WebDAV) redirector supports the WebDAV protocol for remote document sharing over HTTP. The WebDAV redirector supports the use of existing applications and allows file sharing across the Internet (through firewalls, routers, and so forth) to HTTP servers. With the WebDAV redirector, you can host Web repositories that can be accessed from anywhere on the Internet and with any application, not just those that interpret Web publishing protocols.

**Command-line support for disk management**

With the new **DiskPart** command, you can perform many disk management tasks from the command line. For more information, see Managing disks and volumes from the command line and DiskPart.

**GUID partition table (Itanium-based versions only)**

Windows XP 64-bit Edition (Itanium) and the Itanium-based versions of Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, support a new disk partitioning style, the GUID partition table (GPT). Unlike master boot record (MBR) partitioned disks, data that is critical to platform operation is located in partitions instead of in unpartitioned or hidden sectors. In addition, GPT partitioned disks have redundant primary and backup partition tables for improved partition data structure integrity. For more information, see GUID partition table.

**Shadow copies of shared folders**

With shadow copies of shared folders, you can open, view, and save point-in-time versions of files that are stored in shared network folders. For example, if you accidentally delete a file from a network share, you can use the shadow copy feature to retrieve a previous version of the file. For more information, see Shadow Copies for Shared Folders.

**File management improvements**

With improved folder options, you can manage files more effectively. For example, you can customize your folder view to show common tasks for files and folders, which makes it easier to send files through e-mail or give a user access to a place on a Web server. Increased thumbnail size makes it easier to identify documents.

**Support for storage area networks (SANs)**

For better interoperability in storage area network (SAN) environments, on Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, volumes on new basic disks are not automatically mounted and assigned drive letters by default when added to the system. You must manually mount basic volumes and assign the drive letters using Disk Management or the DiskPart and mountvol commands. Dynamic disks, removable media devices (such as Zip or Jaz drives), and optical discs (such as CD-ROM or DVD-RAM) are always automatically mounted by the system when they are detected.

# Printer and protocol support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

### Printer and protocol support

This topic contains a brief overview of the printer and protocol support features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

The Windows Server 2003 family provides a variety of printer and protocol support features for print servers. For links to more information about the features in this release, see New Features.

### New and updated features since Windows NT 4.0

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for print servers:

**Printers published in Active Directory**

Users can quickly search for and locate the most convenient printing resources through an intuitive user interface.

**Broad device and protocol support**

You can choose from among thousands of different printers.

**Plug and Play**

With Plug and Play, a combination of hardware and software support, the server can recognize and adapt to hardware configuration changes automatically, without your intervention and without restarting.

**Internet Printing Protocol**

With Internet Printing Protocol (IPP), users can print directly to a Uniform Resource Locator (URL) over an intranet or the Internet. In addition, servers that run products in the Windows Server 2003 family can automatically generate print job information in Hypertext Markup Language (HTML) format, so that users can view it in their browsers.

**Printer management features**

You can monitor the operation of local and remote printers using System Monitor. You can set counters for a variety of criteria, such as Bytes Printed/Second, Job Errors, and Total Pages Printed.

**Network printing features**

You can remotely administer a print server running Windows Server 2003 by using Microsoft Management Console (MMC) from anywhere on the network. In addition, if the client computer is running Windows 2000 or Windows XP, you do not have to install a printer driver for that client computer to use a printer. The driver is downloaded automatically when the client connects to the print server. This simplifies printing across a network.

### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for print servers:

**New command-line support for printing**

With new command-line utilities, you can manage printers and print queues by using a Windows Management Instrumentation (WMI) provider. You can also develop scripts or batch files to manage printers more efficiently.

**Easier printer driver installation on server clusters (Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition only)**

In Windows 2000, each printer driver had to be installed manually on every node of a server cluster. With Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition, when you install a printer driver on a cluster, the driver is automatically propagated to all nodes.

# Features for Internet, Application, and Networking Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Features for Internet, application, and networking services**
The Windows Server 2003 family includes a variety of Internet capabilities, support for applications and application development, and networking and communications capabilities.

For links to more information about the features in this release, see New Features.

This section covers:

- Microsoft .NET Framework
- Internet and e-mail services and features
- Application and Development Support
- Network protocols and technologies

# Microsoft .NET Framework

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft .NET Framework**

Microsoft .NET Framework provides the most comprehensive and powerful means to build, deploy, and manage the broad range of Web services that are made possible by XML and related technologies. For more information, see the .NET Framework page at the Microsoft Web site.

**XML Web services**

XML Web services allow applications to communicate and share data over the Internet, regardless of operating system or programming language. The Windows Server 2003 family is the foundation of the Microsoft .NET vision, delivering an unprecedented computing foundation to organizations of all sizes.

**.NET Framework tools**

Using the tools that are provided with .NET Framework, application developers can easily build Windows applications that blend XML Web services with traditional applications, improving communication, collaboration, and connectivity inside and outside their organizations.

**Other .NET technologies**

Other .NET technologies that are included in the Windows server 2003 family are the integration of Microsoft .NET Passport with Active Directory, native support for Simple Object Access Protocol (SOAP) as the foundation for XML message passing in Message Queuing, and integration of component architecture with XML Web services.

Universal Description, Discovery, and Integration (UDDI) Services is also included with some products in the Windows server 2003 family. UDDI Services is not included with Windows Server 2003, Web Edition. In addition, Windows Server 2003, Standard Edition, supports only stand-alone installations of UDDI Services. Distributed installation support is available with Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. In a stand-alone installation of UDDI Services, both the UDDI Web server component and the UDDI database component are installed onto a single server. In a distributed installation, UDDI components are distributed across multiple servers.

For more information about Message Queuing, see Using Message Queuing. For more information about SOAP, see Network protocols and technologies. For more information about Internet-related services, see Internet and e-mail services and features. For more information about UDDI Services, see UDDI Services overview.

**Built on industry standards**

The Windows Server 2003 family is built on industry standards so that you can extend existing applications and quickly develop new ones.

The Microsoft .NET Framework is built into all products in the Windows Server 2003 family except for the 64-bit versions.

The 32-bit version of .NET Framework 1.1 is supported by 64-bit versions of Windows Server operating systems and can be installed for 32-bit applications running on 64-bit versions of Windows operating systems (WOW64).

To install .NET Framework 1.1, see "Microsoft .NET Framework Version 1.1 Redistributable Package" at the Microsoft Download Center Web site. To install the service pack, see "Microsoft .NET Framework 1.1 Service Pack 1" at the Microsoft Download Center Web site.

**Important performance and scalability information**

If a 32-bit version of the .NET Framework is installed on the 64-bit Itanium-based systems, applications created for the 32-bit version of the Framework will bind and run against it. Therefore, applications created with the Microsoft .NET Framework Version 1.1 run only in a 32-bit process within the WOW64 compatibility environment. Due to the design of x86 emulation for the Itanium processor family and the WOW64 subsystem, applications are restricted to execution on one processor.

Single processor execution and x86 emulation reduce the performance and scalability of 32-bit .NET Framework applications running on Itanium-based systems. We recommend that applications using the .NET Framework Version 1.1 be used for interactive, client applications. With .NET Framework applications that demand high performance and scalability, such as high-load ASP.NET applications, we do not recommend this environment. We suggest that application developers instead evaluate the .NET Framework Version 2.0, which includes 64-bit support for Itanium-based systems, for increased performance and scalability.

# Internet and e-mail services and features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet and e-mail services and features**

This topic contains a brief overview of the Internet services and features in this release. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0, and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family includes improved support for a wide variety of Internet capabilities.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of support for Internet services:

### Group Policy additions under "Internet Communication Management"

Windows Server 2003 with SP1 contains Group Policy settings that were not available in the original release of Windows Server 2003. Some of these settings can be found in Group Policy under the key called Internet Communication Management. This key is located within GPMC in Computer Configuration\Administrative Templates\System and in User Configuration\Administrative Templates\System.

The settings under the Internet Communication Management key are designed to help you control the way components in Windows Server 2003 with SP1 communicate with the Internet.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for Internet services:

### Active Server Pages

Active Server Pages (ASP) is a server-side scripting environment for creating dynamic, interactive Web server applications. With ASP, developers can combine Hypertext Markup Language (HTML) pages, script commands, and Component Object Model (COM) components as needed to create flexible Web-based applications.

### Windows Media Services

Using Windows Media Services, you can deliver high-quality streaming multimedia to users on the Internet and intranets.

Windows Media Services is not included with Windows Server 2003, Web Edition or the Itanium-based versions of the Windows Server 2003 family.

### Web Distributed Authoring and Versioning

Using Web Distributed Authoring and Versioning (WebDAV), remote authors can use a Hypertext Transfer Protocol (HTTP) connection to work with files. For more information, see Disk and file management features.

### Application recycling

Application recycling enhances the reliability and health of servers. You can refresh applications and prevent possible resource leaks, which increases the reliability and availability of your servers.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for Internet services:

### Microsoft .NET Framework components

Microsoft .NET Framework offers a wide range of possibilities for building, deploying, and managing Web services. For more information, see Microsoft .NET Framework.

### Internet Information Services 6.0

Internet Information Services (IIS) 6.0 is a full-featured Web server that has been optimized for running Web applications and Web services in a hosting environment. Many new features have been included in IIS 6.0 to enhance reliability, security, manageability, and performance.

**Note**

- By default, IIS is not installed with new installations of Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. You can add it by using the Configure Your Server Wizard or by using Add or Remove Programs.

**Universal Description, Discovery, and Integration Services**

Universal Description, Discovery, and Integration (UDDI) is an industry specification for publishing and locating information about Web services. Some products in the Windows Server 2003 family include UDDI Services, a Web service that provides UDDI capabilities for use within an enterprise or across organizations. UDDI Services is a standards-based XML Web service designed for enterprise developers to efficiently discover, share, and reuse Web services directly through their development tools.

UDDI Services is not included with Windows Server 2003, Web Edition. In addition, Windows Server 2003, Standard Edition, supports only stand-alone installations of UDDI Services. Distributed installation support is available with Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. In a stand-alone installation of UDDI Services, both the UDDI Web server component and the UDDI database component are installed onto a single server. In a distributed installation, UDDI components are distributed across multiple servers.

For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

**E-mail services (POP3, SMTP)**

The POP3 service provides e-mail transfer and retrieval services. Administrators can use the POP3 service to store and manage e-mail accounts on the mail server. Simple Mail Transfer Protocol (SMTP) supports the transfer of e-mail between servers. For more information, see POP3 Service and Simple Mail Transfer Protocol (SMTP) service.

**Configuration Database WMI Provider**

The Configuration Database WMI Provider for IIS facilitates cross-application administration of servers that are running IIS. Windows Management Instrumentation (WMI) has a rich schema and associative approach to modeling application configuration, which makes it possible to write scripts that manage all aspects of a Web application, including system configuration, application files, and databases.

# Application and Development Support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Application and development support**
For a table that relates the types of support listed in this topic to other types of support in this release, see Choosing the features that are most useful for your server.

This section covers:

- Support for existing systems
- Application support
- Management and deployment
- Terminal Server features
- Development support

# Support for existing systems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Support for existing systems**

This topic contains a brief overview of the interoperability features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family supports Windows NT 4.0, Windows 2000, UNIX, and Macintosh, as well as interoperability with various client operating systems. You can introduce products in the Windows Server 2003 family incrementally into a network environment, because migration paths are provided from any number of existing systems, devices, and applications.

This release includes the following design features to ensure that it is compatible with as many systems and applications as possible.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for existing systems:

### Industry standards

The Windows Server 2003 family supports the latest in industry standards, including:

- XML
- Simple Object Access Protocol (SOAP)
- Lightweight Directory Access Protocol (LDAP)
- DNS
- Active Directory Service Interfaces (ADSI)
- Kerberos V5 authentication protocol
- Universal Description, Discovery, and Integration (UDDI)

  UDDI Services is not included with Windows Server 2003, Web Edition. In addition, Windows Server 2003, Standard Edition, supports only stand-alone installations of UDDI Services. Distributed installation support is available with Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. In a stand-alone installation of UDDI Services, both the UDDI Web server component and the UDDI database component are installed onto a single server. In a distributed installation, UDDI components are distributed across multiple servers.

### Support for existing server applications

Existing server applications, such as Microsoft Exchange Server and Microsoft SQL Server, are supported on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. For full support, you may need to install the latest product updates. For more information, see the Windows Update site at the Microsoft Web site. Also, see the Application Center at the Microsoft Web site.

### Integration with existing operating systems

Products in the Windows Server 2003 family integrate seamlessly with existing operating systems and contain support for earlier Windows operating systems, as well as for other popular operating systems. The following features are included in this release:

- Interoperability with Windows NT Server 4.0 and Windows 2000 Server.
- Support for clients running a variety of operating systems, including Windows 3.x, Windows 95, Windows 98,

Windows Millennium Edition, Windows NT Workstation 4.0, Windows 2000 Professional, and Windows XP.

- UNIX interoperability, provided through an add-on pack called Windows Services for UNIX. The add-on pack provides support for Network File System (NFS), password synchronization, a UNIX command shell, and a collection of UNIX utilities. The add-on pack also supports Network Information Service (NIS). Telnet services (for remote access and administration) are also included.

- File Server for Macintosh, allowing Macintosh clients to use the TCP/IP protocol (AFP over IP) to share files and to access shares on a server running Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition.

  This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for existing systems:

### Compatibility Mode

Compatibility Mode provides an environment for running applications that more closely reflects the behavior of Windows 95, Windows 98, Windows NT 4.0, or Windows 2000 operating systems. These modes resolve several of the most common issues that prevent older applications from working correctly. You can also use this technology to create solutions for your own applications.

### Program Compatibility Wizard

You can use the Program Compatibility Wizard to detect and test compatibility settings. For more information, see Troubleshooting compatibility issues.

# Application support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Application support**

This topic contains a brief overview of the application support features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family provides support for a wide range of turnkey independent software vendor (ISV) solutions and a comprehensive set of Internet application services for rapid development of custom applications.

**Note**

- The Windows Server 2003, Web Edition operating system is intended for Web application services and not as a general application server.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for applications:

**Widest range of turnkey applications**

You can run a wide and varied range of applications on the Windows Server 2003 family of products. For the most recent information on compatible applications, see Software compatibility information in the Windows Catalog at the Microsoft Web site.

**Comprehensive Internet application services**

Using the integrated Web, component management, transaction processing, and message queuing services in this release, programmers can rapidly develop and deploy scalable, component-based applications.

**Microsoft Active Accessibility**

Microsoft Active Accessibility is an application programming interface (API) that makes it easy for developers to build applications that can be customized for people with varying degrees of disabilities. Because Active Accessibility reduces the need for application-specific code, it reduces overall maintenance costs and allows software developers to innovate in their user interface without sacrificing compatibility with accessibility aids. For more information, see the Accessibility page at the Microsoft Web site.

**TAPI 3.1**

TAPI 3.1 unifies Internet Protocol (IP) and traditional telephony to enable developers to create computer telephony applications that work as effectively over the Internet or an intranet as over the traditional telephone network.

**Transaction services**

The integrated transaction services in the Windows Server 2003 family provide simple building blocks that can reliably and efficiently execute complex transactions across widespread distributed networks.

**Message queuing**

Integrated message queuing functionality helps developers build and deploy applications that run more reliably over networks, including the Internet. These applications can interoperate with applications running on different platforms, such as mainframes and UNIX-based systems.

**Component Services**

Component Services is a set of services based on extensions of the Component Object Model (COM) and on Microsoft Transaction Server (an earlier release of a component-based transaction processing system). Component Services provides threading and security, transaction management, object pooling, queued components, and application administration and packaging.

**Job objects**

Products in the Windows Server 2003 family contain an extension to the process model called a job. Job objects are nameable, securable, sharable objects that control attributes of the processes that are associated with them. A job object's basic function is to allow groups of processes to be managed and manipulated as a unit. For example, a Web application can

use a job object to account for CPU usage.

**Host data integration**

Products in the Windows Server 2003 family provide an excellent platform for running database applications by including native support for Open Database Connectivity (ODBC), Oracle, and Microsoft SQL Server.

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for applications:

**Compatibility Mode**

Compatibility Mode provides an environment for running applications that more closely reflects the behavior of Windows 95, Windows 98, Windows NT 4.0, or Windows 2000 operating systems. These modes resolve several of the most common issues that prohibit older applications from working correctly. You can also use this technology to create solutions for your own applications. For more information, see Accessing information about compatibility.

**Web gardens in Internet Information Services**

In Internet Information Services (IIS), a Web garden is an application pool that has multiple worker processes serving the requests that are routed to that pool. A Web garden can be configured so that the processes serving it have affinity for particular processors on a multiprocessor computer. Using Web gardens, Web applications have increased scalability. If one worker process experiences a problem with an Active Server Page (ASP), the other worker processes can still serve content and take over for the locked worker process.

# Management and deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Management and deployment**

This topic contains a brief overview of the application management and deployment features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The following features help simplify the deployment of applications on desktop and portable systems. Terminal Server provides additional options and features that simplify deployment. For more information, see Terminal Server features.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for management and deployment:

**Change and configuration management with Group Policy**

You can use policy settings to define the permitted actions and settings for users and computers. In contrast with local policy, Group Policy can be used to set policy settings that apply across a given site, domain, or organizational unit in Active Directory. For more information about Group Policy, see Group Policy (pre-GPMC). The Windows Server 2003 family includes more than 200 new policy settings.

**Directory consolidation in Active Directory**

With Active Directory, you can organize and simplify the management of users, computers, applications, and devices and make it easier for users to find the information they need. You can take advantage of synchronization support through Lightweight Directory Access protocol (LDAP)-based interfaces and work with directory consolidation requirements that are specific to your applications.

**IntelliMirror**

To help reduce costs, administrators need the highest levels of control over portable and desktop systems. IntelliMirror provides this control on client systems running Windows 2000 Professional or Windows XP Professional. You can use IntelliMirror to define policy settings based on business roles, group memberships, and locations. With these policy settings, Windows 2000 Professional desktops and Windows XP Professional desktops are automatically reconfigured to meet a specific user's requirements each time that user logs on to the network, regardless of where the user logs on. For more information about IntelliMirror, see IntelliMirror.

**Remote Installation Services**

With Remote Installation Services (RIS), you can create installation images of operating systems or even of complete computer configurations, including desktop settings and applications. You can then make these images available to users at client computers. The client computers must support remote booting with the Pre-Boot eXecution Environment (PXE) ROM, or else they must be started with a remote-startup floppy disk. For more information, see Remote Installation Services.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Windows Management Instrumentation**

Windows Management Instrumentation (WMI) is a scalable management infrastructure that is based on the Web-Based Enterprise Management (WBEM) initiative. Using WMI, which includes command-line and scripting capabilities, you can monitor, track, and control system events that are related to software applications, hardware components, and networks. WMI is both standards-based (coming out of the Common Information Model (CIM)) and flexible, allowing you to customize the way that information is gathered and filtered. For more information about WMI, see WMI Overview.

**Side-by-side component sharing**

Side-by-side sharing minimizes application fragility by enabling multiple versions of the same Component Object Model (COM) or Win32 component, such as a .dll file, to run at the same time in memory. This means that applications can use the specific components that they were designed for and tested with, even if another application requires a different version of the same component. This allows developers to build more reliable applications, because developers can choose the version of the component that they want to use for their application, independent of the other applications on the system.

**Add or Remove programs**

With Add or Remove programs, you can easily add or remove programs or components and keep track of the list of programs that are currently installed.

**Windows Installer**

With Windows Installer, you can customize your deployments of software components, as well as monitoring file resiliency and maintaining basic system recovery with rollbacks. For more information, see Windows Installer.

**Application management**

With application management, you can make changes in controlled ways to applications, without recompiling or rereleasing.

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for management and deployment:

**Remotely administered server support**

Remotely administered server support provides the ability to install and manage a computer that does not have a monitor, VGA display adaptor, keyboard, or mouse. This feature also includes Emergency Management Services, which provides a mechanism to manage the remotely administered server when the operating system is not functional, such as when the computer is restarted, when the server is unavailable on a network, or during use of Remote Installation Services (RIS).

**Windows Management Instrumentation improvements**

Windows Management Instrumentation (WMI) filtering enhances the Group Policy infrastructure by helping you to determine the effect of a Group Policy object (GPO).

**Scripting support**

The Windows Server 2003 family has better scripting support, including new command-line tools and improvements to Windows Script Host. For a list of new command-line tools, see New command-line tools. For more information about the improvement to Windows Script Host, see Windows Script Host overview.

**Resultant Set of Policy**

You can use Resultant Set of Policy (RSoP) to simulate and test policy settings that are applied to computers or users through Group Policy. RSoP is a query engine that polls existing policy settings--and also planned policy settings--and then reports the results of those queries. It polls existing policy settings based on site, domain, domain controller, and organizational unit. RSoP gathers this information from Windows Management Instrumentation (WMI).

**Remote Installation Services improvements**

Enhancements to Remote Installation Services (RIS) include support for both Windows Server 2003 family and Windows XP product installations, more control over answer file processing for a Remote Installation Services installation, and access to network files in recovery modes.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Terminal Server features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server features**

This topic contains a brief overview of the Terminal Server features in this release. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

Terminal Server provides remote computers with access to Windows-based programs running on Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. With Terminal Server, you can provide a single point of installation that gives multiple users access to any computer that is running one of these products. Users can run programs, save files, and use network resources--all from a remote location--as if these resources were installed on their own computers.

### Notes

- Several Terminal Server and Remote Desktop features have been renamed or replaced in this release. For a table that lists the new names for features in Terminal Server, see New ways to do familiar Terminal Server tasks. For a table that lists the new names for Remote Desktop for Administration (formerly Terminal Services in Remote Administration mode), see New ways to do familiar Remote Desktop for Administration tasks.

- Remote Desktop for Administration is another part of the Terminal Services technology that is offered in this release. Remote administration of servers with Remote Desktop for Administration can be enabled on any computer running the Windows Server 2003 family of products, whether or not Terminal Server is installed. For more information, see Remote Desktop for Administration.

- Terminal Server (previously known as Terminal Services in Application Server mode) is not included on computers running the Windows Server 2003, Web Edition operating system. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT) that help provide increased levels of support for Terminal Server:

### Centralized deployment of programs

With Terminal Server, all program execution, data processing, and data storage occur on the server, which centralizes the deployment of programs. Terminal Server ensures that all clients can access the same version of a program. Software is installed only once on the server, rather than on every desktop throughout the organization, which reduces the costs that are associated with updating individual computers.

### Remote access to applications

Terminal Server efficiently sends the application display, rather than the underlying application data, from server to client. This means that you can give users access to data-heavy applications over lower-bandwidth connections (for example, a 28.8-Kbps dial-up connection) and provide higher performance than would be possible without Terminal Server.

### Single-application access

Terminal Server can provide users with access to a single published application when access to a full Windows XP desktop is not required.

### Terminal Services Manager

With Terminal Services Manager, you can view information about terminal servers in trusted domains. This information includes all sessions, users, and processes for each terminal server. You can also use this utility to perform various actions to manage the server.

### Remote control

Terminal Services provides built-in remote control for the Windows Server 2003 family.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for Terminal Server:

**Audio redirection**

Audio redirection enables sound reproduction on a client computer with any application that attempts to play a wave sound inside a Terminal Server session. This feature provides the capability for basic audio, for example, for attached .wav files in e-mail, documents, or simple streaming media.

**Group Policy integration**

Terminal Server is integrated with Group Policy, so that you can manage how a server that has Terminal Server enabled can be used by enforcing redirection capabilities, password access, and wallpaper settings.

**Resolution and color enhancements**

Terminal Services, the underlying technology for Terminal Server, now supports greater color depth and screen resolution. Using Remote Desktop Connection, color depth can be any setting from 256 colors to True Color, and resolution can be set from 640 × 480 to the highest level that is supported by the client video devices. Resolution and color limits must be enabled on both the server and the client.

# Development support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Development support**

This topic contains a brief overview of the development support features in the Windows Server 2003 family. It is divided into two sections: New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

Developers writing server-based applications can work with the tools that are available in Microsoft Visual Studio® and also with other development tools. The system architecture in the Windows Server 2003 family allows developers to design applications that are easily translated and modified into local versions.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide increased levels of support for developers:

### Visual Studio .NET

Visual Studio .NET is designed to address the major requirements of organizations creating modern enterprise solutions. The design themes for Visual Studio .NET include:

- A complete suite of tools for component-based development
- Enhanced life cycle productivity
- Enterprise database tools
- Enhanced support for teams
- Integration with application services

### Multilingual technology

Because of the system architecture in the Windows Server 2003 family, the operating system, utilities, and properly written applications can be translated and modified into local versions for hundreds of languages.

**New and updated features since Windows 2000**

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for developers:

### Automatic generation of link IDs

Link IDs are used by applications as they build new Active Directory structures (extensions to the Active Directory schema). If an application requests a new link ID that duplicates a link ID that is already in use, the schema extension fails to load. Automatic generation of link IDs avoids this problem by giving the application developer the option to request that the link ID be generated automatically.

### Background Intelligent Transfer Service

Background Intelligent Transfer Service (BITS) is a background file transfer mechanism. BITS prioritizes requests, and you can use it to specify that low-priority transfers occur only when the network is not at full capacity. The transfers continue even after network disconnections or computer restarts. You can write an application that downloads or uploads files in the background using BITS. For example, if a user has requested that Windows Update perform multiple downloads, Windows Update retrieves those updates in the background by submitting a request to BITS. The BITS service then downloads the files in the background and notifies the user when the files are downloaded.

# Network protocols and technologies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network protocols and technologies**

This topic contains a brief overview of the network protocols and technologies in the Windows Server 2003 family. It is divided into three sections: New and updated features since Windows Server 2003 (without SP1), New and updated features since Windows NT 4.0 and New and updated features since Windows 2000.

For links to more information about the features in this release, see New Features.

The Windows Server 2003 family includes a variety of network protocols and technologies to extend the capabilities of your server. For information about additional technologies related to networking, see Performance and tuning features.

### Notes

- The following network protocols have been removed from all products in the Windows Server 2003 family: the Data Link Control (DLC) protocol (related to certain models of printers) and the NetBIOS Extended User Interface (NetBEUI).
- The following network protocols have been removed from the Itanium-based versions of the Windows Server 2003 family: Internetwork Packet Exchange/Sequenced Packet Exchange (IPX/SPX), IPX-dependent services, and Open Shortest Path First (OSPF).
- In the Windows Server 2003 family, only Windows Server 2003, Standard Edition supports infrared (IR) networking.

**New and updated features since Windows Server 2003 (without SP1)**

Windows Server 2003 operating systems with Service Pack 1 (SP1) offer the following improvements (compared to Windows Server 2003 without SP1) that help provide increased levels of support for network protocols and technologies:

### Remote Access Quarantine Service, part of Network Access Quarantine Control

Remote Access Quarantine Service is an essential component of Network Access Quarantine Control for Windows Server 2003 with SP1.

Network administrators can enforce network access requirements on remote computers with Network Access Quarantine Control. Lack of access makes it difficult to enforce network requirements (such as the use of antivirus software) on remote computers. By deploying the components of Network Access Quarantine Control, including installing the optional Remote Access Quarantine Service (RQS.exe) component on Windows Server 2003 with SP1, and by including the RQC.exe component with the advanced customization features of Connection Manager, network administrators can create connections that check for required programs, registry settings, files, or combinations thereof. They can also quarantine a remote-access session until these checks have been performed.

Installing the Remote Access Quarantine Service does not automatically start the Remote Access Quarantine Agent service, another aspect of Network Access Quarantine Control. As the network administrator, you must decide the best time to start the service in relation to the configuration of the Routing and Remote Access service.

The Remote Access Quarantine Agent service depends on the Routing and Remote Access service. However, when the Routing and Remote Access service is restarted, the Remote Access Quarantine Agent service is not automatically restarted. You must manually restart the Remote Access Quarantine Agent service.

For more information, see the following:

*Network Access Quarantine Control in Windows Server 2003* at the Microsoft Web site.

*VPN Quarantine Sample Scripts for Verifying Client Health Configurations* at the Microsoft Web site.

### ValueAdd folder has been replaced by Support folder

The ValueAdd folder has been removed from Windows Server 2003 with SP1. To install support tools that were previously found in that folder, such as Phone Book Administrator, go to the Support folder on your Setup CD.

**New and updated features since Windows NT 4.0**

The Windows Server 2003 family offers the following improvements (in comparison to Windows NT 4.0) that help provide

increased levels of support for network protocols and technologies:

**Winsock Direct**

With Winsock Direct, applications that use Winsock can perform faster and with less CPU overhead when they communicate across a system area network (SAN). Winsock Direct has the effect of streamlining communications between distributed components if there is a SAN in place.

**DHCP with DNS and Active Directory**

Dynamic Host Configuration Protocol (DHCP) works with DNS and Active Directory on Internet Protocol (IP) networks, helping to free you from assigning and tracking static IP addresses. DHCP dynamically assigns IP addresses to computers or other resources connected to an IP network.

**Internet Connection Sharing**

With the Internet Connection Sharing feature of Network Connections, you can connect your home network or small office network to the Internet. For example, you might have a home network that connects to the Internet with a digital subscriber line (DSL) connection. By enabling Internet Connection Sharing on the computer that uses DSL, you can provide network address translation, addressing, and name resolution services for all computers on your home network. For more information, see Internet Connection Sharing and network address translation.

Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Network Address Translation**

Network Address Translation (NAT) hides internally managed IP addresses from external networks by translating private internal addresses to public external addresses. This reduces IP address registration costs by letting you use private IP addresses internally, with translation to a small number of registered IP addresses externally. It also hides the internal network structure, reducing the risk of attacks against internal systems.

**Virtual private networking**

You can give users ready access to your organization's network even when they are out of the office, and reduce the cost of such access, by implementing a virtual private network (VPN). The VPN connection creates a secure tunnel across the Internet into the private network.

There are two types of VPN technology in the Windows Server 2003 family:

- Point-to-Point Tunneling Protocol (PPTP), which employs user-level Point-to-Point Protocol (PPP) authentication methods and Microsoft Point-to-Point Encryption (MPPE) for data encryption.

- Layer Two Tunneling Protocol (L2TP) with Internet Protocol security (IPSec). L2TP employs user-level PPP authentication methods and computer-level certificates with IPSec for data encryption.

On Windows Server 2003, Web Edition, and Windows Server 2003, Standard Edition, you can create up to 1,000 Point-to-Point Tunneling protocol (PPTP) ports, and you can create up to 1,000 Layer Two Tunneling protocol (L2TP) ports. However, Windows Server 2003, Web Edition, can accept only one virtual private network (VPN) connection at a time. Windows Server 2003, Standard Edition, can accept up to 1,000 concurrent VPN connections. If 1,000 VPN clients are connected, further connection attempts are denied until the number of connections falls below 1,000.

**Routing and Remote Access**

Routing and Remote Access replaces the Routing and Remote Access Service (RRAS) and Remote Access Service (RAS) features in Windows NT 4.0. Routing and Remote Access is a single, integrated service that terminates connections from either dial-up or VPN clients or that provides routing (IP, IPX, and AppleTalk), or both. With Routing and Remote Access, your server can function as a remote access server, a VPN server, a gateway, or a branch-office router. For more information, see Routing and Remote Access.

**Asynchronous transfer mode**

Asynchronous transfer mode (ATM) is a high-speed, connection-oriented protocol designed to transport multiple types of traffic across a network. It is applicable to both local area networks (LANs) and wide area networks (WANs). Using ATM, your network can simultaneously transport a wide variety of network traffic: voice, data, image, and video.

#### New and updated features since Windows 2000

The Windows Server 2003 family offers the following improvements (in comparison to Windows 2000) that help provide increased levels of support for network protocols and technologies:

**Simple Object Access Protocol**

Simple Object Access Protocol (SOAP) is an XML-based protocol for exchanging information in a decentralized, distributed environment. It consists primarily of two core parts: an envelope for handling extensibility and modularity and an encoding mechanism for representing data types within the envelope. It does not require synchronous execution or request/response interaction. SOAP provides a simple protocol with an extensibility mechanism for adding functionality, such as message routing, security, and guaranteed delivery. By relying on the availability of ubiquitous protocols, including not only XML and Hypertext Transfer Protocol (HTTP) but Simple Mail Transfer Protocol (SMTP) and File Transfer Protocol (FTP), SOAP is available to the broadest assortment of platforms and clients.

**Fibre Channel support**

Fibre Channel is a technology for 1-gigabit-per-second data transfer that maps common transport protocols such as small computer system interface (SCSI) and Internet Protocol (IP), merging networking and high-speed I/O into a single connectivity technology. Fibre Channel technology gives you a way to address the distance and the address-space limitations of conventional channel technologies. For more information, see Fibre Channel hardware configuration.

**Automatic configuration for multiple networks**

Automatic configuration for multiple networks provides easy access to network devices and the Internet. It also provides the mobile computer user with seamless operations on both office and home networks without having to reconfigure TCP/IP settings manually. With automatic configuration for multiple networks, TCP/IP can use an alternative configuration if a DHCP server is not found.

**Connection Manager improvements**

Connection Manager offers several new features:

- **Automatic proxy configuration for Connection Manager clients.** Configure user proxy settings to ensure that the user has appropriate access to internal and external resources while connected to your service.
- **Connection Manager Favorites.** Eliminates repetitive configuration of Connection Manager properties when users switch among common dialing locations.
- **Client log files.** Troubleshoot problems with Connection Manager connections.
- **Connection Manager Administration Kit.** Customize Connection Manager for your needs using the Connection Manager Administration Kit (CMAK) Wizard.

**Web Distributed Authoring and Versioning redirector**

The Web Distributed Authoring and Versioning (WebDAV) redirector supports the WebDAV protocol for remote document sharing over HTTP. The WebDAV redirector supports the use of existing applications, and it supports file sharing across the Internet (through firewalls, routers, and so forth) to HTTP servers.

**Internet Authentication Service as RADIUS proxy**

This feature supports the ability of Internet Authentication Service (IAS) to forward Remote Authentication Dial-In User Service (RADIUS) authentication and accounting requests to another RADIUS server. This includes flexible, rule-based forwarding, load balancing, and failover between multiple IAS/RADIUS server and load balancing RADIUS-EAP requests; the ability to force the client into a compulsory tunnel with or without user authentication; and selective forwarding of authentication and accounting requests to different RADIUS servers.

This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition. In Windows Server 2003, Standard Edition, you can configure IAS with a maximum of 50 RADIUS clients and a maximum of 2 remote RADIUS server groups. For more information about these limits, see Internet Authentication Service.

**Wireless networking**

Wireless networking functionality in the Windows Server 2003 family supports the IEEE 802.11 standard, and it minimizes the configuration that is required to access wireless networks. The automatic wireless network configuration feature makes it possible for users to roam across different wireless networks in different locations, without the need to reconfigure their network connection settings for each new location. Security options for 802.11 include authentication services and encryption services that are based on the Wired Equivalent Privacy (WEP) algorithm. For enhanced security, 802.1X authentication is enabled by default in the Windows Server 2003 family of products. IEEE 802.1X authentication provides authenticated access to 802.11 wireless networks and to wired Ethernet networks. IEEE 802.1X authentication provides support for Extensible Authentication Protocol (EAP) security types, so that users can use authentication methods such as certificates.

**IP version 6**

The Windows Server 2003 family supports IP version 6 (IPv6), which is a suite of standard protocols that is the next generation of network layer protocols for the Internet. For more information, see IP Version 6.

# Installing and Upgrading the Operating System

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing and upgrading the operating system**

These topics can help you plan for upgrading to or installing Windows Server 2003 operating systems in a network with one to five servers and 100 or fewer clients. For help with planning the upgrade or installation of a larger number of servers, see the Windows Server 2003 Deployment Kit at the Microsoft Windows Server System Web site. For information about obtaining the Windows Server 2003 Resource Kit, see Using the Windows Deployment and Resource Kits.

- Before running Setup, see Checklists for installing and upgrading the operating system.
- For tips about installing, see Best practices for installing and upgrading the operating system.
- For help with specific tasks, see How to install and upgrade the operating system.
- For general background information, see Concepts for installing and upgrading the operating system.
- For problem-solving instructions, see Troubleshooting for installing and upgrading the operating system.

# Checklists for installing and upgrading the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Performing an upgrade
- Checklist: Performing a new installation

# Checklist: Performing an upgrade

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Performing an upgrade**

| Step | Reference |
|---|---|
| Check system requirements. | System Requirements and Hardware Compatibility |
| Read Relnotes.htm and hardware compatibility information. | Important files to review<br><br>Hardware compatibility |
| Determine whether your current operating system is one from which you can upgrade to Windows Server 2003. | Upgrading or Installing |
| If you have server clusters, review the choices for upgrading on cluster nodes. | Upgrading to Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition on Cluster Nodes<br><br>Checklist: Preparation for upgrading a cluster |
| For upgrades in any domain where all domain controllers run Windows NT 4.0, review the upgrade plan. | Upgrades in a Windows NT 4.0 Domain |
| Decide whether to upgrade any FAT or FAT32 partitions to NTFS. | Choosing a File System for the Installation Partition |
| Check the system log for errors that could cause problems during the upgrade. | Preparing your system for an upgrade |
| Back up files. | Preparing your system for an upgrade |
| If upgrading from Windows NT 4.0, prepare mirror sets or other disk sets for upgrade. | Working with volume, mirror, or stripe sets or stripe sets with parity |
| Disconnect UPS devices. | Preparing your system for an upgrade |
| Review hardware and software. | Preparing your system for an upgrade |
| Start Setup, and follow the instructions provided. | Start Setup on an x86-based computer<br><br>Start Setup on an Itanium architecture-based computer<br><br>Start Setup on an x64-based computer |
| If domain controller upgrades are complete, review concepts about domain functional levels and, if appropriate, raise the functional level. | Domain and forest functionality<br><br>Upgrading from a Windows NT domain |

# Checklist: Performing a new installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Performing a new installation**

| Step | Reference |
|---|---|
| Check system requirements. | System Requirements and Hardware Compatibility |
| Read Relnotes.htm and hardware compatibility information. | Important files to review Hardware compatibility |
| Decide whether to upgrade or install. | Upgrading or Installing |
| If you have server clusters, review the process for installation on cluster nodes. | Checklist: Preparation for installing a cluster |
| Decide what licensing mode to use: Per Device or Per User or Per server. | Choosing a licensing mode |
| Decide whether you want to be able to choose between different operating systems each time you start the computer. | Deciding Whether a Computer Will Contain More Than One Operating System |
| Decide what file system to use: NTFS, FAT, or FAT32. | Choosing a File System for the Installation Partition |
| Decide what partition you will install on, or whether you will need a new partition for your installation. | Planning Disk Partitions or Volumes for New Installations |
| Decide how to handle networking, IP addresses, and TCP/IP name resolution. | Networks: TCP/IP, IP Addresses, and Name Resolution |
| Decide whether to create domains or workgroups for your servers. | Deciding Between Workgroups and Domains |
| If the computer already has a working operating system on it, back up files, and check the system log for errors. | Preparing your system for a new installation |
| Uncompress any DriveSpace or DoubleSpace volumes. | Preparing your system for a new installation |
| If the computer runs Windows NT 4.0 and uses mirror sets or other disk sets, prepare the disks. | Working with volume, mirror, or stripe sets or stripe sets with parity |
| Disconnect UPS devices. | Preparing your system for a new installation |
| Start Setup, and follow the instructions provided. | Start Setup on an x86-based computer<br><br>Start Setup on an Itanium architecture-based computer<br><br>Start Setup on an x64-based computer |

# Best practices for installing and upgrading the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for installing and upgrading the operating system**

**Prepare the server before upgrading or installing.**

- If you are performing an upgrade, see:
  - Checklist: Performing an upgrade
  - Preparing your system for an upgrade
- If you are performing a new installation, see:
  - Checklist: Performing a new installation
  - Preparing your system for a new installation

**Confirm server settings after running Setup.**

- **Check Event Viewer.** Check Event Viewer for messages associated with the installation or startup process. For more information, see Event Viewer.
- **Set Event Viewer log size and wrap setting.** Define your event log size and wrap (overwrite) setting to match your business and security requirements. For information, see Set event logging options.
- **Check server optimization.** Adjust the server optimization setting to match the role the computer will play in your organization. For information about how to access server optimization settings, see To configure memory-related settings on your computer.
- **Verify settings such as IP, DNS, WINS, and default gateway settings.** Use the administrative tools described in Network Services to configure and verify your settings. You can also open a command prompt, type **ipconfig /all** and verify the displayed settings.
- **View the full computer name.** Open a command prompt and type **net config rdr** to view the full computer name. Compare the results against the Active Directory name to confirm that they match or vary as intended.
- **Validate server cluster settings.** Follow the steps in Checklist: Validating your clustering system to confirm the basic configuration settings for your cluster storage.
- **Specify options for paging files and memory dumps.** Set the paging file size and placement based on memory size and server usage. For information about how to do this, see Change virtual memory settings. Also, set the options for the operating system to use if the system stops unexpectedly (for example, the options for memory dumps). For more information, see Specify what happens when the system stops unexpectedly
- **Configure for remote administration.** Identify the remote administration methods you plan to use, and configure them as necessary. For more information, see Remote Administration.

**Confirm server security settings after running Setup.**

- **Review startup settings for services.** Open Computer Management. In the Services folder under Services and

Applications, change the **Startup Type** of services so that services necessary for your server, and only those services, start automatically. Also, confirm that all services that are set to start automatically can start without user intervention or multiple retries. For a list of topics about services, see Services Snap-in. For specific information about services that start by default after Setup (which are different than in Windows 2000), see Default settings for services.

- **Review Internet Explorer security settings.** In Windows server 2003 family of operating systems, the Internet Explorer Enhanced Security Configuration is enabled by default. The security settings in this configuration can help make your computer more secure by limiting its exposure to malicious Web sites. Therefore, with this enhanced level of security, you might find that some Web sites do not display correctly in Internet Explorer when you are browsing Internet and intranet Web sites. Also, you might be prompted to enter your credentials when accessing network resources, such as files in Universal Naming Convention (UNC) shared folders. You can easily change the enhanced security settings. For more information, see Internet Explorer Enhanced Security Configuration overview.

- **Review open network ports.** To help protect servers against attacks, close ports that are not necessary for the system to function properly. You can review ports with the **netstat** command. It is useful to also use an external port scanner and compare the results with the **netstat** results. Be sure to notify other system administrators or affected operations staff before running the port scanner, in case it affects system behavior or sets off your existing triggers for detecting intrusion. For more information about **netstat** and how you can determine which process is associated with each open port, see Netstat. For more information, also see port number assignments at the Internet Assigned Numbers Authority (IANA) Web site.

  **Note**

  - Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

- **Rename or disable the Administrator account; set up or review permissions and accounts that are relevant for this server.** Rename or disable the Administrator account created during Setup (it cannot be deleted). Set up the appropriate accounts and permissions for configuring, backing up, operating, and using this server. For both users and administrators, limit access to the minimum access that is necessary; for example, for someone who only performs backups, use the Backup Operators group. Also, set up policies to ensure that users maintain strong passwords. For more information, see:

  - Best practices for security and Best practices for Active Directory Users and Computers
  - Understanding Groups and Default groups
  - Strong passwords

- **Understand the security implications that apply to your server.** The questions to ask about security vary with the intended server use. For example, for a file server, who needs access to a given file or directory, what type of access is needed, and what are the possible consequences of unauthorized access? For a Web server, what Web applications do you want to use, what risks are inherent in those applications, and what settings will help mitigate the risks? For more information, see the links in the following table:

| Type of server | Suggested security topics |
|---|---|
| Any server | See Best practices for security and topics for the technologies you use in Best practices: pointers to recommendations and tips. |
| File server | If you are using Shared Folders, see Best practices for Shared Folders for Shared Folders. If you are using Active Directory, see Security overview. |
| Multimedia server | See security sections in the documentation for Windows Media Services, which is available when you install Windows Media Services. For more information, see Using Windows Media Services. |
| Print server | See Printing Best practices for printing. |

| | |
|---|---|
| Terminal server | See Terminal Server Best practices for Terminal server. |
| Web server | See the Security section of the server Administration Guide for Internet Information Services (IIS); this documentation is available when you install IIS. |

- **Configure auditing settings, set up system protections, and install a virus scanner.** Review and implement auditing settings, including those for security events, so that you can track all changes to the system and protect against unwanted changes to software. For more information, see:

  - Auditing Security Events

  - Topics about system information and the protection of system files and drivers:

    System Information

    Windows File Protection

    Driver signing for Windows

    System File Checker (sfc)

    Using File Signature Verification

    To set file signature verification options

  - Best practices for security

- **Ensure that an appropriate firewall is in place.** A firewall is a security system that acts as a protective boundary between a network and the outside world. For information about the firewall functionality that is available in Windows Server 2003 operating systems, see Help: Windows Firewall.

- **Consider using the Security Configuration Wizard.** The Security Configuration Wizard reduces the attack surface of servers that are running Windows Server 2003 with Service Pack 1 (SP1). The wizard asks the user a series of questions designed to determine the functional requirements of the server. Any functionality that is not required by the roles being performed by the server is then disabled. In addition to being a fundamental security best practice, reducing the attack surface increases the diversity of your Windows landscape, and reduces the number of systems that need to be immediately updated if a security issue arises. For more information, see Windows Server 2003 TechCenter.

**Begin routine operations such as backups.**

- **Analyze the hard disk for fragmentation.** After you run Setup and install programs, analyze the hard disk to see if it needs to be defragmented. For more information, see Analyze a volume.

- **Perform backups and install the Recovery Console.** Perform backups, install the Recovery Console so that it is readily available whenever you start the computer, and practice or simulate recovery operations (at times when demand on the server is low). For more information, see:

  - Backup

  - Install the Recovery Console as a startup option

  - Disaster Recovery

**Familiarize yourself with available information.**

- **Review the Best practices topics and checklists that relate to the features and components you will use.** For a

list of Best Practices topics, see Best practices: pointers to recommendations and tips. For a list of Checklists, see Checklists Provided in Windows Server 2003 Help.

- **Familiarize yourself with other sources of information and tools.** There are a variety of lists of resources in Help and Support, including the Resources for installing and upgrading the operating system topic for Getting Started. A variety of information is also available at the sources listed in Support resources.

# How to install and upgrade the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Start Setup on an x86-based computer
- Start Setup on an Itanium architecture-based computer
- Start Setup on an x64-based computer
- Enter Server Settings for a New Installation

# Start Setup on an x86-based computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Start Setup on an x86-based computer**

- Start Setup from the CD on a computer running Windows
- Start Setup from a network
- Start Setup for a new installation from the CD on a computer running MS-DOS
- Start Setup for a new installation by starting the computer from the CD
- Start Setup and provide a mass storage driver or a HAL file

# Start Setup from the CD on a computer running Windows

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup from the CD on a computer running Windows**

1. Insert the CD in the drive.
2. To begin Setup, do one of the following:
   - For a computer running any version of Windows other than Windows 3.*x*, wait for Setup to display a dialog box.
   - For a computer running Windows 3.*x*, use File Manager to change to the CD-ROM drive and to change to the I386 directory, and then double-click **Winnt.exe**.
3. Follow the Setup instructions.

## Notes

- To run Setup for an upgrade, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If you are running Setup on a computer running Windows 3.*x* or MS-DOS, for best efficiency, use disk caching. Otherwise, the Setup process (started from Winnt.exe) could take a long time. To enable disk caching on a computer running Windows 3.*x* or MS-DOS, you can use SMARTDrive. For information about SMARTDrive, see the documentation for Windows 3.*x* or MS-DOS.
- Setup works in several stages, prompting you for information, copying files, and restarting.
- For information about unattended Setup, see Related Topics.
- If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, see Related Topics for information about how to ensure that the controller driver file is available to the Setup program.
- If you have specialized hardware requiring a custom hardware abstraction layer (HAL) file supplied by your computer manufacturer, see Related Topics for information about how to make the HAL file available during Setup.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start Setup from a network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup from a network**

1. On a network server, share the installation files, either by inserting the CD and sharing the CD-ROM drive, or by copying the files from the I386 folder on the CD to a shared folder.

2. On the computer on which you want to install, connect to the shared Setup files:

   - If you are sharing the CD-ROM drive, connect to the shared drive and change to the I386 folder.

   - If you are sharing a folder, connect to that folder.

3. Find and run the appropriate file in the I386 directory of the CD or in the shared folder:

   - From a computer running MS-DOS or Windows 3.*x*, run Winnt.exe.

   - From a computer running Windows 95, Windows 98, Windows Millennium Edition, Windows NT with Service Pack 5 or later, Windows 2000, or Windows XP, run Winnt32.exe.

4. Follow the Setup instructions.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- Setup works in several stages, prompting you for information, copying files, and restarting.

- For information about unattended Setup, see Related Topics.

- If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, see Related Topics for information about how to ensure that the controller driver file is available to the Setup program.

- If you have specialized hardware requiring a custom hardware abstraction layer (HAL) file supplied by your computer manufacturer, see Related Topics for information about how to make the HAL file available during Setup.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start Setup for a new installation from the CD on a computer running MS-DOS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup for a new installation from the CD on a computer running MS-DOS**

1. Insert the CD in the drive.
2. At the command prompt, type:

   ***d*:**

   where *d* is the drive letter of the CD-ROM drive.
3. Type:

   **cd i386**
4. Type:

   **winnt**
5. Follow the Setup instructions.

## Notes

- If you are running Setup on a computer running Windows 3.*x* or MS-DOS, for best efficiency, use disk caching. Otherwise, the Setup process (started from Winnt.exe) could take a long time. To enable disk caching on a computer running Windows 3.*x* or MS-DOS, you can use SMARTDrive. For information about SMARTDrive, see the documentation for Windows 3.*x* or MS-DOS.
- Setup works in several stages, prompting you for information, copying files, and restarting.
- For information about unattended setup, see Related Topics.
- If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, see Related Topics for information about how to ensure that the controller driver file is available to the Setup program.
- If you have specialized hardware requiring a custom hardware abstraction layer (HAL) file supplied by your computer manufacturer, see Related Topics for information about how to make the HAL file available during Setup.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start Setup for a new installation by starting the computer from the CD

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup for a new installation by starting the computer from the CD**

1. Determine whether the computer on which you want to start Setup can be started from the CD-ROM drive, and whether you want to perform a new installation (not an upgrade). Continue only if both are true.

2. Insert the CD in the drive, and then restart the computer.

3. Follow the instructions for your operating system to boot the computer from the CD.

4. Wait for Setup to display a dialog box, and then follow the Setup instructions.

## Notes

- This method applies only if you want to perform a new installation, not an upgrade. Using this method, you can perform an installation on a computer that does not have an operating system, although you can also use this method on computers that have operating systems.

- Setup works in several stages, prompting for information, copying files, and restarting.

- For information about unattended Setup, see Related Topics.

- If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, see Related Topics for information about how to ensure that the controller driver file is available to the Setup program.

- If you have specialized hardware requiring a custom hardware abstraction layer (HAL) file supplied by your computer manufacturer, see Related Topics for information about how to make the HAL file available during Setup.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start Setup and provide a mass storage driver or a HAL file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup and provide a mass storage driver or a HAL file**

1. Determine whether you need to supply Setup with a special file (a mass storage driver or a hardware abstraction layer (HAL) file) supplied by your hardware manufacturer:

   - If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, check to see if the manufacturer has supplied a separate driver file for use with the Windows Server 2003 family.
   - If you have a highly specialized computer system, review your hardware documentation to see if a custom HAL file is supplied by your computer manufacturer.

2. If you determine that you need a driver or HAL file supplied by your hardware manufacturer, before beginning Setup, locate the floppy disk or other medium containing the file.

3. During the early part of Setup, watch the bottom of the screen for a line that prompts you to press F6. Press the appropriate key as follows:

   - To supply the driver for a mass storage controller to Setup, press F6 as instructed.
   - To supply a HAL file to Setup, press F5.

4. Follow further prompts for guidance in supplying the driver file to Setup so that it can gain access to the mass storage controller.

### Note

- If you are not sure whether you must obtain a separate driver file from the manufacturer of your mass storage controller, you can try running Setup. If the controller is not supported by the driver files on the Setup CD and therefore requires a driver file that is supplied by the hardware manufacturer, Setup stops and displays a message saying that no disk devices can be found, or it displays an incomplete list of controllers. After you obtain the necessary driver file, restart Setup, and press F6 when you are prompted.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start Setup on an Itanium architecture-based computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup on an Itanium architecture-based computer**

1. Immediately after turning on the computer, insert the Setup CD in the CD-ROM drive.
2. When the **EFI Boot Manager** menu appears, select the CD-ROM option.
3. When prompted, press any key to start from the CD-ROM.
4. Follow the on-screen Setup instructions.

### Important

- Itanium architecture-based computers require a minimum 100-MB FAT partition for the operation of the Extensible Firmware Interface (EFI). This EFI system partition is created automatically during Setup, and it stores programs and information files that the EFI uses to start the operating system. Do not delete or reformat this partition.
- Setup also creates a Microsoft Reserved (MSR) partition, which is required by the operating system. The size of this partition depends on the size of the hard disk. On drives less than 16 GB in size, the MSR is 32 MB. On drives greater than or equal to 16 GB, the MSR is 128 MB. Do not delete or reformat this partition.

### Notes

- Before installing, verify that you are using the correct version of the firmware. For more information, refer to the hardware manufacturer's documentation.
- The EFI defines a new partition style called GUID partition table (GPT). The installation partition on an Itanium architecture-based computer must be on a GPT disk. Setup automatically specifies GPT as the disk to be used for installation. You can still read and write to master boot record (MBR) volumes, which are common to most computers, but you cannot install on master boot record volumes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start Setup on an x64-based computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Setup on an x64-based computer**

1. Determine whether the computer on which you want to start Setup can be started from the CD-ROM drive.
2. Insert the CD in the drive, and then restart the computer.
3. Follow the instructions for your operating system to boot the computer from the CD.
4. Wait for Setup to display a dialog box, and then follow the Setup instructions.

# Enter Server Settings for a New Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enter server settings for a new installation**

- Specify regional and language options and user's name during Setup
- Specify licensing mode during Setup
- Enter your computer name
- Set the Administrator account password
- Set the date and time
- Allow Setup to assign or obtain an IP address
- Specify a static IP address and settings needed for DNS and WINS
- Specify the workgroup or domain name

## Notes

- The topics in this section provide details about entering server settings for a new installation. If you are upgrading, you can skip these topics because Setup will use your previous settings.
- If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, or if you have a specialized computer requiring a custom hardware abstraction layer (HAL) file supplied by your computer manufacturer, see Start Setup and provide a mass storage driver or a HAL file.
- After you start Setup, a process begins in which necessary Setup files are copied to the hard disk. During this process, Setup displays dialog boxes that you can use to select various options.

# Specify regional and language options and user's name during Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify regional and language options and user's name during Setup**

1. During Setup, in the **Regional and Language Options** dialog box, follow the instructions for customizing language and locale settings. You can use multiple regional and language options.

2. In the **Personalize Your Software** dialog box, type your name and, optionally, your organization.

3. Continue with Setup.

## Notes

- To open Regional and Language Options, click **Start**, click **Control Panel**, and then double-click **Regional and Language Options**.

- If you select a European country or region in the list of countries/regions, or if you live in a country or region where the euro has been introduced, it is a good idea to verify that the default currency settings in **Regional and Language Options** meet your needs.

- After you run Setup, you can modify regional and language options in Control Panel. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Choosing components to install

# Specify licensing mode during Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify licensing mode during Setup**

1. During Setup, in the **Licensing Modes** dialog box, select your client licensing mode:

    - **Per Server**
    - **Per Device or Per User**

2. Continue with Setup.

### Note

- If you are unsure which mode to use, select Per Server, because you can change once from Per Server to Per Device or Per User at no cost. For more information about licensing modes, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Licensing

# Enter your computer name

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enter your computer name**

- During Setup, in the **Computer Name and Administrator Password** dialog box, follow the instructions for entering your computer name. The recommended length for most languages is 15 characters or less. For languages that require more storage space per character, such as Chinese, Japanese, and Korean, the recommended length is 7 characters or less.

## Notes

- It is recommended that you use only Internet-standard characters in the computer name. The standard characters are the numbers from 0 through 9, uppercase and lowercase letters from A through Z, and the hyphen (-) character. Computer names cannot consist entirely of numbers.

- If you are using DNS on your network, you can use a wider variety of characters, including Unicode characters and other nonstandard characters, such as the ampersand (&). Using nonstandard characters may affect the ability of non-Microsoft software to operate on your network. For more information about DNS, see Related Topics.

- The maximum length for a computer name is 63 bytes. If the name is longer than 15 bytes (15 characters in most languages, 7 characters in some), computers running Windows NT Server 4.0 and earlier will recognize this computer by the first 15 bytes of the name only. In addition, there are additional configuration steps for a name that is longer than 15 bytes. For more information, see Related Topics.

- If a computer is part of a domain, you must choose a computer name that is different from any other computer in the domain. To avoid name conflicts, the computer should be unique on the domain, workgroup, or network. If this computer is part of a domain, and it contains more than one operating system, you must use a unique computer name for each operating system that is installed. For example, if the computer name is FileServerNT when the computer is started with Windows NT Server 4.0, the computer must have a different name, perhaps FileServerNew, when it is started with a product in the Windows Server 2003 family. This requirement also applies to a computer that contains multiple installations of the same operating system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the Administrator account password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the Administrator account password**

1. During Setup, in the **Computer Name and Administrator Password** dialog box, type a password of up to 127 characters in the **Administrator Password** box. For the strongest system security, use a password of at least 7 characters, and use a mixture of uppercase and lowercase letters, numbers, and other characters, such as *, ?, or $.

2. In the **Confirm Password** box, type the password again.

3. Continue with Setup.

### Important

- After Setup is completed, for best security, change the name of the Administrator account (it cannot be deleted) and keep a strong password on the account at all times. For more information, see Strong passwords.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
User and computer accounts

# Set the date and time

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the date and time**

1. During Setup, in the **Date and Time Settings** dialog box, set the date, time, and time zone.
2. If you want the system to automatically adjust for daylight saving time, select the **Automatically adjust clock for daylight saving changes** check box.
3. Continue with Setup.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow Setup to assign or obtain an IP address

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow Setup to assign or obtain an IP address**

- During Setup, in the **Networking Settings** dialog box, click **Typical settings**.

## Notes

- When you click **Typical settings** in the **Networking Settings** dialog box, Setup checks to see if there is a DHCP server on your network. If there is a DHCP server on your network, DHCP provides an IP address. If there is no DHCP server on your network, Setup will use a limited IP addressing option called Automatic Private IP Addressing (APIPA). On a server using APIPA, complete the network configuration after Setup, because a server using APIPA can communicate only with other computers using APIPA on the same network segment.

- For information about configuring automatic IP addressing after Setup, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify a static IP address and settings needed for DNS and WINS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a static IP address and settings needed for DNS and WINS**

1. During Setup, in the **Networking Settings** dialog box, click **Custom settings**, and then click **Next**.
2. In the **Networking Components** dialog box, click **Internet Protocol (TCP/IP)**.
3. Click **Properties**.
4. In the **Internet Protocol (TCP/IP) Properties** dialog box, click **Use the following IP address**.
5. In **IP address**, **Subnet mask**, and **Default gateway**, type the appropriate addresses.
6. Under **Use the following DNS server addresses**, type the address of a preferred DNS server and, optionally, an alternate DNS server.

   If the local server is the preferred or alternate DNS server, type the same IP address as assigned in the previous step.
7. If you will use a WINS server, click **Advanced**, and then click the **WINS** tab in the **Advanced TCP/IP Settings** dialog box to add the IP address of one or more WINS servers.
8. Click **OK** in each dialog box, and continue with Setup.

**Note**

- For information about configuring networking settings (including a static IP address) after Setup, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify the workgroup or domain name

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify the workgroup or domain name**

1. During Setup, in the **Workgroup or Computer Domain** dialog box, choose whether your server will be in a workgroup or in a domain.

2. Specify the workgroup or domain name.

3. Continue with Setup.

## Notes

- To avoid name conflicts, the computer should be unique on the domain, workgroup, or network. If this computer is part of a domain, and it contains more than one operating system, you must use a unique computer name with each of the operating systems that is installed. For example, if the computer name is FileserverNT when the computer is started with Windows NT Server 4.0, the computer must have a different name, perhaps FileserverNew, when it is started with Windows Server 2003, Standard Edition. This requirement also applies to a computer that contains multiple installations of the same operating system.

- For more information about the requirements for joining either a workgroup or a domain, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Concepts for installing and upgrading the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts for installing and upgrading the operating system**
This section provides background for planning the installation of Windows Server 2003, Standard Edition, Windows Server 2003, Web Edition, Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. For information about which topics apply if you are upgrading and which apply if you are performing a new installation, see the following:

- Checklist: Performing an upgrade
- Checklist: Performing a new installation

The following topics provide background information for the choices you make during the installation process.

- Important files to review
- Choosing a licensing mode
- Using Dynamic Update for updated drivers and other setup files
- Planning for unattended Setup
- System Requirements and Hardware Compatibility
- Upgrading or Installing
- Deciding Whether a Computer Will Contain More Than One Operating System
- Choosing a File System for the Installation Partition
- Planning Disk Partitions or Volumes for New Installations
- Networks: TCP/IP, IP Addresses, and Name Resolution
- Deciding Between Workgroups and Domains
- Preparing Your System Before Running Setup
- Resources for installing and upgrading the operating system

# Important files to review

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Important files to review**

At some point in the process of planning for a new installation or an upgrade, familiarize yourself with the **ReInotes.htm** file found in the \Docs folder on the CD for the Windows Server 2003 operating systems. This file contains important usage information about hardware, networking, applications, and printing. Also familiarize yourself with information about hardware compatibility for products in the Windows Server 2003 family. For more information, see Hardware compatibility.

For the most recent information on compatible applications for products in the Windows Server 2003 family, see the software compatibility section of the Microsoft Web site.

Most of the information contained in the Getting Started topics also appears in the \Docs folder on the Windows Server 2003 operating systems CDs, in text files (which use a file name extension of "TXT").

# Choosing a licensing mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Choosing a licensing mode**

Products in the Windows Server 2003 family support two licensing modes:

- Per Device or Per User
- Per Server

The following diagram illustrates the two modes:

If you choose the **Per Device or Per User** mode, each device or user that accesses a server running a product in the Windows Server 2003 family requires a separate Client Access License (CAL). With one CAL, a particular device or user can connect to any number of servers running products in the Windows Server 2003 family. This is the most commonly used licensing method for companies with more than one server running products in the Windows Server 2003 family.

In contrast, Per Server licensing means that each concurrent connection to this server requires a separate CAL. In other words, this server can support a fixed number of connections at any one time. For example, if you select the **Per Server** client licensing mode with five licenses, this server could have five concurrent connections at any one time (if each client requires one connection, this is five clients at any one time). The clients using the connections do not need any additional licenses.

The Per Server licensing mode is often preferred by small companies with only one server. It is also useful for Internet or remote access servers where the client computers might not be licensed as network clients for products in the Windows Server 2003 family. You can specify a maximum number of concurrent server connections and reject any additional logon requests.

If you are unsure which mode to use, choose **Per Server**, because you can change once from Per Server mode to Per Device or Per User mode at no cost. For more information about licensing and licensing modes, see Licensing overview and the Licensing Checklists for licensing.

**Note**

- If you use Terminal Server, you need to take additional steps to set up and activate Terminal Server Licensing. For more information, see Terminal Server Licensing.

# Using Dynamic Update for updated drivers and other setup files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Dynamic Update for updated drivers and other setup files**

If you have a working Internet connection on the computer on which you run Setup, you can choose Dynamic Update during Setup and obtain the most up-to-date Setup files, including drivers and other files. Whenever an important update is made to any crucial Setup file, that update is made available through Dynamic Update functionality built into the Windows Update Web site. Some of the updated files will be replacements (for example, an updated driver or updated Setup file) and some will be additions (for example, a driver not available at the time that the Setup CD was created). It is recommended that you use Dynamic Update when running Setup.

Dynamic Update has been carefully designed so that it is reliable and easy to use:

- The files on the Dynamic Update section of the Windows Update Web site have been carefully tested and selected. Only files that are important in ensuring that Setup runs well are made available through Dynamic Update. Files with minor updates that will not significantly affect Setup are not part of Dynamic Update.

- Because Dynamic Update downloads only the files that are required for your computer, the Dynamic Update software briefly examines your computer hardware. No personal information is collected, and no information is saved. The only purpose is to select appropriate drivers for your hardware configuration. This keeps the download as short as possible and ensures that only necessary drivers are downloaded to your hard disk.

- You can use Dynamic Update when running a preinstallation compatibility check from the product CD, or when running Setup itself. Either way, you obtain the most up-to-date files for running Setup. For information about running the compatibility check, see Hardware compatibility.

- You can use Dynamic Update with unattended Setup. Preparing for this requires several steps. For a brief description of unattended Setup, see Planning for unattended Setup. For details about how to use Dynamic Update with unattended Setup (also called automated installation), see *Automating and Customizing Installations* at the Microsoft Windows Server System Web site. For information about the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

The Windows Update Web site offers a variety of updates that you can use after completing Setup. For more information, see Windows Update at the Microsoft Web site. For a description of the different ways you can use Windows Update, see Windows Update.

# Planning for unattended Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning for unattended Setup**

This topic provides general information about unattended Setup. For detailed instructions on running unattended Setup (also called automated installation), see "Automating and Customizing Installations" at the Microsoft Windows Server System Web site. Also see the Windows XP Professional Resource Kit at the Microsoft Windows XP Resource Kits Web site. For information about the Windows Deployment and Resource Kits, see Using the Windows Deployment and Resource Kits.

To simplify the process of setting up a product in the Windows Server 2003 family on multiple computers, you can run Setup unattended. To do this, you create and use an *answer file*, a customized script that answers the Setup questions automatically. Then, you run Winnt32.exe or Winnt.exe with the appropriate options for unattended Setup. Choose the command according to the operating system that is running when you start unattended Setup:

- To start unattended Setup on a computer running MS-DOS or Windows 3.*x*, use Winnt.exe (with the appropriate options).
- To start unattended Setup on a computer running Windows 95, Windows 98, Windows Millennium Edition, Windows NT, Windows 2000, Windows XP, or a product in the Windows Server 2003 family, use Winnt32.exe (with the appropriate options). With Windows NT 4.0, before starting unattended Setup, apply Service Pack 5 or later.

To learn about unattended Setup, see the following sources:

- **For detailed instructions on running unattended Setup (also called automated installation):** See the Windows Deployment and Resource Kits listed in the first paragraph of this topic.
- **To view the command options available for Winnt.exe:** On a computer running Windows 3.*x* or MS-DOS, insert the Setup CD for a product in the Windows Server 2003 family in the CD-ROM drive and open the command prompt. Then, change to the CD-ROM drive, change to the I386 directory, and type:

  **winnt /?**
- **To use an x86-based or x64-based computer to view the command options available for Winnt32.exe:** On a computer running Windows 95, Windows 98, Windows Millennium Edition, Windows NT, Windows 2000, Windows XP, or a product in the Windows Server 2003 family, insert the Setup CD for Windows Server 2003, Standard Edition, in the CD-ROM drive, and open the command prompt (click **Start**, click **Run**, and then type **cmd**). Then, change to the CD-ROM drive, change to the I386 directory, and type:

  **winnt32 /?**
- **To use an Itanium-based computer to view the command options available for Winnt32.exe:** On an Itanium-based computer running Windows XP 64-Bit Edition; the Itanium-based version of Windows Server 2003, Enterprise Edition; or the Itanium-based version of Windows Server 2003, Datacenter Edition, insert the Setup CD for the product in the CD-ROM drive and open the command prompt (click **Start**, click **Run**, and then type **cmd**). Then, change to the CD-ROM drive, change to the IA64 directory, and type:

  **winnt32 /?**

For information about using Winnt.exe or Winnt32.exe for interactive setup (not unattended Setup), see How to install and upgrade the operating system.

# System Requirements and Hardware Compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System requirements and hardware compatibility**

- Windows Server 2003, Standard Edition: System requirements
- Windows Server 2003, Web Edition: System requirements
- Windows Server 2003, Enterprise Edition: System requirements
- Windows Server 2003, Datacenter Edition: System requirements
- Hardware overview
- Hardware compatibility
- Taking an inventory of devices that do not use Plug and Play
- Mass storage drivers and the setup process
- Understanding the ACPI BIOS for an x86-based computer

# Windows Server 2003, Standard Edition: System requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Standard Edition: System requirements**
To ensure adequate performance, make sure that computers on which you install or upgrade to Windows Server 2003, Standard Edition meet the following requirements:

- **For an x86-based computer**:
  - One or more processors with a recommended minimum speed of 550 megahertz (MHz). The minimum supported speed is 133 MHz. A maximum of four processors per computer is supported. Processors from the Intel Pentium/Celeron family, AMD K6/Athlon/Duron family, or compatible processors are recommended.
  - 256 megabytes (MB) of RAM (recommended minimum). 128 MB is the minimum supported, and 4 gigabytes (GB) is the maximum supported.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- **For an x64-based computer**:
  - One or more processors with a minimum speed of 1.4 gigahertz (GHz). A maximum of four processors per computer is supported.
  - 512 MB of RAM (minimum).

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- A hard disk partition or volume with enough free space to accommodate the setup process. To ensure that you have flexibility in your later use of the operating system, we recommend that you allow considerably more space than the minimum required for running Setup, which is approximately 1.25 GB to 2 GB for x86-based versions of Windows Server 2003, and 4 GB for x64-based versions of Windows Server 2003. The larger amount of space is required if you are running Setup across a network instead of from a CD-ROM, or if you are installing on a FAT or FAT32 partition (NTFS is the recommended file system).

  In addition, a domain controller upgrade from Windows NT 4.0 could require much more space than other upgrades or installations, because the existing user accounts database can expand by as much as a factor of ten during the upgrade, as Active Directory functionality is added.

  **Note**

  - The setup process requires the free disk space described in the previous paragraphs. After Setup is finished, actual hard disk space used for the operating system will be more than the free space required for Setup, because of space needed for the paging file, for any optional components you install, and (on domain controllers) for user accounts and other Active Directory information. The usual size for the paging file is 1.5 times the size of the RAM. For more information, see the following:

    Change virtual memory settings

    Specify what happens when the system stops unexpectedly

    Choosing components to install

    Understanding Active Directory

Directory data store

For additional information about planning the sizes of disk partitions or volumes, including information about creating a separate partition for Remote Installation Services, see Considerations when planning disk partitions and Remote Installation Services system requirements.

- A VGA or higher-resolution monitor (Super VGA 800x600 or higher is recommended), keyboard, and (optionally) a mouse or other pointing device.

  As an alternative, for operation without a monitor or keyboard, you can choose a remote diagnostic and support processor that is designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

*For CD-ROM installation:*

- A CD-ROM or DVD drive.

*For network installation:*

- One or more network adapters and related cables that are designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

- A server from which to offer network access for the Setup files.

*For additional hardware-based functionality:*

- Appropriate hardware for the functionality you require. For example, if you require sound, you must have a compatible sound card with speakers or headphones. If you plan to support network clients, the servers and clients must have appropriate network adapters and cables. For more details about your hardware, click the appropriate link in Support resources.

# Windows Server 2003, Web Edition: System requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Web Edition: System requirements**
To ensure adequate performance, make sure that computers on which you install or upgrade to Windows Server 2003, Web Edition meet the following requirements:

- **For an x86-based computer**:

  - One or two processors with a recommended minimum speed of 550 megahertz (MHz). The minimum supported speed is 133 MHz. A maximum of two processors per computer is supported. Processors from the Intel Pentium/Celeron family, AMD K6/Athlon/Duron family, or compatible processors are recommended.

  - 256 megabytes (MB) of RAM (recommended minimum). 128 MB is the minimum supported and 2 gigabytes (GB) is the maximum supported.

  - A hard disk partition or volume with enough free space to accommodate the setup process. To ensure that you have flexibility in your later use of the operating system, we recommend that you allow considerably more space than the minimum required for running Setup, which is approximately 1.25 GB to 2 GB. The larger amount of space is required if you are running Setup across a network, instead of from a CD-ROM.

    You must use NTFS as the file system with Windows Server 2003, Web Edition.

    **Note** The setup process requires the free disk space described in the previous paragraphs. After Setup is finished, actual hard disk space used for the operating system will be more than the free space required for Setup, because of space needed for the paging file, for any optional components you install, and (on domain controllers) for user accounts and other Active Directory information. The usual size for the paging file is 1.5 times the size of the RAM. For more information, see the following:

    Change virtual memory settings

    Specify what happens when the system stops unexpectedly

    Choosing components to install

    Understanding Active Directory

    Directory data store

    For additional information about planning the sizes of disk partitions or volumes, including information about creating a separate partition for Remote Installation Services, see Considerations when planning disk partitions and Remote Installation Services system requirements.

  - A VGA or higher-resolution monitor (Super VGA 800x600 or higher is recommended), keyboard, and (optionally) a mouse or other pointing device.

  - As an alternative, for operation without a monitor or keyboard, you can choose a remote diagnostic and support processor that is designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

*For CD-ROM installation:*

  - A CD-ROM or DVD drive.

*For network installation:*

- One or more network adapters and related cables that are designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

- A server from which to offer network access for the Setup files.

*For additional hardware-based functionality:*

- Appropriate hardware for the functionality you require. For example, if you require sound, you must have a compatible sound card with speakers or headphones, and if you plan to support network clients, the servers and clients must have appropriate network adapters and cables. For more details about your hardware, click the appropriate link in Support resources.

# Windows Server 2003, Enterprise Edition: System requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Enterprise Edition: System requirements**
To ensure adequate performance, make sure that computers on which you install or upgrade to Windows Server 2003, Enterprise Edition meet the following requirements:

- **For an x86-based computer**:
  - One or more processors with a recommended minimum speed of 550 megahertz (MHz). The minimum supported speed is 133 MHz. A maximum of eight processors per computer is supported. Processors from the Intel Pentium/Celeron family, AMD K6/Athlon/Duron family, or compatible processors are recommended.
  - 256 megabytes (MB) of RAM (recommended minimum). 128 MB is the minimum supported, and 32 gigabytes (GB) is the maximum supported.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- **For an Itanium-based computer**:
  - One or more processors with a minimum speed of 733 MHz. A maximum of eight processors per computer is supported.
  - 1 GB of RAM minimum, 1024 GB (1 Terabyte) maximum.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- **For an x64-based computer**:
  - One or more processors with a minimum speed of 1.4 GHz. A maximum of eight processors per computer is supported.
  - 1 GB of RAM minimum, 1024 GB (1 Terabyte) maximum.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- A hard disk partition or volume with enough free space to accommodate the setup process. To ensure that you have flexibility in your later use of the operating system, we recommend that you allow considerably more space than the minimum required for running Setup, which is approximately 2 GB to 3 GB for x86-based versions of Windows Server 2003, and 4 GB for Itanium-based and x64-based versions of Windows Server 2003. The larger amount of space is required if you are running Setup across a network instead of from a CD-ROM, or if you are installing on a FAT or FAT32 partition in the case of x86-based or x64-based versions of Windows Server 2003. (NTFS is the recommended file system for both x86-based and x64-based versions of Windows Server 2003. Itanium-based versions of Windows Server 2003 support only NTFS).

  In addition, a domain controller upgrade from Windows NT 4.0 could require much more space than other upgrades or installations, because the existing user accounts database can expand by as much as a factor of ten during the upgrade, as Active Directory functionality is added.

  **Note**

- The setup process requires the free disk space described in the previous paragraphs. After Setup is finished, actual hard disk space used for the operating system will be more than the free space required for Setup, because of space needed for the paging file, for any optional components you install, and (on domain controllers) for user accounts and other Active Directory information. The usual size for the paging file is 1.5 times the size of the RAM. For more information, see the following:

  Change virtual memory settings

  Specify what happens when the system stops unexpectedly

  Choosing components to install

  Understanding Active Directory

  Directory data store

  For additional information about planning the sizes of disk partitions or volumes, including information about creating a separate partition for Remote Installation Services, see Considerations when planning disk partitions and Remote Installation Services system requirements.

- A VGA or higher-resolution monitor (Super VGA 800x600 or higher recommended), keyboard, and (optionally) a mouse or other pointing device.

  As an alternative, for operation without a monitor or keyboard, you can choose a remote diagnostic and support processor that is designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

*For CD-ROM installation:*

- A CD-ROM or DVD drive.

*For network installation:*

- One or more network adapters and related cables that are designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

- A server from which to offer network access for the Setup files.

*For additional hardware-based functionality:*

- Appropriate hardware for the functionality you require. For example, if you plan to support network clients, the servers and clients must have appropriate network adapters and cables. As another example, if you require a server cluster, the entire cluster solution must be listed as compatible with Windows Server 2003, Enterprise Edition, (for more details, see information about cluster hardware and drivers in Planning and preparing for cluster installation). For more details about your hardware, click the appropriate link in Support resources.

# Windows Server 2003, Datacenter Edition: System requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Datacenter Edition: System requirements**
Computers that run Windows Server 2003, Datacenter Edition must be on the compatibility list for Windows Server 2003, Datacenter Edition. For details, see the hardware compatibility information in the Windows Server Catalog at the Microsoft Web site.

The requirements for systems on the compatibility list for Windows Server 2003, Datacenter Edition include the following:

- **For an x86-based computer**:
  - Must be able to support eight or more processors with a minimum speed of 400 megahertz (MHz). For new installations, the minimum processor speed is 550 MHz. A maximum of 32 processors per computer is supported.
  - 512 megabytes (MB) of RAM minimum, 128 gigabytes (GB) maximum.
  - 2 GB of free hard-disk space (minimum) for Setup.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- **For an Itanium-based computer**:
  - Must be able to support eight or more processors with a minimum speed of 733 MHz. A maximum of 64 processors per computer is supported.
  - 1 GB of RAM minimum, 1024 GB (1 Terabyte) maximum.
  - 4 GB of free hard-disk space (minimum) for Setup.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- **For an x64-based computer**:
  - Must be able to support eight or more processors with a minimum speed of 1.4 GHz. A maximum of 64 processors per computer is supported.
  - 1 GB of RAM minimum, 1024 GB (1 Terabyte) maximum.
  - 4 GB of free hard-disk space (minimum) for Setup.

    For computers with more than 4 GB of RAM, be sure to confirm hardware compatibility by clicking the appropriate link in Support resources.
- A hard-disk partition or volume with enough free space to accommodate the setup process. To ensure that you have flexibility in your later use of the operating system, we recommend that you allow considerably more space than the minimum required for running Setup, which is approximately 2 to 3 GB on an x86-based computer, and 4 GB on an Itanium-based or x64-based computer. The larger amount of space is required if you are running Setup across a network instead of from a CD-ROM.

  **Note**

- The setup process requires the free disk space described in the previous paragraphs. After Setup is finished, the actual hard-disk space used for the operating system will be more than the free space required for Setup. This is because of the space that is needed for the paging file, for any optional components you install, and (on domain controllers) for user accounts and other Active Directory information. The usual size for the paging file is 1.5 times the size of the RAM. For more information, see the following:

  Change virtual memory settings

  Specify what happens when the system stops unexpectedly

  Choosing components to install

  Understanding Active Directory

  Directory data store

  For additional information about planning the sizes of disk partitions or volumes, including information about creating a separate partition for Remote Installation Services, see Considerations when planning disk partitions and Remote Installation Services system requirements.

- A VGA or higher-resolution monitor (Super VGA 800x600 or higher recommended), keyboard, and (optionally) a mouse or other pointing device.

  As an alternative, for operation without a monitor or keyboard, you can choose a remote diagnostic and support processor that is designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

*For CD-ROM installation:*

- A CD-ROM or DVD drive.

*For network installation:*

- One or more network adapters and related cables that are designed for products in the Windows Server 2003 family. For more information about hardware compatibility, click the appropriate link in Support resources.

- A server from which to offer network access for the Setup files.

*For additional hardware-based functionality:*

- Appropriate hardware for the functionality you require. For example, if you plan to support network clients, the servers and clients must have appropriate network adapters and cables. As another example, if you require a server cluster, the entire cluster solution must be listed as compatible with Windows Server 2003, Datacenter Edition, (for more details, see information about cluster hardware and drivers in Planning and preparing for cluster installation). For more details about your hardware, click the appropriate link in Support resources.

# Hardware overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware overview**

Hardware includes any device that is connected to your computer and is controlled by your computer's microprocessor. This includes equipment that was connected to your computer when it was manufactured, as well as peripheral equipment that you added later. The following are examples of devices:

- Universal Serial bus (USB)
- IEEE 1394
- Modems
- Disk drives
- CD-ROM drives
- Digital video disc (DVD) drives
- Printers
- Network adapters
- Keyboards
- Video adapter cards
- Monitors
- Game controllers

Devices (Plug and Play and non-Plug and Play) can be connected to your computer in several ways. Some devices, such as network adapters and sound cards, are connected to expansion slots inside your computer. Other devices, such as printers and scanners, are connected to ports on the outside of your computer. Some devices, known as PC Cards, connect only to PC Card slots on a portable computer.

For a device to work properly with Windows, software known as a device driver must be installed on the computer. Each device is supported by one or more device drivers, which are typically supplied by the device manufacturer. However, some device drivers are included with Windows. If the device is Plug and Play, Windows can automatically detect it and install the appropriate device drivers.

If the device is not automatically installed by Windows, the Found New Hardware Wizard will appear and ask you to insert any media (such as compact discs or floppy disks) that were provided with the device. Non-Plug and Play devices are installed using the Add Hardware Wizard in Control Panel. If you want to manually install device drivers, you must use Device Manager. Before manually installing device drivers, you should consult the device documentation provided by the manufacturer.

**Important**

- You must be logged on as an administrator or as a member of the Administrators group in order to install or configure a device if:
- The device driver does not have the Designed for Windows Logo or a digital signature.

- Further action is required to install the device, requiring Windows to display a user interface.
- The device driver is not already on your computer.
- You need to configure a device using Device Manager.
- Your computer is connected to a network; network policy settings may also prevent you from installing hardware.

**Note**

- For the latest updates, including security fixes, service packs, new Help files, and device drivers, see Windows Update Web site.

# Hardware compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware compatibility**

One of the most important steps to take before running Setup on a server is to confirm that your hardware is compatible with products in the Windows Server 2003 family. You can do this by running a preinstallation compatibility check from the Setup CD or by checking the hardware compatibility information available from Microsoft. Also, as part of confirming hardware compatibility, check to see that you have obtained updated hardware device drivers and an updated system BIOS (or for an Itanium architecture-based computer, the correct firmware).

Regardless of whether you run a preinstallation compatibility check, Setup checks hardware and software compatibility at the beginning of an upgrade or new installation and displays a report if there are incompatibilities.

**Running a preinstallation compatibility check from the Setup CD**

You can run a hardware and software compatibility check from the Setup CD. The compatibility check does not require you to actually begin an upgrade or an installation. To run the check, insert the Setup CD in the CD-ROM drive and, when a display appears, follow the prompts for checking system compatibility. You will be offered the option to download the latest Setup files (through Dynamic Update) when you run the check. If you have Internet connectivity, it is recommended that you allow the download.

For more information about downloading the latest Setup files, see Using Dynamic Update for updated drivers and other setup files.

Another way to run the compatibility check is to insert the Setup CD in the CD-ROM drive, open a command prompt, and type

***d*:\i386\winnt32 /checkupgradeonly**

where *d* represents the CD-ROM drive.

**Checking hardware and software compatibility information available from Microsoft**

Another way to confirm that your hardware and software are designed for products in the Windows Server 2003 family is to click the appropriate links for compatibility information in Support resources.

Note that one type of hardware no longer supported is the microchannel bus.

**Checking drivers and system BIOS or firmware**

Check that you have obtained updated drivers for your hardware devices and that you have the latest system BIOS (for an x86-based or x64-based computer) or the correct firmware (for an Itanium architecture-based computer). The device manufacturers can help you obtain these items. For information about the Advanced Configuration and Power Interface (ACPI) standard for the BIOS, see Understanding the ACPI BIOS for an x86-based computer.

Finally, if you have devices that do not use Plug and Play, or you are aware that your Plug and Play devices are not implemented exactly to the standards, consider taking a device inventory of the hardware devices in your computer. For more information, see Taking an inventory of devices that do not use Plug and Play.

# Taking an inventory of devices that do not use Plug and Play

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Taking an inventory of devices that do not use Plug and Play**

This section describes steps you can take if the devices in your computer do not use Plug and Play technology. For important information about hardware compatibility (including the compatibility of devices), see:

- Windows Server 2003, Enterprise Edition: System requirements
- Hardware compatibility

For specific information about using a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) with a driver that was supplied by the manufacturer, see Mass storage drivers and the setup process.

Products in the Windows Server 2003 family include Plug and Play technology so that devices (for example, video and network adapters) can be automatically recognized by the operating system, configuration conflicts are avoided, and you do not have to specify each device's settings by hand. However, if you have devices that do not use Plug and Play, or you are aware that your Plug and Play devices are not implemented exactly to the standards, you might want to take steps to avoid device configuration conflicts. This section describes steps you can take, if you choose, to understand your device configuration before running Setup.

To take an inventory of your devices, if your computer has an existing operating system, use it to obtain the current settings, such as memory address and interrupt request (IRQ), used with your devices. For example, with Windows NT 4.0, you can use Control Panel to view settings (on the **Start** menu, point to **Settings**, click **Control Panel**, and then double-click icons such as **Network** and **Ports**). You might also choose to view system BIOS information. To do this, watch the screen while starting the computer, and then press the appropriate key when prompted.

At the beginning of an installation or upgrade, the Setup program automatically takes a device inventory as well. For devices that do not use Plug and Play, or that are not implemented exactly to Plug and Play standards, taking your own inventory helps prevent the following difficulties:

- If two or more adapters share IRQ settings or memory addresses, the Setup program might not be able to resolve the conflict. To prevent this, you can take one of two approaches.

  You can remove one of the adapters before running Setup and reinstall it afterward.

  As an alternative, you can modify one adapter's IRQ settings and memory addresses before running Setup, so that each adapter's settings are unique.

- If adapters do not respond in a standard way to the attempts by Setup to detect or enumerate them, Setup might receive indecipherable or inaccurate information. In this case, you might need to remove these devices before running Setup, and reinstall and configure them afterward.

The following table lists the kinds of information to gather if you have devices that do not use Plug and Play, and you decide to take a device inventory before starting Setup.

| Adapter | Information to gather |
|---|---|
| Video | Adapter or chip set type and how many video adapters |
| Network | IRQ, I/O address, DMA (if used) connector type (for example, BNC or twisted pair), and bus type |
| SCSI controller | Adapter model or chip set, IRQ, and bus type |
| Mouse | Mouse type and port (COM1, COM2, or PS/2) or USB |

| | |
|---|---|
| I/O port | IRQ, I/O address, and DMA (if used) for each I/O port |
| Sound adapter | IRQ, I/O address, and DMA |
| Universal serial bus (USB) | Which devices and hubs are attached |
| PC card | Which adapters are inserted and in which slots |
| Plug and Play | Whether enabled or disabled in BIOS |
| BIOS settings | BIOS revision and date |
| External modem | COM port connections (COM1, COM2, and so on) |
| Internal modem | COM port connections; for nonstandard configurations, IRQ and I/0 address |
| Advanced Configuration and Power Interface (ACPI); Power Options | Enabled or disabled; current setting |
| PCI | Which PCI adapters are inserted and in which slots |

# Mass storage drivers and the setup process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mass storage drivers and the setup process**

If you have a mass storage controller (such as a SCSI, RAID, or Fibre Channel adapter) for your hard disk, confirm that the controller is designed for products in the Windows Server 2003 family by clicking the appropriate link in Support resources.

If your controller is compatible, but you are aware that the manufacturer has supplied a separate driver file for use with products in the Windows Server 2003 family, obtain the file (on a floppy disk) before you begin Setup. During the early part of Setup, a line at the bottom of the screen will prompt you to press F6. Further prompts will guide you in supplying the driver file to Setup so that it can gain access to the mass storage controller.

If you are not sure whether you must obtain a separate driver file from the manufacturer of your mass storage controller, you can try running Setup. If the controller is not supported by the driver files on the Setup CD, and therefore requires a driver file that is supplied by the hardware manufacturer, Setup stops and displays a message saying that no disk devices can be found, or it displays an incomplete list of controllers. After you obtain the necessary driver file, restart Setup, and press F6 when you are prompted.

# Understanding the ACPI BIOS for an x86-based computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding the ACPI BIOS for an x86-based computer**
For an x86-based computer, the basic input/output system (BIOS) is a set of software through which the operating system (or Setup) communicates with the computer's hardware devices. The Advanced Configuration and Power Interface (ACPI) is the current standard for the way the BIOS works. Products in the Windows Server 2003 family support not only ACPI-compliant BIOS versions, but also some BIOS versions based on older advanced power management (APM) and Plug and Play designs.

Some ACPI-based BIOS versions are not compliant with the standard. The more recent the version of an ACPI BIOS, the more likely that it is compliant. An ACPI-based BIOS that is not compliant with the ACPI standard might not support workable communication between the operating system (or Setup) and your hardware. If workable communication is not supported, Setup stops and displays instructions for contacting your hardware manufacturer and taking other steps to solve the problem. If this happens, follow the instructions provided.

To learn more about the ACPI compliance of your BIOS:

- For information about your BIOS version, before running Setup, restart the computer and watch the text on the screen. Pay particular attention to blocks of text containing the words "BIOS" or "ACPI BIOS."

- For information about BIOS versions for your hardware, check your hardware documentation and contact your hardware manufacturer.

- If you think your BIOS might be a noncompliant ACPI BIOS, see the section about ACPI BIOS in the "System Recovery and Troubleshooting" appendix of the printed *Getting Started* manual.

# Upgrading or Installing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrading or installing**
This section provides information that will help you decide whether to upgrade or to install. It provides details about upgrading and installing, such as a list of the operating systems from which you can upgrade. In addition, it provides information about the steps to take when upgrading a small domain.

- Windows Server 2003, Standard Edition: Upgrade or new installation?
- Windows Server 2003, Enterprise Edition: Upgrade or new installation?
- Windows Server 2003, Datacenter Edition: Upgrade or new installation?
- Upgrades in a domain containing Windows 2000 domain controllers
- Upgrades in a Windows NT 4.0 Domain

# Windows Server 2003, Standard Edition: Upgrade or new installation?

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Standard Edition: Upgrade or new installation?**
After you have reviewed System Requirements and Hardware Compatibility and Important files to review, and before you run Setup, you will need to determine whether to upgrade or to perform a new installation. *Upgrading* is either replacing Windows NT 4.0 (with Service Pack 5 or later) or Windows 2000 with a product in the Windows Server 2003 family. In contrast, *installing* means completely removing the previous operating system, or installing a product in the Windows Server 2003 family on a disk or disk partition with no previous operating system.

If you have already decided whether to upgrade or to perform a new installation, see Checklist: Performing an upgrade or Checklist: Performing a new installation.

The following lists describe points to consider when deciding between an upgrade and a new installation.

**Points to consider for an upgrade**

- With an upgrade, configuration is simpler and your existing users, settings, groups, rights, and permissions are retained.
- With an upgrade, you do not need to reinstall files and applications. As with any major changes to the hard disk, however, we recommend that you back up the disk before beginning an upgrade.
- Before planning to perform an upgrade, see "Operating systems from which you can upgrade" later in this topic.
- If you are upgrading in a domain that includes domain controllers running Windows 2000, be sure to read Upgrades in a domain containing Windows 2000 domain controllers.
- If you are upgrading in a domain where all domain controllers are running Windows NT 4.0, be sure to read Upgrades in a Windows NT 4.0 Domain.
- If you want to upgrade and then use the same applications as before, be sure to review applications information in Relnotes.htm (in the \Docs folder on the product CD). Also, for the most recent information on compatible applications for products in the Windows Server 2003 family, see the software compatibility section of the Microsoft Web site.

**Points to consider for a new installation**

- If you reformat your hard disk and then perform a new installation, the efficiency of your disk might improve (compared to not reformatting it). Reformatting also gives you the opportunity to modify the size or number of disk partitions, to make them match your requirements more closely.
- If you want to practice careful configuration management, for example for a server where high availability is important, you might want to perform a new installation on that server instead of an upgrade. This is especially true on servers on which the operating system has been upgraded several times in the past.
- It is possible to install Windows Server 2003, Standard Edition, and also allow the computer to sometimes run another operating system. Setting up the computer this way, however, presents complexities because of file system issues. For more information, see Deciding Whether a Computer Will Contain More Than One Operating System.

**Note**

- If you used Windows NT 4.0 to create a volume set, mirror set, stripe set, or stripe set with parity, and you want to run Setup for Windows Server 2003, Standard Edition on that computer, you must prepare the disk set first. For details, see Working with volume, mirror, or stripe sets or stripe sets with parity.

**Operating systems from which you can upgrade**
If you upgrade, Setup automatically installs Windows Server 2003, Standard Edition into the same folder as the currently installed operating system. You can upgrade to Windows Server 2003, Standard Edition from the following versions of Windows:

- Windows NT Server 4.0 with Service Pack 5 or later
- Windows NT Server 4.0, Terminal Server Edition with Service Pack 5 or later
- Windows 2000 Server

### Note

- You cannot upgrade from an earlier version of a Windows server operating system to an Itanium-based or x64-based version of a Windows server operating system.

# Windows Server 2003, Enterprise Edition: Upgrade or new installation?

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Enterprise Edition: Upgrade or new installation?**
After you have reviewed System Requirements and Hardware Compatibility and Important files to review, and before you run Setup, you will need to determine whether to upgrade or to perform a new installation. *Upgrading* is either replacing Windows NT 4.0 (with Service Pack 5 or later) or Windows 2000 with a product in the Windows Server 2003 family. In contrast, *installing* means completely removing the previous operating system, or installing a product in the Windows Server 2003 family on a disk or disk partition with no previous operating system.

If you have already decided whether to upgrade or to perform a new installation, see Checklist: Performing an upgrade or Checklist: Performing a new installation.

The following lists describe points to consider when deciding between an upgrade and a new installation.

**Points to consider for an upgrade**

- With an upgrade, configuration is simpler and your existing users, settings, groups, rights, and permissions are retained.
- With an upgrade, you do not need to reinstall files and applications. As with any major changes to the hard disk, however, we recommend that you back up the disk before beginning an upgrade.
- Before planning to perform an upgrade, see "Operating systems from which you can upgrade" later in this topic.
- If you are upgrading in a domain that includes domain controllers running Windows 2000, be sure to read Upgrades in a domain containing Windows 2000 domain controllers.
- If you are upgrading in a domain where all domain controllers run Windows NT 4.0, be sure to read Upgrades in a Windows NT 4.0 Domain.
- If you want to upgrade and then use the same applications as before, be sure to review applications information in Relnotes.htm (in the \Docs folder on the product CD). Also, for the most recent information on compatible applications for products in the Windows Server 2003 family, see the software compatibility section of the Microsoft Web site.

**Points to consider for a new installation**

- If you reformat your hard disk and then perform a new installation, the efficiency of your disk might improve (compared to not reformatting it). Reformatting also gives you the opportunity to modify the size or number of disk partitions, to make them match your requirements more closely.
- If you want to practice careful configuration management, for example for a server where high availability is important, you might want to perform a new installation on that server instead of an upgrade. This is especially true on servers on which the operating system has been upgraded several times in the past.
- It is possible to install more than one operating system. Setting up the computer this way, however, presents complexities because of file system issues. For more information, see Deciding Whether a Computer Will Contain More Than One Operating System.

  **Note**

  - Do not install Windows Server 2003 on a compressed drive unless the drive was compressed with the NTFS file system compression utility. Uncompress a DriveSpace or DoubleSpace volume before running Setup on it.
- If you used Windows NT 4.0 to create a volume set, mirror set, stripe set, or stripe set with parity, and you want to run

Setup for Windows Server 2003 on that computer, you must prepare the disk set first. For details, see Working with volume, mirror, or stripe sets or stripe sets with parity.

**Operating systems from which you can upgrade**

If you upgrade, Setup automatically installs Windows Server 2003 into the same folder as the currently installed operating system. You can upgrade to Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition, from the following versions of Windows:

- Windows NT Server 4.0 with Service Pack 5 or later
- Windows NT Server 4.0, Terminal Server Edition with Service Pack 5 or later
- Windows NT Server 4.0, Enterprise Edition with Service Pack 5 or later
- Windows 2000 Server
- Windows 2000 Advanced Server

**Notes**

- You can also upgrade from Windows Server 2003, Standard Edition to Windows Server 2003, Enterprise Edition.
- If you have a version of Windows NT earlier than Windows NT 4.0, you cannot upgrade directly to a product in the Windows Server 2003 family. You must first upgrade to Windows NT 4.0 and apply Service Pack 5 before upgrading to a product in the Windows Server 2003 family.
- If you have servers or client computers that run Windows NT 3.51, we recommend that you install or upgrade to a newer operating system on all these computers, or retire them from operation. If you have more than one domain, you must upgrade domain controllers running Windows NT 3.51 for reliable logon validation. In any case, upgrading or retiring computers running Windows NT 3.51 strengthens security and reduces the number of version differences between computers, simplifying management and troubleshooting.
- You cannot upgrade from an earlier version of a Windows server operating system to an Itanium-based or x64-based version of a Windows server operating system.

# Windows Server 2003, Datacenter Edition: Upgrade or new installation?

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003, Datacenter Edition: Upgrade or new installation?**
After you have reviewed System Requirements and Hardware Compatibility and Important files to review, and before you run Setup, you will need to determine whether to upgrade or to perform a new installation. *Upgrading* is replacing Windows 2000 Datacenter Server with Windows Server 2003, Datacenter Edition. In contrast, *installing* means completely removing the previous operating system, or installing a product in the Windows Server 2003 family on a disk or disk partition with no previous operating system.

If you have already decided whether to upgrade or to perform a new installation, see Checklist: Performing an upgrade or Checklist: Performing a new installation.

The following lists describe points to consider when deciding between an upgrade and a new installation.

**Points to consider for an upgrade**

- With an upgrade, configuration is simpler and your existing users, settings, groups, rights, and permissions are retained.
- With an upgrade, you do not need to reinstall files and applications. As with any major changes to the hard disk, however, we recommend that you back up the disk before beginning an upgrade.
- If you want to upgrade and then use the same applications as before, be sure to review applications information in Relnotes.htm (in the \Docs folder on the product CD). Also, for the most recent information on compatible applications for products in the Windows Server 2003 family, see the software compatibility section of the Microsoft Web site.

**Points to consider for a new installation**

- If you reformat your hard disk and then perform a new installation, the efficiency of your disk might improve (compared to not reformatting it). Reformatting also gives you the opportunity to modify the size or number of disk partitions, to make them match your requirements more closely.
- If you want to practice careful configuration management, for example, for a server where high availability is important, you might want to perform a new installation on that server instead of an upgrade. This is especially true on servers on which the operating system has been upgraded several times in the past.

# Upgrades in a domain containing Windows 2000 domain controllers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrades in a domain containing Windows 2000 domain controllers**

If you are upgrading servers in a domain containing Windows 2000 domain controllers, there are a few points to keep in mind. The following points are the most important:

- The first step in planning the upgrade of a particular server is to check the compatibility of the hardware with products in the Windows Server 2003 family. For more information, see Hardware compatibility.

- Before you upgrade the first domain controller in a domain where one or more domain controllers run Windows 2000, or add a domain controller running a product in the Windows Server 2003 family, you must prepare the domain (and the forest in which it is located) using a simple tool on the Setup CD for Windows Server 2003.

  Before preparing the domain (and the forest in which it is located), it is recommended that you apply Service Pack 2 or later to all domain controllers running Windows 2000.

- If you have Internet Information Services (IIS) 5.0 installed on a server, when you upgrade the operating system, IIS is upgraded to IIS 6.0. However, for application compatibility, IIS runs in IIS 5.0 isolation mode after the upgrade. For more information about IIS isolation modes, see the IIS 6.0 Help.

- The Internet Explorer Enhanced Security Configuration is enabled by default when you upgrade. The security settings in this configuration can help make your computer more secure by limiting its exposure to malicious Web sites. Therefore, with this enhanced level of security, you might find that some Web sites do not display correctly in Internet Explorer when you are browsing Internet and intranet Web sites. Also, you might be prompted to enter your credentials when accessing network resources, such as files in Universal Naming Convention (UNC) shared folders. You can easily change the enhanced security settings. For more information, see Internet Explorer Enhanced Security Configuration overview.

- As you complete domain controller upgrades and reduce the number of different operating system versions running on them, you can adjust the domain and forest functional levels appropriately. For more information about functional levels, see Domain and forest functionality and Raising domain and forest functional levels. For general information about Active Directory, see Active Directory.

If you have servers running Windows NT, also review the following points:

- Before running Setup, it is recommended that you review the file systems and partitions that exist on the server. You must have at least one NTFS partition on domain controllers. It is recommended that you use NTFS on all partitions on all the servers in the domain, because any FAT or FAT32 partition lacks many security features. For example, on FAT or FAT32 partitions, a shared folder can be protected only by the permissions set on the shared folder, not on individual files, and there is no software protection against local access to the partition. For more information, see Reformatting or converting a partition to use NTFS and Convert.

- If some of your domain controllers run Windows 2000 and some run Windows NT, it is recommended that you upgrade the Windows NT domain controllers as soon as is practical, to reduce the number of version differences between computers, simplify management and troubleshooting, and strengthen security.

- Before you begin an upgrade from Windows NT 4.0, you must apply Service Pack 5 or later.

- If you have servers or client computers that run Windows NT 3.51, it is recommended that you install or upgrade to a newer operating system on all these computers, or retire them from operation. If you have more than one domain, you must upgrade domain controllers running Windows NT 3.51 for reliable logon validation. In any case, upgrading or retiring computers running Windows NT 3.51 strengthens security and reduces the number of version differences between computers, simplifying management and troubleshooting.

After the domain and forest are prepared, there are two stages in the upgrade of a domain controller. First you run Setup to upgrade the operating system and then, when Setup is complete, you run the Active Directory Installation Wizard (which appears on the screen the first time you log on).

# Upgrades in a Windows NT 4.0 Domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrades in a Windows NT 4.0 domain**
This section provides information about upgrading servers in a Windows NT 4.0 domain, that is, a domain where all domain controllers run Windows NT 4.0. The guidelines provided are for a network with one to five servers and 100 or fewer clients (the size of network discussed in these Getting Started topics). For information about upgrading servers in a domain where one or more domain controllers run Windows 2000, see Upgrades in a domain containing Windows 2000 domain controllers.

The following list describes the topics about upgrading servers in a Windows NT 4.0 domain:

- For information about initial preparations such as checking hardware compatibility and reviewing the size of partitions on server hard disks, see Basic preparations for the upgrade of servers in a Windows NT domain.
- For more information about planning steps that help you tailor the upgrade to your specific situation, see the following topics:
  - Planning server roles and the order of server upgrades from Windows NT
  - Planning the order of server upgrades in a Windows NT 4.0 domain
  - Planning DNS for the upgrade of domain controllers running Windows NT 4.0
- For more information about the final preparations to make just before beginning an upgrade, and guidelines about choices to make during the upgrade of domain controllers, see Performing final preparations and carrying out upgrades of domain controllers running Windows NT 4.0.

**Important**

- If you have servers or client computers that run Windows NT 3.51, it is recommended that you install or upgrade to a newer operating system on all these computers, or retire them from operation. If you have more than one domain, you must upgrade domain controllers running Windows NT 3.51 for reliable logon validation. In any case, upgrading or retiring computers running Windows NT 3.51 strengthens security and reduces the number of version differences between computers, simplifying management and troubleshooting.

**Note**

- The Internet Explorer Enhanced Security Configuration is enabled by default when you upgrade. The security settings in this configuration can help make your computer more secure by limiting its exposure to malicious Web sites. Therefore, with this enhanced level of security, you might find that some Web sites do not display correctly in Internet Explorer when you are browsing Internet and intranet Web sites. Also, you might be prompted to enter your credentials when accessing network resources, such as files in Universal Naming Convention (UNC) shared folders. You can easily change the enhanced security settings. For more information, see Internet Explorer Enhanced Security Configuration overview.

For additional information, see:

- For more information about Active Directory in relation to an upgrade from Windows NT, see Upgrading from a Windows NT domain and Domain and forest functionality.
- For information about deployments and upgrades in multiple domains or in domains larger than five servers, see the *Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site. For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

# Basic preparations for the upgrade of servers in a Windows NT domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Basic preparations for the upgrade of servers in a Windows NT domain**

There are a small number of basic preparations you must carry out to lay the groundwork for upgrading servers in a domain where all the domain controllers run Windows NT 4.0. For information about how these preparations fit into the overall process of the upgrade, see Upgrades in a Windows NT 4.0 Domain.

**Important**

- If you have servers or client computers that run Windows NT 3.51, it is recommended that you install or upgrade to a newer operating system on all these computers, or retire them from operation. If you have more than one domain, you must upgrade domain controllers running Windows NT 3.51 for reliable logon validation. In any case, upgrading or retiring computers running Windows NT 3.51 strengthens security and reduces the number of version differences between computers, simplifying management and troubleshooting.

**Compatibility check**

Check to see whether the applications and hardware on your systems are compatible with products in the Windows Server 2003 family, and then update or replace them as necessary. For important details about how to do this, see Hardware compatibility and Important files to review.

**Review partition sizes, especially on domain controllers**

Review the partitions on the servers to make sure there is plenty of free space available for the Windows Server 2003 family operating system to run. It is especially important to allow plenty of free space on domain controllers, because the existing user accounts database can expand by as much as a factor of ten when Active Directory functionality is added. For information about the disk requirements for the operating system, see Windows Server 2003, Enterprise Edition: System requirements.

**Review file systems on server partitions**

You must have at least one NTFS partition on domain controllers. It is recommended that you use NTFS on all partitions on all the servers in the domain, because any FAT or FAT32 partition lacks many security features. For example, on FAT or FAT32 partitions, a shared folder can be protected only by the permissions set on the shared folder, not on individual files, and there is no software protection against local access to the partition. For more information, see Reformatting or converting a partition to use NTFS and Convert.

**Service Pack**

Obtain Service Pack 5 or later, because it is necessary for the upgrade.

**Mirror sets or other disk sets**

If you used Windows NT 4.0 to create a volume set, mirror set, stripe set, or stripe set with parity, and you want to run Setup for Windows Server 2003 on that computer, you must prepare the disk set first. For details, see Working with volume, mirror, or stripe sets or stripe sets with parity.

# Planning server roles and the order of server upgrades from Windows NT

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning server roles and the order of server upgrades from Windows NT**

This section provides a list of basic guidelines to use when planning server roles and the order of server upgrades in a domain where all the domain controllers run Windows NT 4.0. For information about how this planning fits into the overall process of the upgrade, see Upgrades in a Windows NT 4.0 Domain.

Use the following guidelines when planning server roles and the order of server upgrades from Windows NT:

- Familiarize yourself with the slight differences between the naming of server roles for servers running Windows NT as compared to servers running Windows Server 2003:

  - In Windows NT, there are two kinds of domain controllers, the primary domain controller, which is limited to one per domain and contains a read-write database, and backup domain controller, which is not limited in number and contains a read-only database.

  - For domain controllers running Windows Server 2003, there is only one kind of domain controller, without a "primary" or "backup" designation. All domain controllers contain matching copies of the user accounts and other Active Directory data in a given domain, and provide read-write access to that data.

  - In addition to domain controllers, the possible roles for either operating system include member server, which belongs to a domain but does not contain a copy of the Active Directory data, and stand-alone server, which belongs to a workgroup instead of a domain.

- Note that in contrast with Windows NT, you can change the role of a server without rerunning Setup. However, as a general practice, it is best to plan the roles ahead of time and change them only as necessary.

- As was true with Windows NT, a domain must have at least one domain controller, but it is recommended that a domain have multiple domain controllers for resilience in the handling of logon requests and directory updates.

- If the features you need most are not Active Directory features, you can focus on upgrading member servers first. For information about reasons for upgrading a particular member server early in the process, see Planning the order of server upgrades in a Windows NT 4.0 domain.

- If the features you need most are Active Directory features, focus on upgrading domain controllers first, and carry out the advance planning that is necessary for this part of the upgrade.

  **Important**

  - When you begin the upgrade of domain controllers running Windows NT 4.0, you must upgrade the primary domain controller first.

  For information about the features that come with Active Directory, see Planning the order of server upgrades in a Windows NT 4.0 domain. For information about the planning necessary before upgrading to Active Directory, see Planning DNS for the upgrade of domain controllers running Windows NT 4.0.

- When you begin upgrading domain controllers, if you have a remote access server that is a *member* server, it is recommended that you upgrade it before the last domain controller is upgraded. Such a server is dependent on domain controllers for user information, and therefore should not be "left behind" when domain controllers are upgraded. As an alternative, you can weaken the security permissions in Active Directory so that the remote access server running Windows NT can read user attributes from the domain controllers running products in the Windows Server 2003 family. For more information, see the *Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site.

For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

# Planning the order of server upgrades in a Windows NT 4.0 domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning the order of server upgrades in a Windows NT 4.0 domain**
This topic lists the features available with the upgrade of any server running Windows NT 4.0 and also lists the features available with the upgrade of the first domain controller from Windows NT 4.0. Plan the order of server upgrades according to the features you are most interested in.

The following topics provide additional information:

- For information about other features in products in the Windows Server 2003 family, see New Features.
- For more information about upgrading servers in a domain where all domain controllers run Windows NT 4.0, see Upgrades in a Windows NT 4.0 Domain.
- For information about Active Directory, see Active Directory.

**Features available with the upgrade of any server in a Windows NT domain**
If you are interested in the features in the following list, you might want to focus on upgrading the member servers in your Windows NT 4.0 domain. For information about reasons to upgrade the domain controllers, see "Features Available with the First Domain Controller Upgrade in a Windows NT Domain," later in this topic.

- **Management tools**:

  Microsoft Management Console

  Plug and Play

  Device Manager

  Add Hardware Wizard (in Control Panel)

  Support for universal serial bus

  Enhanced Backup utility

- **File system support**: The version of NTFS in the Windows Server 2003 family includes support for disk quotas, the ability to defragment directory structures, and compressed network I/O.
- **Application services**: Win32 Driver Model, DirectX 7.0, and Windows Script Host.
- **Printer protocol support**: Device and protocol support allowing choices from more than 2,500 different printers. Other printing enhancements are included; for example, Internet Printing Protocol support, which allows users to print directly to a URL over an intranet or the Internet.
- **Scalability and availability**: Improved symmetric multiprocessor support as compared to Windows NT.
- **Security**: Encrypting file system.

**Features available with the first domain controller upgrade in a Windows NT domain**
If you are interested in the features in the following list, all of which are features of Active Directory, focus on upgrading the primary domain controller, as opposed to member servers. (The first domain controller that you upgrade must be the primary domain controller. It is recommended that you also upgrade backup domain controllers.) For information about the DNS

planning necessary before beginning the upgrade of domain controllers running Windows NT, see Planning DNS for the upgrade of domain controllers running Windows NT 4.0.

**Note**

- When a domain controller is upgraded, it has all the features of the Windows Server 2003 family operating system, which means it has all the features in the following list, plus the features in "Features available with the upgrade of any server in a Windows NT Domain," earlier in this topic.

When you upgrade a domain controller to run the Windows Server 2003 family operating system instead of Windows NT, many Active Directory features become available in the domain:

- **Simplified management** of network-resource information and user information.
- **Group Policy**, which you can use to set policies that apply across a given site, domain, or organizational unit in Active Directory.
- **Security and authentication features**, including support for Kerberos V5, Secure Sockets Layer (SSL) 3.0, and Transport Layer Security (TLS) using X.509v3 certificates.
- **Directory consolidation**, through which you can organize and simplify the management of users, computers, applications, and devices, and make it easier for users to find the information they want. You can take advantage of synchronization support through interfaces based on LDAP, and work with directory consolidation requirements specific to your applications.
- **Directory-enabled applications and infrastructure**, which make it easier to configure and manage applications and other directory-enabled network components.
- **Scalability without complexity**, a result of Active Directory scaling to millions of objects per domain and using indexing technology and advanced replication techniques to speed performance.
- **Use of Internet standards**, including access through LDAP and a namespace based on the Domain Name System (DNS).
- Active Directory Service Interfaces (ADSI), a powerful development environment.
- **Additional features**, as described in Features for Active Directory.

# Planning DNS for the upgrade of domain controllers running Windows NT 4.0

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning DNS for the upgrade of domain controllers running Windows NT 4.0**
The Domain Name System (DNS) is a hierarchical naming system used for locating computers on the Internet and private TCP/IP networks. This topic describes the planning for DNS that is recommended before you upgrade to Active Directory, that is, before you upgrade the primary domain controller in a Windows NT domain to become a domain controller running Windows Server 2003.

DNS is the name resolution service used by Active Directory. Products in the Windows Server 2003 family can support both the Windows Internet Name Service (WINS) common in Windows NT networks, and DNS. You must deploy DNS to support Active Directory; for information, see Active Directory integration. You can choose to migrate from WINS to DNS or configure your new DNS infrastructure to support your current WINS infrastructure.

For the upgrading of a network with one to five servers and 100 or fewer clients (which is the size of network discussed in these Getting Started topics), only a simple DNS plan is needed, because there will be no parent or child domains. For information about upgrading networks with more than five servers, see the *Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site. For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

DNS names consist of name labels separated by periods. A simple DNS domain name for a Windows Server 2003 family domain could take the form *domainname.ext* where *ext* is an established "top-level domain" type such as com or org. With a domain name of that form, the form of a computer name in the domain would be:

*computername.domainname.ext*

When you upgrade the primary domain controller in a Windows NT 4.0 domain (the primary domain controller must be upgraded first, before backup domain controllers), you will be offered several different options for the handling of DNS. If there is no DNS server available to work with Active Directory, you will be offered, by default, the option of installing DNS on the domain controller you are upgrading (formerly the primary domain controller). In a network with one to five servers, the simplest approach is to accept this default. Then, after completing the upgrade of the server on which DNS was installed, take note of its static IP address, and configure other computers to send any DNS requests to that IP address.

See the following for more information:

- For additional basic information about DNS and how to configure it during Setup, see Name resolution for TCP/IP.
- For more detailed information about DNS, see DNS.
- For specific information about namespace planning for DNS, see Namespace planning for DNS.

# Performing final preparations and carrying out upgrades of domain controllers running Windows NT 4.0

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performing final preparations and carrying out upgrades of domain controllers running Windows NT 4.0**
During the final preparations before beginning an upgrade from Windows NT 4.0, you can remove a backup domain controller temporarily from the network to protect your existing network integrity. During the upgrade, there are a few choices to make for the upgrade of a network of two to five servers (a network within the size of those discussed in these Getting Started topics). This topic describes the removal of a backup domain controller from the network, and provides guidelines for making choices during the upgrade.

Before beginning this stage of the upgrade process, be sure to review the important information in other topics listed in Upgrades in a Windows NT 4.0 Domain.

**Removing a backup domain controller from the network**
Before beginning an upgrade of servers in a domain where all the domain controllers run Windows NT 4.0, you can perform an additional precautionary step at the final preparatory stage, when you are confirming that Service Pack 5 or later has been applied, and you are performing server backups.

If you are preparing to upgrade the primary domain controller, to protect your existing network integrity, consider removing a backup domain controller temporarily from the network. To do this, in your existing Windows NT network, choose a backup domain controller, ensure that it has a current copy of the user accounts database, and back it up. Then disconnect its network cable. After the upgrade of your primary domain controller to become a domain controller running Windows Server 2003 (you must upgrade the primary domain controller first), this disconnected system is available for promotion to a Windows NT primary domain controller if necessary. However, in the course of an uneventful upgrade, you would not and could not promote the Windows NT backup domain controller to primary domain controller. Instead, you would continue the upgrade process, eventually reconnecting the disconnected server and upgrading it.

**Running the Active Directory Installation Wizard after upgrading the primary domain controller**
To upgrade the primary domain controller to become a domain controller running Windows Server 2003, you must first run Setup to upgrade the operating system. After the operating system is installed, you can run the Active Directory Installation Wizard (which appears on the screen the first time you log on). This section provides guidelines for making choices in the Active Directory Installation Wizard when upgrading the primary domain controller.

**Important**

- When you begin the upgrade of domain controllers running Windows NT 4.0, you must upgrade the primary domain controller first.

The following table shows the choices that are recommended when running the Active Directory Installation Wizard on the server that was formerly the primary domain controller. These recommendations are for a network of two to five servers (a network within the size of those discussed in these Getting Started topics):

| **Choices on the server that was formerly the primary domain controller** | **Recommended action for a network of two to five servers** |
|---|---|
| **Domain in a new forest** or **Child domain in an existing domain tree** or<br>**Domain tree in an existing forest** | Choose **Domain in a new forest**. |
| Forest functional level of **Windows Server 2003 interim**<br><br>(This choice appears only if **Domain in a new forest** was previously selected.) | Choose **Windows Server 2003 interim**.<br><br>With this domain functional level, you can have domain controllers running Windows NT 4.0 or Windows Server 2003, but no domain controllers running Windows 2000. |

During the upgrade, you can choose the location of three important items: the database containing user accounts and other Active Directory data, the log file, and the system volume (Sysvol) folder. The database and the log file can be on any kind of

partition (FAT, FAT32, or NTFS); the database can expand by as much as a factor of ten from the size it had with Windows NT, so allow plenty of room for it. (Initially, the log file will take up very little space.) The system volume folder must be on an NTFS partition. (For information about NTFS and other file systems, see Choosing a File System for the Installation Partition.)

**Note**

- When you begin upgrading domain controllers, if you have a remote access server that is a *member* server, it is recommended that you upgrade it before the last domain controller is upgraded. For more information, see Planning server roles and the order of server upgrades from Windows NT.

For additional information about upgrades in relation to Active Directory, see Domain and forest functionality and Upgrading from a Windows NT domain. For a general list of topics on Active Directory, see Active Directory.

# Deciding Whether a Computer Will Contain More Than One Operating System

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deciding whether a computer will contain more than one operating system**

- Considerations for computers that contain more than one operating system
- Multiple operating systems and file system compatibility
- Computers that contain multiple Windows Server 2003 family partitions
- Computers that contain Windows 2000 and Windows Server 2003
- Computers that contain Windows NT 4.0 and Windows Server 2003
- Computers that contain Windows 98 or Windows Millennium Edition and Windows Server 2003
- Computers that contain MS-DOS and Windows Server 2003

# Considerations for computers that contain more than one operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Considerations for computers that contain more than one operating system**

On a computer with an appropriate disk configuration (outlined in the table later in this topic), you can install more than one operating system, and then choose between the operating systems each time you restart the computer.

**Note**

- On an Itanium architecture-based computer, you can install Windows XP 64-bit Edition (Itanium) and the Itanium-based versions of Windows Server 2003. In this topic and other topics about installing multiple operating systems, information about operating systems that you cannot install does not apply. For example, information about Windows 2000 or Windows NT 4.0 does not apply to an Itanium architecture-based computer.

For example, on an x86-based or x64-based computer, you could set up a server to run Windows Server 2003, Enterprise Edition, most of the time, but allow it to sometimes run Windows NT Server 4.0 Enterprise Edition in order to support an older application. (However, to do this you would need to make specific file system choices and would need Service Pack 5 or later, as described in Multiple operating systems and file system compatibility.) During restarts, a display would appear for a specified number of seconds, allowing you to select between the two operating systems. (You can specify a default operating system that will run if no selection is made during the restart process.)

The following table shows the disk configurations on which you can install more than one operating system.

**Important**

- You must follow the requirements in the following table. For example, on a basic disk, you must install each operating system in a separate partition. This ensures that each operating system does not overwrite crucial files that are needed by another operating system.

| Disk configuration | Requirements for multiple operating systems |
|---|---|
| Basic disk or disks | You can install multiple operating systems, including Windows NT 4.0 and earlier operating systems, on a basic disk. Each operating system must be on a separate partition or logical drive on the disk. A partition or logical drive is a section of the disk that functions as a separate unit. Different partitions often have different drive letters; for example, C: and D:. |
| Single dynamic disk | You can install only one operating system.<br><br>However, if you used Windows 2000 or Windows XP to change a disk with no partitions directly to a dynamic disk, you must revert the disk to basic before you can install an operating system on it. For more information, see the Note after this table. |
| Multiple dynamic disks | Each dynamic disk can contain one installation of Windows 2000, Windows XP, or a product in the Windows Server 2003 family. No other operating systems can start from a dynamic disk.<br><br>However, if you used Windows 2000 or Windows XP to change a disk with no partitions directly to a dynamic disk, you must revert the disk to basic before you can install an operating system on it. For more information, see the Note after this table. |
| Master boot record (MBR) disk on an Itanium architecture-based computer | You cannot start operating systems from an MBR disk on an Itanium architecture-based computer. You must use a GPT disk for this purpose. |

| | |
|---|---|
| GUID partition table (GPT) disk on an Itanium architecture-based computer | You can install one or more operating systems on a GPT disk on an Itanium architecture-based computer. The guidelines in this table for basic and dynamic disks apply to GPT disks on Itanium architecture-based computers.<br><br>On an Itanium architecture-based computer, the operating systems that you can install include Windows XP 64-bit Edition (Itanium) and the Itanium-based versions of Windows Server 2003. On an Itanium architecture-based computer, you cannot install earlier operating systems, such as Windows 2000. |

**Note**

- If you used Windows 2000 or Windows XP to change a disk with no partitions directly to a dynamic disk, you must revert the disk to basic before you can install an operating system on it. All data will be lost in this process, so back it up first. You can then use Windows 2000 or Windows XP to revert the disk, or you can use Windows Server 2003 Setup. To use Windows 2000 or Windows XP, follow the instructions in Help for your operating system. To use Windows Server 2003 Setup, during the partitioning phase, find the dynamic disk among the list of available partitions and then delete it (which erases all data on all volumes). You will be prompted to confirm your action. After you do this, the disk will contain only unpartitioned space, and you can use Setup to create a new (basic disk) partition on it.

**Reasons to install only one operating system**

Setting up a computer so that you can choose between two or more operating systems at startup does have an advantage: it allows you to use applications that run only with a particular operating system. However, there are definite reasons to install only one operating system:

- Each operating system uses valuable disk space.
- Compatibility issues, especially file system compatibility, can be complex. For more information, see Multiple operating systems and file system compatibility.
- On a dynamic disk (a storage type available with products in the Windows Server 2003 family), you can have only one operating system per disk. Dynamic disks also will not work with some operating systems. For more information, see the table earlier in this topic.
- It is no longer necessary to maintain multiple operating systems as a safeguard against problems with starting the computer. With products in the Windows Server 2003 family, you have other options for system recovery. For example, if you have a problem with a newly installed device driver, you can use Safe Mode, in which Windows Server 2003 restarts with default settings and the minimum number of drivers. For more information about Safe Mode and other options, see Understanding Disaster Recovery.

**Specific details to consider**

Before you decide to set up a computer with more than one operating system, review the topics that apply to your situation:

| Operating system that can alternate with Windows Server 2003 | Topics to review |
|---|---|
| Another product in the Windows Server 2003 family | • Computers that contain multiple Windows Server 2003 family partitions |
| Windows 2000 | • Computers that contain Windows 2000 and Windows Server 2003 |
| Windows NT 4.0 | • Multiple operating systems and file system compatibility<br>• Computers that contain Windows NT 4.0 and Windows Server 2003 |
| Windows 98 or Windows Millennium Edition | • Computers that contain Windows 98 or Windows Millennium Edition and Windows Server 2003 |

| | |
|---|---|
| MS-DOS | • Computers that contain MS-DOS and Windows Server 2003 |

# Multiple operating systems and file system compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Multiple operating systems and file system compatibility**

On computers that contain multiple operating systems, compatibility becomes more complex when you consider file system choices. The file systems to choose from are NTFS, FAT, and FAT32. (For more information, see Choosing a File System for the Installation Partition.)

NTFS is normally the recommended file system because it is more efficient and reliable, and supports important features including Active Directory and domain-based security. With NTFS, however, you need to take file system compatibility into account when considering whether to set up a computer to contain more than one operating system, because with Windows 2000 and the Windows Server 2003 family, NTFS has new features in addition to those in Windows NT. Files that use any new features will be completely usable or readable *only* when the computer is started with Windows 2000 or a product in the Windows Server 2003 family.

For example, a file that uses the new encryption feature will not be readable when the computer is started with Windows NT Server 4.0 or Windows NT 4.0 Server Enterprise Edition, which were released before the encryption feature existed.

For more information about features that affect file accessibility with products in the Windows Server 2003 family, see NTFS.

**Notes**

- If you want to set up a computer with both Windows NT and Windows Server 2003 operating systems, and you want to have an NTFS partition, the only appropriate version of Windows NT is version 4.0 with the latest released Service Pack. Using the latest Service Pack maximizes compatibility between Windows NT 4.0 and Windows Server 2003. (Specifically, you must have Service Pack 5 or later.) Even the latest Service Pack, however, does not provide access to files using the new features in NTFS.

- Using NTFS as the only file system on a computer that contains both Windows Server 2003 and Windows NT is *not* recommended. On these computers, a FAT partition containing the Windows NT 4.0 operating system ensures that when started with Windows NT 4.0, the computer will have access to needed files. In addition, if Windows NT is not installed on the system partition, which is almost always the first partition on the disk, it is recommended that the system partition also be formatted with FAT.

- If you set up a computer so that it starts with Windows NT 3.51 or earlier on a FAT partition, and Windows Server 2003 on an NTFS partition, when that computer starts with Windows NT 3.51, the NTFS partition will not be visible. If you set up a computer this way, and the partition containing Windows NT 3.51 is not the system partition (which is almost always the first partition on the disk), the system partition must also be formatted with FAT.

# Computers that contain multiple Windows Server 2003 family partitions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computers that contain multiple Windows server 2003 family partitions**

You can set up a server so that it contains some combination of Windows XP and products in the Windows Server 2003 family, or contains multiple installations of products in the Windows Server 2003 family. If you plan to do this, note the following:

- Install each operating system on a different partition or, for dynamic disks, on a different disk, and install the applications used with an operating system on the same disk or partition with it. If an application is used with two different operating systems, install it in two places.

- For an x86-based computer, choose any product in the Windows Server 2003 family for installation on a specific partition. For example, you could install Windows Server 2003, Standard Edition, in one location and Windows Server 2003, Enterprise Edition, in another.

  For an x64-based computer, you can choose among Windows XP Professional x64 Edition; the x64-based version of Windows Server 2003, Standard Edition; the x64-based version of Windows Server 2003, Enterprise Edition; and the x64-based version of Windows Server 2003, Datacenter Edition. In addition, you can choose to install any x86-based operating system, such as Microsoft® Windows® XP.

  For an Itanium architecture-based computer, you can choose among Windows XP 64-bit Edition (Itanium); the Itanium-based version of Windows Server 2003, Enterprise Edition; and the Itanium-based version of Windows Server 2003, Datacenter Edition.

- If the computer participates in a domain, use a different computer name for each installation. Because a unique security identifier (SID) is used for each installation of Windows Server 2003 on a domain, the computer name for each installation must be unique, even for multiple installations on the same computer.

- If you set up a server so that it contains some combination of Windows Server 2003 and Windows 2000 or Windows XP, or contains multiple partitions with products in the Windows Server 2003 family, and you want to use the Encrypting File System (EFS) on the computer, you must take certain steps. These steps make encrypted files readable between the different installations.

  - One approach is to ensure that all the installations are in the same domain and that the user of these installations has a roaming profile.

  - Another approach is to export the user's file encryption certificate and associated private key from one installation and import it into the other installations.

  For more information, see Introduction to using Encrypting File System, Using roaming user profiles, and Importing and exporting certificates.

# Computers that contain Windows 2000 and Windows Server 2003

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computers that contain Windows 2000 and Windows Server 2003**

You can set up a server so that it contains both Windows 2000 and Windows Server 2003. If you plan to do this, note the following:

- Install each operating system on a different partition or, for dynamic disks, on a different disk, and install the applications used with an operating system on the same disk or partition with it. If an application is used with two different operating systems, install it in two places.

- Windows Server 2003 must be installed last. Otherwise, important files that are needed for starting Windows Server 2003 will be overwritten.

- If the computer participates in a domain, use a different computer name for each installation. Because a unique security identifier (SID) is used for each installation on a domain, the computer name for each installation must be unique, even for multiple installations on the same computer.

- If you use the Encrypting File System (EFS) on a computer containing Windows 2000 and a product in the Windows Server 2003 family, the encrypted files will not be readable between the different installations unless you take one of the following approaches:

  - One approach is to ensure that all the installations are in the same domain and that the user of these installations has a roaming profile.

  - Another approach is to export the user's file encryption certificate and associated private key from one installation and import it into the other installations.

  For more information, see Introduction to using Encrypting File System, Using roaming user profiles, and Importing and exporting certificates.

# Computers that contain Windows NT 4.0 and Windows Server 2003

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computers that contain Windows NT 4.0 and Windows Server 2003**

If you plan to set up a computer so that it contains Windows NT 4.0 and Windows Server 2003 operating systems, first review the following precautions:

- It is no longer necessary to maintain multiple operating systems as a safeguard against problems with starting the computer. With products in the Windows Server 2003 family, you have other options for system recovery. For example, if you have a problem with a newly installed device driver, you can use Safe Mode, in which Windows Server 2003 restarts with default settings and the minimum number of drivers. For more information about Safe Mode and other options, see Understanding Disaster Recovery.

- Using NTFS as the only file system on a computer that contains both Windows Server 2003 and Windows NT is *not* recommended. For more information, see Multiple operating systems and file system compatibility.

- Make sure that Windows NT 4.0 has been updated with the latest released Service Pack. For details, see Multiple operating systems and file system compatibility.

- Install each operating system on a different partition, and install the applications used with an operating system on the same partition with it. If an application is used with two different operating systems, install it on two partitions.

- Do not install Windows Server 2003 on a compressed drive unless the drive was compressed with the NTFS file system compression feature.

- Windows Server 2003 must be installed last. Otherwise, important files that are needed for starting Windows Server 2003 will be overwritten.

- If the computer participates in a domain, use a different computer name for each installation.

# Computers that contain Windows 98 or Windows Millennium Edition and Windows Server 2003

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computers that contain Windows 98 or Windows Millennium Edition and Windows Server 2003**
If you plan to set up a computer so that it contains Windows 98 or Windows Millennium Edition and Windows Server 2003, note the following:

- Install each operating system on a different partition, and install the applications used with an operating system on the same partition with it. If an application is used with two different operating systems, install it on two partitions.
- Windows 98 or Windows Millennium Edition must be installed on a basic disk on a partition formatted with FAT or FAT32. If either Windows 98 or Windows Millennium Edition is not installed on the system partition, which is almost always the first partition on the disk, the system partition must also be formatted with FAT or FAT32.
- Windows Server 2003 must be installed last. Otherwise, important files that are needed for starting Windows Server 2003 will be overwritten.
- File system compatibility might be an issue. See Multiple operating systems and file system compatibility.

# Computers that contain MS-DOS and Windows Server 2003

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computers that contain MS-DOS and Windows Server 2003**

If you plan to set up a computer so that it contains MS-DOS and Windows Server 2003, note the following:

- Install each operating system on a different partition, and install the applications used with an operating system on the same partition with it. If an application is used with two different operating systems, install it on two partitions.
- MS-DOS must be installed on a basic disk on a partition formatted with FAT. If MS-DOS is not installed on the system partition, which is almost always the first partition on the disk, the system partition must also be formatted with FAT.
- Windows Server 2003 must be installed last. Otherwise, important files that are needed for starting Windows Server 2003 will be overwritten.
- File system compatibility might be an issue. See Multiple operating systems and file system compatibility.

# Choosing a File System for the Installation Partition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Choosing a file system for the installation partition**

- Choosing a file system: NTFS, FAT, or FAT32
- Reformatting or converting a partition to use NTFS
- NTFS compared to FAT and FAT32
- NTFS

# Choosing a file system: NTFS, FAT, or FAT32

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Choosing a file system: NTFS, FAT, or FAT32**
You can choose among three file systems for an installation partition: NTFS, FAT, and FAT32. NTFS is strongly recommended in most situations.

For details about each file system or the process of converting or reformatting a partition, see:

- Reformatting or converting a partition to use NTFS
- NTFS compared to FAT and FAT32
- NTFS

**Note**

- You can use important features such as Active Directory and domain-based security only by choosing NTFS as your file system.

**Important**

- On globally unique identifier (GUID) partition table disks (GPT disks), it is strongly recommended that you use NTFS for the installation partition. However, if you have an Itanium architecture-based computer, and you see that it has a small FAT partition of 100 megabytes (MB) or more, do not delete or reformat this partition. The partition is required for the loading of the operating system. For more information, see Start Setup on an Itanium architecture-based computer.

The following table lists a number of installation or upgrade scenarios for x86-based and x64-based computers (the last two scenarios are fairly uncommon) and provides file system guidelines for each one:

| Installation or upgrade scenario for an x86-based or x64-based computer | File system to use and additional information to read |
|---|---|
| The computer currently uses NTFS only (no FAT or FAT32). | Continue to use NTFS.<br><br>No additional information about file systems needed. |
| The computer is x86-based and has one or more FAT or FAT32 partitions.<br><br>AND<br><br>The computer contains only one operating system, or the operating systems on the computer include Windows 2000, Windows XP, or a product in the Windows Server 2003 family, but no other operating systems.<br><br>If the computer is Itanium architecture-based, see the important note earlier in this topic. | Consider reformatting or converting partitions so all partitions use NTFS.<br><br>For more information, see Reformatting or converting a partition to use NTFS. |
| The computer is x64-based. | Use NTFS. |

| | |
|---|---|
| The computer will contain multiple operating systems, one of which is MS-DOS, Windows 95, Windows 98, or Windows Millennium Edition. | For any partition that must be accessible from MS-DOS, Windows 95, Windows 98, or Windows Millennium Edition, use FAT (or when appropriate, FAT32).<br><br>For more information, see Deciding Whether a Computer Will Contain More Than One Operating System. |
| The computer will contain multiple operating systems, one of which is Windows NT. | Read Multiple operating systems and file system compatibility. |

# Reformatting or converting a partition to use NTFS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Reformatting or converting a partition to use NTFS**

If you have a FAT or FAT32 partition on which you want to install a product in the Windows Server 2003 family, and you want to use NTFS instead, you have two choices:

- You can convert the FAT or FAT32 partition to NTFS. This leaves files intact, although the partition may have somewhat more fragmentation and slower performance than a partition formatted with NTFS. However, it is still advantageous to use NTFS, regardless of whether the partition was formatted with NTFS or converted.

  If you install a product in the Windows Server 2003 family on a FAT or FAT32 partition, you are offered the option to convert the partition to NTFS. You can also convert a FAT or FAT32 partition after Setup by using Convert.exe. For more information about Convert.exe, see Convert.

- You can reformat the partition with NTFS. This erases all files on the partition, but results in less fragmentation and better performance than with a converted partition.

**Important**

- If you have an Itanium architecture-based computer and you see that it has a small FAT partition of 100 MB or more, do not delete or reformat this partition. The partition is required for the loading of the operating system. For more information, see Start Setup on an Itanium architecture-based computer.

If you format a partition during Setup, the file systems choices are listed as NTFS and FAT. The following table provides information about the relationship between partition size and file system choices during Setup.

| State and size of partition | Setup choices and responses (when formatting the partition) |
|---|---|
| Unformatted, less than 2 GB. | Setup offers NTFS or FAT. Setup uses the format chosen. |
| Unformatted, 2 GB or larger, up to a maximum of 32 GB. | Setup offers NTFS or FAT. If FAT is chosen, Setup uses FAT32. |
| Unformatted, larger than 32 GB. | Setup allows only NTFS. |
| Previously formatted with FAT32 and larger than 32 GB. (Partition created with Windows 95, Windows 98, or Windows Millennium Edition.) | No formatting needed, even though an unformatted partition of this size, when formatted during or after Setup for a product in the Windows Server 2003 family, would have to use NTFS. In other words, previously-formatted FAT32 partitions of this size continue to be supported by the Windows Server 2003 family. |

If you format a partition during Setup, you can choose between a quick format and a full format:

**Quick format**

Quick format creates the file system structure on the disk without verifying the integrity of every sector. Choose this method for any disk that has no bad sectors and no history of file-corruption problems that might be related to bad sectors.

**Full format**

A full format identifies and tracks bad sectors so that they are not used for storing data. Choose this method for any disk that has bad sectors or has a history of file-corruption problems that might be related to bad sectors.

# NTFS compared to FAT and FAT32

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NTFS compared to FAT and FAT32**

NTFS has always been a more powerful file system than FAT and FAT32. Windows 2000, Windows XP, and the Windows Server 2003 family include a new version of NTFS, with support for a variety of features including Active Directory, which is needed for domains, user accounts, and other important security features. For more details about features in NTFS, see NTFS.

FAT and FAT32 are similar to each other, except that FAT32 is designed for larger disks than FAT. The file system that works most easily with large disks is NTFS.

The following table describes the compatibility of each file system with various operating systems.

**Note**

- File system choices have no effect on access to files across the network. For example, using NTFS on all partitions on a server does not affect clients connecting across a network to shared folders or shared files on that server, even if those clients run an earlier operating system such as Windows 98 or Windows NT.

| NTFS | FAT | FAT32 |
|---|---|---|
| A computer running Windows 2000, Windows XP, or a product in the Windows Server 2003 family can access files on a local NTFS partition. A computer running Windows NT 4.0 with Service Pack 5 or later might be able to access some files. Other operating systems allow no local access. | Access to files on a local partition is available through MS-DOS, all versions of Windows, and OS/2. | Access to files on a local partition is available only through Windows 95 OSR2, Windows 98, Windows Millennium Edition, Windows 2000, Windows XP, and products in the Windows Server 2003 family. |

The following table compares disk and file sizes possible with each file system.

| NTFS | FAT | FAT32 |
|---|---|---|
| Recommended minimum volume size is approximately 10 MB.<br><br>Maximum volume and partition sizes start at 2 terabytes (TB) and range upward. For example, a dynamic disk formatted with a standard allocation unit size (4 KB) can have partitions of 16 TB minus 4 KB. For more information about maximum volume and partition sizes, see the *Windows Server 2003 Resource Kit, Server Management Guide* at the Microsoft Windows Resource Kits Web site.<br><br>Cannot be used on floppy disks. | Volumes from floppy disk size up to 4 GB.<br><br>Does not support domains. | Volumes from 33 MB to 2 TB can be written to or read using products in the Windows Server 2003 family.<br><br>Volumes up to 32 GB can be formatted as FAT32 using products in the Windows Server 2003 family.<br><br>Does not support domains. |
| Maximum file size is potentially 16 TB minus 64 KB, although files cannot be larger than the volume or partition they are located on. | Maximum file size is 2 GB. | Maximum file size is 4 GB. |

**Notes**

On Itanium-based computers with more than one disk, on x64-based computers, and on x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), you can choose not only the sizes of partitions but the partition style for each disk. The partition style determines the way that information about the partition is stored. There are two partition styles: master boot record (MBR) and GUID partition table (GPT). On GPT disks, unlike MBR disks, data critical to platform operation is located in partitions instead of unpartitioned or hidden sectors. In addition, GPT disks have redundant primary and backup partition tables for improved partition data structure integrity.

On Itanium-based computers, you must install Windows XP 64-bit Edition (Itanium) or the Itanium-based versions of Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, on a GPT disk. On x86-based and x64-based computers running Windows Server 2003, you must install the operating system on an MBR disk. Other disks can use either the MBR or GPT partition style. With GPT disks, you can create more partitions and larger volumes and can take advantage of other benefits.

For more information about GPT disks, see GUID partition table. For more information about MBR and GPT partition styles, see Partition styles. For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

# NTFS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NTFS**

Some of the features you can use when you choose NTFS are:

- Better scalability to large drives. The maximum partition or volume size for NTFS is much greater than that for FAT, and as volume or partition sizes increase, performance with NTFS does not degrade as it does with FAT.
- Active Directory (and domains, which are part of Active Directory). With Active Directory, you can view and control network resources easily. With domains, you can fine-tune security options while keeping administration simple. Domain controllers and Active Directory require NTFS.
- Compression features, including the ability to compress or uncompress a drive, a folder, or a specific file. (However, a file cannot be both compressed and encrypted at the same time.)
- File encryption, which greatly enhances security. (However, a file cannot be both compressed and encrypted at the same time.)
- Permissions that can be set on individual files rather than just folders.
- Remote Storage, which provides an extension to your disk space by making removable media such as tapes more accessible.
- Recovery logging of disk activities, which allows NTFS to restore information quickly in the event of power failure or other system problems.
- Sparse files. These are very large files created by applications in such a way that only limited disk space is needed. That is, NTFS allocates disk space only to the portions of a file that are written to.
- Disk quotas, which you can use to monitor and control the amount of disk space used by individual users.

This is only a partial list of the features in NTFS in the Windows Server 2003 family. For more information about new features, see New Features.

For information about maximum file sizes possible with NTFS, see NTFS compared to FAT and FAT32. For information about converting or reformatting a FAT or FAT32 partition, see Reformatting or converting a partition to use NTFS.

# Planning Disk Partitions or Volumes for New Installations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning disk partitions or volumes for new installations**

- Considerations when planning disk partitions
- Options when partitioning a disk
- Working with dynamic disks and Setup

# Considerations when planning disk partitions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Considerations when planning disk partitions**

You must plan your disk partitions before you run Setup only if both of the following conditions are true:

- You are performing a new installation, not an upgrade.
- The disk on which you are installing is a basic disk, not a dynamic disk. Basic disks are the disk type that existed before Windows 2000; most disks are basic disks. Dynamic disks are disks that once were basic but were changed to dynamic using Windows 2000, Windows XP, or a product in the Windows Server 2003 family. If you plan to install to a dynamic disk, you cannot change the volume or partition sizes on the disk during Setup, and therefore no planning is needed regarding partition sizes. Instead, review the guidelines in Working with dynamic disks and Setup.

Disk partitioning is a way of dividing your physical disk so that each section functions as a separate unit. When you create partitions on a basic disk, you divide the disk into one or more areas that can be formatted for use by a file system, such as FAT or NTFS. Different partitions often have different drive letters (for example, C: and D:). A basic disk can have up to four primary partitions, or three primary partitions and one extended partition. (An extended partition can be subdivided into logical drives, while a primary partition cannot be subdivided.)

**Important**

- If you plan to delete or create partitions on a hard disk, be sure to back up the disk contents beforehand, because these actions will destroy any existing data. As with any major change to disk contents, it is recommended that you back up the entire contents of the hard disk before working with partitions, even if you plan to leave one or more of your partitions alone.

Before you run Setup to perform a new installation, determine the size of the partition on which to install. There is no set formula for figuring a partition size. The basic principle is to allow plenty of room for the operating system, applications, and other files that you plan to put on the installation partition. The files for setting up Windows Server 2003 require approximately 1.25 GB to 3 GB on an x86-based computer and 3 GB to 4 GB on an Itanium architecture-based computer, as described in the topics about system requirements listed in System Requirements and Hardware Compatibility. It is recommended that you allow considerably more disk space than the minimum amount. It is not unreasonable to allow 4 GB to 10 GB on the partition, or more for large installations. This allows space for a variety of items, including optional components, user accounts, Active Directory information, logs, future service packs, the paging file used by the operating system, and other items.

For information about some of the items that require space on the disk, see the following:

- Change virtual memory settings
- Specify what happens when the system stops unexpectedly
- Choosing components to install
- Understanding Active Directory
- Directory data store

When you perform a new installation, you can specify the partition on which to install. If you specify a partition on which another operating system exists, you will be prompted to confirm your choice.

During Setup, create and size only the partition on which you want to install Windows Server 2003. After installation is complete, you can use Disk Management to manage new and existing disks and volumes. This includes creating new partitions from unpartitioned space; deleting, renaming, and reformatting existing partitions; adding and removing hard disks; and changing a basic disk to the dynamic disk storage type, or dynamic to basic. (If you want to have a dynamic disk on a computer that contains more than one operating system, be sure to read Considerations for computers that contain more than one

operating system.)

On Itanium-based computers with more than one disk, on x64-based computers, and on x86-based computers running Windows Server 2003 with Service Pack 1 (SP1), you can plan to choose not only the sizes of partitions but the partition style for each disk. The partition style determines the way that information about the partition is stored. There are two partition styles: master boot record (MBR) and GUID partition table (GPT). On GPT disks, unlike MBR disks, data critical to platform operation is located in partitions instead of unpartitioned or hidden sectors. In addition, GPT disks have redundant primary and backup partition tables for improved partition data structure integrity.

On Itanium-based computers, you must install Windows XP 64-bit Edition (Itanium) or the Itanium-based versions of Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, on a GPT disk. On x86-based and x64-based computers running Windows Server 2003, you must install Windows on an MBR disk. Other disks can use either the MBR or GPT partition style. With GPT disks, you can create more partitions and larger volumes, and can take advantage of other benefits. For more information about GPT disks, see GUID partition table. For more information about MBR and GPT partition styles, see Partition styles. For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

**Important**

- If you are setting up a computer so that it contains multiple operating systems, you must install Windows Server 2003 on its own partition or logical drive. This ensures that Windows Server 2003 will not overwrite crucial files that are needed by the other operating system. For more information, see Deciding Whether a Computer Will Contain More Than One Operating System.

**Disk partition requirements for Remote Installation Services**

If you plan to use Remote Installation Services on this server so that you can install operating systems onto other computers, a separate partition for use by Remote Installation Services is necessary. Plan on using NTFS on this partition: NTFS is required for the Single Instance Store feature of Remote Installation Services.

If you need to create a new partition for Remote Installation Services, plan on doing it after Setup, and leave enough unpartitioned disk space so that you can create it (at least 4 GB of space is recommended). As an alternative, for the system disk (not cluster disks), you can plan to make the disk a dynamic disk, which allows more flexibility in the use of the disk space than a basic disk. (However, if you want to have a dynamic disk on a computer that contains more than one operating system, see Deciding Whether a Computer Will Contain More Than One Operating System.)

For information about requirements for Remote Installation Services, see Remote Installation Services system requirements. For additional information about disk and partition choices, see Disk Management. For an overview, checklists, and other information about Remote Installation Services, see Remote Installation Services.

# Options when partitioning a disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Options when partitioning a disk**

You can change the partitions on your disk during Setup *only* if you are performing a new installation, not an upgrade. You can modify the partitioning of the disk after Setup by using Disk Management.

If you are performing a new installation, Setup examines the hard disk to determine its existing configuration, and then offers the following options:

- If the hard disk is unpartitioned, you can create and size the partition on which you will install a product in the Windows Server 2003 family.
- If the hard disk is partitioned but has enough unpartitioned disk space, you can create the partition for your Windows Server 2003 family product by using the unpartitioned space.
- If the hard disk has an existing partition that is large enough, you can install a product in the Windows Server 2003 family on that partition, with or without reformatting the partition first. Reformatting a partition erases all data on the partition. If you do not reformat the partition but you do install a Windows Server 2003 family product where there is already an operating system, that operating system will be overwritten, and you must reinstall any applications you want to use with the Windows Server 2003 family product.
- If the hard disk has an existing partition, you can delete it to create more unpartitioned disk space for a partition for a Windows Server 2003 family product. Deleting an existing partition also erases any data on that partition.

# Working with dynamic disks and Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Working with dynamic disks and Setup**

A dynamic disk is a disk using the new storage type introduced with Windows 2000. If you changed a disk to dynamic and you want to perform a new installation on the disk, review the following.

- If you used Windows 2000 or Windows XP to change a disk with no partitions directly to a dynamic disk, you must revert the disk to basic before you can install an operating system on it.

  **Caution**

  - All data will be lost in the process of reverting the disk to basic, so back it up first.

  You can use Windows 2000 or Windows XP to revert the disk, or you can use the Setup program for a product in the Windows Server 2003 family. To use Windows 2000 or Windows XP, follow the instructions in Help for your operating system. To use Setup for a product in the Windows Server 2003 family, during the partitioning phase, find the dynamic disk among the list of available partitions and then delete it (which erases all data on all volumes). You will be prompted to confirm your action. After you do this, the disk will contain only unpartitioned space, and you can use Setup to create a new (basic disk) partition on it.

- If you plan to rerun Setup on a computer on which a product in the Windows Server 2003 family was already installed, and the computer contains dynamic disks, be sure to read about the limitations for installing operating systems on disks that are changed to dynamic using a product in the Windows Server 2003 family. For more information, see Dynamic disks and volumes.

# Networks: TCP/IP, IP Addresses, and Name Resolution

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Networks: TCP/IP, IP addresses, and name resolution**

- Overview of networking and TCP/IP
- Internet Protocol (IP) addresses
- Name resolution for TCP/IP

# Overview of networking and TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Overview of networking and TCP/IP**

TCP/IP is the network protocol that provides Internet access. It is the protocol used by most servers, although you can use additional or different network adapters and their associated protocols on your servers.

To use TCP/IP, make sure that each server is provided with an IP address, either a dynamic or automatic address provided through software, or a static address that you obtain and set. Because these addresses are numbers and therefore hard to remember, you will also have to provide users with names that are easier to use. Mapping this type of name to an IP address is called name resolution, and can be accomplished by various methods, primarily the Domain Name System (DNS) and Windows Internet Name Service (WINS). For more information, see Internet Protocol (IP) addresses and Name resolution for TCP/IP.

# Internet Protocol (IP) addresses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Protocol (IP) addresses**

As outlined in Overview of networking and TCP/IP, using TCP/IP requires that an IP address be provided for each computer. This topic provides a brief description of the options for doing this. For more detailed information, see DHCP and IP Addressing and Routing.

There are two basic approaches for providing an IP address for a server you are installing:

**Dynamic Host Configuration Protocol (DHCP)**

You can provide IP addresses to the computers on your network by configuring one or more DHCP servers, which provide IP addresses dynamically to other computers. A DHCP server must itself be assigned a static IP address.

One server or several servers can provide DHCP along with one or more name resolution services, which are called Domain Name System (DNS) and Windows Internet Name Service (WINS).

If you want to run Setup before you have finalized your decisions about which server to use as your DHCP server and what static IP address to assign to that server, you can choose **Typical settings** in the **Networking Settings** dialog box during Setup and complete the network configuration later. If you do this and there is no DHCP server in the network, Setup will use a limited IP addressing option called Automatic Private IP Addressing (APIPA). During the time that a server is using APIPA, it can communicate only with other computers using APIPA on the same network segment. A server that is using APIPA cannot make connections to the Internet (for browsing or email), and cannot be used with DNS or Active Directory (which depends on DNS).

If you know which server you want to use as your DHCP server, when installing that server, in the **Networking Settings** dialog box in Setup, choose **Custom settings**, and specify a static IP address and related network settings. For more information, see Specify a static IP address and settings needed for DNS and WINS.

**Static IP addressing**

For certain types of servers, you must assign a static IP address and subnet mask during or after Setup. These servers include DHCP servers, DNS servers, WINS servers, and any server providing access to users on the Internet. It is also recommended that you assign a static IP address and subnet mask for each domain controller. If a computer has more than one network adapter, you must assign a separate IP address for each adapter.

If you want to run Setup on a server before you have finalized your decision about the static IP address you want to assign to that server, you can choose **Typical settings** in the **Networking Settings** dialog box during Setup and configure that server later. In this situation, if there is a DHCP server in the network, Setup will obtain an IP address configuration from DHCP. If there is no DHCP server in the network, Setup will use Automatic Private IP Addressing (APIPA). APIPA is described in the previous item in this list.

For more information about static IP addresses, including private IP addresses (which you choose from certain ranges of addresses) and public IP addresses (which you obtain from an Internet service provider), see IP Addressing and Routing.

After you have formed a plan for IP addressing, the next components to consider are those for name resolution, which is the process of mapping a computer name (something that users can recognize and remember) to the appropriate IP address. For more information, see Name resolution for TCP/IP.

# Name resolution for TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Name resolution for TCP/IP**

Name resolution is a process that provides users with easy-to-remember server names, instead of requiring them to use the numerical IP addresses by which servers identify themselves on the TCP/IP network. The name-resolution services are Domain Name System (DNS) and Windows Internet Name Service (WINS).

**DNS**

DNS is a hierarchical naming system used for locating computers on the Internet and private TCP/IP networks. One or more DNS servers are needed in most installations. DNS is required for Internet e-mail, Web browsing, and Active Directory. DNS is often used as a name resolution service in domains with clients running Windows 2000, Windows XP, or products in the Windows Server 2003 family. DNS is installed automatically when you create a domain controller (or when you install Active Directory on an existing member server, which makes it a domain controller), unless Windows Server 2003 software detects that a DNS server already exists for that domain. You can also install DNS by choosing the DNS server role in Manage Your Server or by using Control Panel.

If you plan to install DNS on a server, specify a static IP address on that server and configure that server to use that IP address for its own name resolution.

For more information, see the following:

- To choose from a list of topics about configuring DNS, see DNS.
- For information about installing DNS by choosing the DNS server role in Manage Your Server, see Configuring Roles for Your Server.
- For information about how to install DNS by using Control Panel, see Install a DNS server.
- For information about assigning a static IP address during Setup, see Specify a static IP address and settings needed for DNS and WINS.
- For information about assigning a static IP address after Setup, see Configure TCP/IP for static addressing.
- For information about installing a domain controller (or about installing Active Directory on an existing member server, which makes it a domain controller), see Manage Domain Controllers.

**WINS**

If you provide support for clients running Windows NT or any earlier Microsoft operating system, you might need to install Windows Internet Name Service (WINS) on one or more servers in the domain. You might also need to install WINS if it is required by your applications. You can install WINS by choosing the WINS server role in Manage Your Server or by using Control Panel.

If you plan to install WINS on a server, specify a static IP address on that server.

For more information, see the following:

- To choose from a list of topics about configuring WINS, see WINS.
- For information about installing WINS by choosing the WINS server role in Manage Your Server, see Configuring Roles for Your Server.
- For information about how to install WINS by using Control Panel, see Install a WINS server.
- For information about assigning a static IP address during Setup, see Specify a static IP address and settings needed for DNS and WINS.

- For information about assigning a static IP address after Setup, see Configure TCP/IP for static addressing.

# Deciding Between Workgroups and Domains

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deciding between workgroups and domains**
This section contains information that will help you decide whether to place your servers in a workgroup or a domain. It also contains other information that, if you create a domain, will help with basic planning of the roles of servers within the domain.

For information about upgrading servers in a domain where all domain controllers run Windows NT 4.0, see Upgrades in a Windows NT 4.0 Domain. For information about upgrading servers in a domain containing one or more Windows 2000 domain controllers, see Upgrades in a domain containing Windows 2000 domain controllers. For information about networks larger than five servers, see the *Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site. For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

For additional information, see:

- Workgroups compared with domains
- Planning for domain controllers and member servers
- Special aspects of Windows Server 2003 family domain controllers
- Additional information about domains

# Workgroups compared with domains

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Workgroups compared with domains**

A *domain* is a group of accounts and network resources that share a common directory database and set of security policies, and might have security relationships with other domains. A *workgroup* is a more basic grouping, intended only to help users find objects such as printers and shared folders within that group. Domains are the recommended choice for all networks except very small ones with few users.

In a workgroup, users might have to remember multiple passwords, one for each network resource. (In addition, different users can use different passwords for each resource.) In a domain, passwords and permissions are simpler to keep track of, because a domain has a single, centralized database of user accounts, permissions, and other network details. The information in this database is replicated automatically among domain controllers. You determine which servers are domain controllers and which are simply members of the domain. You can determine these roles not only during Setup but afterward.

Domains, and the Active Directory directory system of which they are a part, provide many options for making resources easily available to users while maintaining good monitoring and security. For more information, see Active Directory.

# Planning for domain controllers and member servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning for domain controllers and member servers**

With Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition; servers in a domain can have one of two roles: *domain controllers*, which contain matching copies of the user accounts and other Active Directory data in a given domain, and *member servers*, which belong to a domain but do not contain a copy of the Active Directory data. (A server that belongs to a workgroup, not a domain, is called a *stand-alone server*.) It is possible to change the role of a server back and forth from domain controller to member server (or stand-alone server), even after Setup is complete. However, it is recommended that you plan your domain before running Setup and change server roles (and server names) only when necessary.

Multiple domain controllers provide better support for users, compared to a single domain controller. With multiple domain controllers, you have multiple copies of user account data and other Active Directory data; however, it is still important to perform regular backups, including Automated System Recovery backups, and familiarize yourself with the methods for restoring a domain controller. In addition, multiple domain controllers work together to support domain controller functions, such as carrying out logon validations.

For more information, see Active Directory server roles.

# Special aspects of Windows Server 2003 family domain controllers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Special aspects of Windows Server 2003 family domain controllers**

As you manage your Windows Server 2003 family domains, you might want to learn more about operations master roles. This topic describes operations master roles briefly. A variety of domain topics are discussed in more depth in Active Directory.

Operations master roles are special roles that are assigned to one or more domain controllers in an Active Directory domain. The domain controllers that are assigned these roles perform operations that are single-master (not permitted to occur at different places in a network at the same time). For example, the creation of security identifiers for new resources (such as new computers) must be overseen by a single domain controller to ensure that the identifiers are unique.

The first domain controller installed in a domain is automatically assigned all the operations master roles. You can change the assignment of operations master roles after Setup, but in most cases this is not necessary. You will need to be particularly aware of operations masters roles if problems develop on an operations master or if you plan to take one out of service. For more information, see Operations master roles.

# Additional information about domains

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Additional information about domains**

For information about upgrading servers in a domain where all domain controllers run Windows NT 4.0, see Upgrades in a Windows NT 4.0 Domain. For information about upgrading servers in a domain containing one or more Windows 2000 domain controllers, see Upgrades in a domain containing Windows 2000 domain controllers.

For detailed information about domains and forests, domain functional level and forest functional level, operations master roles, the global catalog, and other domain-related topics, see Active Directory.

For information about setting up multiple domains with structured relationships, see the *Microsoft Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site. For information about obtaining the *Windows Server 2003 Resource Kit*, see Using the Windows Deployment and Resource Kits.

# Preparing Your System Before Running Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Preparing your system before running Setup**

- Preparing your system for an upgrade
- Preparing your system for a new installation
- Working with volume, mirror, or stripe sets or stripe sets with parity

# Preparing your system for an upgrade

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Preparing your system for an upgrade**
This topic describes basic steps to take in preparing your server for an upgrade.

If you are upgrading to Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, on server cluster nodes, be sure to read Upgrading to Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition on Cluster Nodes.

**Checking the system log for errors**
Use Event Viewer to review the system log for recent or recurring errors that could cause problems during the upgrade. For information about Event Viewer, see Event Viewer overview, or Help for the operating system that you are running.

**Backing up files**
Before upgrading, it is recommended that you back up your current files, including anything containing configuration information, for example, the System State and the system and boot partitions. You can back up files to a variety of different media, such as a tape drive or the hard disk of another computer on the network.

**Preparing mirror sets and other disk sets for upgrade (Windows NT 4.0 only)**
With the disk management technologies in Windows NT 4.0, you could create volume sets, mirror sets, stripe sets, or stripe sets with parity, each with specific capabilities and limitations. By using dynamic disks, introduced with Windows 2000, you can take advantage of similar technologies, and with the Windows Server 2003 operating systems, you can also extend dynamic volumes without repartitioning or reformatting.

This transition from the technologies used in Windows NT 4.0 means that you must make certain choices before running Setup for Windows Server 2003. For important information about these choices, see Working with volume, mirror, or stripe sets or stripe sets with parity.

**Disconnecting UPS devices**
If you have an uninterruptible power supply (UPS) connected to your target computer, disconnect the connecting serial cable before running Setup. Setup automatically attempts to detect devices connected to serial ports, and UPS equipment can cause problems with the detection process.

**Reviewing hardware and software**
When you start Setup for an upgrade, the first process it carries out is a check for compatible hardware and software on your computer. Setup displays a report before continuing. Use this report, along with information in Relnotes.htm (in the \Docs folder on the Setup CD), to find out whether you need to update your hardware, drivers, or software before upgrading.

### Important

- If you use an Internet service provider (ISP), pay special attention to any recommendations about updating the ISP software necessary for your Internet connectivity.

For the most recent information on compatible hardware and software for products in the Windows Server 2003 family, click the appropriate links in Support resources. If you have hardware devices that do not use Plug and Play, see Taking an inventory of devices that do not use Plug and Play.

# Preparing your system for a new installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Preparing your system for a new installation**
This topic describes basic steps to take in preparing your server for a new installation.

If you are installing Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, on server cluster nodes, be sure to read Installing Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition on Cluster Nodes.

**Checking the system log for errors**
If the computer already has a working operating system, review the system log for recent or recurring errors (especially hardware errors) that could cause problems during the installation. For information about viewing event logs, see Help for the operating system on your computer.

**Backing up files**
Before you perform a new installation, it is recommended that you back up your current files, unless the computer has no files or the current operating system files have been damaged. You can back up files to a variety of different media, such as a tape drive or the hard disk of another computer on the network.

**Uncompressing the drive**
Uncompress any DriveSpace or DoubleSpace volumes before installing. Do not install Windows Server 2003 on a compressed drive unless the drive was compressed with the NTFS file system compression feature.

**Preparing mirror sets and other disk sets (Windows NT 4.0 only)**
With the disk management technologies in Windows NT 4.0, you could create volume sets, mirror sets, stripe sets or stripe sets with parity, each with specific capabilities and limitations. By using dynamic disks, introduced with Windows 2000, you can take advantage of similar technologies, and with Windows Server 2003, you can also extend dynamic volumes without repartitioning or reformatting.

This transition from the technologies used in Windows NT 4.0 means that you must make certain choices before running Setup for Windows Server 2003. For important information about these choices, see Working with volume, mirror, or stripe sets or stripe sets with parity.

**Disconnecting UPS devices**
If you have an uninterruptible power supply (UPS) connected to your target computer, disconnect the connecting serial cable before running Setup. Setup automatically attempts to detect devices connected to serial ports, and UPS equipment can cause problems with the detection process.

# Working with volume, mirror, or stripe sets or stripe sets with parity

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Working with volume, mirror, or stripe sets or stripe sets with parity**

With the disk management technologies in Windows NT 4.0, you could create volume sets, mirror sets, stripe sets, or stripe sets with parity, each with specific capabilities and limitations. By using the dynamic disk technology introduced with Windows 2000, you can use similar technologies, with the added flexibility of being able to extend disk volumes without repartitioning or reformatting.

This transition from the technologies used in Windows NT 4.0 means that you must make certain choices before running Setup for Windows Server 2003. Any volume sets, mirror sets, stripe sets, or stripe sets with parity that you created with Windows NT 4.0 are not supported in the Windows Server 2003 operating systems, although they were supported to a limited extent in Windows 2000.

If you used Windows NT 4.0 to create a volume set, mirror set, stripe set, or stripe set with parity, and you want to run Setup for Windows Server 2003 on that computer, you must choose one of the following methods.

For information about other preparations to make before running Setup, see Checklists for installing and upgrading the operating system and Preparing Your System Before Running Setup.

**For a mirror set, break the mirror**

If you are running Windows NT 4.0 on a computer that has a mirror set and you want to run Setup for Windows Server 2003 on that computer, first back up the data (as a safeguard-the data will not be erased) and then break the mirror. Ensure that you have applied Service Pack 5 or later, required before running Setup for Windows Server 2003. Then run Setup.

**For a volume set, stripe set, or stripe set with parity, back up the data and delete the set**

If you are running Windows NT 4.0 on a computer that has a volume set, stripe set, or stripe set with parity, and you want to run Setup for Windows Server 2003 operating systems on that computer, first back up the data. Next, delete the set (which will delete the data). Ensure that you have applied Service Pack 5 or later, required before running Setup for Windows Server 2003. Then run Setup.

After running Setup for Windows Server 2003, you can make the disk dynamic, restore backed-up data as necessary, and make use of the volume options shown in the table later in this section. For more information about dynamic disks, see Dynamic disks and volumes and Using Dynamic Disks.

**If necessary, use the Ftonline support tool**

The preceding methods are the recommended methods for preparing to run Setup for Windows Server 2003 on a computer that contains a volume set, mirror set, stripe set, or stripe set with parity created with Windows NT 4.0. However, if you do not use these methods and you must access one of these sets after running Setup for Windows Server 2003, you can use the Ftonline tool. The Ftonline tool is part of the Windows Server 2003 family Support Tools. For more information, see Install Windows Support Tools.

**Types of multidisk volumes on dynamic disks**

The disk sets described in the previous section have different names in the Windows Server 2003 family than they had in Windows NT 4.0:

| Windows NT 4.0 name | Windows Server 2003 family name |
|---|---|
| Volume set | Spanned volume on a dynamic disk |
| Mirror set | Mirrored volume on a dynamic disk |
| Stripe set | Striped volume on a dynamic disk |
| Stripe set with parity | RAID-5 volume on a dynamic disk |

# Resources for installing and upgrading the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources for installing and upgrading the operating system**

This topic provides sources of additional information about getting a new server ready for use in your enterprise.

- To confirm that your computers, system components, and peripherals are compatible with products in the Windows Server 2003 family, click the appropriate link in Support resources.
- For the most recent information on compatible applications for products in the Windows Server 2003 family, see the software compatibility section of the Microsoft Web site.
- For enhancements and updates to Windows software and other Microsoft software, see Windows Update at the Microsoft Web site. For a description of the different ways you can use Windows Update, see Windows Update.
- For information about the Windows Deployment Resource Kit, Windows Server 2003 Technical Reference, and Windows Server TechCenter, which provide technical background information on products in the Windows Server 2003 family and also on deploying Windows XP, see the following:
    - The *Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site.
    - The *Windows Server 2003 Technical Reference* at the Microsoft Windows Server System Web site.
    - The *Windows Server TechCenter* at the Microsoft Web site.
    - The *Windows XP Professional Resource Kit* at the Microsoft Windows XP Resource Kits Web site.
    - Using the Windows Deployment and Resource Kits
- For information about the differences between Windows Server 2003 and the version of Windows Server 2003 that includes Service Pack 1 (SP1), see Changes to Functionality in Microsoft Windows Server 2003 Service Pack 1.
- Microsoft TechNet is a service that contains resources for Information Technology (IT) professionals. This includes access to white papers and articles written by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software. For more information, see TechNet at the Microsoft Web site.
- The Information Technology Infrastructure Library (ITIL) Web site provides guidance for Information Technology professionals. The following is an excerpt from the site: "ITIL consists of a series of books giving guidance on the provision of quality IT services, and on the accommodation and environmental facilities needed to support information technology." (Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.)

# Troubleshooting for installing and upgrading the operating system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section outlines the steps to troubleshoot Stop messages, which are the result of a system error in the operating system. Following a system error, your computer stops responding, and a message is displayed on a blue or black background.

For information about how to obtain product support, see Product Support at the Microsoft Web site.

This section covers:

- Troubleshooting Stop messages: general strategies
- Troubleshooting specific Stop messages

# Troubleshooting Stop messages: general strategies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting Stop messages: general strategies**
This topic describes a general method for troubleshooting Stop messages or unexpected shutdowns. For more information, see the following:

- For information about specific Stop messages, see Troubleshooting specific Stop messages.
- For articles about specific Stop messages, see Search the Knowledge Base at the Microsoft Web site.
- For information about support options, see Support resources.
- For information about troubleshooting specific technologies or components (for example, disks and file systems), see the *Windows Server 2003 Technical Reference* at the Microsoft Windows Server System Web site.

You can use the System Information tool to gather important information about system settings, problem devices, and hardware resources. For more information, see System Information.

**Important**

- To ensure system stability, install the latest service pack that is appropriate for your system (follow service pack instructions) and use only signed drivers. For more information, see Windows Update at the Microsoft Web site. For a description of the different ways you can use Windows Update, see Windows Update.

Follow these steps for any Stop error that does not display identifying text or specific troubleshooting steps:

1. Use the Windows Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Use the File Signature Verification tool, which identifies unsigned drivers and incompatible system files on your computer. The system files and device driver files that are provided with the Windows Server 2003 family have a Microsoft digital signature, which indicates that the files are original, unaltered system files or that they have been approved by Microsoft for use with Windows. For more information, see Using File Signature Verification.

3. If the Stop message is caused by a driver problem, you can use Device Manager to roll back to a previous version of the driver. For more information, see Roll back to the previous version of a driver. You may need to disable any newly installed drivers.

4. Using a recent version of virus-protection software, check for viruses on your computer. If a virus is found, perform the steps required to eliminate it from your computer. See your antivirus software documentation for these steps.

5. You can search the Knowledge Base for updated information on Stop messages. See Search the Knowledge Base at the Microsoft Web site, and then follow the instructions on the page. When typing keywords, use the Stop message number (for example, **stop 0x0000000A**).

   For more information about articles, troubleshooting wizards, and items that you can download, see Updated technical information.

6. If you can start the operating system, check the System Log in Event Viewer for additional information that might help

determine the device or driver that is causing the problem. Many Stop messages produce specific events that you can search for, such as Event ID 1001 (generated by various Stop messages) and Event ID 6008 (usually caused by an unexpected shutdown or a computer that does not restart correctly). To display a description of an event, in Event Viewer, double-click the event. For more information about Event Viewer, see Event Viewer.

You can search the Knowledge Base for updated information on Event IDs. See Search the Knowledge Base at the Microsoft Web site, and then follow the instructions on the page.

7. If you cannot start your computer, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

8. Remove any newly installed hardware (RAM, adapters, hard disks, modems, and so on).

9. Ensure that you have updated drivers for your hardware devices. Also, ensure that you have the latest system BIOS (for x86-based or x64-based computers) or the correct firmware (for Itanium architecture-based computers). The device or hardware manufacturers can assist you in obtaining these items.

10. Run the system diagnostics supplied by your computer manufacturer, especially the memory check.

11. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

12. If Safe Mode and other startup options do not work, you can consider using the Recovery Console. This method is recommended only if you are an advanced user who can use basic commands to identify and locate problem drivers and files. In addition, you must be an administrator to use the Recovery Console. For more information, see Recovery Console overview.

# Troubleshooting specific Stop messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting specific Stop messages**
This topic discusses how to troubleshoot specific Stop messages. For general information about troubleshooting Stop messages, and for a list of other sources of information, see Troubleshooting Stop messages: general strategies.

You can use the System Information tool to gather important information about system settings, problem devices, and hardware resources. For more information, see System Information.

**What Stop message are you receiving?**

- Stop message 0x0000001E Descriptive text: KMODE_EXCEPTION_NOT_HANDLED
- Stop message 0x000000D1 Descriptive text: DRIVER_IRQL_NOT_LESS_OR_EQUAL
- Stop message 0x000000EA Descriptive text: THREAD_STUCK_IN_DEVICE_DRIVER
- Stop message 0x00000050 Descriptive text: PAGE_FAULT_IN_NONPAGED_AREA
- Stop message 0x000000BE Descriptive text: ATTEMPTED_WRITE_TO_READONLY_MEMORY
- Stop message 0x0000000A on an existing installation Descriptive text: IRQL_NOT_LESS_OR_EQUAL
- Stop message 0x0000000A on a new installation Descriptive text: IRQL_NOT_LESS_OR_EQUAL
- Stop messages 0x00000023 and 0x00000024 Descriptive text: FAT_FILE_SYSTEM or NTFS_FILE_SYSTEM
- Stop message 0x0000007B Descriptive text: INACCESSIBLE_BOOT_DEVICE
- Stop message 0x0000007F Descriptive text: UNEXPECTED_KERNEL_MODE_TRAP
- Stop message 0x0000009F Descriptive text: DRIVER_POWER_STATE_FAILURE
- Stop message 0xC000021A Descriptive text: FATAL_SYSTEM_ERROR
- Stop message 0xC0000221 Descriptive text: BAD_IMAGE_CHECKSUM
- Stop message 0xC0000218 Descriptive text: UNKNOWN_HARD_ERROR

**Stop message 0x0000001E Descriptive text: KMODE_EXCEPTION_NOT_HANDLED**
**Usual cause:** This message has several possible causes.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Check that you have adequate disk space, especially for new installations.

3. Disable any newly installed drivers. You might also want to disable a service associated with the driver or any newly

installed programs.

4. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

5. Ensure that you have the latest system BIOS (for x86-based and x64-based computers) or the correct firmware (for Itanium architecture-based computers). Contact your hardware manufacturer if you need assistance in performing this step.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x0000001E**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x000000D1 Descriptive text: DRIVER_IRQL_NOT_LESS_OR_EQUAL**
**Usual cause:** An attempt was made to touch pageable memory at a process internal request level (IRQL) that was too high. This is usually caused by drivers using improper addresses. Kernel-mode drivers are forbidden to access pageable memory at a high IRQL.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Use the File Signature Verification tool, which identifies unsigned drivers and incompatible system files on your computer. The system files and device driver files that are provided with the Windows Server 2003 family have a Microsoft digital signature, which indicates that the files are original, unaltered system files or that they have been approved by Microsoft for use with Windows. For more information, see Using File Signature Verification.

3. Use Device Manager to roll back to a previous version of the driver. For more information, see Roll back to the previous version of a driver.

4. Disable the driver identified in the Stop message or any newly installed drivers.

5. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

- When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

6. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, go to the see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x000000D1**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x000000EA Descriptive text: THREAD_STUCK_IN_DEVICE_DRIVER**
**Usual cause:** The display driver is caught in an infinite loop. This usually indicates a problem with the video hardware or with the display driver.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Disable the driver identified in the Stop message or any newly installed drivers.

3. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

4. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x000000EA**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x00000050 Descriptive text: PAGE_FAULT_IN_NONPAGED_AREA**
**Usual cause:** Requested data is not found in memory. This might be caused by a printer driver or remote access driver.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Use Device Manager to roll back to a previous version of the driver. For more information, see Roll back to the previous version of a driver.

3. Disable any newly installed drivers.

4. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

5. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x00000050**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x000000BE Descriptive text: ATTEMPTED_WRITE_TO_READONLY_MEMORY**
**Usual cause:** A device driver attempted to write to read-only memory. This problem can occur during an upgrade, although it is not limited to upgrades.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

3. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

- When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x000000BE**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x0000000A on an existing installation Descriptive text: IRQL_NOT_LESS_OR_EQUAL**
**Usual cause:** Drivers are using improper memory addresses.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. If you can start the operating system, check the System Log in Event Viewer for additional information that might help determine the device or driver that is causing the problem. To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.

3. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

4. Disable any newly installed drivers and remove any newly added programs.

5. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

6. Remove any newly installed hardware (RAM, adapters, hard disks, modems, and so on).

7. Ensure that you have updated drivers for your hardware devices. Also, ensure that you have the latest system BIOS (for x86-based and x64-based computers) or the correct firmware (for Itanium architecture-based computers). The device manufacturers can assist you in obtaining these items.

8. Run system diagnostics supplied by your hardware vendor, especially a memory check.

9. Disable memory caching in the BIOS (for x86-based and x64-based computers) or EFI (for Itanium architecture-based computers). Contact your hardware manufacturer if you need assistance in performing this step.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x0000000A**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x0000000A on a new installation Descriptive text: IRQL_NOT_LESS_OR_EQUAL**
**Usual cause:** Drivers are using improper memory addresses.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. During the installation process, at the "Setup is inspecting your computer's hardware configuration" message, press F5. Select the correct computer type when you are prompted. For example, if you have a single-processor computer, select **Standard PC**.

3. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

4. Disable memory caching in the BIOS (for x86-based and x64-based computers) or EFI (for Itanium architecture-based computers). Contact your hardware manufacturer if you need assistance in performing this step.

5. Remove all adapters and disconnect all hardware devices that are not essential.

6. If you are using a SCSI adapter, obtain the latest driver from the adapter vendor, disable sync negotiation, check termination, and check the SCSI IDs of the devices.

7. If you are using Integrated Device Electronics (IDE) devices, define the onboard IDE port as the primary channel. Check the master/subordinate settings for the IDE devices. Remove all IDE devices except for the hard disk. See your hardware manufacturer's documentation for more information.

8. Run the system diagnostics supplied by your hardware vendor, especially the memory check.

9. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x0000000A**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical

information.

**Stop messages 0x00000023 and 0x00000024 Descriptive text: FAT_FILE_SYSTEM or NTFS_FILE_SYSTEM**

**Usual cause:** The hard disk is fragmented or there is excessive file I/O. This Stop error may also be cause by drive-mirroring or some antivirus software.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Disable any antivirus or backup programs, and disable any defragmentation utilities.

3. Check for hard disk corruption by running **chkdsk** and then restarting the computer. If you cannot run **chkdsk**, you might have to move the hard disk to another computer that is running a product in the Windows Server 2003 family and then run the **chkdsk** command. For more information, see chkdsk. (Note that **chkdsk** is available, with a limited set of options, in Recovery Console.)

4. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on these Stop messages. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x00000023** or **stop 0x00000024**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x0000007B Descriptive text: INACCESSIBLE_BOOT_DEVICE**

**Usual cause:** A problem occurred during the initialization of the I/O system (usually the startup device or the file system).

**Solution:**

1. Check for viruses on your computer. This Stop message is frequently displayed when there is a virus in the boot sector.

2. Repair or recover the hard disk. For ways to fix the hard disk, see Repair overview and Recovery Console overview.

3. Remove any newly added hard disks or controllers.

4. If you are using a SCSI adapter, obtain the latest driver from the adapter vendor, disable sync negotiation, check termination, and check the SCSI IDs of the devices.

5. If you are using Integrated Device Electronics (IDE) devices, define the onboard IDE port as the primary channel. Check the master/subordinate settings for the IDE devices. Remove all IDE devices except for the hard disk. See your hardware

manufacturer's documentation for more information.

6. Check for hard disk corruption by running **chkdsk**. If you cannot run chkdsk, you might have to move the hard disk to another computer that is running a product in the Windows Server 2003 family and then run the **chkdsk** command. For more information, see chkdsk. (Note that **chkdsk** is available, with a limited set of options, in Recovery Console.)

7. If the computer will not start normally, try starting it in Last Known Good Configuration. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x0000007B**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x0000007F Descriptive text: UNEXPECTED_KERNEL_MODE_TRAP**
**Usual cause:** There is a hardware or software problem. This is usually caused by a hardware failure.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Run system diagnostics supplied by your hardware vendor, especially a memory check. This Stop message is often displayed in the case of faulty or mismatched memory.

3. Disable memory caching in the BIOS (for x86-based and x64-based computers) or EFI (for Itanium architecture-based computers). Contact your hardware manufacturer if you need assistance in performing this step.

4. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

5. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x0000007F**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0x0000009F Descriptive text: DRIVER_POWER_STATE_FAILURE**
**Usual cause:** A driver is in an inconsistent or invalid power state.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Disable the driver identified in the Stop message or any newly installed drivers.

3. Update any software that uses filter drivers, such as antivirus or backup programs.

4. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

5. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, go to the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0x0000009F**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0xC000021A Descriptive text: FATAL_SYSTEM_ERROR**
**Usual cause:** The Windows Logon Process system process terminated unexpectedly.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Disable the driver identified in the Stop message or any newly installed drivers.

3. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

4. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0xC000021A**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0xC0000221 Descriptive text: BAD_IMAGE_CHECKSUM**
**Usual cause:** This message might be caused by a corrupted system file or driver or a hardware problem.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Replace the identified file.

3. If the computer will not start normally, try starting it in Last Known Good Configuration or in Safe Mode, and then replace the file. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0xC0000221**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

**Stop message 0xC0000218 Descriptive text: UNKNOWN_HARD_ERROR**
**Usual cause:** A registry file might be corrupted.

**Solution:**

1. Use the Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. If the computer will not start normally, try starting it in Last Known Good Configuration. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

3. If you have an Automated System Recovery (ASR) backup, you might need to use this recovery option. For more information, see Automated System Recovery (ASR) overview.

**Note**

- You can search the Microsoft Web site for updated information on this Stop message. To do this, see Welcome to Microsoft Help and Support at the Microsoft Web site, click a search option, and then follow the instructions on the page. When typing keywords, use **stop 0xC0000218**.

  For more information about articles, troubleshooting wizards, and items you can download, see Updated technical information.

# Installing and Upgrading on Cluster Nodes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing and upgrading on cluster nodes**
With Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition, you can use clustering to ensure that users have constant access to important server-based resources. With clustering, you create several cluster nodes that appear to users as one server. If one of the nodes in the cluster fails, another node begins to provide service (a process known as failover). Mission-critical applications and resources remain continuously available.

The following topics describe the options for upgrading or installing on cluster nodes.

- Before performing an upgrade, see Checklist: Preparation for upgrading a cluster
- Before performing a new installation, see Checklist: Preparation for installing a cluster
- For tips on upgrading and installing on cluster nodes, see Best practices for installing and upgrading cluster nodes
- For help with specific tasks, see How to upgrade cluster nodes
- For general background information, see Concepts for installing and upgrading cluster nodes
- For problem-solving instructions, see Troubleshooting cluster node installations.

# Checklists for installing and upgrading on cluster nodes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Preparation for upgrading a cluster
- Checklist: Preparation for installing a cluster

# Checklist: Preparation for upgrading a cluster

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Preparation for upgrading a cluster**

| Step | Reference |
|---|---|
| Check that your hardware, including your cluster storage hardware, is compatible with Windows Server 2003, Enterprise Edition.<br><br>Be aware that geographically dispersed (majority node set) server clusters are built on a networking and storage infrastructure with characteristics that are very different than a standard quorum device server cluster, and, as such, are certified under a separate testing program. If you are considering converting your existing server cluster to a geographically dispersed server cluster, you must work with your hardware vendor to obtain a geographically dispersed server cluster configuration that has been certified by Microsoft.<br><br>For more information on majority node set server clusters, see Choosing a Cluster Model. | Hardware compatibility |
| Check with the manufacturer of your cluster storage hardware and be sure you have the drivers you need. | Mass storage drivers and the setup process |
| Review concepts for upgrading cluster nodes, choose the method you will use, and review the instructions for the method you chose.<br><br>**Caution**<br><br>• If you are using any method other than a rolling upgrade (or a rolling upgrade with one or more resources offline), be sure to review and follow the instructions carefully to prevent corruption of the cluster storage. That is, for methods other than a rolling upgrade, be sure to complete the upgrade and start the Cluster service on one node before allowing another node to gain access to the cluster storage. | Concepts for installing and upgrading cluster nodes<br><br>How to upgrade cluster nodes |
| Review the checklist for upgrading the operating system. | Checklist: Performing an upgrade |
| Review procedures for starting and running Setup. | Start Setup on an x86-based computer<br><br>Start Setup on an Itanium architecture-based computer<br><br>Start Setup on an x64-based computer |

# Checklist: Preparation for installing a cluster

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Preparation for installing a cluster**

**Important**

- If you are using a shared storage device, make sure that Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, and the Cluster service are installed and running on one server before starting the operating system on another server in the cluster. If the operating system is started on multiple servers before the Cluster service is running on one server, the cluster storage could be corrupted. Once the first server is configured, the remaining servers may be installed simultaneously.

| Step | Reference |
|---|---|
| Check that your hardware, including your cluster storage hardware, is compatible with Windows Server 2003, Enterprise Edition. | Hardware compatibility |
| Check with the manufacturer of your cluster storage hardware and be sure you have the drivers you need. | Mass storage drivers and the setup process |
| Plan basic network details for the cluster, including details about network adapters, IP addressing, and the name and account the cluster will use. Also, plan for the volume needed for cluster configuration data. | Planning and preparing for cluster installation |
| Review the checklist for installation of the operating system and make decisions about such items as whether to install additional components. | Checklist: Performing a new installation |
| Follow the remaining steps for creating a server cluster. | Checklist: Planning and creating a server cluster |

# Best practices for installing and upgrading cluster nodes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Follow the appropriate checklist when installing or upgrading on cluster nodes**

- Checklist: Preparation for upgrading a cluster
- Checklist: Preparation for installing a cluster

**Use the Typical (full) configuration option when creating a new cluster**

With the Cluster Administrator New Server Cluster Wizard, you can choose between Typical (full) configuration and Advanced (minimum) configuration options. Typical configuration is appropriate for most installations and results in a completely configured cluster. Use the Advanced configuration option only for clusters that have complex storage configurations that the New Server Cluster Wizard cannot validate or for configurations in which you do not want the cluster to manage all of the storage. The following examples describe each situation:

- In some complex storage solutions, such as a fiber channel switched fabric that contains several switches, a particular storage unit might have a different identity on each computer in the cluster. Although this is a valid storage configuration, it violates the storage validation heuristics in the New Server Cluster Wizard. If you have this type of storage solution, you might receive an error when you are trying to create a cluster using the Typical configuration option. If your storage configuration is set up correctly, you can disable the storage validation heuristics and avoid this error by restarting the New Server Cluster Wizard, selecting the Advanced configuration option instead.
- On particular nodes in a cluster, you may want to have some disks that are to be clustered and some disks that are to be kept private. The Typical configuration option configures all disks as clustered disks and creates cluster resources for them all. However, with the Advanced configuration option, you can keep certain disks private because this configuration creates a cluster in which only the quorum disk is managed by the cluster (if you chose to use a physical disk as the quorum resource). After the cluster is created, you must then use Cluster Administrator to add any other disks that you want the cluster to manage.

For more information, see Storage configuration options.

**Important**

- If you are using a shared storage device: Before creating a cluster, when you turn the computer on and start the operating system, it is very important that only one node has access to the cluster disk. Otherwise, the cluster disks can become corrupted. To prevent the corruption of the cluster disks, shut down all but one cluster node, or use other techniques (for example, LUN masking, selective presentation, or zoning) to protect the cluster disks before creating the cluster. Also, before starting the installation of the second and subsequent nodes, ensure that all disks that are to be managed by the cluster have disk resources associated with them. If these disks do not have disk resources associated with them at this time, the disk data will be corrupted because the disks will not be protected and multiple nodes will attempt to connect to them at the same time.
- Do not use Manage Your Server to configure cluster nodes.

**Secure your server cluster**

To keep your server cluster secure from unauthorized users:

- Do not set the Cluster service account to be a member of the domain Administrators group. By giving the minimal possible user rights to the Cluster service account, you avoid potential security issues if that account is compromised.
- Limit and audit access to shared data (for example, files and folders on cluster disks).

- Limit client access to cluster resources.
- Use different accounts for the Cluster service and applications in the cluster.
- Use different Cluster service accounts for multiple clusters.
- If you upgraded from a Windows NT 4.0 or Windows 2000 cluster, remove the read permission on the Windows\Cluster directory and the MSCS directory on the quorum disk (which contains the quorum log) from all nonadministrator user accounts.
- Follow standard best practices for securing servers.

If you want to audit access to shared data, enable auditing on all cluster nodes. For more information, see Securing shared data in a cluster. For more information on the user rights required by the Cluster service account, see Change the account under which the Cluster service runs. For more information on security in a server cluster, see Managing Security in a Cluster. For more information on best practices for securing servers, see Best practices for security.

**Review other server cluster best practices**
For more information, see the Server Cluster Server Cluster Best Practices.

# How to upgrade cluster nodes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**
These sections explain how to set up clustering with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. Before beginning the installation or upgrade of a cluster, review Checklist: Preparation for upgrading a cluster or Checklist: Preparation for installing a cluster.

- Upgrade a Cluster from Windows 2000
- Upgrade a Cluster from Windows NT 4.0

# Upgrade a Cluster from Windows 2000

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrade a cluster from Windows 2000**
If you are upgrading from Windows 2000 to Windows Server 2003, Enterprise Edition on cluster nodes, you might be able to perform a *rolling upgrade* of the operating system. In a rolling upgrade, you sequentially upgrade the operating system on each node, making sure that one node is always available to handle client requests. When you upgrade the operating system, the Cluster service is automatically upgraded also. A rolling upgrade maximizes availability of clustered services and minimizes administrative complexity.

The following topics describe the processes and procedures for upgrading from Windows 2000 to Windows Server 2003.

- Perform a rolling upgrade from Windows 2000
- Perform a last node rolling upgrade from Windows 2000
- Upgrade from Windows 2000 on a cluster containing IIS using the provided script
- Upgrade from Windows 2000 on a cluster containing IIS without using the provided script
- Upgrade from Windows 2000 on a cluster containing Message Queuing

# Perform a rolling upgrade from Windows 2000

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To perform a rolling upgrade from Windows 2000**

1. Confirm that your systems are running Windows 2000 and use resources that are supported during a rolling upgrade, as described in "Resource behavior during rolling upgrades" in Related Topics.

2. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. For more information, see "Checklist: Preparation for upgrading a cluster" in Related Topics.

3. In Cluster Administrator, click the node that you want to upgrade first.

4. On the **File** menu, click **Pause Node**.

5. In the right details pane, click **Active Groups.**

6. In the details pane, click a group, and then on the **File** menu, click **Move Group**. Repeat this step for each group listed.

   The services will be interrupted during the time they are being moved and restarted on the other node. After the groups are moved, one node is idle, and the other node handles all client requests.

7. Use Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, Setup to upgrade the paused node from Windows 2000.

For information about starting Setup, see Related Topics.

Setup detects the earlier version of clustering on the paused node and automatically installs clustering for Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. The node automatically rejoins the cluster at the end of the upgrade process, but it is still paused and does not handle any cluster-related work.

**Notes**

- As you begin the setup process, you will receive a warning message about using the **tempdrive** option for Setup. Provided you have followed the preceding steps, you can click **OK** and proceed with Setup without using this option.

- Manage Your Server will appear when you initially log on to the newly upgraded node as an Administrator. Close Manage Your Server to continue with the rolling upgrade.

1. To verify that the node that was upgraded is fully functional, perform validation tests such as confirming that the operating system recognizes your network connections and, using Device Manager, ensuring that the operating system recognizes all of your storage devices.

2. In Cluster Administrator, click the node that was paused, and then on the File menu click **Resume Node**.

   **Note**

   - When you use Cluster Administrator for the first time on the upgraded node, Cluster Administrator will prompt you to **Open connection to cluster**. In the **Cluster or server name** field, type a period (**.**). This will connect you to the cluster on the local upgraded node. Although you can connect to the cluster by typing the cluster name, if you do so you will be connected to the cluster on the Windows 2000 node and then will be required to respond to several warning messages.

3. Repeat the preceding steps for the remaining node.

### Important

- For information about what resources are supported during rolling upgrades, see Related Topics.

### Notes

- After you upgrade a cluster node from Windows 2000, you must log on with an account that is a member of both the Domain Admins group and the Administrators group on each cluster node before you can restart the Cluster service. This step is required even if the Domain Admins group is already a member of the Administrators group on each cluster node.

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- If minor problems occur when you are in the midst of a rolling upgrade, we recommend that you complete the upgrade. This might correct the problems.

- tok:changequorumlater1

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Alternatives to rolling upgrades

# Perform a last node rolling upgrade from Windows 2000

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To perform a last node rolling upgrade from Windows 2000**

1. Confirm that your systems are running Windows 2000.

2. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition. For more information, see "Checklist: Preparation for upgrading a cluster" in Related Topics.

3. Using the information in "Resource behavior during rolling upgrades" in Related Topics, identify the resources in your cluster that are not supported by Windows Server 2003 and remove those resources.

4. Again using the information in "Resource behavior during rolling upgrades" in Related Topics, identify the resources in your cluster that are not supported during rolling upgrades and are not covered by other technology specific upgrade procedures listed in Related Topics.

5. Move all of the resources identified in the previous step to a single node by double clicking the Groups folder in Cluster Administrator's console tree. Click the group that contains the resource and then in the **File** menu, click **Move Group**.

6. Upgrade the operating system on each of the nodes that is not hosting the resources moved in the previous step. After you upgrade each node, close Manage Your Server if it is displayed.

7. Move all of the resources that you moved in the earlier steps from the node that has not been upgraded to one of the newly upgraded nodes.

8. Once all of the resources have been moved, upgrade the final node. After you upgrade, close the **Manage Your Server** dialog box if it is displayed.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- After you upgrade a cluster node from Windows 2000, you must log on with an account that is a member of both the Domain Admins group and the Administrators group on each cluster node before you can restart the Cluster service. This step is required even if the Domain Admins group is already a member of the Administrators group on each cluster node.

- It is not mandatory to move all of the resources to a single node and upgrade that node last. However, following the procedure as described will typically give you the highest availability of the resources that do not support rolling upgrades.

- If minor problems occur when you are performing a rolling upgrade, we recommend that you complete the upgrade. This might correct the problems.

- tok:changequorumlater1

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Perform a rolling upgrade from Windows 2000
Resource behavior during rolling upgrades
Upgrade from Windows 2000 on a cluster containing IIS without using the provided script

# Upgrade from Windows 2000 on a cluster containing IIS using the provided script

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade from Windows 2000 on a cluster containing IIS using the provided script**

1. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

2. Upgrade all nodes except the node containing the IIS instance resource from Windows 2000 to Windows Server 2003. You can perform either a rolling upgrade, or a non-rolling upgrade, whichever is appropriate for your installation. Prior to upgrading, be sure to remove the resources that are not supported by Windows Server 2003. For more information, see Related Topics.

3. If you do not already have a Distributed Transaction Coordinator (DTC) resource on the cluster that you are upgrading, create a DTC resource for this cluster on an upgraded node.

4. On an upgraded node, open Command Prompt and navigate to the %systemroot%\system32\inetsrv directory.

5. Type:

   **iis switch** *cluster name [group name]*

| Value | Description |
|---|---|
| cluster name | The name of a physical node in the cluster that has been upgraded or the name of a virtual server. |
| group name | This is optional. By default the script will upgrade all IIS Web and FTP resources in the cluster. However, if instead you want to upgrade only one particular group, you can specify the name of that resource group. |

**Important**

- The resource group that includes the IIS resource must be on the Windows 2000 node when you run the script.

  The script includes a step that will bring the resource group with the newly created Generic Script resource online. However the script will only bring the group online if all resources in the group were online before the script was run. If the group was only partially online or was offline prior to the script being run, the script will take the entire group offline and will not bring any resources back online after the upgrade.

  Once the script completes, the newly created resource might immediately fail. This is because the W3SVC service is disabled. You can correct this problem by completing the following step.

1. Once the script completes, take the newly created Generic Script resource offline, then start the W3SVC service on this node and set the W3SVC to start automatically.

2. Bring the Generic Script resource online.

3. Using IIS, start the Web site on the upgraded node.

4. Upgrade the final node to Windows Server 2003. Once the upgrade completes, start the W3SVC service on this node and set the service to start automatically.

5. If appropriate, add the final upgraded node to the **Possible Owners** list for the newly created Generic Script resource. For more information, see "Specify which nodes can own a resource" in Related Topics.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- After you upgrade a cluster node from Windows 2000, you must log on with an account that is a member of both the Domain Admins group and the Administrators group on each cluster node before you can restart the Cluster service. This step is required even if the Domain Admins group is already a member of the Administrators group on each cluster node.

- To cluster IIS on Windows Server 2003, you must have a DTC resource on that cluster as well.

- The script will not upgrade IIS resources that are in the cluster group. If you have IIS resources that are in the cluster group, you can instead use the procedure "To upgrade from Windows 2000 without using the provided script on a cluster that includes an IIS resource" in Related Topics.

- Only upgraded nodes can be the owner of the Generic Script Resource created in this procedure because this resource type is not supported in Windows 2000.

- If you prefer to not use the provided script and instead perform each step manually, see "Upgrade from Windows 2000 on a cluster containing IIS without using the provided script" in Related Topics.

- tok:changequorumlater1

- For more information regarding hardware compatibility, see Support resources.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Upgrade from Windows 2000 on a cluster containing IIS without using the provided script

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade from Windows 2000 on a cluster containing IIS without using the provided script**

1. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

2. Upgrade all nodes except the node containing the IIS instance resource from Windows 2000 to Windows Server 2003. You can perform either a rolling upgrade, or a nonrolling upgrade, whichever is appropriate for your installation. Prior to upgrading, be sure to remove the resources that are not supported by Windows Server 2003. For more information, see Related Topics.

3. If you do not already have a Distributed Transaction Coordinator (DTC) resource on the cluster that you are upgrading, create a DTC resource for this cluster on an upgraded node.

4. On the Windows 2000 node, note the dependencies of the IIS instance resource. Note resources that depend on the IIS resource and also note what resources IIS itself is dependent on.

5. Take the group containing the IIS instance resource offline For more information on how to do this see "Take a resource offline" in Related Topics.

6. Remove any dependencies on the IIS instance resource.

7. Delete the IIS instance resource.

8. Move the group to a node running Windows Server 2003 and create a Generic Script resource by following the procedure documented in "Checklist: Creating a clustered IIS Web or FTP service" in Related Topics.

   **Notes**

   - As part of this step, recreate the dependencies of the Generic Script resource identical to those of the now deleted IIS resource. Make everything that was dependent on the IIS resource dependent instead on the Generic Script resource. Also make the Generic Script resource dependent on everything that IIS was dependent on.

   - Only upgraded nodes can be the owner of the Generic Script Resource created in this procedure because this resource type is not supported in Windows 2000.

9. Start the W3SVC service on this node and set the service to start automatically.

10. Bring the group containing the new Generic Script resource online.

11. Using IIS, start the Web site on the upgraded node.

12. Upgrade the final node to Windows Server 2003. Once the upgrade is complete, start the W3SVC on this node and set the service to start automatically.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group

might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- After you upgrade a cluster node from Windows 2000, you must log on with an account that is a member of both the Domain Admins group and the Administrators group on each cluster node before you can restart the Cluster service. This step is required even if the Domain Admins group is already a member of the Administrators group on each cluster node.

- To cluster IIS on Windows Server 2003, you must have a DTC resource on that cluster as well.

- Only upgraded nodes can be the owner of the Generic Script Resource created in this procedure because this resource type is not supported in Windows 2000.

- Many of these steps can be automated using a script provided with Windows Server 2003. For more information, see "Upgrade from Windows 2000 on a cluster containing IIS using the provided script" in Related Topics.

- tok:changequorumlater1

- For more information regarding hardware compatibility, see Support resources.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Upgrade from Windows 2000 on a cluster containing Message Queuing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade from Windows 2000 on a cluster containing Message Queuing**

1. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

2. Take all of the Message Queuing cluster resources offline. For more information on how to do this see "Take a resource offline" in Related Topics.

3. For each Message Queuing resource, take the Network Name resource that depends on it offline also.

4. Upgrade all of the nodes from Windows 2000 to Windows Server 2003. You can perform either a rolling upgrade, or a non-rolling upgrade, whichever is appropriate for your installation. Prior to upgrading, be sure to remove the resources that are not supported by Windows Server 2003. For more information, see Related Topics. Manage Your Server will appear when you initially log on to the newly upgraded node as an Administrator. Close Manage Your Server to continue with the upgrade.

5. Bring the Network Name resources back online. Ensure that the Distributed Transaction Coordinator (DTC) resource is online, then bring the Message Queuing resources online.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- After you upgrade a cluster node from Windows 2000, you must log on with an account that is a member of both the Domain Admins group and the Administrators group on each cluster node before you can restart the Cluster service. This step is required even if the Domain Admins group is already a member of the Administrators group on each cluster node.

# Upgrade a Cluster from Windows NT 4.0

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrade a cluster from Windows NT 4.0**
You cannot perform a rolling upgrade directly from Windows NT Server 4.0, Enterprise Edition to Windows Server 2003, Enterprise Edition. You instead have two options:

- You can maintain cluster availability by performing an upgrade to Windows 2000 first, then to Windows Server 2003, Enterprise Edition.

- For some installations, you can perform a nonrolling upgrade directly from Windows NT Server 4.0, Enterprise Edition to Windows Server 2003, Enterprise Edition, which will not allow you to maintain cluster availability. You can do this if, on each node, the folder that contains the clustering software is called **Cluster** (capitalization is unimportant) and is located in the system root folder, which is the folder where the operating system is installed. If the folder is not called **Cluster** or is not located in the system root folder, you cannot upgrade, but must perform a clean installation.

If you upgrade using Windows 2000, perform an upgrade from Windows NT Server 4.0 to Windows 2000 as documented in the Windows 2000 documentation. Then follow the Windows Server 2003, Enterprise Edition upgrade procedures documented in Upgrade a Cluster from Windows 2000. If you have an IIS resource on your Windows NT Server 4.0 cluster, after you complete both upgrades, you must delete the unsupported IIS resource type by opening the Command Prompt and typing the following command: **Cluster restype "IIS Virtual Root" /delete /type**.

To upgrade without any use of the Windows 2000 product, you must interrupt cluster availability. The steps you perform depend on what resources are included in your cluster. For many installations, the following procedure is appropriate:

- Upgrade a cluster from Windows NT

However, if your cluster contains an IIS resource, you must use the following procedure:

- Upgrade from Windows NT on a cluster containing IIS

If your cluster contains an MSMQ or DTC resource, you must perform the procedure documented in article Q315993, "HOW TO: Upgrade a Windows NT 4.0 Cluster with MSDTC and MSMQ Resources" in the Microsoft Knowledge Base.

# Upgrade a cluster from Windows NT

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade a cluster from Windows NT**

1. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition. For more information, see "Checklist: Preparation for upgrading a cluster" in Related Topics.

2. On each node, locate the folder that contains the clustering software. Confirm that the folder is called **Cluster** (capitalization is unimportant) and is located in the system root folder, which is the folder where the operating system is installed. For example, if the default was used when the cluster was installed, the folder path will be C:\Winnt\Cluster. If the folder is not called **Cluster** or is not located in the system root folder, you cannot upgrade the cluster to Windows Server 2003, but must perform a clean installation.

3. Confirm that you do not have an IIS, MSMQ, or DTC resource on your cluster. For more information, see Notes and Related Topics.

4. Ensure that Service Pack 5 or later has been applied to all computers that will be upgraded from Windows NT Server 4.0 to Windows Server 2003, Enterprise Edition.

5. As appropriate, notify users that you will be shutting down the applications they use on the cluster.

6. Stop the applications that are made available through the cluster.

7. Remove any resources that are not supported by Windows Server 2003, Enterprise Edition, including NNTP Service Instance, SMTP Service Instance and Time Service resources.

8. Shut down and turn off all nodes but one, or bring them to a shut-down state appropriate to your method of termination.

   **Caution**

   - If you are using a shared storage device, when you upgrade and power on and start the operating system, it is of vital importance that only one node has access to the cluster disk. Otherwise the cluster disks can become corrupted. To prevent the corruption of the cluster disks, shut down all but one cluster node, or use other techniques (for example, LUN masking, selective presentation, or zoning) to protect the cluster disks, before creating the cluster. Once the Cluster service is running properly on one node, the other nodes can be installed and configured simultaneously.

9. Upgrade the operating system on the node that is running. For information about running Setup, see "Start Setup" in Related Topics.

   The cluster software will be upgraded automatically during the operating system upgrade. Note that you cannot make configuration changes such as configuring cluster disks as dynamic disks. For more information, see "Limitations of server clusters" in Related Topics.

   Manage Your Server will appear when you initially log on to the newly upgraded node as an Administrator. Close Manage Your Server to continue with the upgrade.

10. On the upgraded node, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.

11. Check to see that the cluster disks are online in Cluster Administrator.

**Caution**

- Be sure that the cluster disks are online in Cluster Administrator before continuing to the next step. When the disks are online, it means that the Cluster service is working, which means that only one node can access the cluster storage at any given time. Otherwise the cluster storage could be corrupted.

12. Shut down and turn off the upgraded node, or bring it to a shut-down state appropriate to your method of termination.

13. Turn on the other node in the cluster and upgrade the operating system on that node.

14. After the second node is upgraded, turn on the first node.

15. If you want to add additional nodes to the cluster, add them after the first two nodes are upgraded.

**Important**

- Confirm that your entire cluster solution is compatible with products in the Windows Server 2003 family by clicking the appropriate link in Support resources.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- If your Windows NT Server 4.0 cluster includes a DTC or MSMQ resource, you must take additional steps when upgrading directly from Windows NT Server 4.0 to Windows Server 2003, Enterprise Edition. For more information, see article Q315993, "HOW TO: Upgrade a Windows NT 4.0 Cluster with MSDTC and MSMQ Resources" in the Microsoft Knowledge Base.

- If your goal is to have more than two nodes in the cluster, you must use Fibre Channel (not SCSI) for the cluster storage. Before adding additional nodes, ensure that your entire cluster solution is compatible with products in the Windows Server 2003 family.

- When upgrading from Windows NT Server 4.0 to Windows Server 2003, Enterprise Edition, the Cluster service user account requires the additional user right "Act as part of the operating system". If possible, Setup will grant this user right automatically. If Setup cannot grant the user right, you will be prompted to make this change.

  For security reasons, you must grant this user right to the specific user account that is used by the Cluster service. You cannot correct this problem by granting the user right to a security group of which the user account is a member. Typically, you must grant this user right as a local user right; it cannot be a domain-level user right. However, if your node is a domain controller, you can use the domain level user right.

  For more information on setting user rights, refer to "To edit a security setting" in the Windows 2000 help documentation or on Windows NT Server 4.0, open User Manager for Domains, click the **Help** menu in User Manager and refer to "Managing the User Rights Policy."

- tok:changequorumlater1

- Before you can begin an upgrade from Windows NT Server 4.0 directly to Windows Server 2003, Enterprise Edition, you must apply Service Pack 5 or later.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Upgrade from Windows NT on a cluster containing IIS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade from Windows NT on a cluster containing IIS**

1. Confirm that your hardware is designed for or is compatible with Windows Server 2003, Enterprise Edition.

2. On each node, locate the folder that contains the clustering software. Confirm that the folder is called **Cluster** (capitalization is unimportant) and is located in the system root folder, which is the folder where the operating system is installed. For example, if the default was used when the cluster was installed, the folder path will be C:\Winnt\Cluster. If the folder is not called **Cluster** or is not located in the system root folder, you cannot upgrade the cluster to Windows Server 2003, but must perform a clean installation.

3. As appropriate, notify users that you will be shutting down the applications they use on the cluster.

4. Ensure that Service Pack 5 or later has been applied to all computers that will be upgraded from Windows NT Server 4.0 to Windows Server 2003, Enterprise Edition.

5. Stop the applications that are made available through the cluster.

6. Remove any resources that are not supported by Windows Server 2003, Enterprise Edition, including NNTP Service Instance, SMTP Service Instance and Time Service resources.

7. Set the Cluster service on all nodes to start manually.

8. Shut down and turn off the node that does not contain the IIS resource, or bring it to a shut-down state appropriate to your method of termination.

   **Caution**

   - If you are using a shared storage device, when you upgrade and power on and start the operating system, it is of vital importance that only one node has access to the cluster disk. Otherwise the cluster disks can become corrupted. To prevent the corruption of the cluster disks, shut down all but one cluster node, or use other techniques (for example, LUN masking, selective presentation, or zoning) to protect the cluster disks, before creating the cluster. Once the Cluster service is running properly on one node, the other nodes can be installed and configured simultaneously.

9. On the running node, note the dependencies of the IIS instance resource. Note resources that depend on the IIS resource and also note what resources IIS itself is dependent on.

10. Take the group containing the IIS instance resource offline. For more information on how to do this see "Take a resource offline" in Related Topics.

11. Remove any dependencies on the IIS instance resource.

12. Delete the IIS instance resource and close Cluster Administrator if it is open. For more information "Delete a resource" in Related Topics.

13. Delete the unsupported resource type: Open Command Prompt. Type the following command and press ENTER:

    **Cluster restype "IIS Virtual Root" /delete /type**

14. Stop the Cluster service on the remaining node.

15. Upgrade the operating system on the node that is running. For information about running Setup, see "Start Setup" in Related Topics.

    The cluster software will be upgraded automatically during the operating system upgrade. Note that you cannot make configuration changes such as configuring cluster disks as dynamic disks. For more information, see "Limitations of server clusters" in Related Topics. After you upgrade, close Manage Your Server if it is displayed.

16. Start the Cluster service on the upgraded node.

17. Reconfigure the Cluster service on the upgraded node to start automatically.

18. Shut down and turn off the upgraded node, or bring it to a shut-down state appropriate to your method of termination.

19. Turn on the other node in the cluster and upgrade the operating system on that node. After you upgrade, close Manage Your Server if it is displayed.

    **Caution**

    - If you are using a shared storage device, when you upgrade and power on and start the operating system, it is of vital importance that only one node has access to the cluster disk. Otherwise the cluster disks can become corrupted. To prevent the corruption of the cluster disks, shut down all but one cluster node, or use other techniques (for example, LUN masking, selective presentation, or zoning) to protect the cluster disks, before creating the cluster. Once the Cluster service is running properly on one node, the other nodes can be installed and configured simultaneously.

20. After the second node is upgraded, start the Cluster service on the second upgraded node. The node automatically rejoins the existing cluster.

21. Reconfigure the Cluster service on the second upgraded node to start automatically.

22. Turn on the first node.

23. On one of the upgraded nodes, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Cluster Administrator**.

24. Check to see that the cluster disks are online in Cluster Administrator.

    **Caution**

    - Be sure that the cluster disks are online in Cluster Administrator before continuing to the next step. When the disks are online, it means that the Cluster service is working, which means that only one node can access the cluster storage at any given time. Otherwise the cluster storage could be corrupted.

25. If you do not already have a Distributed Transaction Coordinator (DTC) resource on the cluster that you are upgrading, create a DTC resource on this cluster.

26. On the node that used to contain the IIS resource, create a Generic Script resource by following the procedure documented in "Checklist: Creating a clustered IIS Web or FTP service" in Related Topics.

    **Notes**

    - As part of this step, recreate the dependencies of the Generic Script resource identical to those of the now deleted IIS resource. Make everything that was dependent on the IIS resource dependent instead on the Generic Script

resource. Also make the Generic Script resource dependent on everything that IIS was dependent on.

- Only Windows Server 2003, Enterprise Edition nodes can be the owner of the Generic Script Resource created in this procedure because this resource type is not supported in Windows NT Server 4.0.

27. Start the W3SVC service on all nodes and set the service to start automatically.

28. Bring the group containing the new Generic Script resource online.

29. Using IIS, start the Web site.

30. If you want to add additional nodes to the cluster, add them after the first two nodes are upgraded.

**Important**

- If your cluster uses SCSI, you can have two nodes in the cluster, but no more. If you want to have more than two nodes in the cluster, you must use Fibre Channel for the cluster storage. Also confirm that your entire cluster solution is compatible with products in the Windows Server 2003 family by clicking the appropriate link in Support resources. Your cluster solution must be in the Cluster category of compatible hardware.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To cluster IIS on Windows Server 2003, Enterprise Edition, you must have a DTC resource on that cluster as well.

- This procedure only applies when you upgrade directly from Windows NT Server 4.0 to Windows Server 2003, Enterprise Edition. If you upgrade from Windows NT Server 4.0 to Windows 2000 and then to Windows Server 2003, Enterprise Edition, follow the steps described in the appropriate topics listed in Related Topics.

- When upgrading from Windows NT Server 4.0 to Windows Server 2003, Enterprise Edition, the Cluster service user account requires the additional user right "Act as part of the operating system". If possible, Setup will grant this user right automatically. If Setup cannot grant the user right, you will be prompted to make this change.

  For security reasons, you must grant this user right to the specific user account that is used by the Cluster service. You cannot correct this problem by granting the user right to a security group of which the user account is a member. Typically, you must grant this user right as a local user right; it cannot be a domain-level user right. However, if your node is a domain controller, you can use the domain level user right.

  For more information on setting user rights, refer to "To edit a security setting" in the Windows 2000 help documentation or on Windows NT Server 4.0, open User Manager for Domains, click the **Help** menu in User Manager and refer to "Managing the User Rights Policy."

- Before you can begin an upgrade from Windows NT Server 4.0 directly to Windows Server 2003, Enterprise Edition, you must apply Service Pack 5 or later.

- tok:changequorumlater1

- For more information regarding hardware compatibility, see the Windows Catalog at the Microsoft Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Planning and preparing for cluster installation

Updated: April 10, 2006

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Planning and preparing for cluster installation**
Before carrying out cluster installation, you need to plan hardware and network details.

**Caution**

- If you are using a shared storage device, before creating a cluster, when you turn on the computer and start the operating system, it is very important that only one node has access to the cluster disk. Otherwise, the cluster disks can become corrupted. To prevent the corruption of the cluster disks, shut down all but one cluster node, or use other techniques (for example, LUN masking, selective presentation, or zoning) to protect the cluster disks before creating the cluster. Once the Cluster service is running properly on one node, the other nodes can be installed and configured simultaneously. Each node of your cluster must be running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition.

In your planning, review the following items:

**Cluster hardware and drivers**
Microsoft supports only complete server cluster systems that are compatible with the Windows Server 2003 family. Confirm that your entire cluster solution is compatible with products in the Windows Server 2003 family by clicking the appropriate link in Support resources.

For cluster disks, you must use the NTFS file system and configure the disks as basic disks. You cannot configure cluster disks as dynamic disks, and you cannot use features of dynamic disks such as spanned volumes (volume sets).

Review the manufacturer's instructions carefully before you begin installing cluster hardware. Otherwise, the cluster storage could be corrupted. If your cluster hardware includes a SCSI bus, be sure to carefully review any instructions about termination of the SCSI bus and configuration of SCSI IDs.

To simplify configuration and eliminate potential compatibility problems, consider using identical hardware for all nodes.

**Network adapters on the cluster nodes**
In your planning, decide what kind of communication each network adapter will carry. The following list provides details about the types of communication that an adapter can carry:

- **Only node-to-node communication (private network).** This implies that the server has one or more additional adapters to carry other communication.

  For node-to-node communication, you connect the network adapter to a private network that is used exclusively within the cluster. Note that if the private network uses a single hub or network switch, that piece of equipment becomes a potential point of failure in your cluster.

  The nodes of a cluster must be on the same subnet but you can use virtual LAN (VLAN) switches on the interconnects between two nodes. If you use a VLAN, the point to point, round-trip latency must be less than 1/2 second and the link between two nodes must appear as a single point-to-point connection from the perspective of the Windows operating system running on the nodes. To avoid single points of failure, use independent VLAN hardware for the different paths between the nodes.

  If your nodes use multiple private (node-to-node) networks, it is a best practice for the adapters for those networks to use static IP addresses instead of DHCP.

- **Only client-to-cluster communication (public network).** This implies that the server has one or more additional adapters to carry other communication.

- **Both node-to-node and client-to-cluster communication (mixed network).** When you have multiple network adapters per node, a network adapter that carries both kinds of communication can serve as a backup for other network adapters.

- **Communication unrelated to the cluster.** If a clustered node also provides services unrelated to the cluster, and there are enough adapters in the cluster node, you might want to use one adapter for carrying communication unrelated to the cluster.

The nodes of a cluster must be connected by two or more local area networks (LANs); at least two networks are required to prevent a single point of failure. A server cluster whose nodes are connected by only one network is not a supported configuration. The adapters, cables, hubs, and switches for each network must fail independently. This usually implies that the components of any two networks must be physically independent.

At least two networks must be configured to handle **All communications (mixed network)** or **Internal cluster communications only (private network)**.

The recommended configuration for two adapters is to use one adapter for the private (node-to-node only) communication and the other adapter for mixed communication (node-to-node plus client-to-cluster communication).

Consider choosing a name for each connection that tells what it is intended for. The name makes it easier to identify the connection whenever you are configuring the server.

**Notes**

- If you use fault tolerant network adapters, create multiple private networks instead of a single fault-tolerant network.
- Do not use teaming network adapters on the private network.
- Do not configure a default gateway or DNS or WINS server on the private network adapters. Do not configure private network adapters to use name resolution servers on the public network; otherwise, a name resolution server on the public network might map a name to an IP address on the private network. If a client then received that IP address from the name resolution server, it might fail to reach the address because no route from the client to the private network address exists.
- Configure WINS and/or DNS servers on the public network adapters. If Network Name resources are used on the public networks, set up the DNS servers to support dynamic updates; otherwise the Network Name resources may not fail over correctly. Also, configure a default gateway on the public network adapters. If there are multiple public networks in the cluster, configure a default gateway on only one of these.
- The adapters on a given node must connect to networks in different subnets.
- When you use either the New Server Cluster Wizard or the Add Nodes Wizard to install clustering on a node that contains two network adapters, by default the wizard configures both of the network adapters for mixed network communications. As a best practice, reconfigure one adapter for private network communications only. For more information, see Change how the cluster uses a network.
- Manually configure the communication settings, such as Speed, Duplex Mode, Flow Control and Media Type of each cluster network adapter. Do not use automatic detection. You must configure all of the cluster network adapters to use the same communication settings.
- Confirm that your entire cluster solution is compatible with the products in the Windows Server 2003 family by clicking the appropriate link in Support resources.

**Cluster IP address**
Obtain a static IP address for the cluster itself. You cannot use DHCP for this address.

**IP addressing for cluster nodes**
Determine how to handle the IP addressing for the individual cluster nodes. Each network adapter on each node requires IP addressing. It is a best practice to assign each network adapter a static IP address. As an alternative, you can provide IP addressing through DHCP. If you use static IP addresses, set the addresses for each linked pair of network adapters (linked node-to-node) to be on the same subnet.

Note that if you use DHCP for the individual cluster nodes, it can act as a single point of failure. That is, if you set up your

cluster nodes so that they depend on a DHCP server for their IP addresses, temporary failure of the DHCP server can mean temporary unavailability of the cluster nodes. When deciding whether to use DHCP, evaluate ways to ensure availability of DHCP services, and consider the possibility of using long leases for the cluster nodes. This helps to ensure that they always have a valid IP address.

**Cluster name**
Determine or obtain an appropriate name for the cluster. This is the name administrators will use for connections to the cluster. (The actual applications running on the cluster typically have different network names.) The cluster name must be different from the domain name, from all computer names on the domain, and from other cluster names on the domain.

**Computer accounts and domain assignment for cluster nodes**
Make sure that the cluster nodes all have computer accounts in the same domain. Cluster nodes cannot be in a workgroup.

**Operator user account for installing and configuring the Cluster service**
To install and configure the Cluster service, you must be using an account that is in the local Administrators group on each node. As you install and configure each node, if you are not using an account in the local Administrators group, you will be prompted to provide the logon credentials for such an account.

**Cluster service user account**
Create or obtain the Cluster service user account. This is the name and password under which the Cluster service will run. You need to supply this user name and password during cluster installation.

It is best if the Cluster service user account is an account not used for any other purpose. If you have multiple clusters, set up a unique Cluster service user account for each cluster. The account must be a domain account; it cannot be a local account. However, do not make this account a domain administrator account because it does not need domain administrator user rights.

As part of the cluster setup process, the Cluster service user account is added to the local Administrators group on each node. As well as being a member of the local administrators group, the Cluster service user account requires an additional set of user rights:

- Act as part of the operating system
- Back up files and directories
- Adjust memory quotas for a process
- Increase scheduling priority
- Log on as a service
- Restore files and directories

In addition, by default, the Cluster service account inherits the following user rights as a result of being a member of the local Administrators group:

- Manage auditing and security log
- Debug programs
- Impersonate a client after authentication

If your organization has removed these user rights from the default set of privileges assigned to the local Administrators group, you need to specifically assign these user rights to the Cluster service account.

The preceding user rights are granted to the Cluster service user account as part of the cluster setup process. Be aware that the Cluster service user account will continue to have these user rights even after all nodes are evicted from the cluster. The risk that this presents is mitigated by the fact that these user rights are not granted domain wide, but rather only locally on each former node. However, remove this account from each evicted node if it is no longer needed.

Be sure to keep the password from expiring on the Cluster service user account (follow your organization's policies for password renewal). For more information, see Passwords.

**Volume for important cluster configuration information (checkpoint and log files)**
Plan on setting aside a volume on your cluster storage for holding important cluster configuration information. This information makes up the cluster quorum resource, which is needed when a cluster node stops functioning. The quorum resource provides node-independent storage of crucial data needed by the cluster.

The recommended minimum size for the volume is 500 MB. It is recommended that you do not store user data on any volume in the quorum resource. Do not use Shadow Copies for Shared Folders for the quorum resource. If you plan to put the quorum resource on a disk with multiple NTFS partitions, ensure that all partitions on the disk are assigned drive letters.

### Note

- When planning and carrying out disk configuration for the cluster disks, configure them as basic disks with all partitions formatted as NTFS (they can be either compressed or uncompressed). Partition and format all disks on the cluster storage device before adding the first node to your cluster. Do not configure them as dynamic disks, and do not use spanned volumes (volume sets) or Remote Storage on the cluster disks. Cluster disks on the cluster storage device must be partitioned as master boot record (MBR) and not as GUID partition table (GPT) disks.

The following section describes the physical installation of the cluster storage.

**Beginning the installation of the cluster hardware**
The steps you carry out when first physically connecting and installing the cluster hardware are crucial. Be sure to follow the hardware manufacturer's instructions for these initial steps.

### Important

- Carefully review your network cables after connecting them. Make sure no cables are crossed by mistake (for example, private network connected to public).

**Initial steps to carry out in the BIOS or EFI when using a SCSI shared storage device**
If you are using a SCSI shared storage device, when you first attach your cluster hardware (the shared bus and cluster storage), be sure to work only from the firmware configuration screens on the cluster nodes (a node is a server in a cluster). On a 32-bit computer, use the BIOS configuration screens. On an Itanium architecture-based computer, use the Extensible Firmware Interface (EFI) configuration screens. The instructions from your manufacturer describe whether these configuration screens are displayed automatically or whether you must, after turning on the computer, press specific keys to access them. Follow the manufacturer's instructions for completing the BIOS or EFI configuration process. Remain in the BIOS or EFI configuration screens, and do not allow the operating system to start, during this initial installation phase. Complete the following steps while the cluster nodes are still displaying BIOS or EFI configuration screens, before starting the operating system on the first cluster node.

### Important

- Make sure you understand and follow the manufacturer's instructions for termination of the SCSI bus.

- Make sure that each device on the shared bus (both SCSI controllers and hard disks) has a unique SCSI ID. If the SCSI controllers all have the same default ID (often it is SCSI ID 7), change one controller to a different SCSI ID, such as SCSI ID 6. If there is more than one disk that will be on the shared SCSI bus, each disk must also have a unique SCSI ID. In addition, make sure that the bus is not configured to reset SCSI IDs automatically on startup (otherwise the IDs will change from the settings you specify).

- Ensure that you can scan the bus and see the drives from all cluster nodes (while remaining in the BIOS or EFI configuration screens).

**Initial steps to carry out in the BIOS or EFI when using a fibre channel shared storage device or no shared storage device**

- Turn on a single node. Leave all other nodes turned off.

- During this initial installation phase, remain in the BIOS or Extensible Firmware Interface (EFI) configuration process, and do not allow the operating system to start. While viewing the BIOS or EFI configuration screens, ensure that you can scan the bus and see the drives from the active cluster node. On a 32-bit computer, use the BIOS configuration screens. On an Itanium architecture-based computer, use the EFI configuration screens. Consult the instructions from your manufacturer

to determine whether these configuration screens are displayed automatically or whether you must, after turning on the computer, press specific keys to access them. Follow the manufacturer's instructions for completing the BIOS or EFI configuration process.

**Final steps to complete the installation**

If you have not already installed Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, on the first cluster node, install it before proceeding. After you complete the BIOS or EFI configuration, start the operating system on one cluster node only and complete the configuration of the Cluster service using Cluster Administrator.

With the Cluster Administrator New Server Cluster Wizard, you can choose between Typical (full) configuration and Advanced (minimum) configuration options. Typical configuration is appropriate for most installations and results in a completely configured cluster. Use the Advanced configuration option only for clusters that have complex storage configurations that the New Server Cluster Wizard cannot validate or for configurations in which you do not want the cluster to manage all of the storage. The following examples describe each situation:

- In some complex storage solutions, such as a fiber channel switched fabric that contains several switches, a particular storage unit might have a different identity on each computer in the cluster. Although this is a valid storage configuration, it violates the storage validation heuristics in the New Server Cluster Wizard. If you have this type of storage solution, you might receive an error when you are trying to create a cluster using the Typical configuration option. If your storage configuration is set up correctly, you can disable the storage validation heuristics and avoid this error by restarting the New Server Cluster Wizard, selecting the Advanced configuration option instead.

- On particular nodes in a cluster, you may want to have some disks that are to be clustered and some disks that are to be kept private. The Typical configuration option configures all disks as clustered disks and creates cluster resources for them all. However, with the Advanced configuration option, you can keep certain disks private because this configuration creates a cluster in which only the quorum disk is managed by the cluster (if you chose to use a physical disk as the quorum resource). After the cluster is created, you must then use Cluster Administrator to add any other disks that you want the cluster to manage.

For more information, see Storage configuration options.

**Important**

- If you are using a shared storage device: Before creating a cluster, when you turn the computer on and start the operating system, it is very important that only one node has access to the cluster disk. Otherwise, the cluster disks can become corrupted. To prevent the corruption of the cluster disks, shut down all but one cluster node, or use other techniques (for example, LUN masking, selective presentation, or zoning) to protect the cluster disks before creating the cluster. Also, before starting the installation of the second and subsequent nodes, ensure that all disks that are to be managed by the cluster have disk resources associated with them. If these disks do not have disk resources associated with them at this time, the disk data will be corrupted because the disks will not be protected and multiple nodes will attempt to connect to them at the same time.

- Do not use Manage Your Server or the Configure Your Server Wizard to configure cluster nodes.

For information about further steps for installing a cluster, see Checklist: Validating your clustering system and Checklist: Planning and creating a server cluster.

For information about unattended setup of a cluster, see Create a cluster and "Designing Unattended Installations" at the Microsoft Windows Server System Web site.

# Quorum resource options when installing server clusters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quorum resource options when installing server clusters**

With server clusters on the Windows Server 2003 operating systems, you can now choose between three ways to set up the quorum resource (the resource that maintains the definitive copy of the cluster configuration data and that must always be available for the cluster to run).

The first is a single node server cluster, which has been available in the past and continues to be supported. A single node cluster is often used for development and testing and can be configured with, or without, external cluster storage devices. For single node clusters without an external cluster storage device, the local disk is configured as the cluster quorum device.

The second option is a single quorum device server cluster, which has also been available in earlier Windows versions. This model places the cluster configuration data on a shared cluster storage device that all nodes can access. The general topology is:

This is the most common model and is recommended for most situations. You might choose the single quorum device model if all of your cluster nodes are in the same location and you want to take advantage of the fact such a cluster continues supporting users even if only one node is running.

The third option, which is new for Windows Server 2003, is a "majority node set." A majority node set is a single quorum resource from a Server Cluster perspective; however, the cluster configuration data is actually stored on multiple disks across the cluster. The majority node set resource ensures that the cluster configuration data is kept consistent across the different disks. This allows cluster topologies as follows:

In the majority node set model, every node in the cluster uses a directory on its own local system disk to store the cluster configuration data. If the configuration of the cluster changes, that change is reflected across the different disks. Be aware that it is also possible to have shared storage devices in a majority node set cluster. The exact configuration depends on your installation's requirements.

Only use a majority node set cluster in targeted scenarios, such as:

- Geographically dispersed cluster: A cluster that spans multiple sites.
- Eliminating single points of failure: Although when using a single cluster storage device the quorum disk itself can be made highly available via RAID, the controller port or the Host Bus Adapters (HBA) itself may be a single point of failure.
- Clusters with no shared disks: There are some specialized configurations that need tightly consistent cluster features without having shared disks.
- Clusters that host applications that can fail over, but where there is some other, application-specific way, to replicate or mirror data between nodes.

Do not configure your cluster as a majority node set cluster unless it is part of a cluster solution offered by your Original Equipment Manufacturer (OEM), Independent Software Vendor (ISV), or Independent Hardware Vendor (IHV).

**Cluster model considerations**
Before implementing your cluster, consider what type of quorum resource solution you plan to use. Take into consideration the following differences between single quorum device clusters and majority node set:

### Note

- The following information is presented to help you make basic decisions about the placement and management of your cluster nodes and quorum resource. It does not provide all the details about the requirements for each cluster model, or how each model handles failover situations. If you are not sure which model to use or where you want to place your cluster nodes, refer to the information in Choosing a Cluster Model.

**Node failover behavior**
The failover behavior of the majority node set is significantly different from the behavior of the single quorum device model:

- Using the single quorum device model, you can maintain cluster availability with only a single operational node.

- If you use a majority node set, more than half, or (*Number of nodes configured in the cluster*/2) + 1 nodes must be operational in order to maintain cluster availability. The following table shows the number of node failures that a given majority node set cluster can tolerate yet continue to operate:

| Number of nodes configured in the cluster | Number of node failures allowed before cluster failure | Number of nodes needed to continue cluster operations |
|---|---|---|
| 1 | 0 | 1 |
| 2 | 0 | 2 |
| 3 | 1 | 2 |
| 4 | 1 | 3 |
| 5 | 2 | 3 |
| 6 | 2 | 4 |
| 7 | 3 | 4 |
| 8 | 3 | 5 |

**Geographic Considerations**
You would commonly use a single quorum resource model if all nodes in your cluster will be in the same geographical location. As part of this requirement, your nodes must be connected to the same physical storage device.

A majority node set on the other hand would typically be appropriate if you have geographically dispersed nodes. The cluster configuration data is stored locally on each node on a file share that is shared out to the other nodes on the network. However, those shares must always be accessible or nodes can fail.

There are other specific requirements for geographically dispersed clusters, including the requirement that round-trip latency of the network between cluster nodes be a maximum of 500 milliseconds. For information on cluster solutions that meet all requirements for a geographically dispersed cluster, refer to the hardware compatibility information, which you can find by clicking the appropriate link in Support resources.

**Hardware**
Microsoft supports only complete server cluster systems that are compatible with the Windows Server 2003 family of products. Confirm that your entire cluster solution is compatible with products in the Windows Server 2003 family by clicking the appropriate link in Support resources.

For more information about majority node set clusters, see Choosing a Cluster Model and Create a cluster.

**Important**

- Before implementing a majority node set, it is highly recommended that you read the information in Choosing a Cluster Model. This information will help you understand all the considerations, requirements, and restrictions for each type of quorum resource solution.

# Upgrading to Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition on Cluster Nodes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrading to Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition on cluster nodes**
If you are upgrading from Windows 2000 to Windows Server 2003, Enterprise Edition or Windows Server 2003, Datacenter Edition on cluster nodes, you might be able to perform a *rolling upgrade* of the operating system. In a rolling upgrade, you sequentially upgrade the operating system on each node, making sure that one node is always available to handle client requests. When you upgrade the operating system, the Cluster service is automatically upgraded also. A rolling upgrade maximizes availability of clustered services and minimizes administrative complexity.

If you are upgrading from Windows NT 4.0, Enterprise Edition to Windows Server 2003, Enterprise Edition on cluster nodes, you cannot perform a rolling upgrade. For more information about how to perform an upgrade from Windows NT 4.0, Enterprise Edition, see Upgrade a Cluster from Windows NT 4.0.

For more information, see the following topics:

- For a diagram and description of a rolling upgrade, see How rolling upgrades work.
- To determine whether you can perform a rolling upgrade, see Restrictions on rolling upgrades.
- For information about support for various types of resources during a rolling upgrade, see the following:
  - Operation of new resource types in mixed-version clusters
  - Resource behavior during rolling upgrades
  - Upgrades that include a Print Spooler resource
- For information about ways to upgrade your cluster nodes if you cannot perform a rolling upgrade, see Alternatives to rolling upgrades.

# How rolling upgrades work

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How rolling upgrades work**
This topic describes rolling upgrades on server clusters. To decide whether you can perform a rolling upgrade, see Restrictions on rolling upgrades. For information about methods, restrictions, and alternatives to rolling upgrades, see the links at the end of this topic.

There are two major advantages to a rolling upgrade. First, there is a minimal interruption of service to clients. (However, server response time might decrease during the phases in which a fewer number of nodes handle the work of the entire cluster.) Second, you do not have to recreate your cluster configuration. The configuration remains intact during the upgrade process.

In this example, the rolling upgrade starts with two cluster nodes that are running Windows 2000 named *Node 1* and *Node 2*. The following diagram depicts the process:

**Phase 1: preliminary**
Each node runs Windows 2000 Advanced Server with the following software:

- The Cluster service component, one of the optional components of Windows 2000 Advanced Server.
- Applications that support a rolling upgrade. For more information, see the application documentation and Resource behavior during rolling upgrades.

At this point, your cluster is configured so that each node handles client requests (an active/active configuration).

**Phase 2: upgrade node 1**
Node 1 is paused, and Node 2 handles all cluster resource groups while you upgrade the operating system of Node 1 to Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition.

You are now running a mixed version cluster. A mixed version cluster is a cluster in which the nodes are running different versions of the operating system. Although mixed version clusters are supported by Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition, they are not the optimal configuration. It is recommended that you upgrade all nodes to the same operating system by completing the final two phases of the rolling upgrade.

When your cluster is in a mixed version state, it is recommended that you do not make any changes to the cluster configuration, such as adding or removing nodes. It is also recommended that you do not make changes to any of the cluster resources while your cluster is in a mixed version state.

**Phase 3: upgrade node 2**
Node 1 rejoins the cluster. Node 2 is paused and Node 1 handles all cluster resource groups while you upgrade the operating system on Node 2.

**Phase 4: final**

Node 2 rejoins the cluster, and you redistribute the resource groups back to the active/active cluster configuration.

**Notes**

- If your goal is to have more than two nodes in the cluster, you must use Fibre Channel (not SCSI) for the cluster storage. Add the additional nodes after completing the rolling upgrade. Before adding additional nodes, confirm that your entire cluster solution is compatible with products in the Windows Server 2003 family by clicking the appropriate link in Support resources. Your cluster solution must be in the Cluster category of compatible hardware.

- For cluster disks, you must use the NTFS file system and configure the disks as basic disks. You cannot configure cluster disks as dynamic disks, and you cannot use features of dynamic disks such as spanned volumes (volume sets). For more information, see Limitations of server clusters.

For more information about rolling upgrades, see:

- Perform a rolling upgrade from Windows 2000
- Restrictions on rolling upgrades
- Operation of new resource types in mixed-version clusters
- Resource behavior during rolling upgrades
- Upgrades that include a Print Spooler resource
- Alternatives to rolling upgrades

# Restrictions on rolling upgrades

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restrictions on rolling upgrades**

There are several basic restrictions to the rolling-upgrade process. The most basic restrictions are as follows:

- You can perform a rolling upgrade only if you are upgrading from Windows 2000 on the cluster nodes. You cannot perform a rolling upgrade if you are upgrading from Windows NT Server 4.0, Enterprise Edition.

- You cannot mix x86-based and Itanium-based computers within the same cluster. Also, you cannot mix x86-based and x64-based computers within the same cluster. Therefore, you cannot perform a rolling upgrade from an x86-based computer to either an Itanium-based or x64-based computer.

The remaining restrictions involve the beginning of Phase 3, in which you operate a *mixed-version cluster*: a cluster in which the nodes run different versions of the operating system. In order for a mixed-version cluster to work, the different versions of the software running on each node must be prepared to communicate with one another. This requirement leads to several basic restrictions on the rolling-upgrade process.

- For a successful rolling upgrade, every resource that the cluster manages must be capable of a rolling upgrade. For more information, see Resource behavior during rolling upgrades.

- During the mixed-version phase of a rolling upgrade, when the cluster nodes are running different versions of the operating system, do not change the settings of resources (for example, do not change the settings of a printer resource). Also, do not make any changes to the quorum resource.

- During the mixed-version phase of a rolling upgrade, minor problems might occur. We recommend that you complete the upgrade rather than trying to troubleshoot symptoms. Completing the upgrade might correct the problems.

If the preceding restrictions cannot be met, do not perform a rolling upgrade. For more information, see Alternatives to rolling upgrades.

# Operation of new resource types in mixed-version clusters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Operation of new resource types in mixed-version clusters**

The operation of a mixed-version cluster is complicated if a resource type that you add to the cluster is supported in one version of the operating system but not the other. For example, the Cluster service in Windows Server 2003 supports the Generic Script resource type. However, older versions of the Cluster service do not support it. A mixed-version cluster can run a Generic Script resource on a node running Windows Server 2003 but not on a node running Windows 2000.

The Cluster service transparently sets the possible owners of new resource types to prevent these resources from failing over to a Windows 2000 node of a mixed-version cluster. In other words, when you view the possible owners of a new resource type, a Windows 2000 node will not be in the list, and you will not be able to add this node to the list. If you create such a resource during the mixed-version phase of a rolling upgrade, the resource groups containing those resources will not fail over to a Windows 2000 node.

# Resource behavior during rolling upgrades

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resource behavior during rolling upgrades**

Although the Cluster service supports rolling upgrades, not all applications have seamless rolling upgrade behavior. The following table describes the resources that are supported during a rolling upgrade. If you have a resource that is not fully supported during rolling upgrades, see Alternatives to rolling upgrades.

**Note**

- You cannot perform a rolling upgrade on a cluster running Windows NT Server 4.0. Only clusters running Windows 2000 support rolling upgrades to Windows Server 2003, Enterprise Edition.

| Resource | Rolling upgrade notes |
|---|---|
| DHCP | DHCP is not fully supported during rolling upgrades. You must instead perform a "Last node rolling upgrade," as described in Perform a last node rolling upgrade from Windows 2000. |
| File Share | Supported during rolling upgrades. |
| IIS | IIS 6.0 is not supported during rolling upgrades. When upgrading a cluster that contains an IIS resource, you must follow the procedure described in Upgrade from Windows 2000 on a cluster containing IIS without using the provided script or Upgrade from Windows 2000 on a cluster containing IIS using the provided script. |
| IP Address | Supported during rolling upgrades. |
| Local Quorum | Supported during rolling upgrades. |
| MSDTC | Supported during rolling upgrades. However, do not create or delete the MSDTC resource while you are operating as a mixed version cluster. Instead create the MSDTC resource before starting the upgrade on any node, or wait until the upgrade is complete on all nodes. For more information on mixed version clusters, see How rolling upgrades work and Restrictions on rolling upgrades. |
| Message Queuing (also known as MSMQ) | Microsoft Message Queuing is not fully supported during a rolling upgrade. To upgrade a cluster that includes Message Queuing, see Upgrade from Windows 2000 on a cluster containing Message Queuing. |
| Network Name | Supported during rolling upgrades. |
| NNTP Service Instance | NNTP Service Instance is not supported in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. You must remove any NNTP Service Instance resources prior to upgrading. |
| Physical Disk | Supported during rolling upgrades. |
| Print Spooler | The only Print Spooler resources supported during a rolling upgrade are those on LPR ports or standard port monitor ports. See Upgrades that include a Print Spooler resource. |
| SMTP Service Instance | SMTP Service Instance is not supported in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. You must remove any SMTP Service Instance resources prior to upgrading. |

| | |
|---|---|
| Time Service | Time Service is not supported in Windows Server 2003, Enterprise Edition, and Windows Server 2003, Datacenter Edition. You must remove any Time Service resources prior to upgrading. |
| WINS | WINS is not fully supported during rolling upgrades. You must instead perform a "Last node rolling upgrade," as described in Perform a last node rolling upgrade from Windows 2000. |
| Other resource types | See Relnotes.htm in the \Docs folder on the Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, setup CD. Also see the product documentation that comes with the application or resource. |

When your cluster is in a mixed version state, it is recommended that you do not make any changes to the cluster configuration, such as adding or removing nodes. It is also recommended that you do not make changes to any of the cluster resources while your cluster is in a mixed version state.

**Last node rolling upgrades**

If you have resources on your cluster such as DHCP and WINS that are not fully supported during a rolling upgrade and are not described by other technology specific procedures (such as IIS), you can perform a "last node rolling upgrade."

Last node rolling upgrades are similar to standard rolling upgrades. In a last node rolling upgrade, you upgrade all nodes except the node which contains the unsupported resources. After all other nodes are upgraded, you then upgrade the final node containing the identified resources.

Last node rolling upgrades are a way to accommodate resources that cannot fail over to an older operating system from a node running Windows Server 2003, Enterprise Edition. Be aware that these resources can, however, fail over the other way, that is, from the older operating system to Windows Server 2003, Enterprise Edition. For more information on how to perform a last node rolling upgrade, see Perform a last node rolling upgrade from Windows 2000.

# Upgrades that include a Print Spooler resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Upgrades that include a Print Spooler resource**

If you want to perform a rolling upgrade of a cluster that has a Print Spooler resource, you must consider two issues.

First, the Print Spooler resource only supports upgrades (including rolling upgrades or any other kind of upgrade) of printers on cluster-supported ports (LPR or Standard Port Monitor ports). For information about what to do if your printer is not supported, see Alternatives to rolling upgrades.

Second, when you operate a mixed-version cluster including a Print Spooler resource, note the following:

- Do not change printer settings in a mixed-version cluster with a Print Spooler resource.
- Avoid adding new printers while you are performing a rolling upgrade. If you do add a new printer, when you install the drivers for that printer, be sure to install both the driver for Windows 2000 and the driver for Windows Server 2003 on all nodes.
- If printing preferences or defaults are important, be sure to check them. Printing preferences in Windows Server 2003 will not necessarily correspond to document defaults for the same printer in Windows 2000. This can be affected by differences in the drivers for the two operating systems.

When the rolling upgrade is complete and both cluster nodes are running the updated operating system, you can make any modifications you choose to your printer configuration.

# Alternatives to rolling upgrades

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Alternatives to rolling upgrades**

Certain situations do not allow you to perform a standard rolling upgrade. In these cases, you must perform alternative procedures. These situations are:

- Upgrading from Windows NT Server 4.0, Enterprise Edition. For more information, see Upgrade a Cluster from Windows NT 4.0.

- Upgrading a node that contains resources that are not supported during rolling upgrades. To determine whether your resources are supported during rolling upgrades, see Resource behavior during rolling upgrades. Also be sure to read Relnotes.htm in the \Docs folder of the operating system setup CD, as well as the product documentation that comes with the application or resource. If you have a resource that is not fully supported during rolling upgrades and is not described by a technology specific procedure, such as Internet Information Server (IIS), see Perform a last node rolling upgrade from Windows 2000.

# Resources for installing and upgrading cluster nodes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

This topic provides sources of additional information about installing and upgrading on cluster nodes.

- Microsoft supports only complete server cluster systems that are compatible with the Windows Server 2003 family. Confirm that your entire cluster solution is compatible with products in the Windows Server 2003 family by clicking the appropriate link in Support resources.
- For the most recent information on compatible and certified applications for products in the Windows Server 2003 family, see the software compatibility section of the Microsoft Web site.
- To better ensure high availability, check for enhancements and updates to Windows software and other Microsoft software. See Windows Update at the Microsoft Web site.
- For additional information about deploying clustering, see "Planning Server Deployments" at the Microsoft Windows Server System Web site.
- For additional general information about clustering and the Windows Deployment and Resource Kits, which provide technical background information on products in the Windows Server 2003 family, see the following:
    - The *Windows Server 2003 Deployment Kit* at the Microsoft Windows Server System Web site.
    - The *Windows Server 2003 Technical Reference* at the Microsoft Windows Server System Web site.
    - The *Windows Server TechCenter* at the Microsoft Web site.
    - Using the Windows Deployment and Resource Kits
- Microsoft TechNet is a service that contains resources for Information Technology (IT) professionals. This includes access to white papers and articles about clustering written by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software. For more information, see TechNet at the Microsoft Web site.
- The Information Technology Infrastructure Library Web site (ITIL) Web site provides guidance for Information Technology professionals and includes detailed information regarding high availability. The following is an excerpt from the site: "ITIL consists of a series of books giving guidance on the provision of quality IT services, and on the accommodation and environmental facilities needed to support information technology." # Troubleshooting cluster node installations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting cluster node installations**
What problem are you having?

- During cluster creation, the New Server Cluster Wizard did not detect all of the potential cluster disks.
- During cluster creation, the New Server Cluster Wizard configured all of the available storage devices to be managed by the cluster, including storage that you did not want to be managed by the cluster.
- When trying to add a node to a cluster, you receive an error stating that a multinode cluster cannot be created because there is not a quorum-capable resource common to all nodes.
- During cluster creation, either the New Server Cluster Wizard or the Add Nodes Wizard did not detect all of the potential network adapters.
- During cluster creation, you are experiencing problems creating the first node of the cluster.
- During cluster creation, you are experiencing problems creating subsequent nodes after creating the first node of the Cluster.
- During cluster creation, the Physical Disk resources are not automatically created for cluster disks.
- After setting up a new cluster, Cluster Administrator cannot connect to the cluster.

**During cluster creation, the New Server Cluster Wizard did not detect all of the potential cluster disks.**
**Possible Cause:** Your hardware, device driver, or software is not configured correctly.

**Solution:** Check Disk Management to see whether the disks you want to use for shared storage are available.

**See also:** Disk Management

**Possible Cause:** You are using incompatible disk hardware or drivers.

**Solution:** Check your disk cabling to make sure that the cables are connected correctly between the node in question and the shared storage.

Confirm that your hardware, including your cluster disks and other cluster hardware, is compatible with Windows Server 2003, Datacenter Edition, by clicking the appropriate link in Support resources.

Make sure that the host adapter is configured correctly according to the manufacturer's instructions, and that all disks are visible to the host adapter.

Make sure that you have the drivers you need in order to use the disks with the Cluster service. Drivers are available from your hardware manufacturer. Review the manufacturer's instructions carefully before you begin installing cluster hardware.

**Note**

- If you make any changes to your disk hardware or drivers, you must restart the New Server Cluster Wizard for the changes to be detected.

**Possible Cause:** Your cluster storage disks are not formatted as NTFS.

**Solution:** Make sure all partitions on the cluster storage disks are formatted to use the NTFS file system. Any disk with a FAT or FAT32 partition will not be recognized during cluster creation.

**See also:** NTFS

**Possible Cause:** Your cluster storage disks are not configured as basic MBR disks.

**Solution:** Make sure your cluster storage disks are configured as basic MBR disks. Windows Server 2003, Datacenter Edition, offers two types of storage configurations: basic disk and dynamic disk. Basic disks use the same disk structures used by Microsoft Windows NT. Dynamic disks were introduced in Windows 2000.

Cluster servers can recognize only basic master boot record (MBR) disks. If a disk you want to use as shared storage is configured as a dynamic or GUID partition table (GPT) disk, change it back to a basic MBR disk.

**See also:** Converting a basic disk to dynamic; Change a GUID partition table disk into a master boot record disk

**During cluster creation, the New Server Cluster Wizard configured all of the available storage devices to be managed by the cluster, including storage that you did not want to be managed by the cluster.**
**Cause:** With the Cluster Administrator New Server Cluster Wizard, you can choose between Typical (full) configuration and Advanced (minimum) configuration options. The Typical configuration configures all disks as clustered disks and creates cluster resources for them all. The only exception is the system disk, which contains the operating system and is the disk from which the computer boots from. The system disk will not be automatically clustered.

**Solution:** Use the Advanced (minimum) configuration option. With the Advanced configuration option, you can keep certain disks private because the configuration creates a cluster in which only the quorum disk is managed by the cluster (if you chose to use a physical disk as the quorum resource). After the cluster is created, you must then use Cluster Administrator to add any other disks that you want the cluster to manage.

**See also:** Planning and preparing for cluster installation; Storage configuration options

**When trying to add a node to a cluster, you receive an error stating that a multinode cluster cannot be created because there is not a quorum-capable resource common to all nodes.**
**Cause:** The wizard was not able to validate your storage configuration. In some complex storage solutions that contain several switches, such as a fiber channel switched fabric, a particular storage unit might have a different identity on each computer in the cluster. Although this is a valid storage configuration, it violates the storage validation heuristics in the New Server Cluster Wizard and the Add Nodes Wizard.

**Solution:** Verify that your storage configuration is set up correctly. Then, if you are in the Add Nodes Wizard, disable the storage validation heuristics by using the Back button to return to the Select Computer page. On the Select Computer page, click Advanced and select the Advanced (minimum) configuration option. If you are not in the Add Nodes Wizard, restart the wizard and use the Advanced configuration option as previously described.

**See also:** Planning and preparing for cluster installation

**During cluster creation, either the New Server Cluster Wizard or the Add Nodes Wizard did not detect all of the potential network adapters.**
**Possible Cause:** The cluster may not be able to detect a network composed of a crossover cable.

A two-node cluster may use a crossover cable to implement a private network. When the cluster is created on the first node, the second node should be turned on, but stopped in the BIOS or at the startup menu. In this state, the Media Sense feature of Windows may not recognize the network adapter as connected.

When this happens:

- In Network Connections, the icon for the connection that represents the network adapter is shown with a red "X".
- The taskbar displays an icon that, when you pause the mouse on it, displays **Network Cable unplugged**.

**Solution:** If you continue creating the cluster, the crossover cable will be detected when you start the second node. The network will be established in the default mode, which is mixed. You can then change the network mode to private using Cluster Administrator.

**See also:** Manage Networks

**Possible Cause:** Your system's network connections are not running. If the following error message appears in the New Server Cluster Wizard tree, your network connections may not be running:

"Warning: This system is not attached to all defined cluster networks."

**Solution:** Make sure that your network connections are enabled. Otherwise, the Cluster service cannot detect and use them.

To check your network connections:

1. Open Network Connections in Control Panel.
2. Double-click the connection that you want to check.
3. On the **General** tab, check the status of the connection. If the connection is not started, start it.

You must click **Reanalyze** in the New Server Cluster Wizard for the changes to be detected.

**See also:** TCP/IP

**Possible Cause:** Your network hardware is not installed correctly.

**Solution:** Verify that your network cables are connected correctly. Make sure that no cables are crossed by mistake (private-to-public, or public-to-private), and that each network adapter is connected as you planned. With more than two nodes, use a dedicated hub (not a switch) for the private network.

Set all multispeed network adapters on a private or mixed network to the same speed. Do not use the autodetect setting.

If fault-tolerant network adapters are used, create multiple private networks instead of a single fault-tolerant network.

Make sure all network adapters are correctly seated and the correct drivers are installed in accordance with the manufacturer's instructions. Confirm that your hardware is compatible with Windows Server 2003, Datacenter Edition, by clicking the appropriate link in Support resources.

**Possible Cause:** The Cluster networks are not on the correct subnet. All network adapters designated for cluster use on a single node need to be on different subnets. Otherwise, only the first network adapter on a subnet is detected by either the New Server Cluster Wizard or the Add Nodes Wizard, and is used for either cluster or client communication (depending on which role you chose).

However, in order for subsequent nodes to pick up the network roles defined on the first node in the cluster, network adapters in each node must be on the same subnets as the corresponding adapters on the first node.

**Solution:** The Cluster service can detect and use multiple network adapters on the same computer if the following requirements are met:

- The network adapters are bound by TCP/IP.
- You are using hardware that is compatible with Windows Server 2003, Datacenter Edition. To confirm this, click the appropriate link in Support resources.
- Each network adapter is on a different subnet.

Do not use the same IP address for two network adapters, even though they are connected to two different networks.

After the network adapters are configured correctly, use the ping command to check each network adapter for connectivity with the loopback address (127.0.0.1), the adapter's own IP address, and the IP address of another computer.

Make sure that each adapter works correctly and can communicate on each network, and then restart the New Server Cluster Wizard or the Add Nodes Wizard.

**See also:** Configure TCP/IP for static addressing

**Possible Cause:** The cluster does not have network connectivity.

**Solution:** Use the ping command to test connectivity. Ping the node's fully qualified domain name.

If you are unable to ping the node's domain controller by name, consult the Hardware Troubleshooter. You can also learn more about the problem by pinging your domain controller by IP address, and by pinging other network servers by name and IP address, including the node's DNS or WINS server.

**See also:** Manage Networks

**During cluster creation, you are experiencing problems creating the first node of the cluster.**

**Possible Cause:** You are not using a valid IP address for the network interface.

**Solution:** The addresses for each linked pair of network adapters must be on the same subnet.

To check for the IP address, Click **Start**, then **Run** and type **ipconfig /all**, and then press ENTER. This displays your IP configuration, including IP address, subnet mask, default gateway, DNS server address, and DHCP availability. Confirm that these settings are correct. If you are using DHCP, change to static IP addresses.

If no IP address or other IP configuration is displayed, and you see **Media State = Cable Disconnected**, you may not have end-to-end network connectivity from the network adapter to the connecting network device. Make sure your physical connections are secure and valid. If you see an Automatic Private IP Addressing (APIPA) address, change it to a static IP.

Do not use an IP address that is on the same IP range as the public network.

**See also:** TCP/IP

**Possible Cause:** The cluster does not have network connectivity.

**Solution:** Use the ping command to test connectivity. Ping the node's fully qualified domain name.

If you are unable to ping the node's domain controller by name, open Network Connections and check the status of your network adapter. You can also attempt to map a drive to the other node in your cluster to verify communication and authentication. If these solutions do not work, consult the Hardware Troubleshooter. You can also learn more about the problem by pinging your domain controller by IP address, and by pinging other network servers by name and IP address, including the node's DNS or WINS server.

**See also:** Manage Networks

**Possible Cause:** You are not using a unique cluster name.

**Solution:** The cluster name must be different from the domain name, from all computer names on the network, from other cluster names on the network, and from all virtual server names on the network.

Use the **net view** command to determine whether your cluster name is unique.

To use the **net view** command, click **Start**, then **Run** and type the following and then press ENTER:

**net view** *clustername*

*Clustername* is the name of the cluster.

If your cluster name is not unique, assign a unique name. When the New Server Cluster Wizard asks you for the cluster name, type an appropriate new cluster name.

**Possible Cause:** The cluster may not be able to detect a network composed of a crossover cable.

A two-node cluster may use a crossover cable to implement a private network. When the cluster is created on the first node, the second node should be turned on, but stopped in the BIOS or at the startup menu. In this state, the Media Sense feature of Windows may not recognize the network adapter as connected.

When this happens:

- In Network Connections, the icon for the connection that represents the network adapter is shown with a red "X".
- The taskbar displays an icon that, when you pause the mouse on it, displays **Network Cable unplugged**.

**Solution:** If you continue creating the cluster, the crossover cable will be detected when you start the second node. The network will be established in the default mode, which is mixed. You can then change the network mode to private using Cluster Administrator.

**See also:** Manage Networks

**Possible Cause:** The Cluster networks are not on the correct subnet. All network adapters designated for cluster use on a single node need to be on different subnets. Otherwise, only the first network adapter on a subnet is detected by either the New Server Cluster Wizard or the Add Nodes Wizard, and is used for either cluster or client communication (depending on which role you chose).

However, in order for subsequent nodes to pick up the network roles defined on the first node in the cluster, network adapters in each node must be on the same subnets as the corresponding adapters on the first node.

**Solution:** The Cluster service can detect and use multiple network adapters on the same computer if the following requirements are met:

- The network adapters are bound by TCP/IP.
- You are using hardware that is compatible with Windows Server 2003, Datacenter Edition. To confirm this, click the appropriate link in Support resources.
- Each network adapter is on a different subnet.

Do not use the same IP address for two network adapters, even though they are connected to two different networks.

After the network adapters are configured correctly, use the ping command to check each network adapter for connectivity with the loopback address (127.0.0.1), the adapter's own IP address, and the IP address of another computer.

Make sure that each adapter works correctly and can communicate on each network, and then restart the New Server Cluster Wizard or the Add Nodes Wizard.

**See also:** Configure TCP/IP for static addressing

**Possible Cause:** Your network hardware is not installed correctly.

**Solution:** Verify that your network cables are connected correctly. Make sure that no cables are crossed by mistake (private-to-public, or public-to-private), and that each network adapter is connected as you planned.

Set all multispeed network adapters on a private or mixed network to the same speed. Do not use the autodetect setting.

If fault-tolerant network adapters are used, create multiple private networks instead of a single fault-tolerant network.

Make sure all network adapters are correctly seated and the correct drivers are installed in accordance with the manufacturer's instructions. Confirm that your hardware is compatible with Windows Server 2003, Datacenter Edition, by clicking the appropriate link in Support resources.

**Possible Cause:** The WINS client is not configured correctly on the node.

**Solution:** If you use WINS, all cluster resource names that have associated IP addresses are registered with WINS. Use the following instructions to check your WINS configuration.

First, check to see whether the client interconnect has at least one WINS server specified in the IP configuration by clicking **Start**, then **Run** and typing **ipconfig /all**. Confirm that the IP address returned for primary and (if listed) secondary WINS servers are the same IP addresses being used successfully on other computers on the same subnet that are looking for the same resources.

Next determine whether the name is resolved by clicking **Start**, then **Run** and typing **ping *server***, where ***server*** is the network name of the server, and then press ENTER.

If you are using static IP addressing for your cluster nodes, you need to configure WINS on the IP addresses made available on the public network.

If clients have problems connecting to virtual servers, disable WINS on the private cluster network.

**Important**

- Do not disable this for the network adapter used for client communication.

After you configure WINS, if you have already created the cluster on at least one node, ping the cluster name to test for connectivity.

**See also:** Configure TCP/IP to use WINS

**Possible Cause:** TCP/IP is not configured correctly.

**Solution:** If any of the following ping tests fail, there is a TCP/IP configuration problem:

- Pinging the loopback address
- Pinging the local Internet protocol (IP) address (public and private interconnects)
- Pinging the IP address of another node (public and private interconnects)

**Note**

- To test name resolution through the public interconnect, disconnect the private interconnect cable.

If pinging another node by name fails, but you can successfully ping that node's IP address, there is a name-resolution problem. Consult your network administrator for assistance.

TCP/IP errors caused by an incorrect IP address or subnet mask are usually recorded in the system log. Use Event Viewer to check the system log for these errors.

Even if there are no TCP/IP errors in the system log, still check your TCP/IP settings to make sure that they are correct by clicking **Start**, then **Run** and typing **ipconfig /all**. Verify that the listed IP address and subnet mask are the correct values for your computer. If you do not know the correct IP address and subnet mask values for your computer, ask your network administrator.

**See also:** TCP/IP

**Possible Cause:** Your system's network connections are not running. If the following error message appears in the New Server Cluster Wizard tree, your network connections may not be running:

"Warning: This system is not attached to all defined cluster networks."

**Solution:** Make sure that your network connections are enabled. Otherwise, the Cluster service cannot detect and use them.

To check your network connections:

1. Open **Network Connections** in Control Panel.
2. Double-click the connection that you want to check.
3. On the **General** tab, check the status of the connection. If the connection is not started, start it.

You must click **Reanalyze** in the New Server Cluster Wizard for the changes to be detected.

**See also:** TCP/IP

**Possible Cause:** You are not using a valid IP address.

**Solution:** Obtain a static IP address for the cluster itself. You cannot use DHCP to assign this address.

Each network adapter on each cluster node also needs an IP address. Assign a static IP address to each adapter. The addresses for each linked pair of network adapters (linked node-to-node) must be on the same subnet.

If your cluster nodes use DHCP to obtain noncluster IP addresses, at the command prompt, use the **ipconfig** command to verify that you have a valid primary IP address for the networks in question.

Use the **ping** command to confirm that you have IP connectivity to the cluster address and that the IP address is assigned to the correct network. If the ping test fails, you do not have basic network connectivity.

If you made any changes, restart the New Server Cluster Wizard. You must restart this wizard for the changes to be detected.

**See also:** Manage Networks

**Possible Cause:** You do not have the correct domain account and appropriate user rights.

**Solution:** Ensure that you are adhering to the following requirements:

- To create a cluster, you must log on with an account that is a member of the local Administrators group on each node. It

is recommended that you use a domain account. Each node must also be a member of that domain, or must be a member of a domain that is trusted by the domain that contains the account you are logging on to.

- You can administer the Cluster service by using either a domain or a local account; however, other nodes can only be joined to a cluster by using a domain account.

If you make any account changes or changes to user rights, you must click **Reanalyze** in the New Server Cluster Wizard for the changes to be detected. You might also have to log off and back on again for the security changes to take effect.

**See also:** Security

**During cluster creation, you are experiencing problems creating subsequent nodes after creating the first node of the Cluster.**
**Possible Cause:** You are not using a valid IP address for the network interface.

**Solution:** The addresses for each linked pair of network adapters must be on the same subnet.

To check for the IP address, click **Start**, then **Run** and type **ipconfig /all**, and then press ENTER. This displays your IP configuration, including IP address, subnet mask, default gateway, DNS server address, and DHCP availability. Confirm that these settings are correct. If you are using DHCP, change to a static IP address.

If no IP address or other IP configuration is displayed, and you see **Media State = Cable Disconnected**, you might not have end-to-end network connectivity from the network adapter to the connecting network device. Make sure your physical connections are secure and valid.

**See also:** TCP/IP

**Possible Cause:** The cluster does not have network connectivity.

**Solution:** Use the **ping** command to test connectivity. Ping the node's fully qualified domain name.

If you are unable to ping the node's domain controller by name, consult the Hardware Troubleshooter. You can also learn more about the problem by pinging your domain controller by IP address, and by pinging other network servers by name and IP address, including the node's DNS or WINS server.

**See also:** Manage Networks

**Possible Cause:** The cluster might not be able to detect a network composed of a crossover cable.

A two-node cluster might use a crossover cable to implement a private network. When the cluster is created on the first node the second node should be turned on but stopped in the BIOS or at the startup menu. In this state, the Media Sense feature of Windows might not recognize the network adapter as connected.

When this happens:

- In Network Connections, the icon for the connection that represents the network adapter is shown with a red "X".

- The taskbar displays an icon that, when you pause the mouse on it, displays **Network Cable unplugged**.

**Solution:** If you continue creating the cluster, the crossover cable will be detected when you start the second node. The network will be established in the default mode, which is mixed. You can then change the network mode to private using Cluster Administrator.

**See also:** Manage Networks

**Possible Cause:** The Cluster networks are not on the correct subnet.

All network adapters designated for cluster use on a single node need to be on different subnets. Otherwise, only the first network adapter on a subnet is detected by either the New Server Cluster Wizard or the Add Nodes Wizard and is used for either cluster or client communication (depending on which role you chose).

However, in order for subsequent nodes to pick up the network roles defined on the first node in the cluster, network adapters in each node must be on the same subnets as the corresponding adapters on the first node.

**Solution:** The Cluster service can detect and use multiple network adapters on the same computer if the following requirements are met:

- The network adapters are bound by TCP/IP.
- You are using hardware that is compatible with Windows Server 2003, Datacenter Edition. To confirm this, click the appropriate link in Support resources.
- Each network adapter is on a different subnet. Make sure to verify your subnet entry for each node.

Do not use the same IP address for two network adapters, even though they are connected to two different networks.

After the network adapters are configured correctly, use the **ping** command to check each network adapter for connectivity with the loopback address (127.0.0.1), the adapter's own IP address, and the IP address of another computer.

Make sure that each adapter works correctly and can communicate on each network, and then restart either the New Server Cluster Wizard or the Add Nodes Wizard

**See also:** Configure TCP/IP for static addressing

**Possible Cause:** Your network hardware is not installed correctly.

**Solution:** Verify that your network cables are connected correctly. Make sure that no cables are crossed by mistake (private-to-public, or public-to-private), and that each network adapter is connected as you planned.

Check Device Manager for resource conflicts.

Set all multispeed network adapters on a private or mixed network to the same speed. Do not use the autodetect setting.

If fault-tolerant network adapters are used, create multiple private networks instead of a single fault-tolerant network.

Make sure all network adapters are correctly seated and the correct drivers are installed in accordance with the manufacturer's instructions. Confirm that your hardware is compatible with Windows Server 2003, Datacenter Edition, by clicking the appropriate link in Support resources.

**See also:** Device Manager

**Possible Cause:** The WINS client is not configured correctly on the node.

**Solution:** If you use WINS, all cluster resource names that have associated IP addresses are registered with WINS. Use the following instructions to check your WINS configuration.

First, check to see whether the client interconnect has at least one WINS server specified in the IP configuration by clicking **Start**, then **Run** and typing **ipconfig /all**. Confirm that the IP address returned for primary and (if listed) secondary WINS servers are the same IP addresses being used successfully on other computers on the same subnet that are looking for the same resources.

Next determine whether the name is resolved by clicking **Start**, then **Run** and typing **ping *server***, where ***server*** is the network name of the server, and then press ENTER.

If you are using static IP addressing for your cluster nodes, you need to configure WINS on the IP addresses made available on the public network.

If clients have problems connecting to virtual servers, disable NetBios over TCP/IP on the private cluster network.

**Important**

- Do not disable this for the network adapter used for client communication.

After you configure WINS, if you have already created the cluster on at least one node, ping the cluster name to test for connectivity.

**See also:** Configure TCP/IP to use WINS

**Possible Cause:** TCP/IP is not configured correctly.

**Solution:** If any of the following ping tests fail, there is a TCP/IP configuration problem:

- Pinging the loopback address

- Pinging the local Internet protocol (IP) address (public and private interconnects)
- Pinging the IP address of another node (public and private interconnects)

**Note**

- To test name resolution through the public interconnect, disconnect the private interconnect cable.

If pinging another node by name fails, but you can successfully ping that node's IP address, there is a name-resolution problem. Consult your network administrator for assistance.

TCP/IP errors caused by an incorrect IP address or subnet mask are usually recorded in the system log. Use Event Viewer to check the system log for these errors.

Even if there are no TCP/IP errors in the system log, still check your TCP/IP settings to make sure that they are correct by clicking **Start**, then **Run** and typing **ipconfig /all**. Verify that the listed IP address and subnet mask are the correct values for your computer. If you do not know the correct IP address and subnet mask values for your computer, ask your network administrator.

Verify the network adapter's bindings and priority. The public network adapter or adapters should be first, then any private network adapters.

**See also:** TCP/IP

**Possible Cause:** Your system's network connections are not running. If the following error message appears in the New Server Cluster Wizard tree, your network connections may not be running:

"Warning: This system is not attached to all defined cluster networks."

**Solution:** Make sure that your network connections are enabled. Otherwise, the Cluster service cannot detect and use them.

To check your network connections:

1. Open Network Connections in Control Panel.
2. Double-click the connection that you want to check.
3. On the **General** tab, check the status of the connection. If the connection is not started, start it.

You must click **Reanalyze** in the New Server Cluster Wizard for the changes to be detected.

**See also:** TCP/IP

**Possible Cause:** You are not using a valid IP address.

**Solution:** Obtain a static IP address for the cluster itself. You cannot use DHCP to assign this address.

Each network adapter on each cluster node also needs an IP address. Assign a static IP address to each adapter. The addresses for each linked pair of network adapters (linked node-to-node) must be on the same subnet.

If your cluster nodes use DHCP to obtain noncluster IP addresses, at the command prompt, use the **ipconfig** command to verify that you have a valid primary IP address for the networks in question.

Use the **ping** command to confirm that you have IP connectivity to the cluster address and that the IP address is assigned to the correct network. If the ping test fails, you do not have basic network connectivity.

If you made any changes, restart the New Server Cluster Wizard. You must restart this wizard for the changes to be detected.

**See also:** Manage Networks

**Possible Cause:** You do not have the correct domain account and appropriate user rights.

**Solution:** Ensure that you are adhering to the following requirements:

- To create a cluster, you must log on with a domain account that is a member of the local Administrators group on each node, and each node must be a member of that domain.

- You can administer the Cluster service by using either a domain or a local account; however, other nodes can only be joined to a cluster by using a domain account.

If you make any account changes or changes to user rights, you must click **Reanalyze** in the New Server Cluster Wizard for the changes to be detected.

**See also:** Security

**Possible Cause:** Your system does not meet the minimum requirements for a cluster.

**Solution:** Verify that all requirements, including hardware, operating system software configuration, network and disk requirements are met.

**See also:** Planning and preparing for cluster installation

**Possible Cause:** Your cluster nodes are in separate domains or are not in a domain.

**Solution:** All cluster nodes must be members or domain controllers of the same domain, and must use the same account for the Cluster service.

To check computer name and domain name for a node right-click **My Computer**, click **Properties**, and then click the **Computer Name** tab. Make sure each cluster node belongs to the same domain. Use the same account and password for service on each node. This account must have the following user rights:

- Back up files and directories

- Increase scheduling priority

- Log on as a Service

If you made any changes, restart the New Server Cluster Wizard. You must restart this wizard for the changes to be detected.

**Possible Cause:** The cluster name is not online.

**Solution:** To make sure that the cluster name is online:

1. On the first node, open Cluster Administrator by clicking **Start**, then **Run**, then typing **CluAdmin**.

2. Open **Groups**, click **Cluster Group** and check the status of **Cluster Name**.

3. If the status is not **Online**, right-click **Cluster Name**, and then click **Bring Online**.

4. Restart the New Server Cluster Wizard. You must restart this wizard for the changes to be detected.

**Note**

- If the Internet protocol (IP) address is not online, the cluster name will not be online. Make sure that the IP address is online before you try to bring the cluster name online.

**Possible Cause:** The Cluster service is not running on the first node.

**Solution:** Confirm that the Cluster service is running on the first node and that all resources within the cluster group are online before you try to install another node.

To confirm that the Cluster service is started:

1. On the first node, open Computer Management.

2. Double-click **Services and Applications**.

3. Click **Services**.

4. In the details pane, find the Cluster service entry and check its Status column. If the service is not started, right-click it, and then click **Start**.

5. Restart the New Server Cluster Wizard. You must restart this wizard for the changes to be detected.

If the Cluster service was not started, review the records in the event log to see why not.

**During cluster creation, the Physical Disk resources are not automatically created for cluster disks.**
**Cause:** Typically when you create a cluster, the Physical Disk resources are automatically created for cluster disks that use drive letters. However, if your cluster disks use mount points, Physical Disk resources will not be automatically created for those disks.

**Solution:** You must manually create disk resources for cluster disks that use mount points.

For more information, see Checklist: Installing a Physical Disk resource.

**After setting up a new cluster, Cluster Administrator cannot connect to the cluster.**
**Cause:** The new cluster was given a name that corresponds to an existing computer object in Active Directory directory service.

**Solution:** Determine if you want the Network Name resource for the cluster to use Kerberos authentication. If you do, perform the following steps:

1. Using the command line, take the Network Name resource for the cluster offline.

2. Using the command line, enable Kerberos authentication for the Network Name resource.

3. Inspect the permissions on the corresponding computer object in Active Directory and ensure that the Cluster service user account has access to that object.

4. Using the command line, bring the Network Name resource of the cluster online.

As an alternative, if you choose not to use Kerberos authentication for the Network Name resource, you must instead delete the corresponding computer object in Active Directory. Before you do so, first ensure that the computer object is not required elsewhere by your installation.

For more information, see article Q307532, "How to Troubleshoot the Cluster Service Account When It Modifies Objects," and article Q302389, "Description of the Properties of the Cluster Network Name Resource in Windows Server 2003," in the Microsoft Knowledge Base. (http://www.microsoft.com/) Also see Cluster resource and Finding directory information.

# Configuring Roles for Your Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring roles for your server**
The Configure Your Server Wizard provides a central location from which you can install or remove the server roles available on a server running Windows Server 2003. After installing a server role you can use Manage Your Server to manage that role.

Manage Your Server provides a central location from which you can manage the server roles installed through the Configure Your Server Wizard. Manage Your Server starts automatically the first time you log on to your server computer with administrative credentials.

- Server roles
- Typical setup for a first server
- File server role: Configuring a file server
- Print server role: Configuring a print server
- Application server role: Configuring an application server
- Mail server role: Configuring a mail server
- Terminal server role: Configuring a terminal server
- Remote access/VPN server role: Configuring a remote access/VPN server
- Domain controller role: Configuring a domain controller
- DNS server role: Configuring a DNS server
- DHCP server role: Configuring a DHCP server
- Streaming media server role: Configuring a streaming media server
- WINS server role: Configuring a WINS server
- To remove a server role

**Note**

- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Server roles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Server roles**
The Windows Server 2003 family provides several server roles. To configure a server role, install the server role by using the Configure Your Server Wizard and manage your server roles by using Manage Your Server. After you finish installing a server role, Manage Your Server starts automatically.

To determine which server role is appropriate for you, review the following information about the server roles that are available with the Windows Server 2003 family:

File server role overview

Print server role overview

Application server role overview

Mail server role overview

Terminal server role overview

Remote access/VPN server role overview

Domain controller role overview

DNS server role overview

DHCP server role overview

Streaming media server role overview

WINS server role overview

**File server role overview**
File servers provide and manage access to files. If you plan to use disk space on this computer to store, manage, and share information such as files and network-accessible applications, configure this computer as a file server.

After configuring the file server role, you can do the following:

- Use disk quotas on volumes formatted with the NTFS file system to monitor and limit the amount of disk space available to individual users. You can also specify whether to log an event when a user exceeds the specified disk space limit or when a user exceeds the specified disk space warning level (that is, the point at which a user is nearing his or her quota limit).
- Use Indexing Service to quickly and securely search for information, either locally or on the network.
- Search in files that are in different formats and languages, either through the **Search** command on the **Start** menu or through HTML pages that users view in a browser.

For more information about implementing this server role, see File server role: Configuring a file server.

**Print server role overview**
Print servers provide and manage access to printers. If you plan to manage printers remotely, manage printers by using Windows Management Instrumentation (WMI), or print from a server or client computer to a print server by using a URL, configure this computer as a print server.

After configuring the print server role, you can do the following:

- Use a browser to manage printers. You can pause, resume, or delete a print job, and view the printer and print job's status.

- Use the new standard port monitor, which simplifies installation of most TCP/IP printers on your network.
- Use Windows Management Instrumentation (WMI), which is the management API created by Microsoft that enables you to monitor and control all system components, either locally or remotely. The WMI Print Provider enables you to manage print servers, print devices, and other printing-related objects from the command line. With WMI Print Provider, you can use Visual Basic (VB) scripts to perform administrative printer functions. For more information, see Windows Management Instrumentation Command-line (WMIC) tool.
- Print from Windows XP clients to print servers running Windows Server 2003 by using a Uniform Resource Locator (URL).
- Connect to printers on your network by using Web point-and-print for single-click installation of a shared printer. You can also install drivers from a Web site.

For more information about implementing this server role, see Print server role: Configuring a print server.

**Application server role overview**
An application server is a core technology that provides key infrastructure and services to applications hosted on a system. Typical application servers include the following services:

- Resource pooling (for example, database connection pooling and object pooling)
- Distributed transaction management
- Asynchronous program communication, typically through message queuing
- A just-in-time object activation model
- Automatic XML Web Service interfaces to access business objects
- Failover and application health detection services
- Integrated security

The Windows Server 2003 family includes an application server that contains all of this functionality and other services for development, deployment, and runtime management of XML Web services, Web applications, and distributed applications.

When you configure this server as an application server you will be installing Internet Information Services (IIS) along with other optional technologies and services such as COM+ and ASP.NET. Together, IIS and the Windows Server 2003 family provide integrated, reliable, scalable, secure, and manageable Web server capabilities over an intranet, the Internet, or through an extranet. IIS is a tool for creating a strong communications platform of dynamic network applications.

For more information about implementing this server role, see Application server role: Configuring an application server.

**Mail server role overview**
To provide e-mail services to users, you can use the Post Office Protocol 3 (POP3) and Simple Mail Transfer Protocol (SMTP) components included with the Windows Server 2003 family. The POP3 service implements the standard POP3 protocol for mail retrieval, and you can pair it with the SMTP service to enable mail transfer. If you plan to have clients connect to this POP3 server and download e-mail to local computers by using a POP3 capable mail client, configure this server as a mail server.

After configuring the mail server role, you can do the following:

- Use the POP3 service to store and manage e-mail accounts on the mail server.
- Enable user access to the mail server so that users can retrieve e-mail from their local computer by using an e-mail client that supports the POP3 protocol (for example, Microsoft Outlook).

For more information about implementing this server role, see Mail server role: Configuring a mail server.

**Terminal server role overview**
With Terminal Server, you can provide a single point of installation that gives multiple users access to any computer that is running a Windows Server 2003 operating system. Users can run programs, save files, and use network resources all from a remote location, as if these resources were installed on their own computer.

After configuring the terminal server role, you can do the following:

- Confirm Internet Explorer Enhanced Security Configuration settings.
- Centralize the deployment of programs on one computer.
- Ensure that all clients use the same version of a program.

### Important

- In addition to configuring a terminal server, you must install Terminal Server Licensing and configure a Terminal Server License Server. Otherwise, your terminal server will stop accepting connections from unlicensed clients when the evaluation period ends 120 days after the first client logon. For more information about Terminal Server Licensing, see Terminal Server Licensing.

For more information about implementing this server role, see Terminal server role: Configuring a terminal server.

**Remote access/VPN server role overview**
Routing and Remote Access provides a full-featured software router and both dial-up and virtual private network (VPN) connectivity for remote computers. It offers routing services for local area network (LAN) and wide area network (WAN) environments. It also enables remote or mobile workers to access corporate networks as if they were directly connected, either through dial-up connection services or over the Internet by using VPN connections. If you plan to connect remote workers to business networks, configure this server as a remote access/VPN server.

Remote access connections enable all of the services that are typically available to a LAN-connected user, including file and print sharing, Web server access, and messaging.

After configuring the remote access/VPN server role, you can do the following:

- Control how and when remote users access your network.
- Provide network address translation (NAT) services for the computers on your network.
- Create custom networking solutions using application programming interfaces (APIs).

For more information about implementing this server role, see Remote access/VPN server role: Configuring a remote access/VPN server.

**Domain controller role overview**
Domain controllers store directory data and manage communication between users and domains, including user logon processes, authentication, and directory searches. If you plan to provide the Active Directory directory service to manage users and computers, configure this server as a domain controller.

### Notes

- You cannot add the domain controller role to a certification authority (CA). If your computer is already a CA, the domain controller role is not available in the Configure Your Server Wizard.
- Computers running Windows Server 2003, Web Edition cannot function as domain controllers. For more information about Windows Server 2003, Web Edition, see Overview of Windows Server 2003, Web Edition.

After configuring the domain controller role, you can do the following:

- Store directory data and make this data available to network users and administrators. Active Directory stores information about user accounts (for example, names, passwords, phone numbers, and so on), and enables other

authorized users on the same network to access this information.

- Add additional domain controllers to an existing domain to improve the availability and reliability of network services.

- Improve network performance between sites by placing a domain controller in each site. With a domain controller in each site, you can handle client logon processes within the site without using the slower network connection between sites.

For more information about implementing this server role, see Domain controller role: Configuring a domain controller.

**DNS server role overview**
The Domain Name System (DNS) is the TCP/IP name resolution service that is used on the Internet. The DNS service enables client computers on your network to register and resolve user-friendly DNS names. If you plan to make resources in your network available on the Internet, configure this server as a DNS server.

**Important**

- If you plan to include computers on the Internet on your network, use a unique DNS domain name. For more information about DNS namespace planning, see Namespace planning for DNS.

After configuring the DNS server role, you can do the following:

- Host records of a distributed DNS database and use these records to answer DNS queries sent by DNS client computers, such as queries for the names of Web sites or computers in your network or on the Internet.

- Name and locate network resources using user–friendly names.

- Control name resolution for each network segment and replicate changes to either the entire network or globally on the Internet.

- Reduce DNS administration by dynamically updating DNS information.

For more information about implementing this server role, see DNS server role: Configuring a DNS server.

**DHCP server role overview**
Dynamic Host Configuration Protocol (DHCP) is an IP standard designed to reduce the complexity of administering address configurations by using a server computer to centrally manage IP addresses and other related configuration details used on your network. If you plan to perform multicast address allocation, and obtain client IP address and related configuration parameters dynamically, configure this server as a DHCP server.

After configuring the DHCP server role, you can do the following:

- Centrally manage IP addresses and related information.

- Use DHCP to prevent address conflicts by preventing a previously assigned IP address from being used again to configure a new computer on the network.

- Configure your DHCP server to supply a full range of additional configuration values when assigning address leases. This will greatly decrease the time you spend configuring and reconfiguring computers on your network.

- Use the DHCP lease renewal process to ensure that client configurations that need to be updated often (such as users with mobile or portable computers that change locations frequently) can be updated efficiently and automatically by clients communicating directly with DHCP servers.

For more information about implementing this server role, see DHCP server role: Configuring a DHCP server.

**Streaming media server role overview**
Streaming media servers provide Windows Media Services to your organization. Windows Media Services manages, delivers,

and archives Windows Media content, including streaming audio and video, over an intranet or the Internet. If you plan to provide audio and video content streams to clients and to other Windows Media servers, configure this computer as a streaming media server.

After configuring the streaming media server role, you can do the following:

- Stream Windows Media-based content, including entertainment programming and advertising, over a network in a variety of ways to create a Web-based radio or television station.
- Stream internal business communications, such as meetings, speeches, and training, over a corporate intranet, and stream external business communications to customers, vendors, and business partners over the Internet.
- Transmit the information only to users who have been authorized to access the content, by distributing unique user licenses and by limiting access to your server resources.

For more information about implementing this server role, see Streaming media server role: Configuring a streaming media server.

**WINS server role overview**

Windows Internet Name Service (WINS) servers map IP addresses to NetBIOS computer names and NetBIOS computer names back to IP addresses. With WINS servers in your organization, you can search for resources by computer name instead of IP address, which can be easier to remember. If you plan to map NetBIOS names to IP addresses or centrally manage the name-to-address database, configure this server as a WINS server.

After configuring the WINS server role, you can do the following:

- Reduce NetBIOS-based broadcast traffic on subnets by permitting clients to query WINS servers to directly locate remote systems.
- Support earlier Windows and NetBIOS-based clients on your network by permitting these types of clients to browse lists for remote Windows domains without requiring a local domain controller to be present on each subnet.
- Support DNS-based clients by enabling those clients to locate NetBIOS resources when WINS lookup integration is implemented. For more information, see WINS lookup integration.

For more information about implementing this server role, see WINS server role: Configuring a WINS server.

# Typical setup for a first server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Typical setup for a first server**

The following information describes how to install and configure the first server on a network by using the **Typical setup for a first server** option in the Configure Your Server Wizard.

**Important**

- Before you configure the first server on a network, see Checklist: Configuring the typical setup for a first server.

The typical setup for a first server will not run if any of the following conditions are met:

- The computer is running Windows Server 2003, Datacenter Edition.
- The computer is running Windows Server 2003, Web Edition.
- The computer is joined to a domain.
- The computer is already configured as a domain controller.
- The computer is not a domain controller, but the Active Directory Installation Wizard has already been started.
- The computer is a certification authority (CA).
- The computer is already configured as a DNS server.
- The computer is already configured as a DHCP server.
- There are zero IP-enabled network adaptors.
- There is only one IP-enabled network adaptor and the DHCP lease test succeeds.
- The computer is already running Routing and Remote Access.
- The computer does not have at least one NTFS partition.
- The current session is a remote session.

**Typical setup configuration process**

The typical setup configuration process implements the following steps:

- Installs Active Directory and promotes the computer to a domain controller.

  When you promote a server to a domain controller, a domain is automatically created on the network. After you promote a server to a domain controller, you can then promote other servers to domain controllers. For more information, see Domain controllers.

  When you configure your server using the typical setup for a first server, the local administrator's password is automatically set as the Restore Mode Administrator password.

- Sets up an application naming context in Active Directory on this domain controller for use by Telephony API (TAPI) client applications. For more information, see Application directory partitions.

- Installs Domain Name System (DNS) and creates a full domain name for your network.

  DNS is a networking protocol for naming computers and network services that is organized into a hierarchy of domains. TCP/IP networks, such as the Internet, use DNS naming to locate computers and services through user-friendly names. When a user enters a DNS name in an application, DNS services can resolve the name to other information associated with the name, such as an IP address.

  For example, most users prefer a friendly name such as server1.example.microsoft.com to locate a computer such as a mail server or Web server on a network. However, computers use numeric addresses to communicate over a network. To make it easier to use network resources, DNS provides a way to map the user-friendly name for a computer or service to its numeric address. For more information, see DNS domain names.

- Changes the default NetBIOS name. You can change the default NetBIOS name on this page. For example, if your Active Directory DNS domain name is yoursmallbusiness.local, the default NetBIOS domain name is YOURSMALLBUSINE. You may want to change this to CORP or to your own abbreviation for your business name for ease of use. For more information about NetBIOS, see NetBIOS name resolution.

- Assigns a preferred DNS server with the same IP address that you specified for this server. For more information, see How DNS query works.

- Assigns a DNS forwarder. For more information, see Understanding forwarders.

- Installs the DHCP Server service.

  DHCP uses a client/server model. The network administrator establishes one or more DHCP servers that maintain TCP/IP configuration information and provide it to clients. With a DHCP server installed and configured on your network, DHCP-enabled clients can obtain their IP address and related configuration parameters dynamically each time they start and join your network. DHCP servers provide this configuration in the form of an address lease offer to requesting clients.

- Assigns a static IP address, if one is not already assigned to the private network connection. For more information, see Name resolution for TCP/IP.

- Assigns a subnet mask (that is, if none has been configured on this server). By default, the Configure Your Server Wizard assigns a subnet mask of 255.255.255.0. For more information, see Subnet masks.

- Installs the Routing and Remote Access service (that is, if more than one network connection is detected).

**Next steps: Typical setup for a first server**
After you complete the Configure Your Server Wizard, the computer is ready for use as the server on your network. It has been configured as a domain controller, a DNS server, a DHCP server, and possibly as a remote access/VPN server. For more information about each of these roles, see

- Domain controller role: Configuring a domain controller

- DNS server role: Configuring a DNS server

- DHCP server role: Configuring a DHCP server

- Remote access/VPN server role: Configuring a remote access/VPN server

The following table lists some of the additional tasks that you can perform on your server. To manage the new services on this server, do the following:

- To open Administrative Tools, click **Start**, click **Control Panel**, and then double-click **Administrative Tools**.

**Note**

- If you demote this server so that it is no longer a domain controller, you must remove the TAPI application partition by using the Tapicfg.exe utility. For more information, see Remove a TAPI application directory partition.

| Task | Reference |
| --- | --- |
| Make additional configuration changes to the DNS server. | Checklist: Installing a DNS server; Configure a new DNS server |
| Install additional domain controllers, if necessary. | Create an additional domain controller |
| Configure additional options for the DHCP server. | Checklist: Installing a DHCP server |
| (Optional) Monitor and measure various aspects of the DNS server to prevent and troubleshoot performance degradation. | Monitoring DNS server performance |
| (Optional) Monitor and measure various aspects of the DHCP server to prevent and troubleshoot performance degradation. | Monitoring DHCP server performance; DHCP performance monitoring reference |
| (Optional) Install and configure additional domain controllers. | Checklist: Creating an additional domain controller in an existing domain |
| (Optional) Select the appropriate security level for domain administration. | Using the Active Directory Installation Wizard |
| (Optional) Configure ports to allow remote administration. | Windows Firewall Settings |

# File server role: Configuring a file server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File server role: Configuring a file server**
A file server provides a central location on your network where you can store and share files with users across your network. When users require an important file such as a project plan, they can access the file on the file server instead of having to pass the file between their separate computers. If your network users will need access to the same files and network-accessible applications, configure this computer as a file server.

This topic explains how to use both the Manage Your Server and the Configure Your Server Wizard to install and configure a file server. When you have finished setting up a basic file server, you can complete additional tasks by using Manage Your Server. After you complete the Configure Your Server Wizard, you will have a fully functioning file server.

This topic covers:

Before you begin

Configuring your file server

Next steps: Completing additional tasks

**Before you begin**
Before you configure your computer as a file server, verify whether or not:

- The operating system is configured correctly. In the Windows Server 2003 family, file services depend on the appropriate configuration of the operating system and its services. If you have a new installation of a Windows Server 2003 operating system, you can use the default service settings. No further action is necessary. If you upgraded to a Windows Server 2003 operating system or you want to confirm that your services are configured correctly for best performance and security, verify your service settings by comparing them to the table in Default settings for services.

- The computer is joined to an Active Directory domain as a member server. If you want to authenticate clients or publish a shared folder to Active Directory, the file server must be joined to a domain. If you do not need to perform either of these tasks, the file server does not need to be joined to a domain.

- All available disk space is allocated. You can use Disk Management or DiskPart.exe to create a new partition out of unallocated space. For more information see Create a partition or logical drive.

- All existing disk volumes use the NTFS file system. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.

- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.

  If Windows Firewall is enabled, you must select **File and Printer Sharing** on the **Exceptions** tab in Windows Firewall in order for the File Server Role to function properly.

- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add a file server role.

| Before adding a file server role | Comments |
|---|---|
| Determine whether you want to configure disk quotas. | Use disk quotas to track and control disk space usage for NTFS volumes on a per-volume basis. Quotas prevent users from exceeding the designated disk space by logging an event when a user exceeds a specified disk space limit. |

| | |
|---|---|
| Determine whether you want to use Indexing Service. | Indexing Service creates indexes of the contents and properties of documents located on your local hard drive or on shared network drives. These indexes enable users to perform faster, easier searches. Indexing Service can slow down the server, so use it only if users frequently search the contents of files on this server. |
| Identify the folders that you want to share on the computer, and specify a folder name and description. | Users view the shared resources on this file server based on file name. It is recommended that you create share names that are easy to remember and indicative of the folder contents. For example, suppose users are provided with 2 gigabytes (GB) each for storing their private information on the file server. You might name the top-level folder on your file server Personal Folders, and then name each of the subfolders according to the user's domain name. |
| Determine what type of permissions you want to set on the folders. | Assign the most restrictive permissions that still allow users to perform required tasks. Access control on the NTFS file system provides more security than share permissions alone. |

**Configuring your file server**

To configure a file server, start the Configure Your Server Wizard by doing either of the following:

- From **Manage Your Server**, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **File server**, and then click **Next**.

This section covers:

File Server Disk Quotas

File Server Indexing Service

Summary of Selections

Using the Share a Folder Wizard

Completing the Configure Your Server Wizard

Removing the file server role

**File Server Disk Quotas**

On the **File Server Disk Quotas** page, you can set up disk quotas, which track and control individual user's disk space usage on NTFS volumes on a per-volume basis. The Configure Your Server Wizard automatically applies disk quotas to new users of any NTFS file system, using whatever disk space quota is already applied. You need to change the information on the **File Server Disk Quotas** page only if you want to prevent a server from consuming a certain amount of disk space or if you have a limited amount of disk space. In most cases, you can accept the default system settings.

If you want to log an event when a user exceeds the specified disk space limit or when a user exceeds the specified disk space warning level (that is, the point at which a user is nearing his or her quota limit), you can specify that on this page.

The following table describes the manual configuration options.

| **Settings** | **Comments** |
|---|---|

| | |
|---|---|
| **Set up default disk quotas for new users of this server** | If you want to enable disk quotas, so that you can limit and track disk space usage on this file server, select this check box.<br><br>If you choose to enable disk quotas, you need to set the disk space limit. It is recommended that you set moderately restrictive default limits for all user accounts, and then modify the limits to allow more disk space for users who work with large files. For example, users who work with scanned photographs or artwork might require large amounts of disk space.<br><br>You can also set the warning level so that users are notified when they exceed the specified disk space limit. If you do not want to use a warning level, set this number higher than the disk space limit. |
| **Deny disk space to users exceeding disk space limit** | If you want to limit disk space usage on the file server, configure this setting. If you only want to track disk space usage on a per-user basis, leave this setting blank. |
| **Log an event when the user exceeds any of the following** | If you want to log a system event when the user exceeds the disk space limit or the warning level, configure these settings. You can view system events by using Event Viewer. To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**. |

After you finish, click **Next**.

#### File Server Indexing Service

On the **File Server Indexing Service** page, do one of the following:

- If users will be searching the contents of the files on the server regularly, click **Yes, leave Indexing Service turned on**.
- If you want to conserve CPU and memory resources, click **No, turn Indexing Service off**. Indexing Service can slow server performance.

Indexing Service provides a fast, easy, and secure way for users to search for information locally or on the network. Users can search in files in different formats and languages, either through Search on the Start menu or through HTML pages that they view in a browser.

After you finish, click **Next**.

#### Summary of Selections

On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected File server on the **Server Role** page, the following appears:

- **Install File Server Management**
- **Run the Share a Folder Wizard to add new shared folders or share existing folders**

To apply the selections shown on the **Summary of Selections** page, click **Next**.

#### Using the Share a Folder Wizard

After you click **Next**, the Configure Your Server Wizard starts the Share a Folder Wizard automatically, which you use to configure shared folders. By sharing resources, you make them available for use by other users on your network.

**Important**

- Use caution when sharing folders that contain system files and resources. Verify that the folder or resource that you specify does not contain information that you do not want users to access.

This section describes the following steps in the Share a Folder Wizard:

Folder Path

Name, Description, and Settings

Permissions

## Sharing was Successful

**Folder Path**

On the **Folder Path** page, specify the path to the folder that you want to share. To search for a folder, click **Browse**.

After you finish, click **Next**.

**Name, Description, and Settings**

On the **Name, Description, and Settings** page, specify the following information about the shared folder:

- In **Share name**, type the name you want to use for the shared resource. The share name is required. Choose a name that is short and descriptive, so that it is easy for users to identify.

- In **Description**, type a description of the shared resource. The description is optional. If you are sharing several resources, descriptions can help you organize and identify those resources. The description you type appears in the **Description** column of File Server Management and Shared Folders.

- In **Offline setting**, specify how you want to make the contents of the shared folder available to users when they are not connected to the network. If you want users to have control over which files are available offline, you can accept the default. To change the offline setting, click **Change**. Use the information in the following table to determine what settings you want to use for your offline files.

| Offline setting | Comments |
|---|---|
| **Only the files and programs that users specify will be available offline** | If you want to give users control over which files are available offline, click this option. |
| **All files and programs that users open from the share will be automatically available offline** | If you want to allow all of the files that users open from the shared folder to be automatically available offline, click this option. If you select the **Optimized for performance** check box, all programs will be automatically cached so that users can run them locally. This option is especially useful for file servers that host applications, because it reduces network traffic and improves server scalability. |
| **Files or programs from the share will not be available offline** | If you want to prevent users from storing files offline, click this option. |

After you finish, click **Next**.

**Permissions**

On the **Permissions** page, specify the share permissions for the shared folder. To ensure that only authorized users have access to the information in the folder, you must set permissions on the folder that you created. Share permissions apply only to users who gain access to the resource over the network. They do not apply to users who gain access to the resource from the computer where the resource is stored. Use the following table to determine which share permissions are appropriate.

| Share permission | Comments |
|---|---|
| All users have read-only access | To restrict all access to read-only, click this option. |
| Administrators have full access; other users have read-only access | If you want users to view files and run programs that are located in the shared resource, click this option. Only members of the Administrators group are allowed to change, add, or delete files. Also, only members of the Administrators group are allowed to change the NTFS file permissions on the shared resource. |
| Administrators have full access; other users have read and write access | If you want to restrict access to read and write for all users except members of the Administrators group, click this option. |

| | |
|---|---|
| Use custom share and folder permissions | If you want to grant or deny access to specific users or groups, click this option. You should assign the most restrictive permissions that still allows users to perform necessary functions. |

After you finish, click **Finish**.

**Sharing was Successful**

On the **Sharing was Successful** page, the Share a Folder Wizard displays a status and summary of your selections. If you want to share another folder, click the **When I click Close, run the wizard again to share another folder** check box. When you finish sharing folders, click **Close**.

**Completing the Configure Your Server Wizard**

After you complete the Share a Folder Wizard, the Configure Your Server Wizard displays the **This Server Is Now a File Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

After completing the Configure Your Server Wizard, be sure to visit Windows Update to download any additional updates available. For more information, see Windows Update.

In addition, you should also run the Security Configuration Wizard to secure your file server. For more information see Security Configuration Wizard.

**Removing the file server role**

If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the file server role, files and folders on this server are no longer shared and network users, programs, or hosts that depend on those shared resources will be unable to connect to them.

To remove the file server role, restart the Configure Your Server Wizard by doing either of the following:

- From **Manage Your Server**, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **File server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the file server role** check box, and then click **Next**. On the **File Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard and create shared resources on the computer, the computer is ready for use as a basic file server that can store, manage, and share information such as files and network-accessible applications. Up to this point, you have completed the following tasks:

- If necessary, established disk space limits by enabling disk quotas.

- If necessary, turned on Indexing Service.

- Created shared folders and set share permissions for each folder.

The Configure Your Server Wizard automatically installs File Server Management, which you use to manage your file server. To open File Server Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **File Server Management**.

The following table lists some of the additional tasks that you can perform on your file server.

| Task | Purpose of task | Reference |
|---|---|---|
| Secure the file server. | To ensure that your file server is secure. | Best practices for security |

| | | |
|---|---|---|
| Implement Encrypting File System (EFS). | To strengthen security of the files and resources on the file server. | Encrypting and decrypting data |
| Configure ports to allow remote administration. | To manage the File Server Role from other computers on the network. | Windows Firewall Settings |
| Set permissions on shared files and folders. | To secure resources on the file server and prevent unauthorized access. Access control on the NTFS file system provides more security than share permissions alone. | Set permissions on a shared resource |
| Make shared resources available offline. | To allow users to store local copies of shared resources, so that they can access these resources when they are not connected to the network. | Configure offline settings for a shared resource |
| Enable shadow copies of shared folders. | To enable shadow copies of shared folders, which provide point-in-time copies of files on network shares. | Enable Shadow Copies for Shared Folders |
| Set up a Distributed File System (DFS). | To make it easier for users to access and manage files that are physically distributed across a network. | Checklist: Creating a distributed file system |
| Ensure that the file server is properly backed up. | To protect data from accidental loss if your system experiences hardware or storage media failure. | Back Up Data |
| Use file compression. | To conserve storage space by compressing files, folders, and programs. | File compression overview |

# Print server role: Configuring a print server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Print server role: Configuring a print server**
If you plan to use this computer to manage and share printers, configure this computer as a print server.

**Note**

- This feature is not included on computers running the Microsoft® Windows Server™ 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

This document explains how to use the Configure Your Server Wizard to quickly meet the most basic requirements of a print server. When you are done setting up a basic print server, you can complete additional configuration tasks, depending on how you want to use this print server.

This topic covers:

- Before you begin
- Configuring your print server
- Next steps: Completing additional tasks

**Before you begin**
Before you configure your server as a print server, verify whether or not:

- The operating system is configured correctly. In the Windows Server 2003 family, print services depend on the appropriate configuration of the operating system and its services. If you have a new installation of a Windows Server 2003 operating system, you can use the default service settings. No further action is necessary. If you upgraded to a Windows Server 2003 operating system or you want to confirm that your services are configured correctly for best performance and security, verify your service settings by comparing them to the table in Default settings for services.
- The computer is joined to an Active Directory domain as a member server. If you want to restrict access to a printer, so that some domain users can print to it and other users cannot, or you want the print server to publish shared printers to Active Directory so that domain users can easily search for those printers, the print server must be joined to a domain. If you do not need to perform either of these tasks, the print server does not need to be joined to a domain.
- All existing disk volumes use the NTFS file system. FAT32 volumes are less secure. For more information about encrypting data stored on NTFS volumes, including spooled print jobs, see Storing Data Securely.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add a print server role.

| Before adding a print server role | Comments |
|---|---|
| Determine the operating system version of the clients that will send jobs to this printer. | You must have this information to select the correct client printer drivers for your client and server computers. After you add this role, the print server can automatically distribute these drivers to the clients. Additionally, the set of client operating systems determines which of these drivers you need to install on the server during the print server role installation. |

| | |
|---|---|
| At the printer, print a configuration or test page that includes manufacturer, model, language, and installed options. | You need this information to choose the correct printer driver. The manufacturer and model are usually enough to uniquely identify the printer and its language. However, some printers support multiple languages, and the configuration printout usually lists them. Also, the configuration printout often lists installed options, such as extra memory, paper trays, envelope feeders, and duplex units. |
| Determine how the print server connects to the printer. | If the printer supports Plug and Play and connects to the print server using infrared technology, a universal serial bus (USB) port, or an IEEE 1394 port, the print server will configure itself automatically. You do not need to follow the remaining steps.<br><br>Otherwise, if the printer is connected to the print server with a cable, note which server port is used. For printers, LPT1 is the most commonly used port.<br><br>If the printer is located away from the print server and uses its own network adapter to receive print jobs, determine the IP address of the network adapter on the printer. |
| (Optional) Determine whether you need a new or updated printer driver. | Most printers are supported by drivers on the installation CD for the Windows Server 2003 operating system. To save time, you can often skip this step because the wizard that you will use to configure your print server provides compatibility information. If the wizard does not list a driver for your printer, you can look for an update from the printer manufacturer or Windows Update. |
| Choose a printer name. | Users running Windows-based client computers choose a printer by using the printer name. The wizard that you will use to configure your print server provides a default name, consisting of the printer manufacturer and model. The printer name is usually less than 31 characters in length. |
| Choose a share name. | A user can connect to a shared printer by typing this name, or by selecting it from a list of share names. The share name is usually less than 8 characters in length for compatibility with MS-DOS and Windows 3.x clients. |
| (Optional) Choose a location description and a comment. | These can help identify the location of the printer and provide additional information. For example, the location could be "Second floor, copy room" and the comment could be "Additional toner cartridges are available in the supply room on floor 1." |

**Configuring your print server**

To set up a print server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Print server**, and then click **Next**.

This section covers:

- Printers and Printer Drivers

- Summary of Selections

- Using the Add Printer Wizard

- Using the Add Printer Driver Wizard

- Completing the Configure Your Server Wizard

- Removing the print server role

**Printers and Printer Drivers**

On the **Printers and Printer Drivers** page, do one of the following:

- If all of the clients on your network run Windows XP Home Edition, Windows XP Professional, or Windows 2000, click **Windows 2000 and** Windows XP **clients only**.
- If any of the clients run Windows XP 64-bit Edition (Itanium), Windows NT 4.0, Windows Millennium Edition, Windows 98, or Windows 95, click **All Windows clients**.

After you finish, click **Next**.

**Summary of Selections**

On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected **Windows 2000 and** Windows XP **clients only** on the previous page, the following appears:

- **Add printers to this server using the Add Printer Wizard**.

If you selected **All Windows clients** on the previous page, the following appears:

- **Add printers to this server using the Add Printer Wizard.**
- **Add printer drivers to this server using the Add Printer Driver Wizard.**

To apply the selections shown on the **Summary of Selections** page, click **Next**.

**Using the Add Printer Wizard**

After you click **Next**, the Configure Your Server Wizard runs the Add Printer Wizard once for each printer that you want to add. If the wizard finishes and you choose to share at least one printer, your server can be used as a print server. If you cancel the Add Printer Wizard, the Print Spooler service remains installed. If you cancel the Add Printer Wizard and no printers are shared, the server does not add the print server role.

**Important**

- If the printer you want to share supports Plug and Play, do not run the Add Printer Wizard. Plug and Play printers complete the configuration steps in the Add Printer Wizard automatically. If the printer you want to share supports Plug and Play, click **Cancel**.

This section describes the following steps in the Add Printer Wizard:

- Local or Network Printer
    - New Printer Detection
    - Select a Printer Port
    - Specify a Printer
- Install Printer Software
- Use Existing Driver
- Name Your Printer
- Printer Sharing
- Location and Comment
- Print Test Page

- Completing the Add Printer Wizard

**Local or Network Printer**
On the **Local or Network Printer** page of the Add Printer Wizard, choose one of the following options:

- To configure this print sever to send print jobs directly to the printer, click **Local printer attached to this computer**. Typically, print servers send print jobs directly to the printer. A printer with its own network adapter is considered to be a local printer. If you want to send print jobs directly to a printer with its own network adapter, click this option.

- To configure this print server to forward print jobs to a second print server, click **A network printer, or a printer attached to another computer**. For example, you can configure a print server at a branch office to forward print jobs to a print server in the main office. You might do this if regulations require you to create printouts of daily transaction logs and store them at the main office. If you want to do this, click this option.

**Note**

- The **A network printer, or a printer attached to another computer** option is included here because this dialog box is used on all computers running a Windows Server 2003 operating system so that users can connect to a network printer. If you need to print from a computer that is not a print server, click **A network printer, or a printer attached to another computer**.

After you finish, click **Next**.

After you click **Next**, one of the following wizard pages appears:

**New Printer Detection**
If you selected the **Automatically detect and install my Plug and Play printer** check box and the wizard is unable to detect any Plug and Play printers, this page appears. Click **Next**.

To complete the steps on the **Select a Printer Port** page, see Select a Printer Port.

**Select a Printer Port**
If you selected **Local printer attached to this computer**, this page appears.

On the **Select a Printer Port** page, choose one of the following options:

- If a cable connects the printer directly to a port on the print server, under **Use the following port**, click the name of that port. LPT1 is the most commonly used port for this type of printer.

- If the printer has its own network adapter and you want to send print jobs to the printer through the network, click **Create a new port**, and then click the type of port that you want to create. If you do not know what type of port to create, **Standard TCP/IP Port** is recommended.

  If you click **Standard TCP/IP Port**, and then click **Next**, the Add Standard TCP/IP Printer Port Wizard starts. In the Add Standard TCP/IP Printer Port Wizard, click **Next**. On the **Add Port** page, type the name or IP address of the printer. The IP address is usually listed on the printer configuration page. As you type the name or IP address, the wizard completes the **Port Name** field for you. Click **Next**.

  The wizard attempts to connect to the printer. If the wizard is able to connect, the **Completing the Add Standard TCP/IP Printer Port Wizard** page appears, and you can click **Finish**. If the wizard is not able to connect, the **Additional Port Information Required** page appears. If you think that the address or name you entered is not correct, click **Back**, retype the name or address, and then click **Next**.

  If you are sure the address or name is correct, select one of the following device types to identify the printer network adapter:

  - **Standard** is the default. If you click **Standard**, click the manufacturer and model of network adapter from the **Standard** list.

- If the printer network adapter uses nonstandard settings, click **Custom** and then click **Settings**. The **Configure Standard TCP/IP Port Monitor** page appears. Specify the settings that are recommended by the manufacturer of the printer network adapter, and then click **OK**.

After you finish, click **Next**.

**Specify a Printer**
If you selected **A network printer, or a printer attached to another computer**, this page appears.

On the **Specify a Printer** page, choose one of the following options to configure your print server to forward print jobs to another print server:

- If the print server that you want to connect to is available on the network, click **Browse for a printer**, click **Next**, and then, under **Shared printers**, click the server and printer from the list.

- If the print server that you want to connect to is temporarily unavailable on the network, click **Connect to this printer (or to browse for a printer, select this option and click Next)**, and then, in **Name**, type the server and printer names.

- If the print server that you want to connect to belongs to another organization and is available on the Internet, click **Connect to a printer on the Internet or on a home or office network**.

**Important**

- Use the options on this page only if you want your print server to forward print jobs to another print server. If this is not what you want, click **Back**, click **Local printer attached to this computer**, click **Next**, and then follow the steps in Select a Printer Port.

After you finish, click **Next**.

For this configuration path, you can skip some of the following steps in this document. To continue the instructions for this configuration path, see Completing the Add Printer Wizard.

**Install Printer Software**
On the **Install Printer Software** page of the Add Printer Wizard, under **Manufacturer**, click the printer manufacturer, and then, under **Printers**, click the printer model.

**Note**

- Write down the manufacturer and model that you select, because you will need this information later if you use the Add Printer Driver wizard to install printer drivers for other Windows-based clients.

If the manufacturer or model is not listed, try each of the steps outlined in the following table, in sequence, to install the correct printer software.

| Step | Comments |
|---|---|
| Check the configuration printout to confirm the exact spelling of the name of your printer manufacturer and model. | The **Manufacturer** and **Printers** lists show the official product names, which might be different from the names that you normally use. |
| Click **Have Disk**, locate the driver files, and then click **OK**. | If you have printer driver files stored somewhere else, follow these steps. For example, the printer manufacturer might include a CD-ROM containing driver files in the packaging of the printer. |
| Click **Windows Update**. | If you want to look for new or updated drivers that are available from Microsoft as part of Windows Update, click this option. When you click **Windows Update**, the **Manufacturer** and **Printers** lists change to show only the drivers that are available from Windows Update. If the printer is not listed, return to the original list by clicking **Back**, and then clicking **Next**. |

| | |
|---|---|
| Select the manufacturer and model of a compatible printer, and then click **Next**. | To determine which printers are compatible, consult the user guide for your printer. Also, some manufacturers list compatibility information on their Web sites. |

After you finish, click Next.

**Use Existing Driver**

If you add an additional printer that is the same manufacturer and model as one previously installed, the **Use Existing Driver** page appears. Decide whether to keep the same driver or replace it with a new one. If you select **Replace existing driver**, the wizard reinstalls the driver files.

After you finish, click **Next**.

**Name Your Printer**

On the **Name Your Printer** page of the Add Printer Wizard, the default name is the manufacturer and model of the printer. You can change this name so that the printer is easier to use and administer. When using applications, users often select a printer from a list that displays the names of the available printers. To help users decide which printer to select, the application might also list the location or a comment.

Under **Do you want to use this printer as the default printer?**, click **Yes** or **No**. Your response applies only when you print from an application that is running on this print server. Your response does not set this printer as the one that clients use by default.

After you finish, click **Next**.

**Printer Sharing**

**Important**

- You must share at least one printer for this server to act as a print server.

On the **Printer Sharing** page of the Add Printer Wizard, **Share name** is selected by default so that the printer is shared. The default share name is the first 8 letters of the printer manufacturer and model, without spaces. You can change this name so that the printer is easier to use and administer.

For compatibility with clients that run MS-DOS or earlier versions of Windows, type a share name that follows these rules:

- The share name contains only letters, digits, and the period (.).
- The share name contains no more than eight letters and digits, and, optionally, followed by a period, which is followed by no more than 3 letters and digits.

After you finish, click **Next**.

**Location and Comment**

On the **Location and Comment** page of the Add Printer Wizard, in **Location**, type a description of the print server location, and then, in **Comment**, type a comment. This step is optional, but recommended because this information makes it easier to use and administer your print server. Many applications display the comment or the location when the user prints a document, so that the user can choose the most appropriate printer.

After you finish, click **Next**.

**Print Test Page**

On the **Print Test Page** page of the Add Printer Wizard, choose whether to print a test page to confirm that the printer is ready to use.

**Note**

- The test page does not print immediately when you click **Next**. Instead, it prints when you finish the wizard.

After you finish, click **Next**.

**Completing the Add Printer Wizard**

On the **Completing the Add Printer Wizard** page, the **Restart the wizard to add another printer** check box is selected by default. If you leave it selected and click **Finish**, the wizard restarts to add another printer. If you have finished adding all of the

printers that you want to share on this server, clear this check box, and then click **Finish**.

When you click **Finish**, the wizard installs the printer driver files. Then, if you chose to print a test page, the wizard attempts to print that page. If the printer does not receive the test page, you might have selected an incorrect port. However, if the printer receives the test page and prints it incorrectly, you might have selected an incompatible manufacturer and model.

When you started the Configure Your Server Wizard to configure this server as a print server, you selected one of the following options on the **Printers and Printer Drivers** page:

- **Windows 2000 and** Windows XP **clients only**
- **All Windows clients**

If you selected **All Windows clients**, the Add Printer Driver Wizard starts after you click **Finish** in the Add Printer Wizard. You can use the Add Printer Driver Wizard to install client printer drivers onto the print server, which can then automatically distribute them to clients.

**Note**

- The Add Printer Driver Wizard does not communicate with the Add Printer Wizard. Therefore, the Add Printer Driver Wizard does not automatically run once for each printer that you add, and it does not automatically install drivers for the same manufacturer and model of printer. Instead, you must decide how many times to run the Add Printer Driver Wizard, and each time it runs you must decide which manufacturer and model of drivers to install.

#### Using the Add Printer Driver Wizard

If you selected **All Windows clients** on the **Printers and Printer Drivers** page of the Configure Your Server Wizard, the Add Printer Driver Wizard starts after the Add Printer Wizard. If you cancel the Add Printer Driver Wizard, the Print Spooler service remains installed, and any printers you have added remain, but the additional client driver files are not installed on the server, and therefore the server cannot distribute those drivers to clients.

This section describes the following steps in the Add Printer Driver Wizard:

- Printer Driver Selection
- Processor and Operating System Selection
- Completing the Add Printer Driver Wizard

#### Printer Driver Selection

On the **Printer Driver Selection** page of the Add Printer Driver Wizard, select the manufacturer and model of a printer that is shared on this print server, and then click **Next**.

**Important**

- The Add Printer Driver Wizard does not automatically select a manufacturer and model for a printer that you have already added. Instead, it selects the first manufacturer in the list, and the name of the first printer model (in alphabetical order) made by that manufacturer. If possible, select the manufacturer and model of a printer that you have added. If you select a different manufacturer or model, the wizard installs drivers that might not work correctly with your printer.

#### Processor and Operating System Selection

On the **Processor and Operating System Selection** page of the Add Printer Driver Wizard, select the client operating systems and processors.

Drivers for your server operating system are installed automatically when you add a printer. As a result, one of the following is selected automatically and you cannot remove it: **Windows 2000, Windows XP and Windows Server 2003** for x86–based processors, **Windows XP and Windows Server 2003** for Itanium–based processors, or **Windows XP and Windows Server 2003** for x64-based processors.

After you finish, click **Next**.

#### Completing the Add Printer Driver Wizard

On the **Completing the Add Printer Driver Wizard** page, the **Restart the wizard to add another printer driver** check box is selected by default. If you leave it selected and click **Finish**, the wizard restarts to add another printer driver. If you have finished adding all of the printer drivers for all of the printers that you want to share on this server, clear this check box, and then click **Finish**.

**Completing the Configure Your Server Wizard**

After you complete the Add Printer Wizard and, if necessary, the Add Printer Driver Wizard, the Configure Your Server Wizard displays the **This Server is Now a Print Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at systemroot\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

Before you start to use your print server, we recommend the following steps:

- Run Windows Update. For more information, see Windows Update.
- Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

**Removing the print server role**

If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the print server role, each client that sent print jobs only to this print server will be unable to print until you reconfigure the client to send print jobs to a different server. Also, each printer managed only by this print server will be unable to receive print jobs until you reconfigure another print server to send print jobs to that printer.

To remove the print server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.
- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Print server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the print server role** check box, and then click **Next**. On the **Print Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard, the server is ready for use as a print server. By following the steps in this document, you have:

- Added one or more printers.
- Shared printers so that clients can send print jobs to the printers.
- If necessary, added client print drivers.

You can use the Add Printer Wizard and Add Printer Driver Wizard to add more printers and client printer drivers. These wizards are available through Manage Your Server.

The following table lists some of the additional tasks that you can perform on your print server.

| Task | Purpose of task | Reference |
|---|---|---|
| Set the configuration to match installed options. | To provide user access to installed printer options, such as an envelope feeder or extra memory, that are available on some printers. If your printer provides additional features, you must update the configuration so that users can use these features. | Set installable options for a printer |

| | | |
|---|---|---|
| Set printing defaults. | To set the default configuration for clients when they connect to the printer. For example, you can set the default layout or paper source. | Set printing defaults |
| Assign printer permissions. | To change the permissions that users have for a printer. | Set or remove permissions for a printer |
| Choose a separator page. | To define a page that appears at the beginning of each printout. | Choose a separator page |
| Configure network clients to use the printer. | To configure clients to connect to the printers that are shared on this print server. | Connect clients to a printer |
| Set advanced printer tasks. | To manage your print server more efficiently and effectively. For example, to schedule alternate printing times, to enable printer location tracking, or to set different priority for different groups. | Use Advanced Options |
| Publish a printer in Active Directory. | To help domain users find printers shared by this print server quickly. For this task, the print server must be a member server. | Publish a printer in Active Directory |
| Configure ports to allow remote administration. | To manage the print server from other computers on the network. | Windows Firewall Settings |

# Application server role: Configuring an application server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Application server role: Configuring an application server**
An application server is a core technology that provides key infrastructure and services to applications hosted on a system. Typical application servers include the following services:

- Resource pooling (for example, database connection pooling and object pooling)
- Distributed transaction management
- Asynchronous program communication, typically through message queuing
- A just-in-time object activation model
- Automatic XML Web Service interfaces to access business objects
- Failover and application health detection services
- Integrated security

The Windows Server 2003 family includes all this functionality, in addition to services for development, deployment, and runtime management of XML Web services, Web applications, and distributed applications.

This topic explains the basic steps that you must follow to configure an application server. This process involves using the Configure Your Server Wizard to configure the server as an application server. When you have finished setting up a basic application server, you can complete additional tasks by using Manage Your Server.

This topic covers:

- Before you begin
- Configuring your application server
- Next steps: Completing additional tasks

**Before you begin**
Before you configure your computer as an application server, verify that:

- All existing disk volumes use the NTFS file system. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions. To find out the file system type, in **My Computer** right-click the disk volume, and then click **Properties**. For information about how to convert a FAT partition to an NTFS partition, see "To convert a volume to NTFS from the command prompt" in Windows Help and Support Center.
- Your computer has network connectivity and a static or dynamic IP address.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add an application server role.

| Before adding an application server role | Comments |
| --- | --- |
| Understand the following technologies that are installed automatically while configuring your application server:<br>• Internet Information Services (IIS)<br>• Application Server console<br>• COM+<br>• Distributed Transaction Coordinator (DTC) | • IIS 6.0 is a full-featured Web server that provides the infrastructure for .NET and existing Web applications and Web services.<br>• COM + is an extension to the Component Object Model (COM). COM+ builds on COM's integrated services and features, making it easier for developers to create and use software components in any language, using any tool.<br>• The Application Server console provides a central location from which you can administer your Web applications. To open the Application Server console, in Manage Your Server, click **Manage this application server**.<br>• Distributed Transaction Coordinator (DTC) coordinates COM+ transactions. |
| Determine whether you would like to install FrontPage Server Extensions. | FrontPage Server Extensions enable users on a client computer to publish and administer Web sites on a server remotely over a network. |
| Determine whether you would like to run ASP.NET applications on your server. | ASP.NET is a unified Web development platform that provides the services necessary for developers to build enterprise-class Web applications. You can enable ASP.NET for developing Web applications. |

**Configuring your application server**

To configure an application server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Application server (IIS, ASP.NET)**, and then click **Next**.

This section covers:

Application Server Options

Summary of Selections

Completing the Configure Your Server Wizard

Removing the application server role

**Application Server Options**

On the **Application Server Options** page, you can choose to install the following optional components with your application server:

- **FrontPage Server Extensions** - FrontPage Server Extensions enable multiple users to administer and publish a Web site from a client computer, remotely. Select this option if you want to enable multiple-users to simultaneously create Web sites, or enable users to create Web applications from their client computers, remotely, over the Internet.

- **Enable ASP.NET** - ASP.NET is a unified Web application platform that provides the services necessary to build and deploy enterprise-class Web applications. ASP.NET offers a new programming model and infrastructure for more secure, scalable, and stable applications that can target any browser or device. If your Web site includes applications that have been developed by using ASP.NET, select this option. If you are not sure that you need to enable ASP.NET, you can enable it later by using IIS Manager. This feature is not available on the Itanium-based versions of the Windows operating systems. By enabling ASP.NET, you can use your application server to host ASP.NET applications. Some of the features of ASP.NET include the following:

- ASP.NET can run side by side with Active Server Pages (ASP) code on Internet Information Services (IIS). If you are already running ASP code you do not need to upgrade your ASP pages, and you can add ASP.NET pages to your applications.

- ASP.NET has enhanced performance.

- ASP.NET supports many languages including Visual Basic .NET, C#, and JScript .NET.

After you finish, click **Next**.

**Summary of Selections**
On the **Summary of Selections** page, you can view and confirm the options that you have selected. If you selected **Application server (IIS, ASP.NET)** on the **Server Role** page, the following appears:

- **Install Internet Information Services (IIS)**

- **Enable COM+ for remote transactions**

- **Enable Microsoft Distributed Transaction Coordinator (DTC) for remote access**

If you selected FrontPage Server Extensions or ASP.NET, the following items also appear:

- **Install FrontPage Server Extensions**

- **Enable ASP.NET**

To apply the selections shown on the **Summary of Selections** page, click **Next**. When you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page.

**Completing the Configure Your Server Wizard**
After the components are configured, the Configure Your Server Wizard displays the **This Server is Now an Application Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

If the installation was not successful, the **Cannot Complete** page appears and IIS could not be installed. To troubleshoot the installation, click **Configure Your Server log**.

Run Windows Update. For more information, see Windows Update.

Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

**Removing the application server role**
If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the application server role, you will uninstall all application server components, such as the IIS. Your server will no longer support serving Web pages, Web applications, or distributed applications.

To remove the application server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Application server (IIS, ASP.NET)**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the application server role** check box, and then click

**Next**. When you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. On the **Application Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard and enable the features that you need to run your applications, the computer is ready for use as a basic application server. Up to this point, you have completed the following tasks:

- Installed Internet Information Services (IIS), ASP.NET, and COM+.
- If necessary, enabled FrontPage Server Extensions.
- If necessary, enabled ASP.NET.

The following table lists some of the additional tasks that you might want to perform on your application server.

| Task | Purpose of task | Reference |
|---|---|---|
| Secure your application server. | To ensure the security of this server, it is recommended that you implement security precautions, such as firewalls and Internet Protocol security (IPSec), before placing it in a production environment. An application server may be targeted by attackers because of its exposure to the Internet and other networks. You can secure your applications by using authentication protocols, access control, Secure Sockets Layer (SSL), and encryption. | Internet Protocol Security (IPSec); Basic Firewall; Security in Microsoft Internet Information Services |
| Secure your files with NTFS. | To secure your Web site, applications, databases, and files use NTFS permissions. This is essential for a secure site. | Set, view, change, or remove permissions on files and folders |
| Configure Web Interface for Remote Administration. | To manage your application server using a Web browser on a remote computer. | Using Web Interface for Remote Administration |
| Create a Web site. | To create a Web site to host your Web applications. | Web Site Setup in Microsoft Internet Information Services |
| Create applications with the latest development tools. | To learn about the latest development tools from Microsoft that can help you develop new applications more quickly and efficiently. | Microsoft Web site |
| Create ASP.NET Web Applications. | To create ASP.NET applications. | Creating ASP.NET Web Application at the Microsoft Web site |
| Secure your ASP.NET Web applications. | To ensure the security of your ASP.NET applications | ASP.NET Web Application Security at the Microsoft Web site |
| Configure ports to allow remote administration. | To manage the application server from other computers on the network. | Windows Firewall Settings |

# Mail server role: Configuring a mail server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mail server role: Configuring a mail server**

Configure this computer as a mail server to install E-mail Services, which provides e-mail transfer and retrieval services. E-mail Services includes the POP3 service, which provides e-mail retrieval, and the SMTP service, which provides e-mail transfer. Administrators can use the POP3 service to store and manage e-mail accounts on the mail server. After configuring this computer as a mail server, users can connect to the mail server and retrieve e-mail to their local computer using an e-mail client that supports the POP3 protocol, such as Microsoft Outlook.

This topic explains how to use the Configure Your Server Wizard to install and configure E-mail Services. After you have completed the Configure Your Server Wizard, you must perform additional required steps to create mailboxes. After you have completed the Configure Your Server Wizard and created the appropriate mailboxes, you will have a fully-functioning mail server.

You can configure both member servers and stand-alone servers to be a mail server. However, the default authentication method and the available authentication methods will vary. For more information about the default authentication methods and the available authentication methods, see Before you begin and Configure POP3 Service.

This topic covers:

- Before you begin
- Configuring your mail server
- Next steps: Completing additional tasks

**Before you begin**

Before you configure your computer as a mail server, verify that:

- The server on which you intend to install e-mail services has a working Internet connection.
- There is an NTFS partition available. With an NTFS partition, you can take advantage of the increased security provided by disk quotas. For more information about disk quotas, see Configuring disk quotas for the POP3 service.
- You have a registered e-mail domain name. Contact your Internet Service Provider for assistance in registering an e-mail domain name.
- A Mail eXchanger (MX) record for your e-mail domain name exists and matches the name of your server. Contact your Internet service provider (ISP) to create an MX record.
- You have configured your server for static addressing. Contact your Internet Service Provider for the information necessary to configure your server for static addressing. For more information on how to configure your mail server with a static IP address, see Configure TCP/IP for static addressing.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know to before you add a mail server role.

| Before adding a mail server role | Comments |
|---|---|

| | |
|---|---|
| Determine the appropriate level of security for this server. | A server in this role may be targeted by attackers because of its exposure to the Internet and other networks. To ensure the security of this server, it is recommended that you implement security precautions, such as firewalls and Internet Protocol security (IPSec), before placing it in a production environment. For more information, see Internet Protocol Security (IPSec) and Basic Firewall. |
| Determine the appropriate authentication method for your configuration. | You must choose an authentication method before you create any e-mail domains on the mail server. The authentication method can be changed only if there are no existing e-mail domains on the mail server.<br><br>If the computer that you are configuring as a mail server is either a member server or a domain controller, the authentication method setting defaults to Active Directory authentication. Otherwise, the setting defaults to local Windows accounts authentication. |
| Determine that you have a registered e-mail domain name. | The e-mail domain must be a registered domain name and it must match the Mail eXchanger (MX) record created by your ISP. If you do not already have an e-mail domain name, contact your ISP for assistance in registering a domain name.<br><br>**Note**<br><br>• The POP3 service supports top-level and third-level domain names. For example, example.com and mailserver.example.com are both supported.<br><br>• |

**Configuring your mail server**

To configure a mail server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Mail server (POP3, SMTP)**, and then click **Next**.

This section covers:

- Configure POP3 Service

- Summary of Selections

- Completing the Configure Your Server Wizard

- Creating mailboxes

- Removing the mail server role

**Configure POP3 Service**

On the **Configure POP3 Service** page, under **Authentication method**, click the appropriate method for your deployment. The Windows Server 2003 family supports the authentication methods listed in the following table.

| **Use this authentication method** | **When** |
|---|---|
| Local Windows accounts | Your mail server is not an Active Directory member server, and you want to store user accounts on the server on which the POP3 service is installed |

| | |
|---|---|
| Active Directory-Integrated | Your mail server is a domain controller or a member server |
| Encrypted Password File | Your mail server is not using Active Directory, or you do not want to have user accounts for the POP3 service on the local computer |

The authentication methods that are available to you depend on the configuration of your server:

- If the computer on which the POP3 service is running is a member server in an Active Directory domain, all three authentication methods are available.
- If the computer on which the POP3 service is running is a domain controller, the available authentication methods are Active Directory integrated authentication and encrypted password file authentication.
- Otherwise, the available authentication methods are local Windows accounts authentication and encrypted password file authentication.

Under **E-mail domain name**, type your registered e-mail domain name. You can create additional e-mail domains later by using the POP3 service snap-in or the Winpop command-line tool.

After you finish, click **Next**.

**Summary of Selections**

On the **Summary of Selections** page, you can view and confirm the options that you have selected. If you selected **Mail server (POP3, SMTP)** on the **Server Role** page, the following appears:

- **Install POP3 and Simple Mail Transfer Protocol (SMTP) to enable POP3 mail clients to send and receive mail**

To apply the selections shown on the **Summary of Selections** page, click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page.

**Completing the Configure Your Server Wizard**

After the components are configured, the Configure Your Server Wizard displays the **This Server is Now a Mail Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

At this stage, you have a fully-functioning mail server, but you must also create mailboxes for all of the users in the domain who will be sending or receiving e-mail. Without mailboxes, users cannot send or receive e-mail.

However, before you start to use your mail server, we recommend the following steps:

- Run Windows Update. For more information, see Windows Update.
- Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.
- For the mail server role to work correctly, you may need to manually configure Windows Firewall by adding the ports required by POP3 service and SMTP service. For additional information on the ports required, see Windows Firewall Settings.

**Creating mailboxes**

To send and receive e-mail, each user must have a unique mailbox in the e-mail domain. You can create mailboxes from either the POP3 service MMC snap-in or at the command line. This procedure uses the POP3 service MMC snap-in. For more information about creating mailboxes or administering the POP3 service at the command line, see Winpop. For more information about creating mailboxes, see Create a mailbox.

| Step | Comments |
|---|---|

| | |
|---|---|
| Open the POP3 service MMC snap-in. | To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.<br><br>**Notes**<br><br>• To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.<br><br>• If you are using Active Directory integrated authentication, you must log on to the Active Directory domain, not the local computer, to perform this procedure. |
| Create one or more mailboxes. | In the console tree, select the e-mail domain that you specified in the Configure Your Server Wizard (for example, example.com). Right-click the e-mail domain, point to **New**, and then click **Mailbox**. Provide the following information:<br><br>• **Mailbox Name--**the name of the mailbox. The maximum length for a mailbox name is 20 characters for local Windows accounts authentication, and 64 characters for encrypted password file authentication or Active Directory integrated authentication. The minimum length is 1 character.<br><br>• **Password--**the password to access the mailbox.<br><br>• **Confirm Password--**retype the password that was specified in **Password**.<br><br>If you are using Active Directory integrated authentication or local Windows accounts authentication, select the **Create associated user for this mailbox** check box, unless a user account already exists with the same name as the mailbox that you want to create. If the check box is already selected, clear it only if an account already exists with the same name as the mailbox that you want to create. |

**Removing the mail server role**

If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the mail server role, you will uninstall all mail server components, such as the POP3 service and SMTP service. After the mail server components are uninstalled, users will no longer be able to send or receive e-mail using that server. Any e-mail that is stored on the computer will not be affected by removing the mail server role and will remain in the mail store.

To remove the mail server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Mail server (POP3, SMTP)**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the mail server role** check box, and then click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. On the **Mail Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard and create mailboxes, the computer is ready for use as a mail server. Up to this point, you have completed the following tasks:

- Installed the POP3 service and the SMTP service.

- Configured the POP3 service to use an authentication method.

- Created an e-mail domain.
- Created mailboxes.

The Configure Your Server Wizard automatically installs the POP3 service MMC snap-in, which you use to manage your mail server. To open the POP3 service snap-in, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **POP3 Service**.

The following table lists additional tasks that you might want to perform on your mail server.

| Task | Purpose of task | Reference |
|---|---|---|
| Provide users with the procedure to configure their e-mail clients to use the mail server. | To connect to the mail server, the user's e-mail client must be configured specifically for the mail server. | Configure E-mail Clients |
| Implement disk quotas. | Disk quotas ensure that the mail store does not use an excessive or unanticipated amount of disk space, which could adversely affect the performance of the server on which the POP3 service is running. You must have an NTFS partition to implement disk quotas. NTFS partitions allow for greater directory and folder security, which better protects e-mail stored on the local hard disk. | Configuring disk quotas for the POP3 service |
| Configure your mail server to require secure e-mail client authentication. | The POP3 service supports Secure Password Authentication (SPA) for Active Directory integrated authentication and local Windows accounts authentication. Secure Password Authentication requires that all e-mail clients transmit both the user name and password using secure authentication. Secure Password Authentication is more secure than the default of plaintext and, therefore, is recommended over plaintext. Secure Password Authentication must be configured on both the server on which e-mail services are running and on every e-mail client that will connect to the mail server. | Configure the mail server to require Secure Password Authentication; Configure Outlook Express for Secure Password Authentication |
| Configure ports to allow remote administration. | To manage the mail server role from other computers on the network. | Windows Firewall Settings |

# Terminal server role: Configuring a terminal server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal server role: Configuring a terminal server**
Configure this computer as a terminal server by installing the Terminal Server component, which provides centralized deployment of applications.

Using a terminal server, users in remote locations can run programs, save files, and use network resources as though those resources were installed on the users' own computers. By installing programs on a terminal server, you can ensure that all users are using the same version of a program. If you plan to use this computer to allow multiple users to access a program at the same time from a single point of installation, configure this computer as a terminal server.

However, if you plan to use this computer for remote administration on Windows Server 2003 operating systems, you do not need to install Terminal Server. Instead, you can use Remote Desktop for Administration (formerly Terminal Services in Remote Administration mode), which is installed by default on computers running one of the Windows Server 2003 operating systems. After you enable remote connections, Remote Desktop for Administration allows you to remotely manage servers from any client over a LAN, WAN, or dial-up connection. Up to two remote sessions, plus the console session, can be accessed at the same time, without requiring Terminal Server Licensing. For more information about Remote Desktop for Administration, see Remote Administration using Terminal Services.

This topic explains how to use the Configure Your Server Wizard to install and configure a terminal server. After you have completed the Configure Your Server Wizard, you must perform the following additional steps in order to have a basic terminal server.

- Confirm Internet Explorer Enhanced Security Configuration settings.
- Configure a Terminal Server License Server. For small deployments, it is acceptable to install both the Terminal Server and Terminal Server Licensing service on the same physical computer. However, for larger deployments, it is recommended that Terminal Server Licensing be installed on a separate server. Install client access licenses (CALs) on the Terminal Server License Server.

  **Important**

- You must configure Terminal Server Licensing correctly in order for your terminal server to continue to accept connections from clients. To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first. For more information, see Terminal Server Licensing grace period.
- Install programs on the terminal server.
- Distribute the latest version of Remote Desktop Connection to clients running earlier versions of Remote Desktop Connection for Windows.
- Specify which users have permission to connect to the terminal server.

After you have completed both the Configure Your Server Wizard and these additional required tasks, you will have a basic terminal server.

This topic covers:

Before you begin

Configuring your terminal server

Next steps: Completing additional tasks

**Before you begin**

Before you configure your computer as a terminal server, verify whether or not:

- The operating system is configured correctly. In the Windows Server 2003 family, a terminal server depends on the appropriate configuration of the operating system and its services. If you have a new installation of a Windows Server 2003 operating system, you can use the default service settings. No further action is necessary. If you upgraded to a Windows Server 2003 operating system or you want to confirm that your services are configured correctly for best performance and security, verify your service settings with the table in Default settings for services.

- The computer is a server on a network or in a domain, but is not a domain controller. Installing Terminal Server on a domain controller affects performance because of the additional memory, network traffic, and processor time required to perform the tasks of a domain controller in a domain.

- The computer meets processor and memory requirements for supporting multiple concurrent sessions where different users are logged on. A terminal server requires a minimum of 128 MB RAM, plus additional RAM for each user to support running each user's programs on the server. An additional 10 MB RAM is recommended for each light user, who typically runs one program at a time, and up to 21 MB RAM for each power user, who typically runs three or more programs at the same time. In addition, if you plan to install 16-bit applications on the terminal server, be aware that they consume additional resources when they run in 32-bit environments such as Windows Server 2003 operating systems.

- There are no programs installed on the computer. You should add the Terminal Server role before you install the programs that you want users to access. If there are programs already installed on the computer, you might have to reinstall them to ensure that they work correctly in the Terminal Server environment.

- No users are able to log on remotely to the computer. You should allow users to access the terminal server only after you have installed programs, tested their installation, and performed any tuning necessary for the programs to work in a multisession environment. For information on disabling terminal services connections temporarily, see Disable Terminal Services connections.

- All existing disk volumes use the NTFS file system. FAT32 volumes do not provide either the required level of security for users in a multisession environment or the ability to set file permissions.

- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.

  **Note**

  Later, you will need to configure Windows Firewall to allow an exception, to ensure that clients running Remote Desktop can connect remotely to the terminal server. Additional exceptions might also be needed, depending on your terminal server deployment and network configuration. For more information, see Windows Firewall Settings.

- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

**Configuring your terminal server**

To configure a terminal server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Terminal server**, and then click **Next**.

This section covers:

Summary of Selections

Completing the Configure Your Server Wizard

Confirming Internet Explorer Enhanced Security Configuration Settings

Configuring a Terminal Server License Server

Installing client access licenses on the Terminal Server License Server

Installing programs on the terminal server

Deploying client software

Giving users permission to access the terminal server

Removing the terminal server role

**Summary of Selections**

On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected **Terminal server** on the **Server Role** page, the following appears:

- **Install Terminal Server**

To apply the selections shown on the **Summary of Selections** page, click **Next**. The following message appears: "During this process, the Configure Your Server Wizard restarts your computer. Before continuing, close any open programs." If you need to close open programs and you want to cancel the configuration of the terminal server role at this time, you must click **Cancel** now. When you click **Cancel**, the **Configure Your Server Wizard** displays the **Cannot Complete** page. To close the Configure Your Server Wizard, click **Finish**. Otherwise, if you click **OK**, the Configure Your Server Wizard begins the configuration process.

Next, the Configure Your Server Wizard displays the message "Installing Terminal Server." The **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. Then, the Configure Your Server Wizard shuts down the computer and restarts it to accept the configuration changes that make the computer a terminal server.

During the restart process, a dialog box displays progress messages, for example, "Windows is starting up" and "Preparing network connections." Depending on the size of your network, preparing network connections could take some time. When the **Welcome to Windows** dialog box appears, press CTRL+ALT+DEL. In the **Log on to Windows** dialog box, in **Password**, type your password. To complete the process, wait for the Configure Your Server Wizard to appear on the screen.

**Completing the Configure Your Server Wizard**

After your server restarts, the Configure Your Server Wizard displays the **This Server is Now a Terminal Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at systemroot\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

To verify that your server is secure and has the most recent updates, do the following:

1. Run Windows Update. For more information, see Windows Update.

2. Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

Next, you must complete the following steps so that your server is ready to function as a basic terminal server:

- Confirm Internet Explorer Enhanced Security Configuration settings.

- Configure a Terminal Server License Server.

- Install client access licenses (CALs) on the Terminal Server License Server.

- Install programs on the terminal server.

- Deploy the Remote Desktop Connection .msi file to clients not running Windows XP or Windows Server 2003 operating systems.

- Give users permission to access the terminal server.

A separate window displays checklists that provide information about these additional requirements. The same information is covered in this document.

To run a terminal server, you need to configure Terminal Server Licensing. For small deployments, you can configure Terminal Server Licensing on the same physical computer as the terminal server. For larger deployments, you should install Terminal Server Licensing on a separate server. If a Terminal Server License Server is already installed, you can skip the steps for configuring a Terminal Server License Server and installing CALs, and begin Installing programs on the terminal server. Otherwise, if the Manage Your Server page displays a message indicating that a Terminal Server License Server was not found, you must configure a Terminal Server License Server before you can use your terminal server.

**Confirming Internet Explorer Enhanced Security Configuration settings**
After you complete the Configure Your Server Wizard and install Terminal Server, you can configure Internet Explorer Enhanced Security Configuration settings.

If you activate these settings, Internet Explorer applies the following security settings to a user who logs on as an administrator:

- High security settings to the Internet and Local intranet security zones

- Medium security settings to the Trusted sites zone

By applying high security settings to the Internet and Local intranet security zones, you disable scripts, Microsoft ActiveX® controls, and the Microsoft virtual machine (Microsoft VM) for HTML content in these zones. You also prevent users from downloading files in these zones.

By applying medium security settings to the Trusted sites zone, you set standard browsing functionality. If you use sites for administrative tasks and Web-based applications that an administrator cannot access after you apply these settings, you can add the site addresses to the list of sites in the Trusted sites zone.

To review or change the Internet Explorer Enhanced Security Configuration settings, in Manage Your Server, click **Internet Explorer Enhanced Security Configuration**.

In the Windows Server 2003 family, you can implement enhanced security settings for Internet Explorer for all users and reduce the exposure of your server to Web sites that might pose a security risk. For more information, see Internet Explorer Enhanced Security Configuration.

**Configuring a Terminal Server License Server**
Configure a Terminal Server License Server, either on the same computer for which you have just configured the terminal server role (for small deployments), or on another computer (recommended for larger deployments). A Terminal Server License Server manages licenses for Terminal Services client connections. You are required to activate a Terminal Server License Server only once, after which the Terminal Server License Server becomes the repository for terminal server client licenses. Until the registration process is completed, your Terminal Server License Server can issue temporary licenses for clients.

**Important**

- You must configure Terminal Server Licensing correctly in order for your terminal server to continue to accept connections from clients. To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first. For more information, see Terminal Server Licensing grace period.

The easiest and quickest way to activate a Terminal Server License Server is by using the Automatic method. To use this method, the computer running the Terminal Services Licensing service must have a direct connection to the Internet. For information on activation methods for computers that are not connected to the Internet, see Activate a Terminal Server license server by using a Web browser and Activate a Terminal Server license server by using the telephone.

The following table shows the steps you must take to configure and activate a Terminal Server License Server by using the

Automatic method.

| Task | Comments |
| --- | --- |
| Install the Terminal Server Licensing service. | Open **Add or Remove Programs** in Control Panel, and then click **Add/Remove Windows Components**. In the Windows Components Wizard, select the **Terminal Server Licensing** check box, and then click **Next**. If your network includes several domains, or if you are installing the Terminal Server Licensing service on a member server, choose **Your entire enterprise**. If you want to maintain a separate Terminal Server License Server for each domain, or if your network includes workgroups or Windows NT 4.0 domains, choose **Your domain or workgroup**. If you want to change the location of the license server database, specify a new location, and then click **Next**. The **Configuring Components** page displays the progress of configuration changes. On the **Completing the Windows Components Wizard** page, click **Finish**, and then click **Close**.<br><br>To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**. |
| Activate the Terminal Server License Server. | Open **Terminal Server Licensing**, right-click the Terminal Server License Server that you want to activate, and then click **Activate Server**. The Terminal Server License Server Activation Wizard starts. On the **Connection method** page, under **Activation method**, click **Automatic connection**, and then click **Next**. On the **Company Information** page, provide the following required information:<br>• First name<br>• Last name<br>• Company name<br>• Country or region<br><br>Confirm that the information you typed is correct, and then click **Next**. On the next **Company Information** page, you can provide the following optional information:<br>• Email address<br>• Organizational unit<br>• Company address<br>• City<br>• State or province<br>• Postal code<br><br>Confirm that the information you typed is correct, and then click **Next**. On the **Completing the Terminal Server License Server Activation Wizard** page, under **Status**, the following message appears: "Your license server has been successfully activated." If you want to install client licenses now, click **Next**. If you want to postpone the installation of client licenses, clear the **Start Terminal Server Client Licensing Wizard now** check box, and then click **Finish**.<br><br>**Note**<br>• To open Terminal Server Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**. |

**Installing client access licenses on the Terminal Server License Server**

After you activate a Terminal Server License Server, the next step is to install client access licenses (CALs) on the Terminal Server License Server.

**Important**

- Your Terminal Server License Server can issue temporary licenses. Temporary licenses are designed to allow you ample time to deploy a license server, and they allow clients to connect to the terminal server for 90 days. There is no limit to the number of temporary licenses that a license server can issue, but a single client is only issued a temporary license once. After the temporary license expires, the client can only connect to the terminal server if the license server can issue a permanent CAL, or if the terminal server is still within its licensing grace period. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first. For more information, see Terminal Server Licensing grace period.

CALs are digitally-signed certificates that each client stores locally. All CALs are installed on a Terminal Server License Server. When a client attempts to log on to a terminal server for the first time, the terminal server recognizes that the client has not been issued a CAL and locates a Terminal Server License Server to issue a new CAL to the client. For information about specific license requirements, see the Microsoft Web Site.

Before you install CALs, you must have your licensing agreement numbers ready, and know which method you used to purchase them.

The easiest and quickest way to install CALs on a Terminal Server License Server is by using the Automatic method. To use this method, the computer running the Terminal Services Licensing service must have a direct connection to the Internet. For information on installing CALs for computers that are not connected to the Internet, see Install client access licenses by using a Web browser and Install client access licenses by using the telephone.

The following table shows the steps you must take to install CALs on a Terminal Server License Server by using the Automatic method.

| Task | Comments |
|---|---|
| Install CALs on the Terminal Server License Server. | On the Terminal Server License Server, open **Terminal Server Licensing**. Verify that the installation method for the Terminal Server License Server is set to Automatic by right-clicking the Terminal Server License Server for which you want to install CALs, and then clicking **Properties**. If necessary, on the **Installation Method** tab, change the installation method to **Automatic connection**, and then click **OK**.<br><br>In the Terminal Server Licensing console tree, right-click the Terminal Server License Server on which you want to install CALs, click **Install Licenses**, and then click Next. The Terminal Server CAL Installation Wizard starts. On the **Licensing program** page, choose the license program under which you purchased your licenses, and then click **Next**. On the **License Code** page, type the license code for each license you have purchased, and then click **Add** after each entry. After you have typed all of the license codes, click **Next**. The **Completing the Terminal Server CAL Installation Wizard** page displays a message that the CALs were successfully installed. To close the wizard, click **Finish**.<br><br>**Note**<br><br>• To open Terminal Server Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Server Licensing**. |

**Installing programs on the terminal server**

At this stage, you have accomplished the following tasks:

- Completed the Configure Your Server Wizard and configured the terminal server role on your server.
- Installed Terminal Server Licensing.
- Activated the Terminal Server License Server.
- Installed CALs on the Terminal Server License Server.

Now you are ready to install programs on the terminal server. **Add or Remove Programs** in Control Panel is the preferred method for program installation, and you should use this method whenever possible. This section describes how to use **Add or Remove Programs** to install programs on a terminal server.

There are other program installation methods, such as the `change user` command, Windows Installer packages (.msi files), and Group Policy Software Installation. For more information about the `change user` command, see Install a program using the change user command. For more information about using Windows Installer, see Assigned and published programs. For more information about Group Policy, see Group Policy.

For improved performance and reduced network traffic, install programs on the local drive of the terminal server instead of on a file server. Ensure that you have enough space to install programs on NTFS file system drives instead of on FAT32 drives. NTFS drives allow you to set file permissions, which you cannot do on FAT32 drives.

If you are installing published programs, you must use another installation method, such as Group Policy Software Installation.

For performance and security reasons, you should use 32-bit programs whenever possible. Most 32-bit programs use the registry to read and write program settings and need to write only to specific registry values. Running 16-bit programs can reduce the number of users a processor supports by 40 percent and increase the memory required for each user by 50 percent. In addition, some 16-bit programs must be able to write to the directory where the program's .ini file is stored.

RAM and CPU requirements increase approximately linearly with the number of sessions running. To reduce RAM and CPU requirements, consider restricting user or group access to certain program types, disabling unnecessary program features, or installing programs on separate terminal servers.

Some programs have known installation issues in a multisession environment. For information about programs that require installation scripts in order to work correctly in a multisession environment, see Optimizing Applications for Windows 2000 Terminal Services and Windows NT Server 4.0, Terminal Server Edition at the Microsoft Web site.

**Application compatibility considerations**

You should install programs from the console session of the terminal server. You can install programs from a remote console session, but this is not the preferred method for installing programs.

Some programs require an application compatibility script to be run after the program is installed. The scripts are stored in the systemroot\Application Compatibility Scripts\Install directory on the terminal server.

You should be aware of the implications of the security mode in which the terminal server operates. There are two security modes:

- *Full security* provides the most secure environment for users connecting to a terminal server. To run in this mode, applications must be written to run in the security context of an ordinary user. For Windows Server 2003 operating systems and Windows 2000, full security is the default.

- *Relaxed security* enables you to run programs that otherwise might not work at all in the more rigorous Full security mode. However, in Relaxed security mode (also known as Windows NT 4.0/Terminal Server Edition permissions compatibility mode), any user on the system can change files and registry settings in many places throughout the system, although others users' data files might not be visible. A malicious user could exploit this situation by replacing a known and trusted program with a program of the same name but some harmful intent. If the operating system on your terminal server was installed using the Upgrade method, the security mode might be set to Relaxed security. When in doubt, you should choose Full security, test your applications in that mode, and change the security mode only if your test results indicate the need to do so.

The following table shows the steps you must take to install programs on a terminal server, using **Add or Remove Programs**.

| Task | Comments |
|---|---|
| Ensure that no users are logged on to the terminal server. | Send a message to all users who are logged on to the terminal server. Program installation often requires restarting the computer, and their sessions will be disconnected. You should not allow users to access the terminal server until programs have been installed and tested. |
| Disable Terminal Services connections temporarily. | Right-click **My Computer**, click **Properties**, click the Remote tab, and then clear the **Allow users to connect remotely to this computer** check box. |

| | |
|---|---|
| Specify **Full Security** as the security mode. | Open **Terminal Services Configuration**. In the console tree, click **Server Settings**, right-click **Permission Compatibility**, and then click **Properties**. In the **Permission Compatibility** dialog box, click **Full Security**, and then click **OK**.<br><br>**Note**<br><br>• To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**. |
| Install programs from a CD or floppy disk. | Ensure that you are logged on as a member of the Administrators group on the terminal server. Open **Add or Remove Programs** in Control Panel, and then click **Add New Programs**. Click **CD or Floppy**. Insert the CD or floppy disk into the appropriate drive, and then click **Next**. Verify that the installation file is specified correctly in the **Open** box on the **Run Installation Program** page, and then click **Finish**. Follow the instructions in the program's installation wizard. After the program is installed, edit and run any applicable scripts to tailor the program for a multisession environment.<br><br>**Note**<br><br>• To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**. |
| Test the installation. | Ensure that event logging is enabled by opening Services in Administrative Tools. Create a temporary user account that mimics the settings of the user or users who will access the program, and use the account to log on to the terminal server. Start the program and step through some basic tasks. Then, use Event Viewer to determine which files or directories need Write access and which registry keys require Read access by the user for correct operation. Note that this process might not find all files, directories, and registry keys for which the application requires access in all user scenarios. The only way to ensure that you have accounted for all access requirements is to perform tasks manually.<br><br>Some programs enable users to start other programs. For example, Microsoft Access has a toolbar that can be used to start other Microsoft Office programs. If you want users to have access only to specified programs when they log on to the terminal server, you should disable toolbar access from within programs that you install on the terminal server.<br><br>**Note**<br><br>• To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**. |
| Tune programs for multisession use. | Use a text editor such as Notepad to modify any scripts, and then run the scripts to tune any programs that require it. To obtain the scripts, see Optimizing Applications for Windows 2000 Terminal Services and Windows NT Server 4.0, Terminal Server Edition at the Microsoft Web site (http://www.microsoft.com/). |
| Run application compatibility scripts. | Navigate to the *systemroot*\Application Compatibility Scripts\Install directory on the terminal server and run scripts for any programs that require them. |
| Enable remote connections on the terminal server. | Right-click **My Computer**, click **Properties**, click the **Remote** tab, and then check the **Allow users to connect remotely to your computer** check box.<br><br>**Note**<br><br>• Depending on your desktop settings, **My Computer** might not appear on your desktop. To show or hide desktop icons, right-click somewhere on the desktop, click **properties**, click the **Desktop** tab, click **Customize Desktop**, and then, under **Desktop icons**, select the check box next to the icon you want to display, or clear the check box next to the icon you want to hide. |

**Deploying Client Software**

Remote Desktop Connection, formerly known as the Terminal Services Client, is installed automatically on computers running Windows XP and Windows Server 2003 operating systems. For performance and security reasons, computers running earlier versions of Microsoft Windows, including Windows 2000 Server, Windows 2000 Professional, Windows NT 4.0, Windows 98, and Windows 95, should have the latest version of Remote Desktop Connection installed.

There are several ways to deploy the client software:

- Share the Msrdpcli.msi file and use Microsoft IntelliMirror to distribute it to workstations running Windows 2000.
- Download Remote Desktop Connection directly from the Microsoft Web site.
- Place the .msi file in a shared folder residing on a server on the network.

This topic describes how to install the client software from a shared folder residing on a server on the network.

Before you deploy the client software, decide whether you want the software to be installed for the use of a single user or for anyone who uses the client computer. You will make this choice during the deployment process.

The following table shows the steps you must take to deploy the latest version of Remote Desktop Connection to clients running earlier versions of either Windows or Remote Desktop Connection.

| Task | Comments |
|---|---|
| Share the client setup folder. | On the computer running a Windows Server 2003 operating system, open **Windows Explorer**. Navigate to the systemroot\System32\Clients\Tsclient\win32 folder, right-click the win32 folder, click **Sharing and Security**. On the **Sharing** tab, click **Share this folder**, and then click **OK**.<br>**Note**<br>• To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**. |
| Install Remote Desktop Connection. | On the client computer, click **Start**, click **Run**, and then, in **Open**, type *ServerName*\win32, where *ServerName* is the name of the computer where the shared folder is located. Double-click the msrdpcli.msi file to start the InstallShield Wizard for Remote Desktop Connection, and then click **Next**. Read the License Agreement, click **I accept the terms in the license agreement**, and then click **Next**. Type your name and organization in the **Customer Information** page, click **Anyone who uses this computer (all users)**, and then click **Next**. On the **Ready to Install the Program** page, either click **Back** to review or change any of your installation settings, or click **Install** to begin the installation. To complete the installation, click **Finish**. |

**Giving users permission to access the terminal server**

By default, on Windows Server 2003 operating systems, members of the Administrators and Remote Desktop Users groups can use Terminal Services connections to connect to a remote computer. The Remote Desktop Users group is not populated by default, so you must decide which users and groups should have permission to log on remotely, and then manually add them to this group.

**Important**

- You must use the Remote Desktop Users group to grant selected users and groups the necessary permission to make Terminal Services connections to remote computers.

Membership in the Remote Desktop Users group does not also put the user into the local Users group. Depending on the contents of your local Users group, you might need to add the user to that group also.

Before you give users permission to access the terminal server, you must:

- Check the membership of the Administrators group to ensure that you know who has access to the terminal server.
- Decide which users should have permission to access the terminal server.
- Determine which users must also be added to the local Users group.

The following table shows the steps you must take to give users permission to access the terminal server.

| Task | Comments |
|---|---|
| Add users to the Remote Desktop Users group. | Open **Computer Management (Local)**, and in the console tree, **click Local Users and Groups**. In the details pane, double-click the **Groups** folder, double-click **Remote Desktop Users**, and then click **Add**. In the **Select Users** dialog box, click **Locations** to specify the search location. To specify the types of objects that you want to search for, click **Object Types**. In this case, you want to search for Users or Groups. Type the name that you want to add in the **Enter the object names to select (examples)** box, and then click **Check Names**. When the name is located, click **OK**.<br>**Note**<br>• To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**. |
| Add users to the local Users group, if they are not already members. | Open **Computer Management (Local)**, and in the console tree, **click Local Users and Groups**. In the details pane, double-click the **Groups** folder, double-click **Users**, and then click **Add**. In **the Select Users** dialog box, click **Locations** to specify the search location. To specify the types of objects that you want to search for, click **Object Types**. In this case, you want to search for Users or Groups. Type the name that you want to add in the **Enter the object names to select (examples)** box, and then click **Check Names**. When the name is located, click **OK**.<br>**Note**<br>• To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**. |

**Removing the terminal server role**

If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the terminal server role, you will need to reinstall all software, review and update any file or registry permissions for which you changed default values, and review and update any software restriction policies that were used to control programs running on the terminal server.

To remove the terminal server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.
- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Terminal server**, and then click **Next**. On **the Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the terminal server role** check box, and then click **Next**. The following message appears: "During this process, the Configure Your Server Wizard restarts your computer. Before continuing, close any open programs." If you need to close open programs and you want to cancel the removal of the Terminal Server role at this

time, you must click **Cancel** now. When you click **Cancel**, the Configure Your Server Wizard displays the **Cannot Complete** page. To close the Configure Your Server Wizard, click **Finish**. Otherwise, if you click **OK**, the Configure Your Server Wizard begins the removal process.

Next, the Configure Your Server Wizard displays the "Removing Terminal Server" message. The **Configuring Components** page of the Windows Components Wizard appears, displays messages about the configuration changes being made to the computer, and then closes. The Configure Your Server Wizard shuts down the computer and restarts it to accept the configuration changes that remove this role.

During the restart process, a dialog box displays progress messages, for example, "Windows is starting up" and "Preparing network connections." Depending on the size of your network, preparing network connections could take some time. When the **Welcome to Windows** dialog box appears, press CTRL+ALT+DEL. In the **Log on to Windows** dialog box, in **Password**, type your password. To complete the process, wait for the Configure Your Server Wizard to appear on the screen. On the **Terminal Server Role Removed** page, click **Configure Your Server log** to see a record of your changes, and then click **Finish**.

After you remove the terminal server role, you should:

- Reinstall all software.
- Review any file or registry permissions for which you changed default values and, if necessary, make changes.
- Review any software restriction policies used to control programs running on the terminal server and, if necessary, make changes.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard and associated tasks, the computer is ready for use as a basic terminal server that can accept multiple connections from remote clients. Up to this point, you have completed the following tasks:

- Run the Configure Your Server Wizard.
- Activated a Terminal Server License Server.
- Installed CALs on the Terminal Server License Server.
- Installed applications on the terminal server.
- Deployed the Remote Desktop Connection .msi file to clients not running Windows XP or Windows Server 2003 operating systems.
- Configured user permissions for user access to the terminal server.

The following table lists some additional tasks you might want to perform on your terminal server.

| Task | Purpose of task | Reference |
|---|---|---|
| Manage Terminal Services connections. | To enable, disable, rename, or delete a connection. | Manage Terminal Services Connections |
| Specify connection permissions. | To grant terminal server access only to selected users and groups.<br><br>To identify which users and groups are permitted to perform a given task or tasks on the terminal server. | Managing Terminal Services users; Managing Permissions on Connections |

| | | |
|---|---|---|
| Configure terminal server settings using either Group Policy or Terminal Services Configuration. | To configure settings such as Active Desktop, temporary folders, and session limits for individual users. | Configure Server Settings |
| Deploy Remote Desktop Web Connection. | To allow users to create a Remote Desktop connection within Internet Explorer, even though the Remote Desktop Connection client is not installed on their computers. | About Remote Desktop Web Connection |
| Control programs running in a terminal server session. | To protect terminal servers and users from unknown, or possibly malicious, programs. | Using Software Restriction Policies in Windows XP and the Windows Server 2003 family to Protect Against Unauthorized Software at the Microsoft Web site |
| Configure Session Directory settings. | To ensure that users are transparently reconnected to the original server hosting their disconnected Terminal Server sessions. This task applies to terminal servers that are part of a cluster of terminal servers, and requires that a server running either Windows Server 2003, Enterprise Edition, or a Windows Server 2003, Datacenter Edition, is visible on the network, and has the Session Directory service enabled. This session directory server should not be the server on which the Terminal Server role is configured. | Load balancing and terminal servers |
| Configure ports to allow incoming connections to terminal servers. | • To ensure that clients running Remote Desktop Connection can connect remotely to terminal servers.<br>• Additional port configuration might also be required, if Remote Desktop Web connection is deployed, SSL is enabled on the Web server, and if the terminal server license server and terminal server are on opposite sides of a firewall. | Windows Firewall Settings |

# Remote access/VPN server role: Configuring a remote access/VPN server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote access/VPN server role: Configuring a remote access/VPN server**
You can configure a server that allows remote users to access resources on your private network over dial-up or virtual private network (VPN) connections. This type of server is called a remote access/VPN server. Remote access/VPN servers can also provide network address translation (NAT). With NAT, the computers on your private network can share a single connection to the Internet. With VPN and NAT, your VPN clients can determine the IP addresses of the computers on your private network, but other computers on the Internet cannot.

This topic explains the basic steps for configuring a remote access/VPN server using Manage Your Server, the Configure Your Server Wizard, and the Routing and Remote Access Server Setup Wizard. After you finish configuring a basic remote access/VPN server, you can complete additional configuration tasks, depending on how you want to use the remote access/VPN server.

This topic covers:

Before you begin

Configuring your remote access/VPN server

Next steps: Completing additional tasks

**Before you begin**
Before you configure your server as a remote access/VPN server, you should verify whether or not:

- The operating system is configured correctly. In the Windows Server 2003 family, remote access/VPN depend on the appropriate configuration of the operating system and its services. If you have a new installation of a product in the Windows Server 2003 family, you can use the default service settings. No further action is necessary. If you upgraded to a product in the Windows Server 2003 family or you want to confirm that your services are configured correctly for best performance and security, verify your service settings by comparing them to the table in Default settings for services.

- Your server is correctly configured for optimal security for your network needs. Because your remote access/VPN server will connect your private network, the Internet, and your remote clients, you must make sure the server is secure. The security of your private network depends on the security of your remote access/VPN server. For more information, see Security information for remote access.

- This computer has two network interfaces, one that connects to the Internet and one that connects to the private network. The connection to the Internet must be a dedicated connection with enough bandwidth that VPN users can connect to your private network and users on your private network can connect to the Internet. The connection to computers on your private network must be made through a hardware device, such as a network adapter.

- All needed network protocols have been installed for your network interfaces. For more information, see Network interfaces.

- Windows Firewall is disabled on the server that you want to configure for remote access/VPN. You will configure the Basic Firewall feature of Routing and Remote Access during setup, which will serve in place of Windows Firewall.

- Internet Connection Sharing is disabled on the server that you want to configure for remote access/VPN. Internet Connection Sharing is not compatible with Routing and Remote Access. Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you configure a remote access/VPN server.

| Before adding a remote access/VPN server role | Comments |
|---|---|
| Determine which network interface connects to the Internet and which network interface connects to your private network. | During configuration, you will be asked to choose which network interface connects to the Internet. If you specify the incorrect interface, your remote access/VPN server will not operate correctly. |
| Determine whether remote clients will receive IP addresses from a Dynamic Host Configuration Protocol (DHCP) server on your private network or from the remote access/VPN server that you are configuring. | If you have a DHCP server on your private network, the remote access/VPN server can lease 10 addresses at a time from the DHCP server and assign those addresses to remote clients. If you do not have a DHCP server on your private network, the remote access/VPN server can automatically generate and assign IP addresses to remote clients. If you want the remote access/VPN server to assign IP addresses from a range that you specify, you must determine what that range should be. |
| Determine whether you want connection requests from VPN clients to be authenticated by a Remote Authentication Dial-In User Service (RADIUS) server or by the remote access/VPN server that you are configuring. | Adding a RADIUS server is useful if you plan to install multiple remote access/VPN servers, wireless access points, or other RADIUS clients to your private network. For more information, see Internet Authentication Service. |
| Determine whether VPN clients can send DHCP messages to the DHCP server on your private network. | If a DHCP server is on the same subnet as your remote access/VPN server, DHCP messages from VPN clients will be able to reach the DHCP server after the VPN connection is established. If a DHCP server is on a different subnet than your remote access/VPN server, make sure that the router between subnets can relay DHCP messages between clients and the server. If your router is running a Windows Server 2003 operating system, you can configure the DHCP Relay Agent service on the router to forward DHCP messages between subnets. |
| Verify that all users have user accounts that are configured for dial-up access. | Before users can connect to the network, they must have user accounts on the remote access/VPN server or in Active Directory. Each user account on a stand-alone server or a domain controller contains properties that determine whether that user can connect. On a stand-alone server, you can set these properties by right-clicking the user account in Local Users and Groups and clicking **Properties**. On a domain controller, you can set these properties by right-clicking the user account in the Active Directory Users and Computers console and clicking **Properties**. For more information, see Dial-in properties of a user account and Windows interface administrative tool reference A-Z: Active Directory Users and Computers. |

**Configuring your remote access/VPN server**

To configure a remote access/VPN server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Configuration Options** page, click **Custom configuration** and click **Next**. On the **Server Role** page, click **Remote access/VPN server**, and then click **Next**.

This section describes the steps in the Routing and Remote Access Server Setup Wizard for configuring a remote access/VPN server that is not part of an Active Directory domain or part of a network with DNS or DHCP servers. If you follow these steps, you will configure a remote access/VPN server that provides both dial-up and VPN access for remote access clients, provides

NAT for computers on your private network, generates and assigns IP addresses for remote access clients, and locally authenticates connection requests.

This section covers:

Summary of Selections

Using the Routing and Remote Access Server Setup Wizard

Completing the Configure Your Server Wizard

Completing configuration in Routing and Remote Access

Removing the remote access/VPN server role

**Summary of Selections**

On the **Summary of Selections** page, you can view and confirm the options that you have selected. If you clicked **Remote access/VPN server** on the **Server Role** page, the following line appears:

- **Run the Routing and Remote Access Server Setup Wizard to set up routing and VPN**

To apply the selections shown on the **Summary of Selections** page, click **Next**. The Configure Your Server Wizard starts the Routing and Remote Access Server Setup Wizard. If you cancel the Routing and Remote Access Server Setup Wizard, your remote access/VPN server will not be configured, the Routing and Remote Access service will not be started, and the Configure Your Server Wizard will display the **Cannot Complete** page.

When you complete the Routing and Remote Access Server Setup Wizard and the Configure Your Server Wizard, the Routing and Remote Access service is started automatically.

**Using the Routing and Remote Access Server Setup Wizard**

After you choose the remote access/VPN role and confirm your Summary of Selections by clicking **Next** in the Configure Your Server Wizard, the Routing and Remote Access Server Setup Wizard starts.

This section describes the following steps in the Routing and Remote Access Server Setup Wizard:

Configuration

VPN Connection

IP Address Assignment

Name and Address Translation Services

Address Assignment Range

Managing Multiple Remote Access Servers

Completing the Routing and Remote Access Server Setup Wizard

**Configuration**

On the **Configuration** page, click **Virtual Private Network (VPN) access and NAT**, and click **Next**.

**Important**

- This document describes the **Virtual Private Network (VPN) access and NAT** configuration only. If you decide to choose a different configuration, review the documentation for Routing and Remote Access before you complete the Routing and Remote Access Server Setup Wizard. This document will not help you complete any other role than **Virtual Private Network (VPN) access and NAT**. For more information about other configurations, see Common server configurations for remote access servers.

**VPN Connection**

On the **VPN Connection** page, click the network interface that connects this computer to the Internet. The network interface that you choose will be configured to receive connections from VPN clients. Any interface that you do not choose will be configured as a connection to your private network.

In Network Interfaces, the **Enable security on the selected interface by setting up Basic Firewall** check box will already be

selected. Do not clear this check box. This option configures Basic Firewall, a dynamic packet filtering service that helps protect your private network from unsolicited network traffic.

After you finish, click **Next**.

**IP Address Assignment**

On the **IP Address Assignment** page, the **Automatically** option is selected automatically. Do not change the selection. This selection configures your server to generate and assign IP addresses to remote clients.

After you finish, click **Next**.

**Name and Address Translation Services**

On the **Name and Address Translation Services** page, the **Enable basic name and address services** option is selected automatically. Do not change the selection. This selection configures your server to automatically assign IP addresses to any computer on your private network that requests one. The selection also configures your server to forward name resolution requests to a DNS server on the Internet.

After you finish, click **Next**.

**Address Assignment Range**

The **Address Assignment Range** page displays the range of addresses that is defined for assignment to any computer on your network that requests one. This range is generated based on the IP address of the network adapter you chose on the **VPN Connection** page. Review the information presented.

After you finish, click **Next**.

**Managing Multiple Remote Access Servers**

On the **Managing Multiple Remote Access Servers** page, the **No, use Routing and Remote Access to authenticate connection requests** option is selected automatically. Do not change the selection. This selection configures your server to authenticate connection requests locally by using Windows authentication, Windows accounting, and locally stored remote access policies.

After you finish, click **Next**.

**Completing the Routing and Remote Access Server Setup Wizard**

On the **Completing the Routing and Remote Access Server Setup Wizard** page, review the summary information. Verify that:

- The correct network interface is configured to provide VPN access.
- Dial-up and VPN clients are assigned to your private network for addressing.
- Client connections are accepted and authenticated using remote access policies for this remote access/VPN server.
- NAT is configured for the correct network interface.
- Clients will be assigned IP addresses from the correct range.

If any of the summary information is incorrect, click **Back**, and then change the information.

If you click **Finish**, you will not be able to open the Routing and Remote Access Server Setup Wizard again, unless you either remove the remote access/VPN server role from within the Configure Your Server Wizard or disable Routing and Remote Access from the Routing and Remote Access snap-in.

After you have ensured that the summary information is correct, click **Finish**. A message will appear informing you that, to support the relaying of DHCP messages from remote access clients to a DHCP server, you must open Routing and Remote Access on the remote access/VPN server and configure DHCP Relay Agent with the IP address of a DHCP server. Click **OK**. The Routing and Remote Access service will be started automatically, and the Configure Your Server Wizard will reappear.

**Completing the Configure Your Server Wizard**

After you complete the Routing and Remote Access Server Setup Wizard, the Configure Your Server Wizard displays the **This Server is Now a Remote Access/VPN Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click

**Finish**.

After you complete the Configure Your Server Wizard:

- Run Windows Update. For more information, see Windows Update.
- Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

You are now ready to complete configuration for your remote access/VPN server in Routing and Remote Access.

**Completing configuration in Routing and Remote Access**

To open Routing and Remote Access, click **Manage this remote access/VPN server** from Manage Your Server. You can also open Routing and Remote Access from Administrative Tools. To open Administrative Tools, click **Start**, click **Control Panel**, and then double-click **Administrative Tools**.

In Routing and Remote Access, double-click the server you have just configured, and then click **Remote Access Policies**. The default remote access policy is set to deny all access to everyone. Your users will not be able to connect to your remote access/VPN server until you edit the default policy to allow access or replace the default policy with your own policies. Review the default policy by double-clicking it, and then edit it to specify the access that you want to allow your users.

If this server has been previously configured as a remote access/VPN server or if IAS has been configured on this server, the remote access policy or policies that appear in Routing and Remote Access might be configured differently from the default remote access policy. Carefully review all of your remote access policies to ensure that you have allowed and denied remote access according to your network needs. Be sure that you are not accidentally allowing or denying more remote access to your network than you intend.

For more information, see Add a remote access policy, Introduction to remote access policies, and Re-create the default remote access policy.

After you have configured remote access policies, you have completed all necessary configuration for a remote access/VPN server on a network without a DHCP server. If your network uses a DHCP server, you must also configure the DHCP Relay Agent before configuration is complete. In Routing and Remote Access, double-click **IP Routing**, right-click **DHCP Relay Agent**, and click **Properties**. Type the IP address of the DHCP server for your network in **Server address**, click **Add**, and then click **OK**.

**Removing the remote access/VPN server role**

If you need to reconfigure your server for a different role, you can remove existing server roles. When you remove the remote access/VPN server role, your server will no longer provide dial-up or VPN access for remote access clients. Additionally, your server will no longer provide NAT for computers on your private network. Remote users will not be able to connect to your private network, and the computers on your private network might not be able to connect to the Internet. Basic Firewall will no longer protect the computers on your private network. After you remove the remote access/VPN server role, consider enabling Windows Firewall or adding another firewall to protect the computers on your private network, if your network does not already have one. Test your private network to make sure computers on the private network have the level of access to the Internet required by your business needs. Reconfigure remote access policies in IAS to deny all remote access attempts.

To remove the remote access/VPN server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.
- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Remote access/VPN server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the remote access/VPN server role** check box, and then click **Next**. In the dialog box that asks you to confirm that you want to disable the router and remove the remote access configuration, click **Yes**. On the **Remote Access/VPN Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard and complete configuration in Routing and Remote Access, your server is ready for use as a remote access/VPN server that provides both VPN access and NAT. Up to this point, you have completed

the following:

- Started the Routing and Remote Access service.
- Configured your server to accept VPN and dial-up connections.
- Configured your server to provide NAT for your private network.
- Configured remote access policies to allow users to connect to the server running Routing and Remote Access.
- If the network uses a DHCP server, configured the DHCP Relay Agent to forward DHCP messages from remote access clients to the DHCP server.

If you have completed all of these tasks, you have created a basic remote access/VPN server that will allow remote computers to connect to your server with a dial-up or a VPN connection and provide network address translation (NAT) for your private network.

The following table lists additional tasks that you might want to perform on your remote access/VPN server.

| **Task** | **Purpose of task** | **Reference** |
|---|---|---|
| Configure static packet filters. | To add static packet filters to better protect your network. | Add local host filters; Packet filtering |
| Configure services and ports. | To choose which services on your private network you want to make available for remote access users. | Configure services and ports |
| Adjust logging levels for routing protocols. | To configure the level of event details that you want to log. You can decide what information you want to track your log files. | Log details for a routing protocol |
| Configure the number of VPN ports. | To add or remove VPN ports. | Add PPTP or L2TP ports |
| Create a Connection Manager profile for your users. | To manage the client connection experience for your users and simplify troubleshooting client connections. | Connection Manager Administration Kit |
| Add Certificate Services. | To configure and manage a certification authority (CA) on a server for use in a public key infrastructure (PKI). | Certificate Services; Computer certificates for L2TP/IPSec VPN connections |
| Increase remote access security. | To protect your remote users and your private network by enforcing the use of secure authentication methods, requiring higher levels of data encryption, and more. | Security information for remote access |
| Increase VPN security. | To protect your remote users and your private network by requiring the use of secure routing and tunneling protocols, configuring account lockout, and more. | VPN Security |

# Domain controller role: Configuring a domain controller

Updated: August 26, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domain controller role: Configuring a domain controller**
This topic is about configuring a domain controller that runs Windows Server 2003. For more information about installing Active Directory Domain Services in Windows Server 2008, see AD DS Installation and Removal Step-by-Step Guide (http://go.microsoft.com/fwlink/?LinkID=139657).

Domain controllers store data and manage user and domain interactions, including user logon processes, authentication, and directory searches. If you plan to use this server to provide the Active Directory directory service to network users and computers, configure this server as a domain controller.

To configure a server as a domain controller, install Active Directory on the server. There are four options available in the Active Directory Installation Wizard. You can create an additional domain controller in an existing domain, a domain controller for a new child domain, a domain controller for a new domain tree, or a domain controller for a new forest. If you are not sure which role you need, read about each role by clicking the role option.

### Notes

- If you have already installed a domain controller role and you want to view next steps, in the list below, click the domain controller configuration that you installed, and then click **Next steps: Completing additional tasks**.

- If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the domain controller role, you will uninstall Active Directory from this server. After Active Directory has been uninstalled, this server will no longer participate in replication of directory objects and domain-based user authentication requests. For more information, see the sections below.

Click the type of domain controller role that you want to create:

Creating an additional domain controller for an existing domain

Creating a domain controller for a new forest

Creating a domain controller for a new child domain

Creating a domain controller for a new domain tree

**Creating an additional domain controller for an existing domain**
Create additional domain controllers when you want to improve the availability and reliability of network services. By adding additional domain controllers, you can provide fault tolerance, balance the load of existing domain controllers, provide additional infrastructure support to sites, and improve performance by making it easier for clients to connect to a domain controller when they log on to the network. For example, as seen in the following illustration, by adding a new domain controller (DC2) to the microsoft.com domain, it helps offset the load on other domain controllers.

This topic explains the basic steps that you must follow to create an additional domain controller in your organization.

This process involves using the **Configure Your Server Wizard** and the **Active Directory Installation Wizard** to install Active Directory on this server. When you have finished setting up your domain controller, you can complete additional configuration tasks.

This topic covers:

Before you begin

Configuring your domain controller

Next steps: Completing additional tasks

**Before you begin**

Before you configure your server as a domain controller, verify whether or not:

- TCP/IP configuration settings for the server are correct, particularly those used for DNS name resolution. For more information, see Configure TCP/IP to use DNS.
- All existing disk volumes use the NTFS file system. Active Directory requires at least one NTFS volume in which to store the SYSVOL folder and its contents. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add a domain controller.

| **Before adding a domain controller role** | **Comments** |
|---|---|
| Determine which sites require a domain controller. | If your network is divided into sites, it is good practice to put at least one domain controller in each site to enhance network performance. When users log on to the network, a domain controller must be contacted as part of the logon process. If clients have to connect to a domain controller located in a different site, the logon process can take a long time. |
| Determine whether to add an additional domain controller over the network or through backup media taken from an existing domain controller. | With the Windows Server 2003 family, you can install Active Directory on member servers using a restored backup taken from a domain controller running Windows Server 2003. You can store this backup on any backup media (for example, tape, CD, or DVD) or a shared network resource. By using restored backup files to create an additional domain controller, you greatly reduce the network bandwidth used when you install Active Directory over a shared network resource. You still need network connectivity to replicate all new objects and recent changes for existing objects to the new domain controller. For more information about creating an additional domain controller from backup media, see Creating an additional domain controller. |
| Determine whether you want your new domain controller to host a global catalog. | A global catalog stores a full copy of all objects in the directory for its host domain and a partial copy of all objects for all other domains in the forest. To optimize network performance in a multiple-site environment, consider adding global catalogs for select sites. In a single-site environment, a single global catalog is usually sufficient to cover common Active Directory queries. However, in a multiple-site environment it is recommended that you use global catalogs in each site. For more information about when to add global catalogs in a multiple site environment, see Global catalogs and sites. |
| Domain controllers running Windows 2000 or Windows Server 2003 are available. | The domain must have at least one other domain controller running Windows 2000 or Windows Server 2003 to add an additional domain controller. Active Directory domain controllers cannot be configured as backup domain controllers (BDCs) for Windows NT domains. |

| | |
|---|---|
| Obtain the administrative credentials necessary to add a domain controller. | To add an additional domain controller to an existing domain, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. |
| Identify the DNS domain name of the Active Directory domain to which you want to add the additional domain controller. | You need to provide the DNS domain name when you use the Active Directory Installation Wizard. |

**Configuring your domain controller**

To configure a domain controller, start the **Configure Your Server Wizard** by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard.**

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**.

This section describes each of the steps in this process and outlines the required choices and decisions you will make as you configure your domain controller.

The following sections cover these configuration steps:

Summary of Selections

Using the Active Directory Installation Wizard

Completing the Configure Your Server Wizard

Removing the domain controller role

**Summary of Selections**

On the **Summary of Selections** page of the Configure Your Server Wizard, you can view and confirm the options that you have selected. If you selected **Domain Controller (Active Directory)** on the previous page, the following appears:

- **Run the Active Directory Installation Wizard to configure this server as a domain controller**

To apply the selections shown on the **Summary of Selections** page, click **Next**.

**Using the Active Directory Installation Wizard**

After you click **Next**, the Active Directory Installation Wizard starts automatically. If this is the first time you have installed Active Directory on a server, on the **Welcome** page of the Active Directory Installation Wizard, click **Active Directory Help**for more information about Active Directory.

After you finish reading about Active Directory, click **Next**. You can return to this page from any place in the wizard until you click **Finish** on the last page. On the **Operating System Compatibility** page, read the information and then click **Next**. If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

This section describes the following steps in the Active Directory Installation Wizard:

Domain Controller Type

Network Credentials

Additional Domain Controller

Database and Log Folders

Shared System Volume

Directory Services Restore Mode Administrator Password

Summary

**Domain Controller Type**
On the **Domain Controller Type** page, click **Domain controller for a new domain**.

After you finish, click **Next**.

**Network Credentials**
On the **Network Credentials** page, type the user name, password, and user domain of the user account that you want to use.

| Option | Comments |
|---|---|
| User name | Type the name of a user account that has the necessary administrative credentials. The user account must be a member of the Domain Admins group (in the forest root domain), or a member of the Enterprise Admins group, or must have been delegated the appropriate authority |
| Password | Type the password for the user account. This should always be a strong password. For more information, see Strong passwords. |
| Domain | Type the full DNS name of the domain in which this user name and password are valid. |

**Additional Domain Controller**
On the **Additional Domain Controller** page, type the full DNS name of the domain to which you want to add this domain controller. A full DNS name is also referred to as a fully qualified domain name (FQDN). Active Directory domains are named with DNS names and follow the same hierarchical structure of DNS.

After you finish, click **Next**.

**Database and Log Folders**
On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location. To avoid any problems with installing or removing Active Directory, it is important to confirm that you have sufficient disk space to host the directory database and log files. The Active Directory Installation Wizard requires 250 megabytes (MB) of disk space for the Active Directory database and 50 MB for the log files. It is recommended that you store these files on an NTFS partition.

After you finish, click **Next**.

**Shared System Volume**
On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location. The Sysvol folder must be stored on an NTFS volume since it contains files that are replicated between domain controllers in a domain or forest. These files include scripts, Windows NT 4.0 and earlier system policies, the NETLOGON and SYSVOL shares, and Group Policy settings.

After you finish, click **Next**.

**Directory Services Restore Mode Administrator Password**
On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the restore mode Administrator account for the server. You should use strong passwords for directory restore mode passwords. For more information, see Strong passwords.

**Important**

- You must know this password to restore a backup copy of the System State for this domain controller.

You use this password when the domain controller starts in Directory Services Restore Mode. If this is the first time you have installed Active Directory on a server, click **Active Directory Help** for more information about the restore mode password.

After you finish, click **Next**.

**Summary**
On the **Summary** page, review the information, and then click **Next**.

After you complete the installation, click **Finish**. To restart your computer and implement the changes, click **Restart Now**.

**Completing the Configure Your Server Wizard**
After your server restarts, the Configure Your Server Wizard displays the **This Server is Now a Domain Controller** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at systemroot\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

After you complete the Configure Your Server Wizard, be sure to visit Windows Update to download any additional updates that are available. For more information, see Windows Update.

In addition, you should also run the Security Configuration Wizard to further secure your domain controller. You can run Windows Firewall on a domain controller, but only if you run the Security Configuration Wizard to install and configure it. For more information see Security Configuration Wizard.

**Removing the domain controller role**
If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the domain controller role, you will uninstall Active Directory from this server. After Active Directory has been uninstalled, this server will no longer participate in replication of directory objects and domain-based user authentication requests.

To remove the domain controller role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the domain controller role** check box, click **Next**, and then follow the steps in the Active Directory Installation Wizard.

---

**Next steps: Completing additional tasks**
After you complete the Active Directory Installation Wizard, the server is configured as a domain controller. You can use it to store data, manage objects, and provide information to users, computers and applications. Up to this point, you have created a new domain or additional domain controller for an existing domain.

The following table lists some of the additional tasks that you might want to perform on your domain controller.

| Task | Purpose of task | Reference |
|---|---|---|
| Secure the new domain controller in a locked room. | To ensure that no one can physically access the domain controller. | Domain controllers; Securing Active Directory |
| Use strong encryption techniques. | To secure account password information stored on the new domain controller. | The system key utility |

**Creating a domain controller for a new forest**
Create a domain controller for a new forest when you want to upgrade a Windows NT domain to become the first domain in a new forest, segment your network for administrative autonomy, provide a boundary to administer data, isolate the scope of directory replication, or use a noncontiguous DNS namespace that is different from an existing forest on your network. For example, as seen in the following illustration, the microsoft.com forest is the first Active Directory domain in an organization.

This topic explains the basic steps that you must follow to configure a domain controller for a new forest in your organization.

This process involves using the Configure Your Server Wizard and the Active Directory Installation Wizard to install Active Directory on this server. When you have finished setting up your domain controller, you can complete additional configuration tasks.

This topic covers:

Before you begin

Configuring your domain controller

Next steps: Completing additional tasks

**Before you begin**

Before you configure your server as a domain controller, verify whether or not:

- TCP/IP configuration settings for the server are correct, particularly those used for DNS name resolution. For more information, see Configure TCP/IP to use DNS.
- All existing disk volumes use the NTFS file system. Active Directory requires at least one NTFS volume in which to store the SYSVOL folder and its contents. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add a domain controller for a new forest.

| **Before adding a new domain controller role for a new forest** | **Comments** |
|---|---|
| Verify that DNS is properly configured for your organization. | You need to confirm that DNS is properly configured on your network and that it supports dynamic updates and service (SRV) resource records. If you are setting up Active Directory for the first time in your organization, and you do not currently have a DNS infrastructure configured, the Active Directory Installation Wizard sets up and configures DNS on this server during the Active Directory installation process. Active Directory requires DNS to function and share the same hierarchical domain structure. For example, microsoft.com is a DNS domain and an Active Directory domain. |
| Obtain the administrative credentials necessary to create a forest. | To create a new forest, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. |

**Configuring your domain controller**
To configure a domain controller, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**.

This section describes each of the steps in this process and outlines the required choices and decisions you will make as you configure your domain controller. The following sections cover these configuration steps:

Summary of Selections

Using the Active Directory Installation Wizard

Completing the Configure Your Server Wizard

Removing the domain controller role

**Summary of Selections**
On the **Summary of Selections** page of the Configure Your Server Wizard, you can view and confirm the options that you have selected. If you selected **Domain Controller (Active Directory)** on the previous page, the following appears:

- **Run the Active Directory Installation Wizard to configure this server as a domain controller**

To apply the selections shown on the **Summary of Selections** page, click **Next**.

**Using the Active Directory Installation Wizard**
After you click **Next**, the Active Directory Installation Wizard starts automatically. If this is the first time you have installed Active Directory on a server, on the **Welcome** page of the Active Directory Installation Wizard click **Active Directory Help**for more information about Active Directory.

After you finish reading about Active Directory, click **Next**. You can return to this page from any place in the wizard until you click **Finish** on the last page. On the **Operating System Compatibility** page, read the information and then click **Next**. If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

This section describes the following steps in the Active Directory Installation Wizard:

Domain Controller Type

Create New Domain

New Domain Name

NetBIOS Domain Name

Database and Log Folders

Shared System Volume

DNS Registration Diagnostics

Permissions

Directory Services Restore Mode Administrator Password

Summary

**Domain Controller Type**
On the **Domain Controller Type** page, click **Domain controller for a new domain**.

After you finish, click **Next**.

**Create New Domain**
On the **Create New Domain** page, click **Domain in a new forest**.

After you finish, click **Next**.

**New Domain Name**
On the **New Domain Name** page, type the full DNS name for the new domain. Provide a full DNS name for the new Active Directory forest that you are about to create (for example, headquarters.example.microsoft.com). A full DNS name is also referred to as a fully qualified domain name (FQDN). Active Directory domains are named with DNS names and follow the same hierarchical structure of DNS. When choosing DNS names to use for your Active Directory forest, start with the registered DNS domain suffix that your organization has reserved for use on the Internet, such as microsoft.com.

Although Dcpromo.exe in Windows Server 2008 and Windows Server 2003 allows you to create a single-label DNS domain name, you should not use a single-label DNS name for a domain for several reasons. In Windows Server 2008 R2, Dcpromo.exe does not allow you to create a single-label DNS name for a domain. For more information, see http://go.microsoft.com/fwlink/?LinkId=92467.

After you finish, click **Next**.

**NetBIOS Domain Name**
On the **NetBIOS Domain Name** page, verify the NetBIOS name. Although Active Directory domains are named according to DNS naming standards, you still need to define a NetBIOS name when you create Active Directory domains. NetBIOS names should match the first label of the DNS domain name whenever possible. When the Active Directory domain has a first label DNS name that is different from its NetBIOS name, the FQDN is constructed using the DNS domain name, not the NetBIOS name. For example, if the first label in the full DNS domain name is "child" (child.microsoft.com is the FQDN) and the NetBIOS domain name is "sales", the FQDN remains "child.microsoft.com".

After you finish, click **Next**.

**Database and Log Folders**
On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location. To avoid any problems with installing or removing Active Directory, it is important to confirm that you have sufficient disk space to host the directory database and log files. The Active Directory Installation Wizard requires 250 megabytes (MB) of disk space for the Active Directory database and 50 MB for the log files. It is recommended that you store these files on an NTFS partition.

After you finish, click **Next**.

**Shared System Volume**
On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location. The Sysvol folder must be stored on an NTFS volume since it contains files that are replicated between domain controllers in a domain or forest. These files include scripts, Windows NT 4.0 and earlier system policies, the NETLOGON and SYSVOL shares, and Group Policy settings.

After you finish, click **Next**.

**DNS Registration Diagnostics**
On the **DNS Registration Diagnostics** page, verify that the DNS settings are correct.

If a diagnostic error appears under **Diagnostic Results**, click **Help** for more information about how to resolve the error.

After you finish, click **Next**.

**Permissions**
On the **Permissions** page, click the level of application compatibility that you want with pre-Windows 2000, Windows 2000, or Windows Server 2003 operating systems.

On servers running Windows NT 4.0 and earlier, read access for user and group information is assigned to anonymous users so that existing applications, including Microsoft BackOffice, SQL Server, and some non-Microsoft applications, function correctly. In Windows 2000 and the Windows Server 2003 family, members of the Anonymous Logon group have read access to this information only when the group is added to the Pre-Windows 2000 Compatible Access group.

| Option | Comments |
|---|---|

| | |
|---|---|
| Permissions compatible with pre-Windows 2000 server operating systems | Click this option if you want the Anonymous Logon group and the Everyone security groups to be added to the Pre-Windows 2000 Compatible Access group. |
| Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems | Click this option to prevent members of the Anonymous Logon group from gaining read access to user and group information. |

After you select one of these options, you can manually switch between the backward compatible and high-security settings on Active Directory objects. To do this, open Active Directory Users and Computers, and then add the Anonymous Logon security group to the pre-Windows 2000 Compatible Access security group.

After you finish, click **Next**.

**Directory Services Restore Mode Administrator Password**
On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the restore mode Administrator account for the server. You should use strong passwords for directory restore mode passwords. For more information, see Strong passwords.

**Important**

- You must know this password to restore a backup copy of the System State for this domain controller.

You use this password when the domain controller starts in Directory Services Restore Mode. If this is the first time you have installed Active Directory on a server, click Active Directory Help for more information about the restore mode password.

After you finish, click **Next**.

**Summary**
On the **Summary** page, review the information, and then click **Next**.

After you complete the installation, click **Finish**. To restart your computer and implement the changes, click **Restart Now**.

**Completing the Configure Your Server Wizard**
After your server restarts, the Configure Your Server Wizard displays the **This Server is Now a Domain Controller** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at systemroot\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

After you complete the Configure Your Server Wizard, be sure to visit Windows Update to download any additional updates that are available. For more information, see Windows Update.

In addition, you should also run the Security Configuration Wizard to further secure your domain controller. You can run Windows Firewall on a domain controller, but only if you run the Security Configuration Wizard to install and configure it. For more information see Security Configuration Wizard.

**Removing the domain controller role**
If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the domain controller role, you will uninstall Active Directory from this server. After Active Directory has been uninstalled, this server will no longer participate in replication of directory objects and domain-based user authentication requests.

To remove the domain controller role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the domain controller role** check box, click **Next**, and then follow the steps in the Active Directory Installation Wizard.

**Next steps: Completing additional tasks**
After you complete the Active Directory Installation Wizard, the server is configured as a domain controller. You can use it to store data, manage objects, and provide information to users, computers and applications. Up to this point, you have created a domain controller for a new forest.

The following table lists some of the additional tasks that you might want to perform on your domain controller.

| Task | Purpose of task | Reference |
|---|---|---|
| Secure the new domain controller in a locked room. | To ensure that no one can physically access the domain controller. | Domain controllers; Securing Active Directory |
| Use strong encryption techniques. | To secure account password information stored on the new domain controller. | The system key utility |
| Verify and authenticate the validity of each user. | To enhance forest-wide security by using public key cryptography. | Public Key Infrastructure |
| Require all domain users to use strong passwords. | To prevent unauthorized access to your organization. | Strong passwords |
| Enable audit policy. | To receive notification of actions that could pose a security risk. | Auditing Policy |
| Enforce account lockouts on user accounts. | To decrease the possibility of an attacker compromising your domain through repeated logon attempts. | User and computer accounts |
| Enforce password history on user accounts. | To decrease the possibility of an attacker compromising your domain. | Enforce password history |
| Enforce minimum and maximum password ages on user accounts. | To decrease the possibility of an attacker compromising your domain. | Minimum password age; Maximum password age |
| Implement SID Filtering. | To prevent attacks from malicious users who might try to grant elevated user rights to another user account. | "Using Security Identifier (SID) Filtering to Prevent Elevation of Privilege Attacks" at the Microsoft Web site. (http://www.microsoft.com/) |
| Implement smart cards. | To provide tamper-resistant user authentication and e-mail security. | Smart cards overview |
| Restrict user, group, and computer access to shared resources and filter Group Policy settings. | To secure resources. | Group types |
| Create forest trusts (as appropriate) | To manage the security relationship between two forests, and simplify security administration and authentication across forests. | Forest trusts |
| Assign user rights to new security groups. | To specifically define the administrative role of members in the domain. | Group types |

**Creating a domain controller for a new child domain**
Create a domain controller for a new child domain when you want to create a domain that shares a contiguous namespace with one or more existing domains. This means that the name of the new domain contains the full name of the parent domain. For example, as seen in the following illustration, child.microsoft.com is a child domain of microsoft.com. As a best practice, create new domains as children of the forest root domain.

microsoft.com forest

This topic explains the basic steps that you must follow to configure a domain controller for a new child domain in your organization.

This process involves using the Configure Your Server Wizard and the Active Directory Installation Wizard to install Active Directory on this server. When you have finished setting up your domain controller, you can complete additional configuration tasks.

This topic covers:

Before you begin

Configuring your domain controller

Next steps: Completing additional tasks

**Before you begin**

Before you configure your server as a domain controller, verify whether or not:

- TCP/IP configuration settings for the server are correct, particularly those used for DNS name resolution. For more information, see Configure TCP/IP to use DNS.
- All existing disk volumes use the NTFS file system. Active Directory requires at least one NTFS volume in which to store the SYSVOL folder and its contents. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add a domain controller.

| Before adding a domain controller | Comments |
|---|---|

| | |
|---|---|
| Identify the DNS domain name of the Active Directory domain to which you want to add the domain controller. | You need to provide the DNS domain name for the parent domain of this new child domain. |
| Verify that the network speed is adequate when installing Active Directory. | The server on which you want to install Active Directory and create a child domain should have access to the network over a high-speed connection. |
| Determine which sites require a domain controller. | If your network is divided into sites, it is good practice to put at least one domain controller in each site to enhance network performance. When users log on to the network, a domain controller must be contacted as part of the logon process. If clients have to connect to a domain controller located in a different site, the logon process can take a long time. |
| Determine whether you want your new domain controller to host a global catalog. | A global catalog stores a copy of all Active Directory objects in a forest on a domain controller. The global catalog stores a full copy of all objects in the directory for its host domain and a partial copy of all objects for all other domains in the forest. To optimize network performance in a multiple-site environment, consider adding global catalogs for select sites. In a single-site environment, a single global catalog is usually sufficient to cover common Active Directory queries. However, in a multiple-site environment it is recommended that you use global catalogs in each site. For more information about when to add global catalogs in a multiple site environment, see Global catalogs and sites. |
| Obtain the administrative credentials necessary to create a child domain. | To add a new child domain, you must be a member of the Domain Admins group (in the parent domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. |

**Configuring your domain controller**

To configure a domain controller, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**.

This section describes each of the steps in this process and outlines the required choices and decisions you will make as you configure your domain controller.

The following sections cover these configuration steps:

Summary of Selections

Using the Active Directory Installation Wizard

Completing the Configure Your Server Wizard

Removing the domain controller role

**Summary of Selections**

On the **Summary of Selections** page of the Configure Your Server Wizard, you can view and confirm the options that you have selected. If you selected **Domain Controller (Active Directory)** on the previous page, the following appears:

- **Run the Active Directory Installation Wizard to configure this server as a domain controller**

To apply the selections shown on the **Summary of Selections** page, click **Next**.

**Using the Active Directory Installation Wizard**
After you click **Next**, the Active Directory Installation Wizard starts automatically. If this is the first time you have installed Active Directory on a server, on the **Welcome** page of the Active Directory Installation Wizard, click **Active Directory Help**for more information about Active Directory.

After you finish reading about Active Directory, click **Next**. You can return to this page from any place in the wizard until you click **Finish** on the last page. On the **Operating System Compatibility** page, read the information and then click **Next**. If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

This section describes the following steps in the Active Directory Installation Wizard:

Domain Controller Type

Create New Domain

Network Credentials

Child Domain Installation

NetBIOS Domain Name

Database and Log Folders

Shared System Volume

DNS Registration Diagnostics

Permissions

Directory Services Restore Mode Administrator Password

Summary

**Domain Controller Type**
On the **Domain Controller Type** page, click **Domain controller for a new domain**.

After you finish, click **Next**.

**Create New Domain**
On the **Create New Domain** page, click **Child domain in an existing domain tree**.

After you finish, click **Next**.

**Network Credentials**
On the **Network Credentials** page, type the user name, password, and domain of the user account that you want to use.

| Option | Comments |
|---|---|
| User name | Type the name of a user account that has the necessary administrative credentials. The user account must be a member of the Domain Admins group (in the parent domain), or a member of the Enterprise Admins group, or must have been delegated the appropriate authority. |
| Password | Type the password for the user account. This should always be a strong password. For more information, see Strong passwords. |
| Domain | Type the full DNS name of the domain in which this user name and password are valid. |

After you finish, click **Next**.

**Child Domain Installation**
On the **Child Domain Installation** page, verify the parent domain, and then the name for the new child domain. Active Directory domains are named with DNS names and follow the same hierarchical structure of DNS. When choosing DNS names to use for your child domain, consider names with either geographical or divisional scope within your organization (for

example, newyork.microsoft.com or sales.microsoft.com).

Following the DNS standards, domain names are fully qualified domain names (FQDN), which consist of the name of the domain appended to the names of the parent domains and root domains using the dot (.) character format. For example, an Active Directory domain named "child" and a parent domain named "microsoft.com" have an FQDN (also referred to as a complete DNS name) of "child.microsoft.com".

After you finish, click **Next**.

**NetBIOS Domain Name**

On the **NetBIOS Domain Name** page, verify the NetBIOS name. Although Active Directory domains are named according to DNS naming standards, you still need to define a NetBIOS name when you create Active Directory domains. NetBIOS names should match the first label of the DNS domain name whenever possible. When the Active Directory domain has a first label DNS name that is different from its NetBIOS name, the FQDN is constructed using the DNS domain name, not the NetBIOS name. For example, if the first label in the full DNS domain name is "child" (child.microsoft.com is the FQDN) and the NetBIOS domain name is "sales", the FQDN remains "child.microsoft.com".

**Database and Log Folders**

On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click Next. To avoid any problems with installing or removing Active Directory, it is important to confirm that you have sufficient disk space to host the directory database and log files. The Active Directory Installation Wizard requires 250 megabytes (MB) of disk space for the Active Directory database and 50 MB for the log files. It is recommended that you store these files on an NTFS partition.

After you finish, click **Next**.

**Shared System Volume**

On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location. The Sysvol folder must be stored on an NTFS volume since it contains files that are replicated between domain controllers in a domain or forest. These files include scripts, Windows NT 4.0 and earlier system policies, the NETLOGON and SYSVOL shares, and Group Policy settings.

After you finish, click **Next**.

**DNS Registration Diagnostics**

On the **DNS Registration Diagnostics** page, verify that the DNS settings are correct.

If a diagnostic error appears under **Diagnostic Results**, click **Help** for more information about how to resolve the error.

After you finish, click **Next**.

**Permissions**

On the **Permissions** page, click the level of application compatibility that you want with pre-Windows 2000, Windows 2000, or Windows Server 2003 operating systems.

On servers running Windows NT 4.0 and earlier, read access for user and group information is assigned to anonymous users so that existing applications, including Microsoft BackOffice, SQL Server, and some non-Microsoft applications, function correctly. In Windows 2000 and the Windows Server 2003 family, members of the Anonymous Logon group have read access to this information only when the group is added to the Pre-Windows 2000 Compatible Access group.

| Option | Comments |
|---|---|
| Permissions compatible with pre-Windows 2000 server operating systems | Click this option if you want the Anonymous Logon group and the Everyone security groups to be added to the Pre-Windows 2000 Compatible Access group. |
| Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems | Click this option to prevent members of the Anonymous Logon group from gaining read access to user and group information. |

After you select one of these options, you can manually switch between the backward compatible and high-security settings on Active Directory objects. To do this, open Active Directory Users and Computers, and then add the Anonymous Logon security group to the pre-Windows 2000 Compatible Access security group.

After you finish, click **Next**.

**Directory Services Restore Mode Administrator Password**

On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the restore mode Administrator account for the server. You should use strong passwords for directory restore mode passwords. For more information, see Strong passwords.

**Important**

- You must know this password to restore a backup copy of the System State for this domain controller.

You use this password when the domain controller starts in Directory Services Restore Mode. If this is the first time you have installed Active Directory on a server, click **Active Directory Help** for more information about the restore mode password.

After you finish, click **Next**.

**Summary**
On the **Summary** page, review the information, and then click **Next**.

After you complete the installation, click **Finish**. To restart your computer and implement the changes, click **Restart Now**.

**Completing the Configure Your Server Wizard**
After your server restarts, the Configure Your Server Wizard displays the **This Server is Now a Domain Controller** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at systemroot\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

After you complete the Configure Your Server Wizard, be sure to visit Windows Update to download any additional updates that are available. For more information, see Windows Update.

In addition, you should also run the Security Configuration Wizard to further secure your domain controller. You can run Windows Firewall on a domain controller, but only if you run the Security Configuration Wizard to install and configure it. For more information see Security Configuration Wizard.

**Removing the domain controller role**
If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the domain controller role, you will uninstall Active Directory from this server. After Active Directory has been uninstalled, this server will no longer participate in replication of directory objects and domain-based user authentication requests.

To remove the domain controller role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the domain controller role** check box, click **Next**, and then follow the steps in the Active Directory Installation Wizard.

**Next steps: Completing additional tasks**
After you complete the Active Directory Installation Wizard, the server is configured as a domain controller. You can use it to store data, manage objects, and provide information to users, computers and applications. Up to this point, you have created a new domain or additional domain controller for an existing domain.

The following table lists some of the additional tasks that you might want to perform on your domain controller.

| Task | Purpose of task | Reference |
|---|---|---|
| Secure the new domain controller in a locked room. | To ensure that no one can physically access the domain controller. | Domain controllers; Securing Active Directory |

| | | |
|---|---|---|
| Use strong encryption techniques. | To secure account password information stored on the new domain controller. | The system key utility |
| Require all domain users to use strong passwords. | To prevent unauthorized access to your organization. | Strong passwords |
| Enable audit policy. | To receive notification of actions that could pose a security risk. | Auditing Policy |
| Enforce account lockouts on user accounts. | To decrease the possibility of an attacker compromising your domain through repeated logon attempts. | User and computer accounts |
| Enforce password history on user accounts. | To decrease the possibility of an attacker compromising your domain. | Enforce password history |
| Enforce minimum and maximum password ages on user accounts. | To decrease the possibility of an attacker compromising your domain. | Minimum password age; Maximum password age |
| Implement SID Filtering. | To prevent attacks from malicious users who might try to grant elevated user rights to another user account. | "Using Security Identifier (SID) Filtering to Prevent Elevation of Privilege Attacks" at the Microsoft Web site.(http://www.microsoft.com/) |
| Implement smart cards. | To provide tamper-resistant user authentication and e-mail security. | Smart cards overview |
| Restrict user, group, and computer access to shared resources and filter Group Policy settings. | To secure resources. | Group types |
| Assign user rights to new security groups. | To specifically define the administrative role of members in the domain. | Group types |

**Creating a domain controller for a new domain tree**

Create a domain controller for a new domain tree when you want to create a domain that has a DNS namespace that is not related to the other domains in the forest. This means that the name of the tree root domain (and all of its children) does not have to contain the full name of the parent domain. A forest can contain one or more domain trees. For example, as seen in the following illustration, msn.com is a new domain tree in the microsoft.com forest.

This topic explains the basic steps that you must follow to configure a domain controller for a new domain tree in your organization.

This process involves using the Configure Your Server Wizard and the Active Directory Installation Wizard to install Active

Directory on this server. When you have finished setting up your domain controller, you can complete additional configuration tasks.

This topic covers:

Before you begin

Configuring your domain controller

Next steps: Completing additional tasks

**Before you begin**

Before you configure your server as a domain controller, verify whether or not:

- TCP/IP configuration settings for the server are correct, particularly those used for DNS name resolution. For more information, see Configure TCP/IP to use DNS.
- All existing disk volumes use the NTFS file system. Active Directory requires at least one NTFS volume in which to store the SYSVOL folder and its contents. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.
- The following table lists the information that you need to know before you add a domain controller.

| **Before adding a domain controller role** | **Comments** |
|---|---|
| Verify that the network speed is adequate when installing Active Directory. | The server on which you want to install Active Directory should have access to the network over a high-speed connection. |
| Determine whether you want your new domain controller to host a global catalog. | A global catalog stores a copy of all Active Directory objects in a forest on a domain controller. The global catalog stores a full copy of all objects in the directory for its host domain and a partial copy of all objects for all other domains in the forest. To optimize network performance in a multiple-site environment, consider adding global catalogs for select sites. In a single-site environment, a single global catalog is usually sufficient to cover common Active Directory queries. However, in a multiple-site environment it is recommended that you use global catalogs in each site. For more information about when to add global catalogs in a multiple site environment, see Global catalogs and sites. |
| Obtain the administrative credentials necessary to add a new domain tree. | To create a new domain tree, you must be a member of the Domain Admins group (in the forest root domain) or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. |

**Configuring your domain controller**

To configure a domain controller, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**.

This section describes each of the steps in this process and outlines the required choices and decisions you will make as you configure your domain controller. The following sections cover these configuration steps:

Summary of Selections

Using the Active Directory Installation Wizard

Completing the Configure Your Server Wizard

Removing the domain controller role

**Summary of Selections**
On the Summary of Selections page of the Configure Your Server Wizard, you can view and confirm the options that you have selected. If you selected **Domain Controller (Active Directory)** on the previous page, the following appears:

- **Run the Active Directory Installation Wizard to configure this server as a domain controller**

To apply the selections shown on the **Summary of Selections** page, click **Next**.

**Using the Active Directory Installation Wizard**
After you click **Next**, the Active Directory Installation Wizard starts automatically. If this is the first time you have installed Active Directory on a server, on the **Welcome** page of the Active Directory Installation Wizard, click **Active Directory Help**for more information about Active Directory.

After you finish reading about Active Directory, click **Next**. You can return to this page from any place in the wizard until you click **Finish** on the last page. On the **Operating System Compatibility** page, read the information and then click **Next**. If this is the first time you have installed Active Directory on a server running Windows Server 2003, click **Compatibility Help** for more information.

This section describes the following steps in the Active Directory Installation Wizard:

Domain Controller Type

Create New Domain

Network Credentials

New Domain Tree

NetBIOS Domain Name

Database and Log Folders

Shared System Volume

DNS Registration Diagnostics

Permissions

Directory Services Restore Mode Administrator Password

Summary

**Domain Controller Type**
On the **Domain Controller Type** page, click Domain controller for a new domain.

After you finish, click **Next**.

**Create New Domain**
On the **Create New Domain** page, click **Domain tree in an existing forest**.

After you finish, click **Next**.

**Network Credentials**
On the **Network Credentials** page, type the user name, password, and user domain of the user account that you want to use.

| Option | Comments |
|---|---|
| User name | Type the name of a user account that has the necessary administrative credentials. The user account must be a member of the Domain Admins group (in the forest root domain), or a member of the Enterprise Admins group, or must have been delegated the appropriate authority. |
| Password | Type the password for the user account. This should always be a strong password. For more information, see Strong passwords. |
| Domain | Type the full DNS name of the domain in which this user name and password are valid. |

**New Domain Name**
On the **New Domain Name** page, type the full DNS name for the new domain tree. Provide a full DNS name for the new domain tree that you want to create. Active Directory domains are named with DNS names and follow the same hierarchical structure of DNS.

Following the DNS standards, domain names are fully qualified domain names (FQDN), which consist of the name of the domain appended to the names of the parent domains and root domains using the dot (.) character format.

Although Dcpromo.exe in Windows Server 2008 and Windows Server 2003 allows you to create a single-label DNS domain name, you should not use a single-label DNS name for a domain for several reasons. In Windows Server 2008 R2, Dcpromo.exe does not allow you to create a single-label DNS name for a domain. For more information, see http://go.microsoft.com/fwlink/?LinkId=92467.

Although Dcpromo.exe in Windows Server 2008 and Windows Server 2003 allows you to create a single-label DNS domain name, you should not use a single-label DNS name for a domain for several reasons. In Windows Server 2008 R2, Dcpromo.exe does not allow you to create a single-label DNS name for a domain. For more information, see http://go.microsoft.com/fwlink/?LinkId=92467.

After you finish, click **Next**.

**NetBIOS Domain Name**
On the **NetBIOS Domain Name** page, verify the NetBIOS name. Although Active Directory domains are named according to DNS naming standards, you still need to define a NetBIOS name when you create Active Directory domains. NetBIOS names should match the first label of the DNS domain name whenever possible. When the Active Directory domain has a first label DNS name that is different from its NetBIOS name, the FQDN is constructed using the DNS domain name, not the NetBIOS name. For example, if the first label in the full DNS domain name is "child" (child.microsoft.com is the FQDN) and the NetBIOS domain name is "sales", the FQDN remains "child.microsoft.com".

After you finish, click **Next**.

**Database and Log Folders**
On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location. To avoid any problems with installing or removing Active Directory, it is important to confirm that you have sufficient disk space to host the directory database and log files. The Active Directory Installation Wizard requires 250 megabytes (MB) of disk space for the Active Directory database and 50 MB for the log files. It is recommended that you store these files on an NTFS partition.

After you finish, click **Next**.

**Shared System Volume**
On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location. The Sysvol folder must be stored on an NTFS volume since it contains files that are replicated between domain controllers in a domain or forest. These files include scripts, Windows NT 4.0 and earlier system policies, the NETLOGON and SYSVOL shares, and Group Policy settings.

After you finish, click **Next**.

**DNS Registration Diagnostics**

On the **DNS Registration Diagnostics** page, verify the DNS settings are correct.

If a diagnostic error appears under **Diagnostic Results**, click **Help** for more information about how to resolve the error.

After you finish, click **Next**.

**Permissions**
On the **Permissions** page, click the level of application compatibility that you want with pre-Windows 2000 and Windows 2000 or Windows Server 2003 operating systems.

On servers running Windows NT 4.0 and earlier, read access for user and group information is assigned to anonymous users so that existing applications, including Microsoft BackOffice, SQL Server, and some non-Microsoft applications, function correctly. In Windows 2000 and the Windows Server 2003 family, members of the Anonymous Logon group have read access to this information only when the group is added to the Pre-Windows 2000 Compatible Access group.

| Option | Comments |
|---|---|
| Permissions compatible with pre-Windows 2000 server operating systems | Click this option if you want the Anonymous Logon group and the Everyone security groups to be added to the Pre-Windows 2000 Compatible Access group. |
| Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems | Click this option to prevent members of the Anonymous Logon group from gaining read access to user and group information. |

After you select one of these options, you can manually switch between the backward compatible and high-security settings on Active Directory objects. To do this, open Active Directory Users and Computers, and then add the Anonymous Logon security group to the pre-Windows 2000 Compatible Access security group.

**Directory Services Restore Mode Administrator Password**
On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password that you want to assign to the restore mode Administrator account for the server. You should use strong passwords for directory restore mode passwords. For more information, see Strong passwords.

**Important**

- You must know this password to restore a backup copy of the System State for this domain controller.

You use this password when the domain controller starts in Directory Services Restore Mode. If this is the first time you have installed Active Directory on a server, click **Active Directory Help** for more information about the restore mode password.

After you finish, click **Next**.

**Summary**
On the **Summary** page, review the information, and then click **Next**.

After you complete the installation, click **Finish**. To restart your computer and implement the changes, click **Restart Now**.

**Completing the Configure Your Server Wizard**
After your server restarts, the Configure Your Server Wizard displays the **This Server is Now a Domain Controller** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at systemroot\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

After you complete the Configure Your Server Wizard, be sure to visit Windows Update to download any additional updates that are available. For more information, see Windows Update.

In addition, you should also run the Security Configuration Wizard to further secure your domain controller. You can run Windows Firewall on a domain controller, but only if you run the Security Configuration Wizard to install and configure it. For more information see Security Configuration Wizard.

**Removing the domain controller role**
If you need to reconfigure your server for a different role, you can remove existing server roles. By removing the domain controller role, you will uninstall Active Directory from this server. After Active Directory has been uninstalled, this server will no longer participate in replication of directory objects and domain-based user authentication requests.

To remove the domain controller role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Domain Controller (Active Directory)**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the domain controller role** check box, click **Next**, and then follow the steps in the Active Directory Installation Wizard.

**Next steps: Completing additional tasks**

After you complete the Active Directory Installation Wizard, the server is configured as a domain controller. You can use it to store data, manage objects, and provide information to users, computers and applications. Up to this point, you have created a new domain or additional domain controller for an existing domain.

The following table lists some of the additional tasks that you might want to perform on your domain controller.

| Task | Purpose of task | Reference |
|---|---|---|
| Secure the new domain controller in a locked room. | To ensure that no one can physically access the domain controller. | Domain controllers; Securing Active Directory |
| Use strong encryption techniques. | To secure account password information stored on the new domain controller. | The system key utility |
| Require all domain users to use strong passwords. | To prevent unauthorized access to your organization. | Strong passwords |
| Enable audit policy. | To receive notification of actions that could pose a security risk. | Auditing Policy |
| Enforce account lockouts on user accounts. | To decrease the possibility of an attacker compromising your domain through repeated logon attempts. | User and computer accounts |
| Enforce password history on user accounts. | To decrease the possibility of an attacker compromising your domain. | Enforce password history |
| Enforce minimum and maximum password ages on user accounts. | To decrease the possibility of an attacker compromising your domain. | Minimum password age; Maximum password age |
| Implement SID Filtering. | To prevent attacks from malicious users who might try to grant elevated user rights to another user account. | "Using Security Identifier (SID) Filtering to Prevent Elevation of Privilege Attacks" at the Microsoft Web site.(http://www.microsoft.com/) |
| Implement smart cards. | To provide tamper-resistant user authentication and e-mail security. | Smart cards overview |
| Restrict user, group, and computer access to shared resources and filter Group Policy settings. | To secure resources. | Group types |
| Assign user rights to new security groups. | To specifically define the administrative role of members in the domain. | Group types |

# DNS server role: Configuring a DNS server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DNS server role: Configuring a DNS server**
Domain Name System (DNS) servers host records of a distributed DNS database and use the records they host to resolve DNS name queries sent by DNS client computers, such as queries for the names of Web sites or computers in your network or on the Internet. If you plan to use this computer to answer DNS queries for computers in your network, then add the DNS server role.

This topic explains the basic steps that you must follow to configure a DNS server for either a small organization or a branch office in a large organization. For both scenarios, this topic explains the basic steps you must follow to configure a DNS server and configure it with a DNS zone for your network. This topic will also cover how to forward queries for external resources to a DNS server either run by an Internet service provider (ISP), as in the case of a small organization, or run by the central office of a large organization, as in the case of the branch office.

This process involves using the Configure Your Server Wizard, the Configure a New DNS Server Wizard, and Manage Your Server to configure the server as a DNS server. When you have finished setting up a DNS server, you can complete additional configuration tasks, depending on how you want to use the DNS server.

**Note**

- A DNS server is not usually necessary in a small business because the Windows Internet Name Service (WINS) name resolution method is used to locate network resources, and resources on the Internet are located using the DNS servers run by an ISP. However, as more networks are becoming integrated with the Internet, DNS is becoming more common in small networks.

  Using DNS in your network does not necessarily require that you administer a DNS infrastructure. If you have a small network in which information is maintained dependably, then you can choose to have your DNS namespace administered by a different organization that specializes in DNS administration, such as your government or an ISP. In this case, the different organization will host and administer your DNS information for you or integrate your computers with an existing DNS server hosted in its network.

This topic covers:

Before you begin

Configuring your DNS server

Next steps: Completing additional tasks

**Before you begin**
Before you configure your computer as a DNS server, verify whether or not:

- The operating system is configured correctly. In the Windows Server 2003 family, the DNS Server service depends on the appropriate configuration of the operating system and its services, such as TCP/IP. If you have a new installation of a Windows Server 2003 operating system, then you can use the default service settings. No further action is necessary. If you upgraded to a Windows Server 2003 operating system, or if you want to verify that your service settings are configured correctly for the best performance and security, then see Default settings for services.

- All available disk space is allocated. You can use Disk Management or DiskPart.exe to create a new partition from unallocated space. For more information, see Create a partition or logical drive.

- All existing disk volumes use the NTFS file system. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.

- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.

- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see

Security Configuration Wizard Overview.

The following table lists the information that you need to know before you add a DNS server role.

| **For all organizations** | |
|---|---|
| **Before adding a DNS server role** | **Comments** |
| Determine if you are adding the DNS server role to support Active Directory. | If you are going to deploy Active Directory, then the DNS servers used to support Active Directory will be installed and configured automatically by the Active Directory Installation Wizard. For more information, see Typical setup for a first server and Domain controller role: Configuring a domain controller. |
| Inventory the security policies of your network and company to see how they can be maintained when broadcasting DNS data over the Internet. | DNS was originally designed as an open protocol and is therefore vulnerable to attackers. Windows Server 2003 DNS provides features for a very secure DNS infrastructure. To configure DNS to support these security policies, have your company's security policies available when designing and deploying your DNS server, zones, and resource records. For more information, see Security information for DNS. |
| Review the DNS checklist. | Review the information in Checklist: Installing a DNS server. |
| **For a small organization** | |
| **Before adding a DNS server role** | **Comments** |
| Choose the first DNS domain name for your company. | Choosing the first DNS domain name for your company involves selecting a domain name that is unique within the DNS namespace of the Internet.<br><br>If your organization has a Web site, use your existing Web site name as a starting point for your DNS domain name. If the name of your Web site is www.humongousinsurance.com, create the first domain name as an extension of this name using the subdomain name *corp*, for example, corp.humongousinsurance.com. |
| Check with your ISP to determine that your network Internet Protocol (IP) addresses are registered with an Internet registrar. | In order for your DNS deployment to work over the Internet, both the IP addresses and DNS domain name used by your network must be registered with an authorized Internet registrar. These organizations are responsible for assigning IP addresses and DNS domain names and keeping public records of the assignments.<br><br>If you are connected to the Internet, then your company's network is most likely a subnet of your ISP's network. In this case, the IP addresses of the subnet will have been registered with the Internet registrar. |
| Register your DNS domain name with an Internet registrar. | Register the DNS domain name you will use for your company even if you are deploying DNS in a private network. If you do not register the name and later attempt to use it on the Internet, or connect to a network that is connected to the Internet, you might find that the name is unavailable because some other company has registered the name. You can also have your ISP register your DNS domain name for you.<br><br>When deciding on your DNS domain name, search the Internet to see what domain names are available using one of the Web sites provided by an authorized Internet registration authority. To search the Internet for available domain names, see the Internet Network Information Center (InterNIC) Web site. Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here. |
| Understand that the name of the first DNS zone this DNS server will host is the same as the DNS domain name you registered. | When you configure the DNS server role, you will define the first DNS zone that this DNS server will host using the domain name of the DNS domain of your network, such as corp.humongousinsurance.com. |

| | |
|---|---|
| Obtain the IP address of one or more DNS servers hosted by your ISP to use as a forwarder. | You will configure the DNS server with a forwarder to send queries for names that are not in your network to a DNS server at your ISP. |
| **For a branch office in a large organization** | |
| **Before adding a DNS server role** | **Comments** |
| Obtain the DNS domain name for your network from your central office. | The first DNS domain name for your branch office is a subdomain of a domain used in the network at your central office. For example, if your central office uses the domain name corp.humongousinsurance.com, the DNS domain name for your branch office could be seattle.corp.humongousinsurance.com. Always confirm that your DNS domain name has been properly delegated from the central office. |

**Configuring your DNS server**

To configure a DNS server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Configure Your Server Wizard**.

On the **Server Role** page, click **DNS server**, and then click **Next**.

This section covers:

Summary of Selections

Setting a static DNS server IP address

Using the Configure a DNS Server Wizard

Completing the Configure Your Server Wizard

Removing the DNS server role

**Summary of Selections**

On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected **DNS Server** on the **Server Role** page, the following appears:

- **Install DNS Server**

- **Run the Configure a DNS Server Wizard to configure DNS**

If the **Summary of Selections** page lists these two items, click **Next**. If the **Summary of Selections** page does not list these two items, click **Back** to return to the **Server Role** page, click **DNS server**, and then click **Next**.

**Setting a static DNS server IP address**

After you click **Next**, the Configure Your Server Wizard installs the DNS Server service. During the installation of the DNS Server service, the Configure Your Server Wizard determines whether the IP address for this server is static or is configured automatically. DNS servers are located by DNS clients by using static IP addresses, and an IP address that is automatically configured can cause problems for DNS clients when the IP address changes.

If this server is currently configured to obtain its IP address automatically, the **Configuring Components** page of the Windows Components Wizard appears, and prompts you to configure this server with a static IP address. In the **Local Area Connection Properties** dialog box, click **Internet Protocol (TCP/IP)**, and then click **Properties**. In the **Internet Protocols (TCP/IP) Properties** dialog box, click **Use the following IP address**, and then type the static IP address, subnet mask, and default gateway for this server. In **Preferred DNS server**, type the IP address of this server. In **Alternate DNS server**, type the

IP address of the DNS server hosted by your ISP or central office. When you finish setting up the static addresses for your DNS server, click **OK**, and then click **Close**.

### Notes

- For a small organization, the static IP address for this server will be used to register the DNS domain name for your company with an authorized Internet registrar. The Internet registrar will map the DNS domain name for your company with the IP address so that computers on the Internet looking for computers in your network will know the IP address of the DNS server for your network.

- For a branch office, the static IP address for this server will be used in the domain name delegation configured on a DNS server at the central office of your organization. Computers in your organization and on the Internet looking for computers in your network will use the IP address of the DNS server for your network. For this reason, it is very important that you do not change the IP address of this server after you have added the DNS server role.

#### Using the Configure a DNS Server Wizard

After you click **Close**, the Configure a DNS Server Wizard starts. If you cancel the Configure a DNS Server Wizard, the DNS Server service remains installed, but it cannot resolve names until you configure DNS settings. If you choose to configure DNS settings later, you can do so using the DNS console.

This section describes the following steps in the Configure a DNS Server Wizard:

Select Configuration Action

Primary Server Location

Zone Name

Dynamic Update

Forwarders

Completing the Configure a DNS Server Wizard

#### Select Configuration Action

On the **Select Configuration Action** page, select **Create a forward lookup zone**, and then click **Next**.

#### Primary Server Location

To specify that this DNS server will host a DNS zone that contains DNS resource records for your network resources, on the **Primary Server Location** page, select **This server maintains the zone**, and then click **Next**.

#### Zone Name

On the **Zone Name** page, in **Zone name**, specify the name of the DNS zone for your network, and then click **Next**. The name of the zone is the same as the name of the DNS domain for your small organization or branch office.

#### Dynamic Update

On the **Dynamic Update** page, click **Allow both nonsecure and secure dynamic updates**, and then click **Next**. This will automate the update of the DNS resource records for the resources in your network.

#### Forwarders

On the **Forwarders** page, click **Yes, it should forward queries to DNS servers with the following IP addresses**, and then click **Next**. By selecting this configuration, you forward all DNS queries for DNS names outside of your network to a DNS server at either your ISP or central office. Type one or more IP addresses used by DNS servers run by either your ISP or central office.

#### Completing the Configure a DNS Server Wizard

On the **Completing the Configure a DNS Server Wizard** page of the Configure a DNS Server Wizard, you can click **Back** to change any of the settings. To apply your selections, click **Finish**.

#### Completing the Configure Your Server Wizard

After you complete the Configure a DNS Server Wizard, the Configure Your Server Wizard displays the **This Server is Now a DNS Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

To verify that your server is secure and has the most recent updates, do the following:

1. Run Windows Update. For more information, see Windows Update.

2. Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

**Removing the DNS server role**

If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the DNS server role from this server you should configure the TCP/IP settings of this server, and any clients using this server as their DNS server, with the IP address of a different DNS server.

To remove the DNS server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **DNS server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the DNS server role** check box, and then click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. On the **DNS Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

After you complete the Configure Your Server Wizard and the Configure a New DNS Server Wizard, your server is ready for use as a DNS server. Up to this point, you have completed the following tasks:

- Set the DNS server to use a static IP address.

- Configured the DNS zone for your network.

- Configured the DNS server to forward all DNS queries for DNS names outside your network to a DNS server at your ISP or central office.

When you complete the Configure Your Server Wizard, it automatically installs the DNS console, which you use to manage your DNS server. To open DNS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DNS**.

The following table lists some of the additional tasks that you might want to perform on your DNS server.

| Tasks | Purpose of task | Reference |
|---|---|---|
| Configure the computers in your network to use this DNS server as their preferred DNS server. | To connect your DNS clients to the DNS server and dynamically update the zone with the DNS resource records required for name resolution. | Configure TCP/IP to use DNS; Dynamic update |
| If this server is a multihomed computer, configure the DNS Server service to respond to queries on the local network IP address only. | To secure your DNS server from external queries. For example, a server acting as proxy server can have two network adapters, one for the intranet and one for the Internet. If that server is also running the Windows Server 2003 DNS Server service, you can configure the service to only use the intranet network adapter. By configuring this server to respond only to queries on the local network IP address, you will secure the server from unwanted Internet queries. | Restrict a DNS server to listen only on selected addresses |

| | | |
|---|---|---|
| Verify the server configuration. | To ensure that the DNS configuration performed using the Configure a New DNS Server Wizard is correct. | Verifying server configuration |
| Verify DNS server responsiveness using the **nslookup** command. | To verify that the DNS server is able to resolve DNS queries for resources in your network. | Verify DNS server responsiveness using the nslookup command |
| Verify that a resource records exist in DNS. | To verify that the computers that use the DNS server can be located on the network. | To verify A resource records exist in DNS |
| Configure ports to allow remote administration. | To manage the DNS server from other computers on the network. | Windows Firewall Settings |

# DHCP server role: Configuring a DHCP server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DHCP server role: Configuring a DHCP server**

DHCP servers centrally manage IP addresses and related information and provide it to clients automatically. This allows you to configure client network settings at a server, instead of configuring them on each client computer. If you want this computer to distribute IP addresses to clients, then configure this computer as a DHCP server.

This topic explains the basic steps that you must follow to configure a DHCP server. When you have finished setting up a basic DHCP server, you can complete additional configuration tasks, depending on how you want to use the DHCP server.

This topic covers:

Before you begin

Configuring your DHCP server

Next steps: Completing additional tasks

**Before you begin**

Before you configure your computer as a DHCP server, verify that:

- You are familiar with DHCP concepts such as scopes, leases, and options. For more information, see DHCP terminology.
- The operating system is configured correctly. In the Windows Server 2003 family, DHCP depends on the appropriate configuration of the operating system and its services. If you have a new installation of a Windows Server 2003 operating system, then you can use the default service settings. No further action is necessary. If you upgraded to a Windows Server 2003 operating system, or if you want to confirm that your services are configured correctly for best performance and security, then verify your service settings using the table in Default settings for services.
- This computer has a static IP address. For more information, see Configure TCP/IP for static addressing.
- All existing disk volumes use the NTFS file system. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

When you add the DHCP server role, you create one scope that defines the range of IP addresses that the DHCP server allocates to the clients on one subnet. You need to create one scope for each subnet that has clients that you want to manage using DHCP. The following table lists the information that you need to know before you add the DHCP server role, so that you can create the first scope. You need to collect the same information for each additional scope.

| Before adding a DHCP server role | Comments |
|---|---|
| Review DHCP security issues. | Security issues might affect the way you deploy DHCP servers. For more information about DHCP security best practices, see Security information for DHCP. |
| Identify the range of IP addresses that the DHCP server should allocate to the clients. | Use the entire range of consecutive IP addresses that make up the local IP subnet. In many cases, a private address range is the best choice. For more information and a list of all the IP address ranges approved for use on private networks, see RFC 1918, "Address Allocation for Private Internets", at the Internet Engineering Task Force Web site. Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here. |

| | |
|---|---|
| Determine the correct subnet mask for the clients. | When the DHCP server leases an IP address to a client, the server can specify additional configuration information, including the subnet mask. |
| Identify any IP addresses that the DHCP server should not allocate to clients. | For example, a server or a network-connected printer often has a static IP address, and the DHCP server must not offer this IP address to clients. |
| Decide the duration of the lease of the IP addresses. | The default is eight days. In general, the duration of the lease should be equal to the average time that the clients on this subnet are active. For example, the ideal duration may be longer than eight days if the clients are desktop computers that are rarely turned off, or it may be shorter than eight days if the clients are mobile devices that frequently leave the network or are moved between subnets. |
| (Optional) Identify the IP address of the router (default gateway) that the clients should use to communicate with clients on other subnets. | When the DHCP server leases an IP address to a client, the server can specify additional configuration information, including the IP address of the router. |
| (Optional) Identify the name of the DNS domain of the clients. | When the DHCP server leases an IP address to a client, the server can specify additional configuration information, including the name of the DNS domain to which the clients belong. |
| (Optional) Identify the IP address of the DNS server that the clients should use. | When the DHCP server leases an IP address to a client, the server can specify additional configuration information, including the IP address of the DNS server that the clients should contact to resolve the name of another computer. |
| (Optional) Identify the IP address of the WINS server that the clients should use. | When the DHCP server leases an IP address to a client, the server can specify additional configuration information, including the IP address of the WINS server that the clients should contact to resolve the NetBIOS name of another computer. |

**Configuring your DHCP server**

To configure a DHCP server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **DHCP server**, and then click **Next**.

This section covers:

Summary of Selections

Using the New Scope Wizard

Completing the Configure Your Server Wizard

Removing the DHCP server role

**Summary of Selections**

On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected **DHCP Server** on the previous page, the following appears:

- **Install DHCP Server**

- **Run the New Scope Wizard to configure a new DHCP scope**

To apply the selections shown on the **Summary of Selections** page, click **Next**. After you click **Next**, the **Configuring**

**Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page.

**Using the New Scope Wizard**

After you click **Next**, the Configure Your Server Wizard installs the DHCP Server service, and then starts the New Scope Wizard to collect information and add the DHCP server role. If you cancel the New Scope Wizard, the DHCP Server service remains installed, but it cannot distribute IP addresses to clients until you create a scope. If you choose to create a scope later, you can do so using the DHCP console.

This section describes the following steps in the New Scope Wizard:

Scope Name

IP Address Range

Add Exclusions

Lease Duration

Configure DHCP Options

Router (Default Gateway)

Domain Name and DNS Servers

WINS Servers

Activate Scope

Completing the New Scope Wizard

**Scope Name**

On the **Scope Name** page, in **Name**, type a name for the scope that you are creating. In **Description**, type a description (this is optional). Most networks have several subnets, and each subnet requires its own scope, so a DHCP server usually manages multiple scopes. Choose a name and description that help you distinguish between the various scopes.

After you finish, click **Next**.

**IP Address Range**

On the **IP Address Range** page, define the range of IP addresses in this scope by typing the IP addresses at the start and the end of that range. The wizard uses the IP addresses that you type to determine the correct subnet mask. The correct subnet mask automatically appears in **Subnet mask**.

In the unusual case where the clients on this subnet need to use a subnet mask other than the one that the wizard provides, you must type it in **Subnet mask**, or type the number of bits of the subnet mask in **Length**.

After you finish, click **Next**.

**Add Exclusions**

On the **Add Exclusions** page, you can define the IP addresses that the DHCP server should not allocate to clients. For example, the DHCP server itself has a static IP address that must not be allocated to clients. The same is true of the default gateway and of various network devices, such as network-connected printers. You must exclude these IP addresses so that the DHCP server does not allocate them to clients.

It is recommended that you exclude more IP addresses than you currently need because it is easier to truncate an exclusion range than it is to expand it. Exclude IP addresses from the beginning or the end of the range of possible IP addresses, not from the middle. For example, if the range of IP addresses on this subnet is from 10.0.0.1 to 10.0.0.255, and you want to exclude ten IP addresses, then define the exclusion range as either of the following:

- 10.0.0.1 to 10.0.0.10
- 10.0.0.245 to 10.0.0.255

For each range of IP addresses that you want to exclude, type the IP address at the beginning of the range in **Start IP address**, type the IP address at the end of the range in **End IP address**, and then click **Add**.

This step eases client administration, but it is optional. If you leave all fields of this page blank and click **Next**, clients will still be

able to obtain IP addresses from the DHCP server.

After you finish, click **Next**.

**Lease Duration**
On the **Lease Duration** page, you can define how long a client can use an IP address from this scope.

The DHCP server leases IP addresses to its clients. Each lease has an expiration date and time. The client must renew the lease if it is going to continue to use that IP address. The default duration of the lease is eight days.

This step eases client administration, but it is optional. If you leave all fields of this page blank and click **Next**, clients will still be able to obtain IP addresses from the DHCP server.

After you finish, click **Next**.

**Configure DHCP Options**
On the **Configure DHCP Options** page, you can specify whether to configure DHCP options.

It is recommended that you accept the default, **Yes, I want to configure these options now**, and click **Next**, even if you do not want to configure the options. If you choose **No, I will configure these options later**, then the following occurs:

- The New Scope Wizard creates the scope but does not activate it, and you must use the DHCP console to activate the scope in order for clients to receive IP addresses from this scope. For information about how to activate a scope using the DHCP console, see Activate a scope.

- You will not see the next four wizard pages described below. Continue reading at Completing the New Scope Wizard.

**Router (Default Gateway)**
On the **Router (Default Gateway)** page, you can specify the routers (also known as default gateways) that clients should use. You can add as many IP addresses as there are routers on this subnet.

This step eases client administration, but it is optional. If you leave all fields of this page blank and click **Next**, clients will still be able to obtain IP addresses from the DHCP server.

After you finish, click **Next**.

**Domain Name and DNS Servers**
On the **Domain Name and DNS Servers** page, you can specify the name of the domain that clients on this subnet should use when they resolve DNS names.

You can also specify the DNS server that clients should use to resolve DNS names. You can type the IP address of that DNS server, or you can type its name and click **Resolve**, and the wizard will determine the IP address for you. You can add several DNS servers.

This step eases client administration, but it is optional. If you leave all fields of this page blank and click **Next**, clients will still be able to obtain IP addresses from the DHCP server.

After you finish, click **Next**.

**WINS Servers**
On the **WINS Servers** page, you can specify the WINS server that clients should communicate with to register and resolve NetBIOS names. You can type the IP address of that WINS server, or you can type its name and click **Resolve**, and the wizard will determine the IP address for you. You can add several WINS servers.

This step eases client administration, but it is optional. If you leave all fields of this page blank and click **Next**, clients will still be able to obtain IP addresses from the DHCP server.

After you finish, click **Next**.

**Activate Scope**
On the **Activate Scope** page, you can activate the scope or choose to activate it later. In most cases, you should accept the default and activate the scope now. If you choose to activate the scope later, you can do so using the DHCP console. You must activate the scope to allow clients on the subnet of this scope to obtain IP addresses from the DHCP server.

After you finish, click **Next**.

**Completing the New Scope Wizard**
On the **Completing the New Scope Wizard** page, you can click **Back** to change any of the settings. To apply your selections, click **Finish**.

**Completing the Configure Your Server Wizard**
After you complete the New Scope Wizard, the Configure Your Server Wizard displays the **This Server is Now a DHCP Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

To verify that your server is secure and has the most recent updates, do the following:

1. Run Windows Update. For more information, see Windows Update.

2. Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

**Removing the DHCP server role**
If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the DHCP server role, you must reconfigure clients to obtain IP addresses from another DHCP server. Also, if you want clients to continue using the IP addresses distributed by this server, you must configure another DHCP server to distribute those addresses.

To remove the DHCP server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **DHCP server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the DHCP server role** check box, and then click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. On the **DHCP Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**
After you complete the Configure Your Server Wizard, the computer is ready for use as a basic DHCP server that can manage IP addresses and related information. Up to this point, you have installed the DHCP Server service and created one scope that manages IP addresses and related information for the clients on one subnet. If you want to manage clients on other subnets, you must create additional scopes. If you have not activated the scope, then you must activate the scope to allow clients on the subnet of this scope to obtain IP addresses from the DHCP server.

When you complete the Configure Your Server Wizard, it automatically installs the DHCP console, which you use to manage your DHCP server. To open DHCP, click **Start**, click **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DHCP**.

The following table lists some of the additional tasks that you might want to perform on your DHCP server.

| Task | Purpose of task | Reference |
|---|---|---|
| Activate existing scopes. | To activate scopes that you created with the New Scope Wizard that are not currently active. | Activate a scope |
| Authorize the DHCP server in Active Directory. | To detect unauthorized DHCP servers and prevent them from starting or running on your network. | Authorizing DHCP servers |
| Add support for a routed network. | To enable the DHCP server to act as a relay agent, which forwards DHCP messages between subnets. | Configure the DHCP Relay Agent |
| Assign a server-based scope option. | To simplify administration by setting default values that all new scopes will inherit. | Assign a server-based option |

| | | |
|---|---|---|
| Change or view scope properties. | To change or view the properties of an existing scope. | Change or view scope properties |
| Create new scopes. | To create scopes that support clients on other subnets. | Create a new scope |
| Add a client reservation. | To define an IP address that the DHCP server should not allocate to a client because another client is permanently using it. | Add a client reservation |
| Configure ports to allow remote administration. | To manage the DHCP server from other computers on the network. | Windows Firewall Settings |

# Streaming media server role: Configuring a streaming media server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Streaming media server role: Configuring a streaming media server**
You can use Windows Media Services to stream audio and video content to clients over the Internet or an intranet. Clients might be computers or devices that play back the content using a player, such as Windows Media Player, or they might be computers running Windows Media Services (called Windows Media servers) that proxy, cache, or redistribute your content. Clients can also be custom applications that have been developed with the Windows Media Software Development Kit (SDK).

If you want this computer to provide audio and video content streams to clients and to other Windows Media servers, then configure this computer as a streaming media server.

### Notes

- This content is not available in this preliminary release.
- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition operating system. For more information, see Overview of Windows Server 2003, Web Edition.

This topic explains the basic steps that you must follow to configure a streaming media server. When you have finished the basic steps, you can complete additional configuration tasks, depending on how you want to use the streaming media server.

This topic covers:

Before you begin

Configuring your streaming media server

Next steps: Completing additional tasks

**Before you begin**
Before you configure your computer as a streaming media server, verify whether or not:

- The operating system is configured correctly. In the Windows Server 2003 family, Windows Media Services depends on the appropriate configuration of the operating system and its services. If you have a new installation of a Windows Server 2003 operating system, you can use the default service settings. No further action is required. If you upgraded to a Windows Server 2003 operating system, or if you want to confirm that your services are configured correctly for best performance and security, then verify your service settings using the table in Default settings for services.
- All existing disk volumes use the NTFS file system. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

**Configuring your streaming media server**
To configure a streaming media server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.
- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and

then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Streaming media server**, and then click **Next**.

This section covers:

Summary of Selections

Completing the Configure Your Server Wizard

Completing the streaming media server role configuration

Removing the streaming media server role

**Summary of Selections**

On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected **Streaming media server** on the **Server Role** page, the following appears:

- **Install Windows Media Services**

To apply the selections shown on the **Summary of Selections** page, click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page.

After you click **Next** on the **Summary of Selections** page, the Configure Your Server Wizard installs Windows Media Services. Unlike many other services, Windows Media Services installs without any input from the administrator.

**Completing the Configure Your Server Wizard**

After the components are configured, the Configure Your Server Wizard displays the **This Server is Now a Streaming Media Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

Before you start to use your streaming media server, we recommend the following steps:

- Run Windows Update. For more information, see Windows Update.

- Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

**Completing the streaming media server role configuration**

After you complete the Configure Your Server Wizard, the computer is ready for use as a basic streaming media server that can provide digital media content to clients and to other streaming media servers. Additional configuration is usually required, and the specific steps depend on your requirements. This section explains the basic decisions you must make in order to configure the streaming media server.

**Note**

- If you have installed Windows Media Services on this computer, you can view Windows Media Services Help. To open Windows Media Services Help, click **Start**, click **Run**, and then type **hh wmserver.chm**.

The streaming media server role supports many scenarios, which Windows Media Services Help describes in detail. For more information, see "Scenarios" in Windows Media Services Help. Most scenarios require you to reconfigure an existing publishing point or create a new one. You need to make one decision, or possibly two, and the results determine which of the three main publishing point configurations you should use. The following table shows how the decisions relate to configurations.

| If you | And you want to use | Use this publishing point configuration |
|---|---|---|
| Want clients to control playback | One server connection per client | On-demand, unicast |

| | | |
|---|---|---|
| Do not want clients to control playback | One server connection per client | Broadcast, unicast |
| Do not want clients to control playback | One server connection, shared by all clients | Broadcast, multicast |

**Control of playback**
Control of playback means that the client should be able to start, stop, pause, rewind, and fast-forward digital media content. With on-demand, unicast, the client controls playback, and the user experience is similar to playing a movie from a VCR or a DVD player. This type of playback requires an on-demand publishing point. An on-demand publishing point distributes pre-recorded content, such as audio and video files. When you add the streaming media server role, the wizard creates an on-demand publishing point named **<Default>**. You can distribute your media files from this publishing point, or you can create another publishing point. The configuration steps for an on-demand publishing point are similar to those presented in "Stream Windows Media files on-demand" in Windows Media Services Help. If you choose to use an on-demand publishing point, you must use unicast delivery.

If the client does not control playback, the user experience is similar to viewing a television program. This type of playback requires a broadcast publishing point. This type of publishing point distributes pre-recorded and live content. When you add the streaming media server role, the wizard creates a broadcast publishing point named **Sample_Broadcast** that contains sample content. You should leave this sample broadcast publishing point intact and create a new broadcast publishing point. If you choose to create a broadcast publishing point, see Server connections.

For more information about on-demand and broadcast publishing point types, see "About publishing point types" in Windows Media Services Help.

**Server connections**
With unicast broadcast, the server creates a separate connection to each client. As a result, unicast delivery can consume a large amount of network bandwidth. For example, delivering the same content to 100 clients simultaneously consumes 100 times as much network bandwidth as delivering the content to one client. However, unicast delivery does not require any configuration of network routers and switches. The steps to configure a publishing point this way are similar to those presented in "Use your server to publish live content from Windows Media Encoder" in Windows Media Services Help. For more information about unicast delivery, see "Delivering content as a unicast stream" in Windows Media Services Help.

With multicast broadcast, the server does not create a connection to any client. Instead, the server delivers the content to a Class D Internet Protocol (IP) address on the network, and any client on the network can receive it. This conserves network bandwidth. For example, a multicast delivery to 100 clients consumes only as much bandwidth as delivery to one client. However, many networks by default do not support multicast delivery. To support multicast delivery, the network routers and switches between the server and the clients must be configured to transmit Class D IP addresses and interpret multicast information packets. The steps to configure a publishing point for multicast broadcast are similar to those presented in "Use your server to broadcast a stream published by Windows Media Encoder" in Windows Media Services Help. For more information about multicast delivery, see "Delivering content as a multicast stream" in Windows Media Services Help.

**Using firewalls**
If you plan to stream content from a Windows Media server on a network to clients on the Internet, you may need to open additional ports in your firewall to prevent clients from having problems receiving the content. Also, to make sure that your content is always available to clients that connect to your server using a URL that starts with a Microsoft Media Server (MMS) moniker (mms://), ensure that ports on your firewall are opened for all of the connection protocols that might be used during protocol rollover. For more information, see "Using firewalls" in Windows Media Services Help.

**Removing the streaming media server role**
If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the streaming media server role, clients will no longer be able to connect to the publishing points of this server, and encoders will no longer be able to send media streams through the server. All content stored or distributed on this server will become unavailable.

To remove the streaming media server role, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **Streaming media server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the streaming media server role** check box, and then click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. On the **Streaming Media Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**

Up to this point, you have installed Windows Media Services. The installation added Windows Media Services to your server, installed the Help file, and created two publishing points that contain sample content.

The following table lists some of the additional tasks that you might want to perform on your streaming media server.

| Task | Purpose of task | Reference |
|---|---|---|
| Configure security options. | To control access to the streaming media server and its content. | "Configuring security options" in Windows Media Services Help |
| Take the tour. | To become more familiar with Windows Media Services capabilities. | Click **Start**, click **Run**, and then type **%systemroot%\system32\windows media\server\admin\mmc\hta\tour_.hta** |
| Review streaming media terms and concepts. | To become more familiar with streaming media concepts such as unicast and multicast, on-demand and broadcast, archiving, publishing points, and announcing content. | "Understanding terminology" in Windows Media Services Help |
| Determine how many streaming media servers you need. | To plan ahead for the number of servers you need to install. | "Streaming media system overview" in Server roles, and "Capacity planning" in Windows Media Services Help |
| Identify port conflicts. | To prevent problems when Windows Media Services attempts to use the same TCP port as a Web server. | "Using HTTP streaming and other services on the same computer" in Windows Media Services Help |
| Review instructions for upgrading an earlier version of Windows Media Services. | To ensure that you understand how to upgrade other servers running earlier versions of Windows Media Services. | "Upgrading Windows Media Services" in Windows Media Services Help |
| Enable the Windows Audio service. | The Windows Audio service is disabled by default on a new installation of Windows Server 2003, Datacenter Edition, or Windows Server 2003, Enterprise Edition. This does not prevent the server from streaming audio to clients, but you should enable audio in order to test content playback on the server. | Enable or disable a service for a hardware profile |
| Start the Windows Media Services management interface. | To configure your streaming media server. | Click **Start**, click **Run**, and then type **%systemroot%\system32\windows media\server\admin\mmc\wmsadmin.msc** |
| Manage your streaming media server. | To configure your streaming media server to stream content over an intranet or the Internet. Before you begin streaming content, you must configure settings for your server running Windows Media Services, add and configure publishing points, and set up your content. | "Managing your Windows Media server" in Windows Media Services Help |

| | | |
|---|---|---|
| Log data and events. | To record the activity of clients that connect to your content. | "Logging data and events" in Windows Media Services Help |
| Manage and produce content. | Content management methods and priorities will differ from one project to another based on a variety of factors, such as audience demographics, content type, and available equipment. | "Content management and production" in Windows Media Services Help |
| Decide how to obtain content from the Windows Media Encoder. | To determine whether to configure the encoder to push a stream to the server or to configure the server to pull a stream from the encoder. | "Sourcing from an encoder" in Windows Media Services Help |
| Implement a cache/proxy system. | To store the most recently streamed content for use by other clients seeking the same material. During live broadcasts, cache/proxy servers can perform a task called stream splitting, which allows many unicast clients to receive content while only a single stream is sent from the origin server. | "Implementing a cache/proxy system" in Windows Media Services Help |
| Administer the streaming media server remotely. | To manage the streaming media server from other computers on the network. | "Using Windows Media Services Administrator for the Web" in Windows Media Services Help. |

# WINS server role: Configuring a WINS server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WINS server role: Configuring a WINS server**

Windows Internet Name Service (WINS) servers dynamically map IP addresses to computer names (NetBIOS names). This allows users to access resources by computer name instead of by IP address. If you want this computer to keep track of the names and IP addresses of other computers in your network, configure this computer as a WINS server.

This topic explains the basic steps that you must follow to configure a WINS server. When you have finished setting up a basic WINS server, you can complete additional configuration tasks, depending on how you want to use the WINS server.

This topic covers:

Before you begin

Configuring your WINS server

Next steps: Completing additional tasks

**Before you begin**

Before you configure your computer as a WINS server, verify that:

- You are familiar with WINS concepts such as NetBIOS names, WINS server, WINS clients, and replication partners. For more information, see Understanding WINS.
- The operating system is configured correctly. In the Windows Server 2003 family, WINS depends on the appropriate configuration of the operating system and its services. If you have a new installation of a product in the Windows Server 2003 family, you can use the default service settings. No further action is necessary. If you upgraded to a product in the Windows Server 2003 family, or if you want to confirm that your services are configured correctly for best performance and security, then verify your service settings using the table in Default settings for services.
- You know how many WINS servers you need to install and where to locate each server on your network. When you add the WINS server role, you configure this server to maintain a database of computer names and IP addresses. In a large network, you may need to add the WINS server role to additional servers in order to ensure that client computers always have access to at least one WINS server. For more information, see Planning WINS networks.
- This computer has a static IP address. For more information, see Configure TCP/IP for static addressing.
- All existing disk volumes use the NTFS file system. FAT32 volumes are not secure, and they do not support file and folder compression, disk quotas, file encryption, or individual file permissions.
- Windows Firewall is enabled. For more information, see Enable Windows Firewall with no exceptions.
- The Security Configuration Wizard is installed and enabled. For information about the Security Configuration wizard, see Security Configuration Wizard Overview.

**Configuring your WINS server**

To configure a WINS server, start the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.
- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **WINS server**, and then click **Next**.

Summary of Selections

Completing the Configure Your Server Wizard

Removing the WINS server role

**Summary of Selections**
On the **Summary of Selections** page, view and confirm the options that you have selected. If you selected **WINS server** on the previous page, the following appears:

- **Install WINS**

To apply the selections shown on the **Summary of Selections** page, click **Next**. After you click **Next**, the **Configuring Components** page of the Windows Components Wizard appears, and then closes automatically. You cannot click **Back** or **Next** on this page. The Configure Your Server Wizard installs the WINS Server service. Unlike many other services, the WINS service installs without any input from the administrator.

If you cancel Configure Your Server, then WINS Server service is not installed. To install it later, restart Manage Your Server and add the WINS role.

**Completing the Configure Your Server Wizard**
After the components are configured, the Configure Your Server Wizard displays the **This Server is Now a WINS Server** page. To review all of the changes made to your server by the Configure Your Server Wizard or to ensure that a new role was installed successfully, click **Configure Your Server log**. The Configure Your Server Wizard log is located at *systemroot*\Debug\Configure Your Server.log. To close the Configure Your Server Wizard, click **Finish**.

To verify that your server is secure and has the most recent updates, do the following:

1. Run Windows Update. For more information, see Windows Update.

2. Run the Security Configuration Wizard. For more information, see Security Configuration Wizard Overview.

**Removing the WINS server role**
If you need to reconfigure your server for a different role, you can remove existing server roles. If you remove the WINS server role, and this server is the only WINS server that clients can use to register and resolve computer names, you need to add the WINS role to another server. Also, if this server is configured to replicate WINS database information with other WINS servers, then you must reconfigure replication on those other WINS servers.

To remove the WINS server role, restart the Configure Your Server Wizard by doing either of the following:

- From Manage Your Server, click **Add or remove a role**. By default, Manage Your Server starts automatically when you log on. To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

On the **Server Role** page, click **WINS server**, and then click **Next**. On the **Role Removal Confirmation** page, review the items listed under **Summary**, select the **Remove the WINS server role** check box, and then click **Next**. On the **WINS Server Role Removed** page, click **Finish**.

**Next steps: Completing additional tasks**
After you complete the Configure Your Server Wizard, the computer is ready for use as a basic WINS server that can keep track of server IP addresses and provide this information when a client requests it. Up to this point, you have installed the WINS Server service on one server. If you want to support WINS clients on a complex network, you may need to install additional WINS servers on other subnets.

The following table lists some of the additional tasks that you might want to perform on your WINS server.

| Task | Purpose of task | Reference |
| --- | --- | --- |
| View WINS name records registered at the server. | Verify that the WINS server is functioning correctly. | Finding and viewing WINS records |
| Modify WINS server defaults. | WINS uses several default server configuration parameters that determine how NetBIOS name records are managed in the WINS server database. These parameters are usually acceptable. You may want to modify them in special circumstances, such as when a host name change must be made, or when you renumber the network so that clients and servers use a different set of IP addresses. | Modifying WINS server defaults |
| Configure replication settings on primary and secondary WINS servers. | WINS servers replicate database changes to each other so that each WINS server has the same information about the servers on the network and the IP address of each. | Configuring WINS replication; Configure Replication |
| Configure ports to allow remote administration. | To manage the WINS server from other computers on the network. | Windows Firewall Settings |

# To remove a server role

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a server role**

1. Open Manage Your Server.
2. Under **Managing Your Server Roles**, click **Add or remove a role**.
3. In the Configure Your Server Wizard, on the **Preliminary Steps** page, click **Next**.
4. On the **Server Role** page, click the role that you want to remove, and then click **Next**.
5. On the **Role Removal Confirmation** page, select the **Remove the *server* role** check box, and then click **Next**.
6. On the ***Server* Role Removed** page, click **Finish**.

**Important**

- When you remove a server role, you might break dependencies that exist between the server role and other programs. Be sure to test removing the server role in a test environment before doing so on your network.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Manage Your Server, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Manage Your Server**.
- For more information about removing specific server roles and any dependencies that might be affected, see the following:

  File server role: Configuring a file server

  Print server role: Configuring a print server

  Application server role: Configuring an application server

  Mail server role: Configuring a mail server

  Terminal server role: Configuring a terminal server

  Remote access/VPN server role: Configuring a remote access/VPN server

  Domain controller role: Configuring a domain controller

  DNS server role: Configuring a DNS server

  DHCP server role: Configuring a DHCP server

  Streaming media server role: Configuring a streaming media server

WINS server role: Configuring a WINS server

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Windows Product Activation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Product Activation**

Due to piracy and other forms of unauthorized use, users cannot always be sure that they have a genuine copy of a Windows Server 2003 operating system. The goal of product activation is to reduce a form of piracy known as casual copying or "softlifting". Casual copying is the sharing and installation of software that is not in compliance with the software's end user license agreement, or EULA, and is estimated to contribute to half of all pirated installations. Microsoft developed Product Activation for Windows Server 2003 operating systems to help ensure that each Windows Server 2003 operating system license is installed in compliance with the EULA and is not installed on more than the limited number (usually one) of computers allowed by the product EULA. Please note, however, that volume licensed versions of Windows Server 2003 operating systems do not require activation.

During software installation, the set up wizard prompts you to enter a product key usually located on the back of the Windows Server 2003 operating system CD-ROM folder. The product key is a 25 character alphanumeric code shown in five groups of five characters each (for example, BCDFG-12345-HJKLM-67890-NPQRS). Keep the product key in a safe location and do not share it with others. This product key forms the basis for your ability to install and use Windows.

The product key also forms the basis for the product ID that is created when members of the Windows Server 2003 family are installed. Each licensed instance of Windows Server 2003 operating systems has a unique Product ID. The Product ID has 20 characters arranged like this: XXXXX-XXX-XXXXXXX-XXXXX. It is listed in the properties for **My Computer**.

For purposes of product activation only, a non-unique hardware hash is also created from general information that is included in the system components. At no time are files on the hard drive scanned, nor is personally-identifiable information of any kind used to create the hardware identifier. None of the information collected during product activation will be used to personally identify you. To ensure your privacy, the hardware identifier is created by what is known as a "one-way hash". To produce a one-way hash, information is processed through an algorithm to create a new alphanumeric string. It is impossible to calculate the original information from the resulting string.

The hardware identifier is used together with the product ID to create a unique installation ID. Whether you choose to activate by using an Internet connection or by speaking with a Microsoft customer service representative, the installation ID is the only piece of information required to activate Windows Server 2003 operating systems.

If you activate via an Internet connection, the installation ID is sent automatically. When you decide to activate over the Internet, the Windows Product Activation Wizard attempts to establish an online connection to Microsoft by way of the Internet. If you do not subscribe to an Internet Service Provider but do have a modem connected to a phone line, the wizard detects the modem and attempts to make a direct connection to Microsoft.

If an online connection cannot be established, you are prompted to contact a customer service representative by telephone. In that message, the installation ID is displayed to you. The customer service representative will ask you to read the installation ID over the telephone. Alternatively, automated telephone response systems will guide you through the activation process.

The installation ID records an association of the product ID to your computer and a confirmation is sent back. The product key can now be used to install Windows on that computer an unlimited number of times. However, if you need to install Windows on a different computer using that product key, you might need to contact a Microsoft customer service representative by telephone.

Until you have activated your copy of your Windows Server 2003 operating system, an Activate icon appears in the Notification Area of the Status Bar of the Desktop. You can click the icon to initiate activation. This icon will not appear in the Notification Area after you have activated the member of the Windows Server 2003 family. Check the Application Event Log to verify activation.

You have normally have a grace period of days--specified in your EULA--in which to activate your Windows Server 2003 operating systems product installation. If the grace period expires and you have not completed activation, you will not be able to complete the login process and Terminal Server sessions will be unavailable. Administrator credentials are required for reactivation. Please note that evaluation CDs and upgrades are not issued an additional grace period. You can logon in Safe Mode to access any available data.

**Notes**

- To view the EULA, click **Start**/**Run**, type "eula.txt".

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- For further information about Windows Product Activation, see How to activate Windows and Windows Product Activation Concepts.

- Windows Product Activation is not available on the Itanium-based versions of the Windows operating systems.

- For the most recently updated information regarding Windows Product Activation, see Microsoft Product Activation Privacy Policy at Microsoft Web site.

# How to activate Windows

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Activate Windows on the Internet
- Activate Windows with your modem when you have no Internet service provider
- Activate Windows by phone
- Activate Windows using Microsoft Text Telephone

# Activate Windows on the Internet

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate Windows on the Internet**

1. Click **Start**, point to **All Programs**, and then click **Activate Windows**.
2. In **Windows Product Activation**, select **Yes, let's activate Windows over the Internet now**. After this selection, you will be given the option to register at the same time.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a system tools item, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click the appropriate icon. Click **Activate Windows**.
- Alternatively, you can open the Windows Product Activation Wizard by clicking **Start**, then **Run**, and then typing "**oobe/msoobe /a**".
- You are strongly encouraged to activate your Windows Server 2003 operating system before using it in a productive environment to prevent loss of time later.
- If you choose not to activate Windows now, reminders will appear periodically during your grace period. After that time has expired, your login process will remain incomplete until activation.
- If you have not yet activated your Windows Server 2003 operating system, you can do so at any time by clicking the Windows Activation icon in the Notification Area on the Status Bar on the Desktop to initiate activation.
- If you have neither an Internet connection or a modem, see "To activate Windows by phone" in Related Topics for instructions on how to contact a customer service representative by phone.
- Activating any of the Windows Server 2003 operating systems is fast and does not require your name or other personal information.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Activate Windows with your modem when you have no Internet service provider

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate Windows with your modem when you have no Internet service provider**

1. Click **Start**, point to **All Programs**, and then click **Activate Windows**.
2. In **Windows Product Activation**, select **Yes, let's activate Windows over the Internet now**. After this selection, you will be given the option to register at the same time.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a system tools item, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click the appropriate icon. Click **Activate Windows**.
- Even without Internet service, you can use your modem to activate, or activate and register, your copy of Windows.
- You are strongly encouraged to activate your Windows Server 2003 operating system before using it in a productive environment to prevent loss of time later.
- When Windows operating systems require activation, a shortcut logo appears in the Notification Area on the Status Bar on the Desktop. You can begin the activation process by clicking on this icon. Once you have activated, this icon disappears. Confirm activation by checking with your Application Event Log.
- Alternatively, you can open the Windows Product Activation wizard by clicking **Start**, then **Run**, and type in "**oobe/msoobe /a**".
- If you choose not to activate now, reminders will appear periodically during the grace period. After that time has expired, you will be required to activate in order to continue to use your Windows Server 2003 operating system.
- Activating any of the Windows Server 2003 operating systems is fast and does not require your name or other personal information.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Activate Windows by phone

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate Windows by phone**

1. Click **Start**, click **All Programs** and then click **Activate Windows**.
2. In **Windows Product Activation**, select **Yes, I want to telephone a customer service representative to activate Windows**.
3. After you select the appropriate location, you are provided with a telephone number and an installation ID that you can give to the customer service representative to complete the activation process.

## Notes

- To open a system tools item, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click the appropriate icon. Click **Activate Windows**.
- Alternatively, you can open the Windows Product Activation Wizard by clicking **Start**, then **Run**, and type in "**oobe/msoobe /a**".
- You are strongly encouraged to activate your Windows Server 2003 server operating system before using it in a productive environment to prevent loss of time later.
- If you have not yet activated your Windows Server 2003 operating system, you can initiate activation at any time by clicking the Windows Activation icon in the Notification Area. Once you have activated, this icon disappears. If you choose not to activate now, reminders will appear periodically during the grace period. After that time has expired, you will be required to activate in order to continue to use your Windows Server 2003 operating system interactively.
- Activating any of the Windows Server 2003 operating systems is fast and does not require your name or other personal information.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Activate Windows using Microsoft Text Telephone

# Activate Windows using Microsoft Text Telephone

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate Windows using Microsoft Text Telephone**

1. Dial (800) 718-1599 on your TT/TTY modem from the United States or Canada.
2. Once you are connected to Microsoft, you will be guided by on-screen instructions for activation.
3. You are strongly encouraged to activate your Windows Server 2003 operating system before using it in a productive environment to prevent loss of time later.

## Notes

- Microsoft Text Telephone (TT/TTY) services are available for individuals who are deaf or hard-of-hearing.
- From outside the United States, dial United States number (716) 871-6859, using your TT/TTY modem, and then follow the on-screen instructions for activation.
- TT/TTY service is available only in English.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Understanding activation and registration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding activation and registration**
There are important distinctions between activating your Windows operating system and registering it.

Product activation and product registration are not the same. Activation is completely anonymous; it requires absolutely no personally identifiable information to complete. Activation is required and ensures that each Windows product is not installed on more than the limited number (usually one) of computers allowed in the software's end user license agreement, or EULA.

During activation, you can also register your copy of Windows. Registration is **not** required; however registering your copy ensures that you receive product support, product update information, and other benefits. The process registration takes only a few minutes to complete. Personal information (for example, "contact" information such as an e-mail address) is required if you decide to register.

You have a short grace period in which to activate your Windows product installation. If the grace period expires and you have not completed activation, login will be incomplete until you activate.

For more information, see the following.

- Activate Windows on the Internet
- Activate Windows with your modem when you have no Internet service provider
- Activate Windows by phone
- Activate Windows using Microsoft Text Telephone

# Microsoft Windows Product Activation privacy statement

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Windows Product Activation privacy statement**
Microsoft asks that you activate Windows so that we may verify that your installation is done with a genuine Microsoft product. When you activate Windows, you are not required to send any personal information to Microsoft. Activation is completely anonymous.

During activation, Windows creates a unique non-hardware identification that represents the configuration of the computer at the time of activation. The hardware identification does not include any personal information, any information about software or data that may reside on your computer, or any information about the specific make or model of your computer. The hardware identification identifies only the computer and only for the sole purpose of activation. Windows can detect and tolerate changes to your computer configuration. Minor upgrades will not require re-activation. If you completely overhaul your computer you may be required to activate Windows again.

During activation you may also provide your name and other contact information if you want to register your product with Microsoft. If you choose to register your product, the information that you provide will be securely stored by Microsoft and will be protected from disclosure to third parties without your consent.

If you believe that Microsoft has not adhered to these privacy principles, please notify us by postal mail at the following address:

**Microsoft**

**Attn: Microsoft Product Activation**

**One Microsoft Way**

**Redmond, Washington 98052-6399 USA**

We will use commercially reasonable efforts to determine and correct the problem promptly.

Here are national and international **Customer Service Centers** telephone numbers:

# Understanding product keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding product keys**

Product keys are required for all versions of the Windows Server 2003 family, for all languages, and for both 32-bit and 64-bit versions. Product keys are 25-character alphanumeric strings that are formatted in groups of five characters, separated by dashes. You must enter the product key during Setup to complete the installation. (If you acquired your computer from an Original Equipment Manufacturer, the manufacturer may have preconfigured the product key for the Windows Server 2003 operating system software that is preinstalled on the computer).

Windows Server 2003 operating systems require you to keep your product keys always available for your use and in a secure place. You must use only the product key assigned to this specific Windows Server 2003 operating system installation if you ever need to reinstall the operating system. If you attempt to use a product key from another Microsoft product, a beta program, or a different version of Windows Server 2003 operating system, your installation will fail.

Each product key can only be used to install the software on a certain number of unique computers. The actual number of computers depends on your End User License Agreement (EULA). If you have received more than one product key, it is essential that you keep track of which product key you use to install the Windows Server 2003 operating system on each computer.

**Automating the product key entry during Windows Product Activation**

If you perform an unattended Setup, you can automate entry of the product key. In the **[UserData]** section of your unattended answer file, include the value of your product key in the **ProductKey** entry. For more information, see the Microsoft Windows Preinstallation Reference, located in the \Support\Tools\deploy.cab file on the Windows CD.

Products in the Windows Server 2003 family provide two methods to automate activation.

You can script Windows Product Activation through the use of WMI (Windows Management Instrumentation), which provides a number of useful query and activation methods.

# Windows Product Activation Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- I can't find Activate Windows program.
- My Windows operating system has been activated, but I need to read the online Help.
- I didn't activate the product, and now I can't logon.

**I can't find Activate Windows program.**
**Cause**: The key icon for Windows Product Activation is located in the Notification Area of the Desktop and may not be obvious.

**Solution**: Locate the icon on the lower right side of the Desktop. Alternatively, click **Start**, point to **All Programs**, and then click **Activate Windows**.

**My Windows operating system has been activated, but I need to read the online Help.**
**Cause**: Once the operating system has been activated, the icon for activation is removed from the Notification Area on the Desktop.

**Solution**: Open the Help and Support Center from the **Start** menu. Click **Getting Started** and select "Windows Product Activation" from either list. Alternatively, click **Start**, then **Run**. Type "hh wpa.chm", click **OK**.

1. Click **Start**.

   **Where?**

   - **Help and Support**/Getting Started/Windows Product Activation

**See also:** Windows Product Activation.

**I didn't activate the product, and now I can't logon.**
**Cause:** After the grace period, Windows Product Activation does not shut down the computer, but it does prevent interactive logon. For example, if the computer or its service is running on the 30th day, it will continue to run on the 31st day if the computer is not activated and not rebooted. On the next reboot and login, the user will be blocked from logging on.

**Solution:** The user can still boot into the Safe Mode minimum (without networking) to activate, upgrade, or simple retrieve data.

# Accessibility for People with Disabilities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessibility for people with disabilities**
Microsoft is committed to making its products and services easier for everyone to use. This topic provides links to information on features and services that make products in the Windows Server 2003 family more accessible for people with disabilities.

**Note**

- The information in this topic applies only to users who license Microsoft products in the United States. If you obtained this product outside the United States, your package contains a subsidiary information card that lists telephone numbers and addresses for Microsoft support services. You can contact your subsidiary to find out whether the type of products and services described in this topic are available in your area.

The following sources of information can help you learn more about accessibility features and services:

- To learn more about Microsoft products that are available for people with disabilities, see Accessibility at the Microsoft Web site.
- For detailed information about accessibility features and options, see Accessibility Options overview.
- For more information about using keyboard shortcuts in Microsoft Management Console (MMC), see Accessibility for MMC.

In addition, the following topics provide basic information about accessibility features, options, and resources.

- Accessibility Features and Options
- Getting More Accessibility Information

**Note**

- To display Accessibility Options Help, click **Start**, click **Run**, and type **hh access.chm**.

# Accessibility Features and Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessibility features and options**
Products in the Windows Server 2003 family include a number of accessibility features that can improve display, sound, mouse, and keyboard settings for users who are blind, have motion disabilities, or are deaf or hard of hearing. Many accessibility features are also useful to people without disabilities.

For detailed information about accessibility features and options, see Accessibility Options overview.

- Accessibility features
- Setting up accessibility options
- Using the keyboard to move the mouse pointer
- Configuring Windows for people who are blind or have impaired vision
- Configuring Windows for people who have a mobility impairment

**Note**

- To display Accessibility Options Help, click **Start**, click **Run**, and type **hh access.chm**.

For a list of links to other information about accessibility features, see Accessibility for People with Disabilities.

# Accessibility features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessibility features**

Products in the Windows Server 2003 family include the following utilities to help meet your vision, hearing, or mobility needs:

- **Magnifier.** Enlarges a portion of your screen display for easier viewing.
- **Narrator.** Reads information on your screen, including dialog box names, menus, and contents. Narrator provides a minimum level of accessibility so that people who are blind or who have low vision can interact with products in the Windows Server 2003 family during configuration or emergency situations.

  **Notes**

  - Narrator is available only with U.S. English.
  - Narrator requires the Windows Audio service, which by default has a **Startup Type** of **Disabled** on computers running Windows Server 2003, Web Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition. To use Narrator, make sure the Windows Audio service is started and set the **Startup Type** to **Automatic**. For more information, see Default settings for services.
- **On-Screen Keyboard.** Allows a pointing device such as a mouse or a switch input device to type on a keyboard displayed on your screen. On-Screen Keyboard is compatible with many, but not all, keyboards and keyboard settings.

Products in the Windows Server 2003 family also offer customizable options for users who are blind, have motion disabilities, or are deaf or hard of hearing:

- **High-contrast desktop color schemes.** Provide more ways to change the colors and font sizes on your screen.
- **Sound schemes.** Give useful audio feedback for important on-screen events, such as the opening and closing of windows.
- **High-visibility mouse pointer schemes.** Give you more options to help you keep track of the pointer visually.

For a list of links to other information about accessibility features, see Accessibility for People with Disabilities.

# Setting up accessibility options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up accessibility options**

You can configure Accessibility options in products in the Windows Server 2003 family in several ways to meet vision, hearing, or mobility needs. Accessibility features are installed on your computer by default.

You can quickly set your accessibility options by using the Accessibility Wizard. The Accessibility Wizard asks you questions about your accessibility needs and automatically configures settings for you. Or, you can open Accessibility Options in Control Panel to directly customize keyboard, display, and mouse functions.

### Note

- If you are using an input device other than a mouse, instead of clicking, use the appropriate action to complete commands or select items.

**To set your accessibility options by using the Accessibility Wizard**

1. Open the **Accessibility Wizard**.
2. Follow the instructions that appear on your screen.

### Note

- To open the Accessibility Wizard, click **Start**, point to **All programs**, point to **Accessories**, point to **Accessibility**, and then click **Accessibility Wizard**.

**To enable or configure accessibility options by using Control Panel**

- Open **Accessibility Options**.

### Note

- To open Accessibility Options, click **Start**, click **Control Panel**, and then double-click **Accessibility Options**.

You can turn some accessibility features on and off by using keyboard combinations, regardless of whether you have the features enabled. When you use one of the following keyboard combinations, your computer responds with both auditory (beeps) and visual (dialog box) cues that indicate that the accessibility function is on or off.

| To | Press |
|---|---|
| Switch FilterKeys on and off | RIGHT SHIFT for eight seconds |
| Switch High Contrast on and off | LEFT ALT+LEFT SHIFT+PRINT SCREEN |
| Switch MouseKeys on and off | LEFT ALT+LEFT SHIFT+NUM LOCK |
| Switch StickyKeys on and off | SHIFT five times |
| Switch ToggleKeys on and off | NUM LOCK for five seconds |

# Using the keyboard to move the mouse pointer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the keyboard to move the mouse pointer**

If you have trouble using a mouse, you can change the MouseKeys settings so that you can use the numeric keypad to move the mouse pointer. You can do this through the Accessibility Wizard, or you can use the following procedure to set this option in Control Panel.

**To turn MouseKeys on**

1. Open Accessibility Options.
2. On the **Mouse** tab, select the **Use MouseKeys** check box.

The following illustration shows which keys to use to replicate mouse actions.

**Note**

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configuring Windows for people who are blind or have impaired vision

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Windows for people who are blind or have impaired vision**

Using Display in Control Panel, people who have impaired vision or are blind can select larger fonts and icons, increase the size of screen elements by using a lower screen resolution, or change the size of windows and window borders. Using Mouse in Control Panel, you can adjust mouse properties to display larger or more visible mouse pointers and control the speed and animation of the mouse pointer.

When using Windows-based programs, you can change font sizes and colors, background color, and window size. In some programs, you can magnify the elements that are displayed in the program's window.

Using the **Properties** or **Default** dialog boxes in MS-DOS programs, you can change font types, sizes, and colors, background color, and the size of the cursor and program window.

The following tools are available with Windows.

**High Contrast**

Using High Contrast, you can specify that Windows uses colors and fonts that are designed for easy reading.

**Magnifier**

Using Magnifier, you can magnify a portion of your screen to make it more easily readable.

**Narrator**

Narrator is a text-to-speech program that reads aloud the text that is displayed on your screen.

**ToggleKeys**

ToggleKeys causes tones to sound when you press CAPS LOCK, NUM LOCK, and SCROLL LOCK.

The accessibility tools that ship with Windows are intended to provide a minimum level of functionality for users with special needs. Most users with disabilities will need utility programs with more advanced functionality for daily use.

**Other Resources**

Windows XP Professional: Accessibility Options overview

# Configuring Windows for people who have a mobility impairment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Windows for people who have a mobility impairment**

People who have motion-related disabilities can use Windows to configure their computer system to provide a more comfortable computing environment and help minimize the impact of mobility impairments on their work.

Keyboard, part of the Printers and Other Hardware category in Control Panel, provides keyboard layouts for users of alternative keyboards. This is especially useful for those who type with one hand.

Mouse, part of the Printers and Other Hardware category in Control Panel, configures the mouse for right-handed or left-handed users; adjusts double-click speed, pointer speed, and acceleration; and causes the mouse pointer to go directly to default buttons in dialog boxes.

**FilterKeys**

Using FilterKeys, located in Accessibility Options in Control Panel, you can tell Windows to ignore brief or repeated keystrokes.

**MouseKeys**

Using MouseKeys, located in Accessibility Options in Control Panel, you can control the pointer with the numeric keypad on your keyboard.

**On-Screen Keyboard**

On-Screen Keyboard users can type using a pointing device.

**SerialKeys**

SerialKeys, located in Accessibility Options in Control Panel, provides alternative access to keyboard and mouse features.

**StickyKeys**

StickyKeys, located in Accessibility Options in Control Panel, enables you to press the SHIFT, CTRL, ALT, or key, and have it remain active until another key is pressed.

The accessibility tools that ship with Windows are intended to provide a minimum level of functionality for users with special needs. Most users with disabilities will need utility programs with more advanced functionality for daily use. For information about accessibility products and aids for Windows operating systems, see the accessibility page (go to http://www.microsoft.com/ and search for "accessibility") on the Microsoft Web site.

# Getting More Accessibility Information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Getting more accessibility information**

For detailed information about accessibility features and options, see Accessibility Options overview.

For a list of links to information about accessibility features, see Accessibility for People with Disabilities.

For additional information, see:

- Documentation in more accessible formats
- Downloading accessibility notes and utilities
- Other accessibility products and services

**Note**

- To display Accessibility Options Help, click **Start**, click **Run**, and type **hh access.chm**.

# Documentation in more accessible formats

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Documentation in more accessible formats**
Documentation for many Microsoft products is available in alternative formats. If you have difficulty reading or handling printed documentation, you can obtain many Microsoft publications. See Accessibility at the Microsoft Web site.

You can also obtain Microsoft publications from Recording for the Blind & Dyslexic, Inc. RFB&D distributes these documents to registered, eligible members of their distribution service, either on audio cassettes or on floppy disks. The RFB&D collection contains more than 80,000 titles, including Microsoft product documentation and books from Microsoft Press.

For more information, contact Recording for the Blind & Dyslexic at:

Recording for the Blind & Dyslexic, Inc.

20 Roszel Road Princeton,

NJ 08540

Phone: (800) 803-7201 (within the United States and Canada) or (609) 452-0606

Recording for the Blind & Dyslexic Web site

# Downloading accessibility notes and utilities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Downloading accessibility notes and utilities**

If you have a modem or another type of network connection, you can view or download accessibility information from the following network services:

- Accessibility information at the Microsoft Web site.

- Microsoft Internet server at ftp.microsoft.com

  Open the /Softlib folder, and then use the readme or index files to learn about the site. In the index, search for words such as "customizing" and "disabilities." Choose a file and locate it in the /Softlib/Mslfiles folder. On your hard disk, create a folder, then run the file you chose from its current location. Follow the instructions to uncompress the file into the folder you created.

# Other accessibility products and services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Other accessibility products and services**

Other products, services, and resources for people with disabilities are available from Microsoft and other organizations.

Microsoft provides a catalog of accessibility aids that you can use with Microsoft operating systems, including the Windows Server 2003 family operating systems. To obtain this catalog, see Accessibility at the Microsoft Web site.

For information on products and services for the Macintosh operating system for people with disabilities, see the Apple Computer Web site.

The Trace R&D Center at the University of Wisconsin-Madison maintains a Web site with a variety of resources for people with disabilities and developers of assistive technology. For information, contact:

# Common Administrative Tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Common administrative tasks**

This section provides information about common administrative tasks:

- Backing up and restoring data
- Changing group memberships
- Checking event logs
- Creating administrative scripts
- Creating logon scripts
- Creating user and group accounts
- Deploying and upgrading software
- Installing a DHCP server
- Installing a domain controller
- Managing applications on a local computer
- Managing applications remotely
- Managing directory replication
- Management tasks for disks and volumes
- File and folder management
- Managing network printers
- Managing servers remotely
- Managing services
- Monitoring network traffic
- Monitoring security-related events
- Monitoring server performance
- Resetting user passwords
- Safeguarding your system
- Scheduling tasks
- Setting up DNS

- Setting up TCP/IP
- Setting user and group security

# Backing up and restoring data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backing up and restoring data**

The Backup utility helps you protect data from accidental loss if your system's hardware or storage media fails. For example, you can use Backup to create a duplicate copy of the data on your hard disk and then archive the data on another storage device. The backup storage medium can be a logical drive such as your hard disk, a separate storage device such as a removable disk, or an entire library of disks or tapes organized and controlled by a robotic changer. If the original data on your hard disk is accidentally erased or overwritten, or becomes inaccessible because of a hard disk malfunction, you can easily restore the data from the archived copy.

Two of the most common tasks are backing up files to a file or tape and restoring files from a file or tape. You can also back up data from the Managing Backup from the command line. For more information about other tasks for backing up and restoring data, see Backup How To ....

**To back up files to a file or tape**

1. Open Backup.

   The Backup or Restore wizard starts by default, unless it is disabled. You can use this wizard or go to the next step to work in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore wizard.

3. Click the **Backup** tab, and then on the **Job** menu, click **New**.

4. Select the files and folders you want to back up by clicking the box to the left of a file or folder in **Click to select the check box for any drive, folder, or file that you want to back up**.

5. In **Backup destination**, do one of the following:

   - Choose **File** if you want to back up files and folders to a file. This is selected by default.
   - Choose a tape device if you want to back up files and folders to a tape.

6. In **Backup media or file name**, do one of the following:

   - If you are backing up files and folders to a file, type a path and file name for the backup (.bkf) file, or click the **Browse** button to find a file.
   - If you are backing up files and folders to a tape, choose the tape you want to use.

7. Select any backup options you want, such as the backup type and the log file type, by clicking the **Tools** menu, and then clicking **Options**. When you have finished selecting backup options, click **OK**.

8. Click **Start Backup**, and then make any changes to the **Backup Job Information** dialog box.

9. If you want to set advanced backup options such as data verification or hardware compression, click **Advanced**. When you have finished setting advanced backup options, click **OK**.

10. Click **Start Backup** to start the backup operation.

**Caution**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

**Notes**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.
- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.
- If the Backup or Restore wizard does not start by default, you can still use it to back up files by clicking **Wizard Mode** on the **Welcome** tab.
- To back up and restore Microsoft SQL Server database files, it is recommended that you use the built-in backup and restore utilities that SQL has. For more information, see the Microsoft SQL Server documentation.
- Some tape drives may not support hardware compression.
- System State data contains most elements of a system's configuration, but it might not include all of the information that you require to recover your system from a failure. Therefore, it is recommended that you back up all boot and system volumes, including the System State, when you back up your system.
- You can only back up the System State data on a local computer. You cannot back up the System State data on a remote computer.
- Backup files usually have the extension .bkf. You can use any extension you like, but it is highly recommended that you use .bkf which has file associations that will ensure that the backup file is recognizable.
- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.
- If you have Windows Media Services running on your computer, and you want to back up the files associated with these services, see "Running Backup with Windows Media Services" in the Windows Media Services online documentation. You must follow the procedures outlined in the Windows Media Services online documentation before you can back up or restore files associated with Windows Media Services.

**To restore files from a file or tape**

1. Open Backup.

   The Backup or Restore wizard starts by default, unless it is disabled.

2. Click the Advanced Mode link on the Backup or Restore wizard.

3. Click the **Restore and Manage Media** tab, in **Click to select the check box for any drive, folder, or file that you want to restore**, select the files and folders you want to restore by clicking the box to the left of a file or folder.

4. In **Restore files to**, do one of the following:

   - Click **Original location** if you want the backed up files and folders to be restored to the folder or folders they were in when they were backed up. Skip to step 6.

- Click **Alternate location** if you want the backed up files and folders to be restored to a folder that you designate. This option will preserve the folder structure of the backed up data; all folders and subfolders will appear in the alternate folder you designate.

- Click **Single folder** if you want the backed up files and folders to be restored to a folder that you designate. This option will not preserve the folder structure of the backed up data; the files will appear only in the folder that you designate.

5. If you selected **Alternate location** or **Single folder**, type a path for the folder under **Alternate location**, or click the **Browse** button to find the folder.

6. On the **Tools** menu, click **Options**, click the **Restore** tab, and then do one of the following:

   - Click **Do not replace the file on my computer** if you do not want the restore operation to copy over files that are already on your hard disk.

   - Click **Replace the file on disk only if the file on disk is older** if you want the restore operation to replace older files on your disk with newer files from your backup.

   - Click **Always replace the file on my computer** if you want the restore operation to replace files on your disk regardless of whether the backup files are newer or older.

   - Click **OK** to accept the restore options you have set.

7. Click **Start Restore**.

8. If you want to change any of the advanced restore options, such as restoring security settings and junction point data, click **Advanced**. When you are done setting advanced restore options click **OK**.

9. Click **OK** to start the restore operation.

**Caution**

- Choosing **Always replace the file on my computer** could cause you to lose data if a file you are working on is contained in the backup.

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

**Notes**

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- You can also use the Restore wizard to restore files by clicking **Restore Wizard** on the **Tools** menu.

- To back up and restore Microsoft SQL Server database files, it is recommended that you use the built-in backup and restore utilities that SQL has. For more information, see the Microsoft SQL Server documentation.

- In order to restore the System State data on a domain controller, you must first start your computer in Directory Services Restore Mode. This will allow you to restore the SYSVOL directory and the Active Directory directory service database.

- You can only restore the System State data on a local computer. You cannot restore the System State data on a remote computer.

- Backup operators and administrators can back up and restore encrypted files and folders without decrypting the files or folders.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Changing group memberships

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Changing group memberships**

A group is a collection of users that you can use to simplify the administration of user permissions and rights. In addition, you can use a group to delegate administrative tasks, filter Group Policy settings, and create e-mail distribution lists. Users belonging to a particular group receive all the permissions and rights assigned to that group. By changing group memberships for a user, you can quickly change the resources to which that user has access, as well as the tasks delegated to the user and the Group Policy settings that apply to the user. You can change the membership of Active Directory groups to change users' permissions and rights within a domain or forest. You can also change the membership of local groups to change users' permissions and rights on a specific computer.

Some of the most common tasks are adding or removing members from Active Directory groups and adding or removing members from groups on a local computer. You can also use the command line to change group memberships, either in a Managing Active Directory from the command line or on a Managing local groups from the command line. For more information about other tasks for managing group memberships in a domain, see Manage Groups. For more information about other tasks for managing group memberships on a local computer, see Manage Local Groups.

**To add or remove a member from an Active Directory group**

1. Open Active Directory Users and Computers.
2. In the console tree, double-click the domain node.
3. Click the folder that contains the group to which you want to add or remove a member.
4. In the details pane, right-click the group, and then click **Properties**.
5. Click the **Members** tab, and then do one of the following:
   - To add a member to a group, click **Add**. In **Enter the object names to select**, type the name of the user, group, or computer that you want to add to the group, and then click **OK**.
   - To remove a member from a group, click the member you want to remove, and then click **Remove**.

### Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- In addition to users and computers, groups can include contacts and other groups.
- To add members to a group, you can click the members you want to add, click the **Add to a group** toolbar button, and then type the name of the group to which they will be added. You can also drag a member object to a group, or right-click the object, and then click **Add to a group** from the shortcut menu.
- When you administer a domain, security principals in the parent domain or other trusted domains are not visible on the **Member Of** tab of a domain users properties. The only domain accounts that you can add or view are the present domain groups. Only domain groups in the present domain are shown, even if the member belongs to other trusted domain groups.

**To add or remove a member from a group on a local computer**

1. Open Computer Management.

2. In the console tree, click **Groups**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Groups

3. Right-click the group to which you want to add or remove a member and click **Properties**.

4. Do one of the following:

   - To add a member to a group, click **Add**. In **Enter the object names to select**, type the name of the user, group, or computer that you want to add to the group, and then click **OK**.

   - To remove a member from a group, click the member you want to remove, and then click **Remove**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- A user who belongs to a group has all the rights and permissions granted to that group. If a user is a member of more than one group, then the user has all the rights and permissions granted to every group he or she belongs to. For more information, see Default local groups.

- You should not add a new user to the Administrators group unless the user will perform only administrative tasks. For more information, see Why you should not run your computer as an administrator.

- If the computer participates in a domain, you can add user accounts and global groups from that domain and from trusted domains to a local group.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Checking event logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checking event logs**

Depending on its server role, a computer running a Windows Server 2003 operating system records events in the following types of logs: application, security, directory service, File Replication service, and DNS server. You can use Event Viewer to monitor these logs and gather information about the hardware, software, and system problems on a computer. Event Viewer displays five types of events within each log: error, warning, information, success audit, and failure audit.

Some of the most common tasks are viewing an event log and connecting to another computer. You can also check event logs from the command line. For more information, see Managing event logs from the command line. For more information about other tasks for checking event logs, see Event Viewer How To....

**To view an event log**

1. Open Event Viewer.
2. In the console tree, click the log you want to view.
3. In the details pane, view the list of individual events.
4. If you want to see more details about a specific event, in the details pane, double-click the event.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- To refresh the view, on the **Action** menu, click **Refresh**. When you open a log, Event Viewer displays the current information for the log. While you view the log, the display is not updated unless you refresh the Event Viewer window. If you switch to another log and then return to the first log, the display for the first log is automatically refreshed. When you refresh the view of an event log, only the view is updated, no changes are made to the log. The **Refresh** command is not available for archived logs, because those files can no longer be updated.

**To connect to another computer**

1. Open Event Viewer.
2. In the console tree, right click **Event Viewer (Local)**, and then click **Connect to another computer**.
3. Click **Another computer**, type the name of the computer, and then click **OK**. You can also find another computer on the network by clicking **Browse**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event**

**Viewer**.

- The other computer can be a workstation running Windows XP Home Edition, Windows XP Professional, Windows 2000 Professional, Windows NT Workstation, or a server or domain controller running Windows NT Server, Windows 2000 Server, or a Windows Server 2003 operating system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Creating administrative scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating administrative scripts**

With scripts, you can automate a wide range of common administrative tasks, such as:

- Administering users, groups, and organizational units.
- Configuring computers.
- Managing event logs.
- Maintaining files, folders, and disks.
- Monitoring performance, processes, and services.

The Windows Server 2003 family supports two scripting environments:

- The command processor runs files that contain batch language commands. Batch language has limited capabilities, but earlier operating systems supported it and you may need to continue using existing batch files. For more information about batch files, see Using batch files.
- Windows Script Host (WSH) runs files that contain Microsoft Visual Basic Scripting Edition (VBScript) or Jscript commands. VBScript and Jscript provide all the capabilities of batch language plus many more. For example, scripts written in VBScript or Jscript can interact with Active Directory Service Interfaces (ADSI) to manage objects stored in Active Directory, and they can interact with Windows Management Instrumentation (WMI) to access system resources.

In addition to the two scripting languages, WSH provides two runtime programs: WScript.exe and CScript.exe. After you create a WSH script containing VBScript or Jscript commands, you use WScript or CScript to run the script. WScript runs the script as a Windows-based process and CScript runs the script as a console-based process.

Administrators often want to manage objects in Active Directory, such as organizational units, groups, and users. The following example script shows how you can use WSH, VBScript, and ADSI to create an Active Directory organizational unit, group, and user. After creating the three Active Directory objects in the current domain, the script assigns a password to the new user account, enables the user account, and adds the user account to the group.

**To create an example script**

1. Open Notepad.
2. Copy and paste, or type, the following:

```
Set oRoot   = GetObject("LDAP://rootDSE")
Set oDomain = GetObject("LDAP://" &
oRoot.Get("defaultNamingContext"))

Set oOU=oDomain.Create("organizationalUnit",
"ou=Demo OU")
oOU.Put "Description", "Demonstration OU"
oOU.SetInfo

Set oGroup = oOU.Create("Group", "cn=Demo
Group")
```

```
oGroup.Put "sAMAccountName", "DemoGroup"
oGroup.Put "Description", "Demonstration
Group"
oGroup.SetInfo

Set oUser = oOU.Create("User", "cn=Demo User")
oUser.Put "sAMAccountName", "DemoUser"
oUser.Put "Description", "Demonstration User"
oUser.SetInfo

oUser.SetPassword "qW5rty"

oUser.AccountDisabled = False
oUser.SetInfo

oGroup.Add oUser.ADSPath
```

3. On the **File** menu, click **Save As**.

4. In **Save as type**, click **All Files**.

5. In **File name**, type a file name, followed by **.vbs**, and then click **Save**. The file is saved as a VBScript.

### Notes

- To open Notepad, click **Start**, point to **All programs**, point to **Accessories**, and then click **Notepad**.

- The root of the current domain cannot contain an organizational unit named Demo OU.

#### To run the example script

1. Open Command Prompt.

2. Change to the directory where the script is located.

3. Type the following:

   **wscript***ScriptName***.vbs**

   where *ScriptName***.vbs** is the name of the script.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- This example starts the script from the command prompt. You can also start the script by clicking **Start**, clicking **Run**, typing **wscript** *ScriptName***.vbs** in **Open**, and then clicking **OK**.

- This example runs the script as a Windows-based process. To run it as a console process, type **cscript** instead of **wscript**.

For more information, see Windows Script Host, Windows Script at the Microsoft Web site, and the *System Administration Scripting Guide* at the Microsoft Windows Resource Kits Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Creating logon scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating logon scripts**

You can use logon scripts to assign tasks that will be performed when a user logs on to a particular computer. The scripts can carry out operating system commands, set system environment variables, and call other scripts or executable programs. The Windows Server 2003 family supports two scripting environments: the command processor runs files containing batch language commands, and Windows Script Host (WSH) runs files containing Microsoft Visual Basic Scripting Edition (VBScript) or Jscript commands. You can use a text editor to create logon scripts. Some tasks commonly performed by logon scripts include:

- Mapping network drives.
- Installing and setting a user's default printer.
- Collecting computer system information.
- Updating virus signatures.
- Updating software.

The following example logon script contains VBScript commands that use Active Directory Service Interfaces (ADSI) to perform three common tasks based on a user's group membership:

1. It maps the H: drive to the home directory of the user by calling the WSH Network object's MapNetworkDrive method in combination with the WSH Network object's UserName property.
2. It uses the ADSI IADsADSystemInfo object to obtain the current user's distinguished name, which in turn is used to connect to the corresponding user object in Active Directory. Once the connection is established, the list of groups the user is a member of is retrieved by using the user's memberOf attribute. The multivalued list of group names is joined into a single string by using VBScript's Join function to make it easier to search for target group names.
3. If the current user is a member of one of the three groups defined at the top of the script, then the script maps the user's G: drive to the group shared drive, and sets the user's default printer to be the group printer.

**To create an example logon script**

1. Open Notepad.
2. Copy and paste, or type, the following:

```
Const ENGINEERING_GROUP     = "cn=engineering"
Const FINANCE_GROUP         = "cn=finance"
Const HUMAN_RESOURCES_GROUP = "cn=human resources"

Set wshNetwork = CreateObject("WScript.Network")
wshNetwork.MapNetworkDrive "h:",
"\\FileServer\Users\" & wshNetwork.UserName

Set ADSysInfo = CreateObject("ADSystemInfo")
Set CurrentUser = GetObject("LDAP://" &
ADSysInfo.UserName)
strGroups = LCase(Join(CurrentUser.MemberOf))
```

```
If InStr(strGroups, ENGINEERING_GROUP) Then

    wshNetwork.MapNetworkDrive "g:",
    "\\FileServer\Engineering\"
    wshNetwork.AddWindowsPrinterConnection
    "\\PrintServer\EngLaser"
    wshNetwork.AddWindowsPrinterConnection
    "\\PrintServer\Plotter"
    wshNetWork.SetDefaultPrinter
    "\\PrintServer\EngLaser"

ElseIf InStr(strGroups, FINANCE_GROUP) Then

    wshNetwork.MapNetworkDrive "g:",
    "\\FileServer\Finance\"
    wshNetwork.AddWindowsPrinterConnection
    "\\PrintServer\FinLaser"
    wshNetWork.SetDefaultPrinter
    "\\PrintServer\FinLaser"

ElseIf InStr(strGroups, HUMAN_RESOURCES_GROUP) Then

    wshNetwork.MapNetworkDrive "g:",
    "\\FileServer\Human Resources\"
    wshNetwork.AddWindowsPrinterConnection
    "\\PrintServer\HrLaser"
    wshNetWork.SetDefaultPrinter
    "\\PrintServer\HrLaser"

End If
```

3. On the **File** menu, click **Save As**.

4. In **Save in**, click the directory that corresponds to the domain controller's Netlogon shared folder (usually *SystemRoot*\SYSVOL\Sysvol*DomainName*\Scripts where *DomainName* is the domain's fully qualified domain name).

5. In **Save as type**, click **All Files**.

6. In **File name**, type a file name, followed by **.vbs**, and then click **Save**. WSH uses the .vbs extension to identify files that contain VBScript commands.

### Notes

- To open Notepad, click **Start**, point to **All programs**, point to **Accessories**, and then click **Notepad**.

- To use the example logon script, you need to change the group names, network drive letters, and Universal Naming Convention (UNC) paths to match your system environment.

- To run a logon script, you need to assign the script to a user or a group. For more information, see Assign a logon script to a user or group.

For more information about creating and using logon scripts, see Logon Scripts, Windows Script at the Microsoft Web site, and the Microsoft Windows Resource Kits Web site.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Creating user and group accounts

Updated: March 25, 2011

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating user and group accounts**
User accounts are used to authenticate, authorize or deny access to resources for, and audit the activity of individual users on your network. A group account is a collection of user accounts that you can use to assign a set of permissions and rights to multiple users simultaneously. A group can also contain contacts, computers, and other groups. You can create user accounts and group accounts in Active Directory to manage domain users. You can also create user accounts and group accounts on a local computer to manage users specific to that computer.

Some of the most common tasks are creating user accounts in Active Directory, creating group accounts in Active Directory, creating user accounts on a local computer, and creating groups on a local computer. You can also use the command line to create user and group accounts in Managing Active Directory from the command line or on a Managing local groups from the command line. For more information about other tasks for managing Active Directory user accounts and groups, see Manage Users, Groups, and Computers. For information about other tasks for managing user accounts and groups on a local computer, see Local Users and Groups How To....

**To create a user account in Active Directory**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the folder in which you want to add a user account.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **User**.

4. In **First name**, type the user's first name.

5. In **Initials**, type the user's initials.

6. In **Last name**, type the user's last name.

7. Modify **Full name** to add initials or reverse order of first and last names.

8. In **User logon name**, type the user logon name, click the UPN suffix in the drop-down list, and then click **Next**.

   If the user will use a different name to log on to computers running Windows 95, Windows 98, or Windows NT, then you can change the user logon name as it appears in **User logon name (pre-Windows 2000)** to the different name.

9. In **Password** and **Confirm password**, type the user's password, and then select the appropriate password options.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- To add a user, you can also click

  on the toolbar.

- To add a user, you can also copy any previously created user account.

- A new user account with the same name as a previously deleted user account does not automatically assume the permissions and group memberships of the previously deleted account because the security ID (SID) for each account is unique. To duplicate a deleted user account, all permissions and memberships must be manually recreated.

- When a user account is created with the new user wizard from within the details pane, you can quickly edit the user properties by closing the wizard, clicking the new account, and then pressing ENTER. To open the new user wizard from within the details pane, right-click in the details pane, click **New**, and then click **User**.

- For interoperability with other directory services, you can create an InetOrgPerson user object. To create a new inetOrgPerson, in step three, click **InetOrgPerson** instead of **User**.

- When creating a new user, the full name attribute is created in the *FirstNameLastName* format by default. The full name attribute also governs the display name format is shown in the global address list. You can change the display name format by using ADSI Edit. If you do so, this will also change the full name format. For more information, see article Q250455, "How to Change Display Names of Active Directory Users" in the Microsoft Knowledge Base.

**To create a group account in Active Directory**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the folder in which you want to add a new group.

   **Where?**

   - Active Directory Users and Computers/*domain node/folder*

3. Point to **New**, and then click **Group**.

4. Type the name of the new group.

   By default, the name you type is also entered as the pre–Windows 2000 name of the new group.

5. In **Group scope**, click one of the options.

6. In **Group type**, click one of the options.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- To add a group, you can also click the folder in which you want to add the group, and then click

  on the toolbar.

- If the domain in which you are creating the group is set to the domain functional level of Windows 2000 mixed, you can select only security groups with **Domain local** or **Global** scopes. For more information, see Group scope.

- When a group account is created with the new group wizard from within the details pane, you can quickly edit the group account properties by closing the wizard, clicking the new account, and then pressing ENTER. To open the new group wizard from within the details pane, right-click in the details pane, click **New**, and then click **Group**.

- A group name cannot be identical to any other group name in the domain.

- A group name (pre–Windows 2000) (**samAccountName** object attribute) can contain up to 63 uppercase or lowercase characters.

- A group name (pre–Windows 2000) (**samAccountName** object attribute) cannot consist solely of periods or spaces.

- In Active Directory Users and Computers, by default, the name that you type is also entered as the pre–Windows 2000 name of the new group.

- A group name (CN) can contain up to 256 uppercase or lowercase characters, except for the following:

  " / \ [ ] : ; | = , + * ? < >

- A group name (CN) cannot consist solely of spaces.

- When you use the **net group** command to create a new group account (**net group <group_name> /add /domain**, for example, **net group Group1 /add /domain**), if you specify a group name that is longer than 64 characters, the directory service sets the group's CN to the automatically generated **objectSID** of the newly created group account and the **samAccountName** object attribute assumes the name that you specify in the **net group** command. For more information about **net group** name restrictions, see NetGroupAdd (http://go.microsoft.com/fwlink/?LinkId=159751).

**To create a user account on a local computer**

1. Open Computer Management.

2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. On the **Action** menu, click **New User**.

4. Type the appropriate information in the dialog box.

5. Select or clear the check boxes for:

   - **User must change password at next logon**
   - **User cannot change password**
   - **Password never expires**
   - **Account is disabled**

6. Click **Create**, and then click **Close**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- A user name cannot be identical to any other user or group name on the computer being administered. It can contain up to 20 uppercase or lowercase characters, except for the following:

  " / \ [ ] : ; | = , + * ? < >

  A user name cannot consist solely of periods (.) or spaces.

- In **Password** and **Confirm password**, you can type a password containing up to 127 characters. However, if the network consists of computers running Windows 95 or Windows 98, consider using passwords no longer than 14 characters. If your password is longer, you may not be able to log on to the network from those computers.

- You should not add a new local user to the local Administrators group unless the user will perform only administrative tasks. For more information, see Why you should not run your computer as an administrator.

**To create a group on a local computer**

1. Open Computer Management.

2. In the console tree, click **Groups**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Groups

3. On the **Action** menu, click **New Group**.

4. In **Group name**, type a name for the new group.

5. In **Description**, type a description of the new group.

6. To add one or more users to a new group, click **Add**.

7. In the **Select Users, Computers, or Groups** dialog box, do the following:

   - To add a user or group account to this group, under **Enter the object names to select**, type the name of the user account or group account that you want to add, and then click **OK**.

   - To add a computer account to this group, click **Object Types**, select the **Computers** check box, and then click **OK**. Under **Enter the object names to select**, type the name of the computer account that you want to add, and then click **OK**.

8. In the **New Group** dialog box, click **Create**, and then click **Close**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- A local group name cannot be identical to any other group or user name on the local computer being administered. It can contain up to 256 uppercase or lowercase characters, except for the following:

  " / \ [ ] : ; | = , + * ? < >

  A group name cannot consist solely of periods (.) or spaces.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

#### Change History

| Date | Revision |
|---|---|
| March 25, 2011 | Corrected the description of the maximum length of the **CN** and **sAMAccountName** attributes for a group object. |

# Deploying and upgrading software

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying and upgrading software**
You can deploy and upgrade software to remote computers in managed environments by using Group Policy Software Installation to assign Windows Installer packages. Windows Installer packages are deployed and managed within a Group Policy object, which is in turn associated with a particular Active Directory container--either a site, a domain, or an organizational unit. You can use Add or Remove programs in Control Panel to install, upgrade, or manage an application on a local computer. You can also use Remote Desktop Connection to install or upgrade an application by using Add or Remove programs on a remote computer. For more information, see Add or Remove programs overview and Remote Desktop Connection.

Some of the most common tasks are deploying software to remote computers, upgrading software on remote computers, and installing or upgrading software on a local computer.

**To deploy software to remote computers**

1. Open Group Policy Object Editor.
2. Do one of the following:
   - To assign software applications to computers, in the console tree, double-click **Computer Configuration**.
   - To assign or publish software applications to users, in the console tree, double-click **User Configuration**.
3. Double-click **Software Settings**, and then click **Software Installation**.

   **Where?**

   - *Group Policy object*/Computer Configuration or User Configuration/Software Settings/Software Installation
4. Right-click **Software Installation**, click **New**, and then click **Package**.
5. Click the Windows Installer package you want to assign, and then click **Open**.
6. In **Deploy Software**, click **Assigned**.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- Group Policy Software Installation is available to computers running Windows 2000, Windows XP Professional, and the Windows Server 2003 family in an Active Directory environment.
- To use Group Policy Software Installation, you must create a new Group Policy object or edit an existing Group Policy object for a site, domain, or organizational unit. You can also link a Group Policy object to a site, domain, or organizational unit in Active Directory Users and Computers or Active Directory Sites and Services. For more information about ways to open Group Policy Object Editor, see Group Policy.
- Many software applications come with Windows Installer packages (.msi files). For more information, see your software manufacturer's documentation.

**To upgrade software on remote computers**

1. Open Group Policy Object Editor.

2. Do one of the following:

   - To upgrade software applications on remote computers, in the console tree double-click, **Computer Configuration**.

   - To upgrade software applications for users, in the console tree, double-click **User Configuration**.

3. Double-click **Software Settings**, and then click **Software Installation**.

   **Where?**

   - *Group Policy object*/Computer Configuration or User Configuration/Software Settings/Software Installation

4. Right-click **Software Installation**, click **New**, and then click **Package**.

5. Click the Windows Installer package that will serve as the upgrade package, and then click **Open**.

6. In **Deploy Software**, click **Assigned**.

7. In the details pane, right-click the Windows Installer package that will function as the upgrade (not the package to be upgraded).

8. Click **properties**, and then click the **Upgrades** tab.

9. Click **Add** to create or add to the list of packages that are to be upgraded by the current package.

10. Under **Choose a package from**, click **Current Group Policy object (GPO)** or **A specific GPO** as the source of the package to be upgraded. If you click **A specific GPO**, click **Browse**, and then click the Group Policy object that you want.

11. Review the list of packages under **Package to upgrade**, which lists all of the other packages that are assigned or published within the selected Group Policy object. Depending on the Group Policy object, this list may have zero or more entries.

12. Click the package that you want to upgrade, and then do one of the following:

    - To replace an application with a completely different application, click **Uninstall the existing package, then install the upgrade package**.

    - To install a newer version of the same product while retaining the user's application preferences, click **Package can upgrade over the existing package**.

13. On the **Upgrades** tab, select the **Required upgrade for existing packages** check box if you want the upgrade to be mandatory. If this is an upgrade under Computer Configuration in the Group Policy console tree, the check box is unavailable and selected, because packages can only be assigned to computers, not published.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- Group Policy Software Installation is available to computers running Windows 2000, Windows XP Professional, and the Windows Server 2003 family in an Active Directory environment.

- To use Group Policy Software Installation, you must create a new Group Policy object or edit an existing Group Policy object for a site, domain, or organizational unit. You can also link a Group Policy object to a site, domain, or organizational unit in Active Directory Users and Computers or Active Directory Sites and Services. For more information about ways to open Group Policy Object Editor, see Group Policy.

- Many software applications come with Windows Installer packages (.msi files). For more information, see your software manufacturer's documentation.

**To install or upgrade software on a local computer by using Add or Remove programs**

1. Open Add or Remove programs in Control Panel.

2. Click **Add New programs**, and then click **CD or Floppy**.

3. Follow the instructions on your screen.

### Notes

- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.

- When using Add or Remove programs, you can only install programs that were written for Windows operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Installing a DHCP server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing a DHCP server**

All computers on a TCP/IP network must have an IP address in order for the network to properly function. You can configure IP addresses manually at each computer, or you can install a DHCP server that automatically assigns IP address leases to each client computer on the network. Most client operating systems seek an IP address lease by default, so no configuration on the client computer is necessary to implement a DHCP-enabled network.

Before a DHCP server can start leasing IP addresses to client computers, you must create and activate a scope. A scope is a range of possible IP addresses for a network. Before you create a scope, make sure that the IP address range you want to use provides enough IP addresses for all of the computers on your network. Also, determine whether any devices on your network, such as DNS servers, WINS servers, or legacy printers, will need to use static IP addresses. If there are devices that need static IP addresses, create an exclusion range of IP addresses at the beginning of the IP address range. An exclusion range is a group of IP addresses that the DHCP server will not lease to client computers. Once the exclusion range has been defined, you can assign all statically configured devices an IP address from the exclusion range.

Some of the most common tasks are installing a DHCP server, creating a scope, and activating a scope. You can also perform these tasks from the Managing DHCP from the command line. For more information about other tasks for managing DHCP, see DHCP How To....

**To install a DHCP server**

1. Open Windows Components wizard.
2. Under **Components**, scroll to and click **Networking Services**.
3. Click **Details**.
4. Under **Subcomponents of Networking Services**, click **Dynamic Host Configuration Protocol (DHCP)**, and then click **OK**.
5. If prompted, type the full path to the Windows Server 2003 distribution files, and click **Continue**.

   Required files are copied to your hard disk.

### Notes

- To open Add/Remove Windows Components, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- DHCP servers must be configured with a static IP address.

**To create a new scope**

1. Open DHCP.
2. In the console tree, click the applicable DHCP server.

   **Where?**

   - DHCP/*applicable DHCP server*

3. On the **Action** menu, click **New Scope**.

4. Follow the instructions in the New Scope wizard.

### Notes

- To open DHCP, click **Start**, click **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DHCP**.
- Depending on the starting and ending IP addresses for your scope, the DHCP console suggests a default subnet mask useful for most networks. If you know a different subnet mask is required for your network, you can modify the value as needed.
- When you finish creating a new scope, you might need to complete additional tasks, such as activating the scope for use or assigning scope options.

#### To activate a scope

1. Open DHCP.
2. In the console tree, click the applicable scope.

   **Where?**

   - DHCP/*Applicable DHCP server*/*Applicable superscope* (if used)/*Applicable scope*

3. On the **Action** menu, click **Activate**.

### Notes

- To open DHCP, click **Start**, click **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DHCP**.
- Activating a scope is needed only for new scopes to start lease distribution. You must activate a scope to make it available for DHCP clients.
- Do not activate a scope until you specify the options you want.
- The **Action** menu command changes to **Deactivate** when the selected scope is currently activated. Do not deactivate a scope unless you are retiring it permanently from use on your network.
- If you want to use DHCP to assign IP address leases to clients on a subnet that is separated from your DHCP server by a router, you must have DHCP message forwarding enabled on the router. If you are using a computer running a member of the Windows Server 2003 family as a router, you can use the DHCP Relay Agent service provided with the Routing and Remote Access service. For more information, see DHCP/BOOTP Relay Agents and Configure the DHCP Relay Agent.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Installing a domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing a domain controller**

Domain controllers provide network users and computers with the Active Directory directory service, which stores and replicates directory data and manages user interactions with the domain, including user logon processes, authentication, and directory searches. Every domain must contain at least one domain controller. You install a domain controller by installing Active Directory on any member or stand-alone server (except those with restrictive license agreements).

When you install the first domain controller in your organization, you are creating the first domain (also called the root domain) and the first forest. You can add additional domain controllers to an existing domain to provide fault tolerance, improve service availability, and balance the load of existing domain controllers.

You can also install a domain controller to create a new child domain or new domain tree. Create a new child domain when you want a new domain that shares a contiguous namespace with one or more domains. This means that the name of the new domain contains the full name of the parent domain. For example, sales.microsoft.com would be a child domain of microsoft.com. Create a new domain tree only when you need a domain whose Domain Name System (DNS) namespace is not related to the other domains in the forest. This means that the name of the new domain tree's root domain (and all of its children) does not contain the full name of the parent domain. A forest can contain one or more domain trees.

Before installing a new domain controller, you will need to consider pre-Windows 2000 compatible security levels and identify the DNS name of the domain. For more information, see Checklist: Creating an additional domain controller in an existing domain.

The most commonly performed tasks when installing a domain controller are creating a new domain in a new forest, creating a new child domain in an existing domain tree, creating a new domain tree in an existing forest, and adding a domain controller to an existing domain.

For information about important decisions you need to make when installing a domain controller, see Using the Active Directory Installation Wizard.

**To create a new domain in a new forest**

1. Open the Active Directory Installation Wizard.
2. On the **Domain Controller Type** page, click **Domain controller for a new domain**, and then click **Next**.
3. On the **Create New Domain** page, click **Domain in a new forest**, and then click **Next**.
4. On the **New Domain Name** page, type the full DNS name for the new domain, and then click **Next**.
5. On the **NetBIOS Domain Name** page, verify the NetBIOS name, and then click **Next**.
6. On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.
7. On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.
8. On the **DNS Registration Diagnostics** page, verify if an existing DNS server will be authoritative for this forest or, if necessary, choose to install and configure DNS on this server by clicking **Install and configure the DNS server on this computer, and set this computer to use this DNS server as its preferred DNS server**, and then click **Next**.
9. On the **Permissions** page, select one of the following:

    - **Permissions compatible with pre-Windows 2000 Server operating systems**

- **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems**

10. Review the **Summary** page, and then click **Next** to begin the installation.

11. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- The server on which you perform this procedure will be promoted to the first domain controller in the forest root domain.

- The wizard options on the **Permissions** page affect application compatibility with pre-Windows 2000 and Windows Server 2003 operating systems and are not related to domain functionality.

- The Active Directory Installation Wizard allows Active Directory domain names up to 64 characters or up to 155 bytes. Although the limit of 64 characters is usually reached before the limit of 155 bytes, the opposite could be true if the name contains Unicode characters consuming three bytes. These limits do not apply to computer names.

**To create a new child domain in an existing domain tree**

1. Open the Active Directory Installation Wizard.

2. On the **Domain Controller Type** page, click **Domain controller for a new domain**, and then click **Next**.

3. On the **Create New Domain** page, click **Child domain in an existing domain tree**, and then click **Next**.

4. On the **Network Credentials** page, type the user name, password, and user domain of the user account you want to use for this operation, and then click **Next**.

5. On the **Child Domain Installation** page, verify the parent domain and type the new child domain name, and then click **Next**.

6. On the **NetBIOS Domain Name** page, verify the NetBIOS name, and click **Next**.

7. On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.

8. On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.

9. On the **DNS Registration Diagnostics** page, verify the DNS configuration settings are accurate, and then click **Next**.

10. On the **Permissions** page, select one of the following:

    - **Permissions compatible with pre-Windows 2000 Server operating systems**

    - **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems**

11. On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password you want to assign to this server's Administrator account that will be used when the computer is started in Directory Services Restore

Mode, and then click **Next**.

12. Review the **Summary** page, and then click **Next** to begin the installation.

13. Restart the computer.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- The server on which you perform this procedure will be promoted to the first domain controller in a new child domain.

- When a child domain is added to an existing tree domain, a two-way, transitive, parent and child trust is established by default.

- The wizard options on the **Permissions** page affect application compatibility with pre-Windows 2000 and Windows Server 2003 operating systems and are not related to domain functionality.

- The Active Directory Installation Wizard allows Active Directory domain names up to 64 characters or up to 155 bytes. Although the limit of 64 characters is usually reached before the limit of 155 bytes, the opposite could be true if the name contains Unicode characters consuming three bytes. These limits do not apply to computer names.

#### To create a new domain tree in an existing forest

1. Open the Active Directory Installation Wizard.

2. On the **Domain Controller Type** page, click **Domain controller for a new domain**, and then click **Next**.

3. On the **Create New Domain** page, click **Domain tree in an existing forest**.

4. On the **Network Credentials** page, type the user name, password, and user domain of the user account you want to use for this operation, and then click **Next**.

5. On the **New Domain Tree** page, type the full DNS name for the new domain, and then click **Next**.

6. On the **NetBIOS Domain Name** page, verify the NetBIOS name, and then click **Next**.

7. On the **Database and Log Folders** page, type the location in which to install the database and log folders, or click **Browse** to choose a location, and then click **Next**.

8. On the **Shared System Volume** page, type the location in which to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next**.

9. On the **DNS Registration Diagnostics** page, verify if an existing DNS server will be authoritative for this forest or, if necessary, choose to install and configure DNS on this server by clicking **Install and configure the DNS server on this computer, and set this computer to use this DNS server as its preferred DNS server**, and then click **Next**.

10. On the **Permissions** page, select one of the following:

    - **Permissions compatible with pre-Windows 2000 Server operating systems**

    - **Permissions compatible only with Windows 2000 or Windows Server 2003 operating systems**

11. On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password you want to assign this server's Administrator account that will be used when the computer is started in Directory Services Restore Mode, and then click **Next**.

12. Review the **Summary** page, and then click **Next** to begin the installation.

13. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- The server on which you perform this procedure will be promoted to the first domain controller in a new domain tree.

- When a new domain tree is created in an existing forest, a two-way, transitive, tree root trust is established by default.

- The wizard options on the **Permissions** page affect application compatibility with pre-Windows 2000 and Windows Server 2003 operating systems and are not related to domain functionality.

- The Active Directory Installation Wizard allows Active Directory domain names up to 64 characters or up to 155 bytes. Although the limit of 64 characters is usually reached before the limit of 155 bytes, the opposite could be true if the name contains Unicode characters consuming three bytes. These limits do not apply to computer names.

**To install an additional domain controller in an existing domain**

1. Open the Active Directory Installation Wizard.

2. On the **Domain Controller Type** page, click **Additional domain controller for an existing domain** , and then click **Next** .

3. On the **Network Credentials** page, type the user name, password, and user domain of the user account you want to use for this operation, and then click **Next** . See Note below for more information.

4. On the **Additional Domain Controller** page, enter the full DNS name of the existing domain for which the server will become a domain controller, and then click **Next** .

5. On the **Database and Log Folders** page, type the location in which you want to install the database and log folders, or click **Browse** to choose a location, and then click **Next** .

6. On the **Shared System Volume** page, type the location in which you want to install the Sysvol folder, or click **Browse** to choose a location, and then click **Next** .

7. On the **Directory Services Restore Mode Administrator Password** page, type and confirm the password you want to assign to this server's Administrators account that will be used when the computer is started in Directory Services Restore Mode, and then click **Next**.

8. Review the **Summary** page, and then click **Next** to begin the installation.

9. Restart the computer.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using

Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To create an additional domain controller from restored backup files, start the Active Directory Installation Wizard by typing **dcpromo /adv** at a command prompt.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing applications on a local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing applications on a local computer**
Managing applications involves adding or removing applications, changing the configuration of an application, or scheduling an application to run at a specific time. You can use Add or Remove Programs in Control Panel to add or remove an application, modify an existing application, repair a damaged application, or add or remove components of Windows. You can use Task Scheduler or the **at** command to schedule an application to run at a specific time.

You can also update your operating system and other Microsoft software by using Windows Update in Help and Support Center to download items such as security fixes, critical updates, the latest Help files, drivers, and Internet products. For more information, see Windows Update.

Some of the most common tasks are adding, removing, or changing an application and scheduling an application to run at a specific time. You can also run an application at a scheduled time from the command line by using the At command. For more information about other tasks for managing applications, see Managing applications remotely.

**To add, remove, or change an application**

1. Open Add or Remove Programs in Control Panel.

2. Do one of the following:

    - To add a new application from a CD or floppy disk, click **Add New Programs**, click **CD or Floppy**, and then follow the instructions on your screen.

    - To add a new application from your network, click **Add New Programs**, click the program you want to add, and then click **Add**. Follow the instructions on your screen.

    - To change or remove an application, click **Change or Remove Programs**, click the program you want to change or remove, and then click **Change/Remove**. Follow the instructions on your screen.

### Caution

- Some programs do not provide Change options and may be removed without prompting you further.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.

- Only applications written for Windows operating systems can be used with Add or Remove Programs.

- Many software applications provide tools for setting configuration properties or adding or removing components. You will often see these tools listed in an application's program group on the **Start** menu or in Control Panel. For more information, see the software manufacturer's documentation.

**To schedule an application to run at a specific time**

1. Open Task Scheduler.

2. Double-click **Add Scheduled Task**.

3. Follow the instructions in the Scheduled Task Wizard.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or Server Operators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.

- For more information, see Task Scheduler.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing applications remotely

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing applications remotely**

You can manage the applications for an entire system from a remote location by using the remote administration features of the Windows Server 2003 family. With the Remote Desktops snap-in, you can access remote computers for installations, deletions, or modifications of applications on those computers. In addition, with Group Policy Software Installation, you can assign or publish applications. You assign an application to users or computers when you want everyone to have the application on his or her computer. When the users log on to their computers, the application installs. You publish an application to users when you want the application to be available to the users who are managed by your Group Policy object. These users then determine when to install the application.

Some of the most common tasks are creating a new connection to a remote computer, assigning an application to users or computers, and publishing an application to users. For more information about other tasks for managing applications remotely, see Remote Desktops snap-in How To....

**To create a new connection to a remote computer**

1. Open Remote Desktops snap-in.
2. In the console tree, right-click **Remote Desktops**.
3. Click **Add new connection**.
4. In the **Add New Connection** dialog box, in **Server name or IP address**, type the name or TCP/IP address of the server. Or, click **Browse** to look for a server.
5. Optionally, in **Connection Name**, type a friendly name for this connection.
6. Clear the **Connect to console** check box if you do not want to connect to the console of the server.
7. Optionally, in **Logon information**, supply the user name, password and domain to automatically log on to the server. Click **OK**.

### Notes

- To open Remote Desktops, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Desktops**.
- Depending on the configuration of the Terminal server, you might be prompted to supply your password upon connection even if you specify it in the **Add New Connection** dialog box.

**To assign an application to users or computers**

1. Open Group Policy Software Installation.
2. In the console tree, click **Software Installation**.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Software Settings/Software Installation

3. In the details pane, right-click, point to **New**, and then click **Package**.

4. In the **Open** dialog box, click the Windows Installer package, and then click **Open**.

5. In the **Deploy Software** dialog box, click **Assigned**, and then click **OK**.

### Notes

- To open Group Policy Software Installation, see Group Policy (pre-GPMC).

- The **Open** dialog box shows the packages that are located at a software distribution point that you specify as the default.

- If the Windows Installer package is located on a different network drive, navigate to the correct software distribution point in the **Open** dialog box, click the package, and then click **Open**.

#### To publish an application to users

1. Open Group Policy Software Installation.

2. In the details pane, right-click, point to **New**, and then click **Package**.

3. In the **Open** dialog box, click the Windows Installer package to be published, and then click **Open**.

4. In the **Deploy Software** dialog box, click **Published**.

### Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Software Installation, see Group Policy (pre-GPMC).

- Packages can be published only to users, not to computers.

- The **Open** dialog box shows the packages that are located at a software distribution point that you specify as the default.

- If the Windows Installer package is located on a different network drive, navigate to the correct software distribution point in the **Open** dialog box, click the package, and then click **Open**.

- The application is available for users to install either by using Add or Remove Programs in Control Panel or by opening a file with an extension that you have associated with the application.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing directory replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing directory replication**
Except for very small networks, directory data must reside in more than one place on the network to be equally useful to all users. Through replication, the Active Directory directory service maintains replicas of directory data on multiple domain controllers, ensuring directory availability and performance for all users. Active Directory relies on configuration information that you provide about sites, subnets, and site links to manage and optimize the process of replication.

Some of the most common tasks are creating sites, creating site links, and creating a subnet and associating it with a site. For more information about other tasks for managing directory replication, see Manage Sites.

**To create a site**

1. Open Active Directory Sites and Services.
2. Right-click the **Sites** folder, and then click **New Site**.
3. In **Name**, type the name of the new site.
4. Click a site link object, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- For more information about sites, see Sites overview.

**To create a site link**

1. Open Active Directory Sites and Services.
2. In the console tree, right-click the intersite transport protocol you want the site link to use, and then click **New Site Link**.

   **Where?**

   - Active Directory Sites and Services/Sites/Inter-Site Transports/*inter-site transport protocol you want the site link to use*

3. In **Name**, type the name to be given to the link.
4. Click two or more sites to connect, and then click **Add**.
5. Configure the site link's cost, schedule, and replication frequency.

### Caution

- If you create a site link that uses SMTP, you must have an enterprise certification authority (Enterprise CA) available and

SMTP must be installed on all domain controllers that will use the site link.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- Creating a site link between two or more sites is a way to influence replication topology. By creating a site link, you provide Active Directory with information about what connections are available, which ones are preferred, and how much bandwidth is available. Active Directory uses this information to choose times and connections for replication that will afford the best performance.
- For more information about configuring the site link's cost, schedule, and replication frequency, see Configure Replication Between Sites and Managing replication.

#### To create a subnet and associate it with a site

1. Open Active Directory Sites and Services.
2. In the console tree, double-click **Sites**.
3. Right-click **Subnets**, and then click **New Subnet**.
4. In **Address**, enter the subnet address.
5. In **Mask**, enter the subnet mask that describes the range of addresses included in this site's subnet.
6. Select a site with which to associate this subnet, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- Any IP address within the subnet range is a valid entry.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Management tasks for disks and volumes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing disks and volumes**
Managing disks and volumes includes creating and formatting partitions, logical drives, and volumes; setting disk quotas to limit disk usage; defragmenting volumes to improve file-system performance; and checking for file-system errors and bad sectors on a hard disk. The Windows Server 2003 family provides many tools you can use to effectively manage disks and volumes on new or existing systems. These tools include Disk Management, Disk Defragmenter, disk quotas, and error checking.

Some of the most common tasks are creating partitions or logical drives, formatting basic volumes, extending basic volumes, and defragmenting volumes. You can also manage disks and volumes from the Managing disks and volumes from the command line. For information about disk quotas, see Disk Quotas. For information about error checking, see Detecting and Repairing Disk Errors. For more information about other tasks for managing disks and volumes, see Disk Managment How To....

**To create a partition or logical drive**

1. Open Computer Management (Local).

2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

3. Right-click an unallocated region of a basic disk, and then click **New Partition**, or right-click free space in an extended partition, and then click **New Logical Drive**.

4. In the New Partition wizard, click **Next**, click **Primary partition**, **Extended partition**, or **Logical drive**, and then follow the instructions on your screen.

### Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- You can create primary partitions, extended partitions, and logical drives only on basic disks. You should create basic volumes instead of dynamic volumes if this computer also runs MS-DOS, Windows 95, Windows 98, Windows Millinnium Edition, Windows NT 4.0, or Windows XP Home Edition.

- On a master boot record (MBR) disk, you can create up to four primary partitions, or three primary partitions, one extended partition, and unlimited logical drives.

- On a GUID partition table (GPT) disk, you can create up to 128 primary partitions.

**To format a basic volume**

1. Open Computer Management (Local).

2. In the console tree, click **Computer Management (Local)**, click **Storage**, and then click **Disk Management**.

3. Right-click the partition, logical drive, or basic volume you want to format (or reformat), and then click **Format**.

4. Select the options you want, and then click **OK**.

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group or Administrators group on the local computer, or you must have been delegated the appropriate authority. To perform this procedure remotely, you must be a member of the Backup Operators group or Administrators group on the remote computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- You cannot format system, boot, OEM, or unknown partitions.

- File compression is supported only on NTFS volumes with cluster sizes 4 KB and smaller.

- If you select the **Perform a quick format** check box, the files are removed from the disk but the disk is not scanned for bad sectors. Use this option only if this disk has been previously formatted and you are sure the disk is not damaged.

**To extend a basic volume**

1. Open Command Prompt.

2. Type:

   **diskpart**

3. At the **DISKPART** prompt, type:

   **list volume**

   Make note of the number of the basic volume you want to extend.

4. At the **DISKPART** prompt, type:

   **select volume***n*

   Selects the basic volume, *n*, you want to extend into contiguous, empty space on the same disk.

5. At the **DISKPART** prompt, type:

   **extend** [**size=***n*]

   Extends the selected volume by size=*n* megabytes (MB).

**Notes**

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**prompt**.

- To extend a basic volume, it must either not be formatted with a file system or it must be formatted with the NTFS file system.
- You can only extend a basic volume onto the same disk.
- You can only extend a basic volume if it is followed by contiguous unallocated space.
- For more information about Disk Management and the **diskpart** command, see Disk Management and DiskPart.

**To defragment a volume**

1. Open Disk Defragmenter.
2. Click the volume that you want to defragment, and then click **Defragment**.

   After the defragmentation is complete, Disk Defragmenter displays the results in **Estimated disk usage after defragmentation**.
3. Click **View Report** to view the Defragmentation Report, which displays detailed information about the volume you defragmented.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Disk Defragmenter, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Disk Defragmenter**.
- You should analyze volumes before defragmenting them. This tells you whether you need to take the time to defragment them.
- A volume must have at least 15% free space for Disk Defragmenter to completely and adequately defragment it. Disk Defragmenter uses this space as a sorting area for file fragments. If a volume has less than 15% free space, Disk Defragmenter will only partially defragment it. To increase the free space on a volume, delete unneeded files or move them to another disk.
- You cannot defragment volumes that the file system has marked as dirty, which indicates possible corruption. You must run **chkdsk** on a dirty volume before you can defragment it. You can determine if a volume is dirty by using the **fsutil dirty query** command. For more information about the **chkdsk** command, see chkdsk. For more information about the **fsutil dirty** command, see Fsutil: dirty.
- The time that Disk Defragmenter takes to defragment a volume depends on several factors, including the size of the volume, the number and size of files on the volume, the percentage of fragmentation in the volume, and available system resources.
- You can defragment only local file system volumes, and you can run only one instance of Disk Defragmenter at a time.
- To stop or temporarily interrupt defragmenting a volume, click **Stop** or **Pause**, respectively.
- If you start Disk Defragmenter while performing a backup on the same volume, Disk Defragmenter stops.
- Running the **defrag** command and Disk Defragmenter are mutually exclusive. If you are using Disk Defragmenter to

defragment a volume and you run the **defrag** command at a command prompt, the **defrag** command fails. Conversely, if you run the **defrag** command, and open Disk Defragmenter, the defragmentation options in Disk Defragmenter are unavailable.

- For more information about Disk Defragmenter and the **defrag** command, see Disk Defragmenter and Defrag.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# File and folder management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing files and folders**
Managing files and folders includes storing and securing resources, making those resources available to network users, and managing changes in those resources. The Windows Server 2003 family provides many tools you can use to manage files and folders. These tools include Shared Folders, shadow copies of shared folders, Distributed File System (DFS), Encrypting File System (EFS), and Offline Files. When a folder is shared, users can connect to the folder over the network and gain access to the contents of the shared folder. With shadow copies of shared folders, users can view the contents of network folders as they existed at points of time in the past.

Some of the most common tasks are sharing a folder or drive, enabling shadow copies of shared folders, and changing settings for shadow copies of shared folders. You can also manage files and folders from the Managing shared folders from the command line. For more information about other tasks for managing files and folders, see Shared Folders How To....

**To share a folder or drive**

1. Open Computer Management.

2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. On the **Action** menu, click **New Share**.

4. Follow the steps in the Share a Folder Wizard, and then click **Finish**.

**Important**

- When you create a shared resource, determine how to secure that resource. There are several methods you can use to secure shared resources. For more information, see Share permissions.

**Notes**

- You must be logged on as a member of the Administrators or the Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**To enable shadow copies of shared folders**

1. Open Computer Management (Local).

2. In the console tree, right-click **Shared Folders**, point to **All Tasks**, and then click **Configure Shadow Copies**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Select the volume where you want to enable shadow copies of shared folders, and then click **Enable**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can also access shadow copies of shared folders by right-clicking on a fixed NTFS volume in **My Computer** or in **Disk Management**, clicking **Properties**, and then clicking the **Shadow Copies** tab.
- You can also use Disk Management to manage shadow copies of shared folders on remote servers. On the **Action** menu, point to **All Tasks**, and then click **Configure Shadow Copies**.
- Enabling shadow copies of shared folders also creates a default schedule and settings for subsequent shadow copies. To make changes to these defaults, click **Settings**
- Shadow copies are enabled on a per volume basis; you cannot select specific shares on a volume to be copied or not copied.

**To change settings for shadow copies of shared folders**

1. Open Computer Management (Local).
2. In the console tree, right-click **Shared Folders**, point to **All Tasks**, and then click **Configure Shadow Copies**.

   **Where?**

   - Computer Management/System Tools/Shared Folders

3. Select the volume where you want to make changes, and then click **Settings**.
4. In this dialog box, you can change the settings described in the following table.

| Setting | Notes |
|---|---|
| **Storage volume** | This indicates where you would like to store the shadow copies of the selected volume. The default is to use the same volume. It is recommended that you use a separate volume on another disk which provides better performance for heavily used file servers. You can only change the storage volume when there are no shadow copies present. If you need to change the storage volume for a volume that already has been enabled, you must delete all of the shadow copies on that volume, then change the storage volume. |
| **Details** | Clicking **Details** will open a dialog box that lists the shadow copies that are currently stored. This dialog box also gives information about the total space and available storage space on the disk. |
| **Storage limits** | The default size is 10 percent of the size of the volume that holds the source files being shadow copied. If the shadow copies are stored on a separate volume from the source files, you should change this default to reflect the amount of the storage volume that you are willing to dedicate to shadow copies. The storage limit must be at least 100 MB, which will only allow for a single shadow copy to be retained. If you set a restrictive storage limit, you should test to ensure that the number of shadow copies you have scheduled will fit within those restraints. If shadow copies are deleted prematurely due to storage limits, you may be defeating the purpose of enabling shadow copies of shared folders. |

| | |
|---|---|
| **Schedule** | Clicking **Schedule** will open the task scheduler with the information needed to create a task schedule for taking shadow copies of shared folders on a regular basis. Before creating the schedule, take a look at your current users work patterns and design a strategy that will schedule shadow copies at a time of day that will work best for your users. The default schedule is Monday through Friday at 7:00 A.M. and 12:00 P.M. For more information about creating a schedule for shadow copies of shared folders, see Defining a schedule for shadow copies. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing network printers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing network printers**
To create a secure and effective network printing environment, you must consider variables such as what client operating systems are used on your network, what printing permissions you want to assign to different users, and what procedures you will use to manage the printers once they are connected to the network. The easiest way to connect and manage network printers is through Active Directory. You can also use Group Policy to change the default behavior of the printing environment and to provide computers and users a standard set of preferences.

Some of the most common tasks are publishing a printer in Active Directory, remotely managing printers, setting Group Policy for printers, and setting or removing permissions for a printer. You can also manage network printers from the Managing printing from the command line. For more information about other tasks for managing network printers, see Printing How To....

**To publish a printer in Active Directory**

1. Open Printers and Faxes.
2. Right-click the printer you want to publish, and then click **Sharing**.
3. On the **Sharing** tab, click **Share this printer**, and then type a name for the shared printer.
4. Select the **List in the Directory** check box to publish the printer in Active Directory.

### Notes

- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- Only a shared printer can be published. If you stop sharing a printer, the printer is no longer published.
- If you add a printer using the Add Printer Wizard and click **Share this printer**, the printer will be published by default if the Group Policy settings **Automatically publish new printers in Active Directory** and **Allow printers to be published** are enabled, as they are by default.
- You must open Active Directory Users and Groups to publish printers that are managed through print servers that are running Windows NT 4.0 or an earlier operating system.
- Printers you add using the Add Printer Wizard are shared by default if you add them from a computer running a product in the Windows Server 2003 family. However, printers are not shared by default if you add them using the Add Printer Wizard from a computer running Windows XP.
- You must have the Manage Printers permission for the printer you want to share or to publish.
- You can create printer names that contain spaces, special characters, and more than eight characters. However, some clients do not recognize or correctly handle such names. The entire qualified name of a shared printer (for example \\PRINTER2\PSCRIPT) must contain 32 or fewer characters.

**To remotely manage printers**

1. Double-click **My Network Places**, and then locate the print server for the printers you want to manage.
2. Double-click the print server, double-click the **Printer folder** icon on that server, and then click a printer.

   **Important**

- To facilitate stronger network security, remote printer management is not available by default. To enable remote printer management, in Group Policy, you must enable the Allow Print Spooler to Accept Client Connections policy.

3. Change the print server, printer, or printing preference settings as required.

### Notes

- You can change printer settings only if you have Manage Printers permission.
- If you are having trouble finding your printer and you are logged on to a Windows Server 2003 domain, you can find your printer by clicking **Start**, pointing to **Search**, and then clicking **Printers**.
- You can also drag the Printers and Faxes folder of any print server (or specific printers from any Printers and Faxes folder) to the Printers and Faxes folder on your computer. This is an easy way to manage any printer without having to search for it.

#### To set Group Policy for printers

1. Start Group Policy according to the object you want to set printer policy to.
2. After selecting the properties page of the object you want to set printer policy to, select the Group Policy node.
    - If you want to set policies that apply only to computers, expand the **Computer Configuration** node, and then expand **Administrative Templates**.
    - If you want to set policies that apply only to users, expand the **User Configuration** node, expand **Administrative Templates**, and then expand **Control Panel**.
3. Double-click **Printers** to open a listing of policies.
4. Double-click the printer policy you want to set.
5. On the **Policy** tab, enable or disable the policy by selecting or clearing the appropriate radio button. With some policies, you might need to enter additional information.

### Note

- If you do not want to change the current state of the policy setting, leave it as it is (not configured) to save processing time.

#### To set or remove permissions for a printer

1. Open Printers and Faxes.
2. Right-click the printer for which you want to set permissions, click **Properties**, and then click the **Security** tab.
3. Do one of the following:
    - To change or remove permissions from an existing user or group, click the name of the user or group.
    - To set up permissions for a new user or group, click **Add**. In **Select Users, Computers, or Groups**, type the name of the user or group you want to set permissions for, and then click **OK** to close the dialog box.

4. In **Permissions**, click **Allow** or **Deny** for each permission you want to allow or deny, if necessary. Or, to remove the user or group from the permissions list, click **Remove**.

### Notes

- To change device settings, you must have the Manage Printers permission. For information about printing security permissions, see Assigning printer permissions.
- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- To view or change the underlying permissions that make up Print, Manage Printers, and Manage Documents, click the **Advanced** button.
- A printer must be shared in order for the permission settings to affect the users and groups listed.
- You can also view the permissions assigned to you by clicking the group you belong to on the **Security** tab. For information on finding out what group you belong to, see Identify members of a local group.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing servers remotely

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing servers remotely**
Windows Server 2003 operating systems provide tools that you can use to manage servers from a remote location. These tools expand your flexibility because you can work as though you are physically present at each computer in your organization. The tools include the Remote Desktops snap-in, Active Directory Users and Computers, Web Interface for Remote Administration, and the Windows Server 2003 Administration Tools Pack. By understanding the advantages and security requirements of each tool, you can choose the most appropriate one for your remote administration and management tasks. For example, if you want to remotely manage a group of servers instead of just one server, Active Directory is the preferred tool to use. Each server that you want to manage remotely must be enabled for remote administration.

Some of the most common tasks are managing servers remotely by using the Remote Desktops snap-in and managing servers remotely by using Active Directory Users and Computers. For more information on installing and using the Windows Server 2003 Administration Tools Pack to manage servers remotely from Windows XP Professional, see Windows Server 2003 Administration Tools Pack. For more information about using Web Interface for Remote Administration, see Using Web Interface for Remote Administration. For more information about other tasks for managing servers remotely, see Remote Desktop for Administration How To....

**To manage servers remotely by using the Remote Desktops snap-in**

1. Open Remote Desktops snap-in.
2. In the console tree, right-click **Remote Desktops**.
3. Click **Add new connection**.
4. In the **Add New Connection** dialog box, in **Server name or IP address**, type the name or TCP/IP address of the server. Or, click **Browse** to look for a server.
5. Optionally, in **Connection Name**, type a friendly name for this connection.
6. Clear the **Connect to console** check box if you do not want to connect to the console of the server.
7. Optionally, in **Logon information**, supply the user name, password and domain to automatically log on to the server. Click **OK**.

### Important

- To complete this procedure, the Remote Desktop option must be enabled on each remote computer.

### Notes

- To open Remote Desktops, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Desktops**.
- Depending on the configuration of the Terminal server, you might be prompted to supply your password upon connection even if you specify it in the **Add New Connection** dialog box.

**To manage servers remotely by using Active Directory Users and Computers**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

**Where?**

- Active Directory Users and Computers/*domain node*/Computers

Or, click the container that contains the computer you want to manage.

3. In the details pane, right-click the computer, and then click **Manage**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- Clicking **Manage** starts Computer Management from which you can administer remote computers. You must have administrative credentials on the local computer to view certain information or to modify computer properties using Computer Management.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Managing services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing services**
A service is an application type that runs in the background and is similar to a UNIX daemon application. Services typically provide access to key features such as file servers, Web servers, database servers, and other server-based applications to users, both locally and across the network.

Some of the most common tasks associated with managing services are starting and stopping a service, disabling a service for a hardware profile, and changing the startup method for a service. For more information about other tasks for managing services, see Services How To....

To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled. You should not change the startup method of a service unless you are sure you are choosing the appropriate startup method. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services.

**To start, stop, pause, resume, or restart a service**

1. Open Services.

2. In the details panel, do one of the following:

    - Click the service, and then, on the **Action** menu, click **Start**, **Stop**, **Pause**, **Resume**, or **Restart**.

    - Right-click the service, and then click **Start**, **Stop**, **Pause**, **Resume**, or **Restart**.

### Caution

- If you stop, start, or restart a service, any dependent services are also affected. Starting a service does not automatically restart its dependent services. For more information, see View service dependencies.

- Changing the default service settings might prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically. In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

- To start a service with startup parameters, right-click the service, click **Properties**, and then type the parameters in **Start parameters** before you click **Start**. These settings are not persistent; they are are used only once, and then the default settings are restored. (A backslash (\) is treated as an escape character; type two backslashes for each backslash in a parameter.)

**To enable or disable a service for a hardware profile**

1. Open Services.

2. In the details pane, right-click the service that you want to enable or disable, and then click **Properties**.

3. On the **Log On** tab, click the hardware profile that you want to configure.

4. Click **Enable** or **Disable**, and then click **OK**.

### Caution

- Changing the default service settings might prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically. In most cases, you should not change the **Allow service to interact with desktop** setting.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

- You may want to set up a hardware profile to test any newly installed services. For example, you can create two hardware profiles for a newly installed service: one profile in which the service is enabled and a second profile in which the service is disabled. This way, you can troubleshoot any problems that may occur, such as a driver not loading properly.

- Use caution when disabling services by using this method. If you disable a service for a certain hardware profile, the **Hardware Profile** settings override the **Startup type** setting for that service.

- Use the options in the **System Properties** dialog box to create and manage hardware profiles.

- If you receive a **Configuration Manager** error message when you open the **Properties** dialog box, verify that the Remote Registry service is running on the target computer. If the Remote Registry service is not running, or if the target computer is running Windows NT 4.0, you cannot view or modify hardware profile settings, but you can perform any other actions. For more information about troubleshooting services, see Troubleshooting Services Snap-in. Also, see "Managing System Services" at the Microsoft Windows Resource Kits Web site.

#### To start, stop, or change the startup method for a service

1. Open Services.

2. In the details pane, right-click the service that you want to configure, and then click **Properties**.

3. On the **General** tab, in **Startup type**, click **Automatic**, **Manual**, or **Disabled**.

4. To specify the user account that the service can use to log on, click the **Log On** tab, and then do one of the following:

    - To specify that the service uses the LocalSystem account, click **Local System account**.

    - To specify that the service uses the LocalService account, click **This account**, and then type **NT AUTHORITY\LocalService**.

    - To specify that the service uses the NetworkService account, click **This account**, and then type **NT AUTHORITY\NetworkService**.

    - To specify another account, click **This account**, click **Browse**, and then specify a user account in the **Select User** dialog box. When you are finished, click **OK**.

5. Type the password for the user account in the **Password** box and in the **Confirm password** box, and then click **OK**. If

you select the Local Service account or Network Service account, the password must be blank.

### Caution

- Most services are not designed to have the default account changed. Changing the default account of a service could result in the service failing to start.
- Changing the default service settings may prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically.
- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on the interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

### Notes

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
- The Local Service account and Network Service account are configured with a null password. Whatever password information you supply is ignored. For more information about service accounts, see Services permissions.
- It is recommended that user accounts that are used to log on as a service have the **Password never expires** check box selected in their properties dialog box and that they have strong passwords.
- If account lockout policy is enabled and the account is locked out, the service will not start.
- If you enable or disable a service and you encounter a problem starting the computer, you can start the computer in Safe Mode. In Safe Mode, core services that are required to start the operating system are started in a default scheme, regardless of any changes that are made to the service settings. After the computer is in Safe Mode, you can change the service configuration or restore the default configuration.
- If you specify an account that does not have permission to log on as a service, the Services snap-in automatically grants the appropriate permissions to that account on the computer that you are managing.
- For more information about the user accounts that a service uses to log on, see "Managing System Services" at the Microsoft Windows Resource Kits Web site.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitoring network traffic

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring network traffic**
As an administrator, you need to monitor and detect problems with traffic on your network. With Network Monitor, you can gather information about the network traffic that flows to and from the network adapter of the computer on which it is installed. Once you capture the information, you can use Network Monitor to analyze the information, diagnose problem traffic patterns, and devise strategies to prevent future network traffic problems.

Some of the most common tasks are installing Network Monitor, specifying data frame patterns to capture, capturing network frames, and viewing a specific frame. You can also monitor network traffic from the Managing Network Monitor from the command line. For more information about other tasks for monitoring network traffic, see Network Monitor How To ....

**To install Network Monitor**

1. Open Windows Components wizard.
2. In the Windows Components wizard, click **Management and Monitoring Tools**, and then click **Details**.
3. In **Subcomponents of Management and Monitoring Tools**, select the **Network Monitor Tools** check box, and then click **OK**.
4. If you are prompted for additional files, insert the installation CD for your operating system, or type a path to the location of the files on the network.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- This procedure automatically installs the Network Monitor driver.

**To specify frame data patterns to capture**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Filter**.
4. In the capture filter decision tree, double-click the **AND (Pattern Matches)** line.
5. Complete the Pattern Match dialog box, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.

- You can define up to four data patterns in a capture filter.

- To capture frames that match any of multiple patterns, create a logical branch by selecting one of the patterns in the decision tree and clicking **OR**.

- To exclude frames that match a pattern, select the pattern in the decision tree and then click **NOT**.

- If you specify more than one pattern in the capture filter decision tree, by default, Network Monitor treats each as a logical OR branch.

**To capture network frames**

1. Open Network Monitor.

2. If prompted, select the local network from which you want to capture data by default.

3. On the **Capture** menu, click **Buffer Settings**, and then set the buffer and frame size as appropriate.

4. On the **Capture** menu, click **Start**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.

- To pause, stop, or display the data capture, on the **Capture** menu, click **Pause**, **Stop**, or **Display Captured Data**. You can also stop and display the capture by clicking **Stop and View**.

- Network Monitor displays session statistics of the first 100 unique network sessions that it detects. To reset statistics and view information about the next 100 detected network sessions, click the **Capture** menu, and then click **Clear Statistics**.

- If you want to capture data from multiple local networks at the same time, install an adapter and start an instance of Network Monitor for each network. In each instance, specify the network from which you want to capture data by, on the **Capture** menu, clicking **Networks** and selecting a network.

- If prompted for additional files, insert the installation CD for your operating system, or type a path to the location of the files on the network.

**To view a specific frame**

1. Open Network Monitor.

2. If prompted, select the local network from which you want to capture data by default.

3. Do one of the following:

- On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
- On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.

4. On the **Display** menu, click **Go To Frame**.
5. In the Go To dialog box, type the number of the frame that you want to view, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. For more information, see Set, view, change, or remove permissions on files and folders.
- The frame number is listed in the **Frame** column.
- Frames are numbered in the order that Network Monitor captures them.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitoring security-related events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring security-related events**
It is important to monitor security related events so that you can find out if changes are made to security policies or other objects, who made the changes, and when they were made. You can monitor security-related events by setting up an auditing policy. An auditing policy is made up of all of the auditing settings that you configure for individual security event categories.

Some of the most common tasks for monitoring security-related events are defining or modifying auditing policy settings for an event category on your local computer, defining or modifying auditing policy settings for an event category across your organization, and viewing the security log. For more information about other tasks for auditing security-related events, see Auditing Security Events How To....

**To define or modify auditing policy settings for an event category on your local computer**

1. Open Local Security Policy.

2. In the console tree, click **Audit Policy**.

   **Where?**

   - Security Settings/Local Policies/Audit Policy

3. In the details pane, double-click an event category that you want to change the auditing policy settings for.

4. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.

   - To audit unsuccessful attempts, select the **Failure** check box.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

- To audit object accesses, enable auditing of the object access event category by following the steps above. Then, enable auditing on the specific object. For information about how to enable auditing on an object, see Apply or modify auditing policy settings for a local file or folder or Apply or modify auditing policy settings for an object using Group Policy.

**To define or modify auditing policy settings for an event category across your organization**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the domain or organizational unit that you want to set Group Policy for.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and

then click **Edit**.

5. In the console tree, click **Audit Policy**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

6. In the details pane, double-click an event category that you want to change the auditing policy settings for.

7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

8. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.

   - To audit unsuccessful attempts, select the **Failure** check box.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- If you are on a server or workstation joined to the domain, you can open Active Directory Users and Computers if you click **Start**, click **Run**, type **mmc**, and then click **OK**. On the File menu, click **Add/Remove Snap-in**, click **Add**, double-click **Active Directory Users and Computers**, click **Close**, and then click **OK**.

- To audit object accesses, enable auditing of the object access event category by following the steps above. Then, enable auditing on the specific object. For information about how to enable auditing on an object, see Apply or modify auditing policy settings for a local file or folder or Apply or modify auditing policy settings for an object using Group Policy.

#### To view the security log

1. Open Event Viewer.

2. In the console tree, click **Security**. The details pane lists individual security events.

3. In the details pane, double-click an event to view more details.

### Notes

- You must be logged on as a member of the Administrators group or you must have been granted the **Manage auditing and security log** right in Group Policy to perform this procedure.

- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.

- For more information about security events, see "Security Events" on the Microsoft Windows Resource Kits Web site

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitoring server performance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring server performance**

In today's business environment, administrators need to ensure their computer systems are efficient and reliable. To optimize the performance of your servers, you need the data supplied by performance monitoring. This topic describes the most common tasks associated with monitoring the performance of a simple server configuration, one that has a few client workstations connected to a single facility that contains one or more servers.

To monitor the performance of a simple server configuration, you need to collect three different types of performance data over a period of time:

- General performance data: Information that can help you identify short-term trends such as memory leaks. After a month or two of data collection, you can average the results and save them in a more compact format. This archived data can assist you in capacity planning as your business grows, and later help you to evaluate the effectiveness of your plan.

- Baseline performance data: Information that can help you discover changes that occur slowly, over time. By comparing the current state of your system with historical data, you can troubleshoot and tune your system. Because this information is collected only periodically, there is no need to compress it for storage.

- Data for service level reports: Information that can help you ensure that your system meets a certain service or performance level, and which you will likely present to decision makers who are not performance analysts. How often you collect and maintain this data depends on your specific business needs.

To collect all three types of data, you can use Performance Logs and Alerts to create a counter log. You can also collect this information from the Monitoring performance from the command line. You can then run the log over time, either manually or with automated scheduling. You can customize a counter log by adding objects and adding counters. For more information about monitoring server performance, including how to further modify counter logs, create reports in various formats, and use the collected data, see Performance monitoring How To....

**To create a counter log**

1. Open Performance.

2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs**.

   Any existing counter logs will be listed in the details pane. A green icon indicates that a log is running; a red icon indicates that a log has stopped.

3. Right-click a blank area of the details pane, and click **New Log Settings**.

4. In **Name**, type the name of the counter log, and then click **OK**.

5. On the **General** tab, click **Add Objects** and select the performance objects you want to add, or click **Add Counters** to select the individual counters you want to log.

   - You must use the Run as text box and Password button to collect counter data from a remotely managed computer. These features enable you to specify the logon account name for the log. You can access them from the **General** tab.

6. If you want to change the default file and schedule information, make the changes on the **Log Files** tab and the **Schedule** tab.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

- To save the settings for a counter log, trace log, or alert, right-click the log or alert in the details pane and click **Save Settings As**. You can then specify an .htm file in which to save the settings. To reuse the saved settings for a new log or alert, right-click the details pane, and then click **New Log Settings From** or **New Alert Settings From**. This is an easy way to generate new settings from a log or alert configuration. You can also open the HTML file in Internet Explorer to display a System Monitor graph.

- Although the extension for a log file is .blg, the file format is changed in the Windows server 2003 family and therefore cannot be read on an earlier version of the operating system. For example, if you copy a binary file from Windows Server 2003, Standard Edition, to Windows 2000, you will be unable to read it on the latter system.

**To add objects to a log**

1. Open Performance.

2. Double-click **Performance Logs and Alerts**, and then double-click **Counter Logs** or **Alerts**.

3. In the details pane, double-click the log or alert you want to modify.

4. On the **General** tab, click **Add Objects**. For each object that you want to add to the log, perform the following steps:

    - To log objects from the computer on which the Performance Logs and Alerts service will run, click **Use local computer counter objects**.

      Or, to log objects from a specific computer regardless of where the service is run, click **Select counter objects from computer:** and specify the Universal Naming Convention (UNC) name, such as *MyLogserver*, of the computer you want to monitor.

    - In **Performance object**, click an object to monitor, and then click **Add**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

- When creating counter log settings for export, make sure to select **Use local computer counter objects**. Otherwise, counter logs will obtain data from the computer named in the text box.

- For a description of an object, click the object in **Performance counters** and then click **Explain**.

- When you specify the name of a remote computer using **Select counter objects from computer**, only the name of the local computer and those computer names entered during the current Performance session are listed. Computer names entered in previous sessions will not be listed.

- The Run as feature enables you to run log collections under different accounts. For example, if you need to log data from a remote computer that requires administrative credentials, you can use the feature to specify an account with the necessary permissions.

**To add counters to a log**

1. Open Performance.

2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs**.

3. In the details pane, double-click the log you want to modify.

4. On the **General** tab, click **Add Counters**. For each counter or group of counters that you want to add to the log, perform the following steps:

   - To log counters from the computer on which the Performance Logs and Alerts service will run, click **Use local computer counters**.

     Or, to log counters from a specific computer regardless of where the service is run, click **Select counters from computer** and specify the Universal Naming Convention (UNC) name, such as *MyLogserver*, of the computer you want to monitor.

   - In **Performance object**, select an object to monitor.

   - In **Select counters from list**, click one or more counters to monitor.

   - To monitor all instances of the selected counters, click **All Instances**. (Binary logs can include instances that are not available at log startup but subsequently become available.)

     Or, to monitor particular instances of the selected counters, click **Select Instances From List**, and then click an instance or instances to monitor.

   - Click **Add**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

- When creating a monitoring console for export, make sure to select **Use local computer counters**. Otherwise, counter logs will obtain data from the computer named in the text box, regardless of where the console file is installed.

- For a description of a counter, click the counter in **Performance counters** and then click **Explain**.

- Some object types have several instances. For example, if a system has multiple processors, the Processor object type will have multiple instances. The PhysicalDisk object type has two instances if a system has two disks. Some object types, such as Memory and server, have only a single instance. If an object type has multiple instances, you can add counters to track statistics for each instance, or in many cases, for all instances at once. By default, counters are shown with both the instance name and an instance index. To turn off this feature, right-click the System Monitor graph, click **Properties**, and click the **General** tab.

- When you specify the name of a remote computer using **Select counters from computer**, only the name of the local computer and those computer names entered during the current Performance session are listed. Computer names entered in previous sessions will not be listed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Resetting user passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resetting user passwords**
Users occasionally forget their passwords to their local user accounts. You can manually reset a user's password. However, by doing so, the following information is lost:

- E-mail that is encrypted with the user's public key
- Internet passwords that are saved on the computer
- Files that the user has encrypted

To prevent information loss when you reset a local user account password, you can create and use a password reset disk.

Some of the most common tasks when administering local user accounts are resetting a local user account password, resetting a domain user account password, and creating a password reset disk. You can also reset a user password from the Dsmod. For more information about other tasks for using passwords, see Password How To....

**To reset a local user account password**

1. Open Computer Management.
2. In the console tree, double-click **Local Users and Groups**.

   **Where?**

   - Computer Management (Local)/System Tools/Local Users and Groups

3. In the console tree, click **Users**.
4. In the details pane, right-click the user name, and then click **Set Password**.
5. Read the warning message, and then, if you want to continue, click **Proceed**.
6. In **New password** and in **Confirm password**, type a new password, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**To reset a domain user account password**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.

   **Where?**

- Active Directory Users and Computers/*Domain name*/Users

3. In the details pane, right-click the user name, and then click **Reset Password**.

4. Type a new password in **New Password** and in **Confirm New Password**, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- If you are on a server or workstation joined to the domain, you can open Active Directory Users and Computers if you click **Start**, click **Run**, type **mmc**, and then click **OK**. On the File menu, click **Add/Remove Snap-in**, click **Add**, double-click **Active Directory Users and Computers**, click **Close**, and then click **OK**.

#### To create a password reset disk

1. Press CTRL+ALT+DEL, and then click **Change Password**.

2. In **User name**, type the user name of the account that you want to create a password reset disk for.

3. In **Log on to**, click your *LocalComputerName*.

4. Click **Backup**.

5. Follow the steps in the Forgotten Password Wizard until the procedure is complete. Store the password reset disk in a safe and secure place.

### Notes

- Password reset disks can only be used for local computer accounts, not for domain accounts.

- You cannot change your password and create a password reset disk at the same time. If you type a new password in **New Password** and in **Confirm New Password** before you click **Backup**, the new password information is not saved. When the wizard prompts you for your current user account password, you must type the old password. You can change your password after you create the password reset disk.

- You can change your password any time after you create a password reset disk. You do not have to create a new password reset disk if you change your password or if the password is reset manually.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Safeguarding your system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Safeguarding your system**

To safeguard your system against a serious failure, you can use the Backup tool to create an Automated System Recovery (ASR) set on a regular basis. The Automated System Recovery Wizard creates a two-part backup that you can use to recover your system after all other recovery attempts have failed, or after you have replaced the hard disk. ASR backs up the system state, system services, and all disks associated with the operating system components. It also creates a startup disk that contains information about the backup, the disk configurations (including basic and dynamic volumes), and how to accomplish a restore. You should create a new ASR set after any major change to the system and also on a regular schedule as part of a comprehensive backup plan.

Some of the most common tasks are creating an Automated System Recovery set using Backup and recovering from a system failure using Automated System Recovery. For more information about other system recovery tools, see Repair overview.

**To create an Automated System Recovery set using Backup**

1. Open Backup.

   The Backup or Restore Wizard starts by default, unless it is disabled. You can use the Backup or Restore wizard to create an ASR set by answering **All information on this computer** in the **What do you want to backup?** section. Otherwise, you can go to the next step to create an ASR set in **Advanced Mode**.

2. Click the Advanced Mode link on the Backup or Restore Wizard.

3. On the **Tools** menu, click **ASR Wizard**.

4. Follow the instructions that appear on your screen.

### Important

- You will need a blank 1.44 MB floppy disk to save your system settings and media to contain the backup files. If your computer does not have a floppy drive, see Backup Troubleshooting.

### Notes

- You can use Backup to back up and restore data on FAT16, FAT32, or NTFS volumes. However, if you have backed up data from an NTFS volume, it is recommended that you restore the data to an NTFS volume of the same version to prevent losing data. Some file systems might not support all of the features of other file systems.

- To start Backup, click **Start**, point to **All programs**, point to **Accessories**, point to **System Tools**, and then click **Backup**.

- This procedure will only back up those system files that are necessary for starting your system. You will need to backup your data separately.

- After creating the ASR set, label this floppy disk and backup media carefully, and keep them together. In order to use the backup media, you must have the floppy disk that you created with that set of media. You cannot use a floppy disk created at a different time or with a different set of media. You must also have your Setup CD available at the time you perform Automated System Recovery.

- Keep the ASR set in a secure location. The ASR set contains information about your systems configuration that could be used to do harm to your system.

- If you are backing up a server cluster, run the Automated System Recovery Preparation Wizard on all nodes of the cluster and make sure that the Cluster service is running when you start each Automated System Recovery backup. Make sure

that one of the nodes on which you run the Automated System Recovery Preparation Wizard is listed as the owner of the quorum resource while the wizard is running.

**To recover from a system failure using Automated System Recovery**

1. Make sure you have the following on hand before you begin the recovery procedure:

    - Your previously created Automated System Recovery (ASR) floppy disk.
    - Your previously created backup media.
    - The original operating system installation CD.
    - If you have a mass storage controller and you are aware that the manufacturer has supplied a separate driver file for it (different from driver files available on the Setup CD), obtain the file (on a floppy disk) before you begin this procedure.

2. Insert the original operating system installation CD into your CD drive.
3. Restart your computer. If prompted to press a key in order to start the computer from CD, press the appropriate key.
4. If you have a separate driver file as described in step 1, use the driver as part of Setup by pressing F6 when prompted.
5. Press F2 when prompted at the beginning of the text-only mode section of Setup. You will be prompted to insert the ASR floppy disk you have previously created.
6. Follow the directions on the screen.
7. If you have a separate driver file as described in step 1, press F6 (a second time) when prompted after the system reboots.
8. Follow the directions on the screen.

## Notes

- Physical access to a server is a high security risk. To maintain a more secure environment, you must restrict physical access to all servers and network hardware.
- ASR will not restore your data files.
- If you are restoring a server cluster in which all nodes failed and the quorum disk cannot be restored from backup, use Automated System Recovery on each node in the original cluster to restore the disk signatures and the partition layout of the cluster disks (quorum and nonquorum).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Scheduling tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Scheduling tasks**
By using Task Scheduler, you can schedule commands, programs, or scripts to run at specific times. For example, if you create a script to install updates on employee workstations, you can schedule the script to run in the evening, when most employees are not at work.

Some of the most common tasks are scheduling a new task and scheduling a task on a remote computer. You can also schedule tasks from the Creating and managing scheduled tasks from the Command Line. For more information about other tasks you can perform by using Task Scheduler, see Task Scheduler How To....

**To schedule a new task**

1. Open Task Scheduler.
2. Double-click **Add Scheduled Task**.
3. Follow the instructions in the Scheduled Task Wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- When creating a scheduled task, you must enter a user name and password, either in the Add Scheduled Task Wizard or in the **Run as** box on the **Task** tab of the properties dialog box for the scheduled task. When the scheduled task runs, the program runs as if it were started by the user you specified, with that user's security context.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- Confirm that the system date and time on your computer are accurate, as Task Scheduler relies on this information to run scheduled tasks. To verify or change this information, double-click the time indicator on the taskbar.
- If you want to configure advanced settings for the task, select the **Open advanced properties for this task when I click Finish** check box in the final page of the wizard. This opens the properties dialog box for the task. You can then change the program being run on the **Task** tab, fine-tune the schedule on the **Schedule** tab, customize settings on the **Settings** tab, or set user and group permissions on the **Security** tab.

**To schedule a task on a remote computer**

1. Open My Network Places.
2. Click **Search for Computers**.
3. In the **Computer name** box, enter the computer name, and then click **Search**.
4. In the details pane, double-click the remote computer on which you want to view scheduled tasks.
5. Double-click **Scheduled Tasks**.
6. From the **File** menu, point to **New**, and then click **Scheduled Task**.

7. Type a name for the new task, and then press ENTER.

8. Right-click the new task, and then click **Properties**.

9. Do the following:

    - To specify the program being run, in **Run**, type the path for the new program.

    - To set the user account name and password that the scheduled task will run as, edit or enter a new name in the **Run as** box, and then click **Set password**.

    - To set the schedule for the task, click the **Schedule** tab.

    - To customize the settings for the task, click the **Settings** tab.

    - To set user and group permissions for the task, click the **Security** tab.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the remote computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open My Network Places, click **Start**, and then click **My Computer**. Under **Other Places**, click **My Network Places**.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Setting up DNS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up DNS**

Domain Name System (DNS) is used in Transmission Control Protocol/Internet Protocol (TCP/IP) networks, such as the Internet, to locate computers and services through user-friendly names. When a user enters a DNS name in an application, DNS can resolve the name to other information associated with the name, such as an IP address. If your network is homogeneous (all hosts use the same operating system), and it uses a name resolution method other than DNS, you can continue to use that method without needing DNS. If your network is heterogeneous (the hosts use different operating systems), or it connects to the Internet, you will want to deploy DNS as the Internet consists of protocols that require DNS.

Setting up DNS in your network does not necessarily require that you administer a large DNS infrastructure or become an expert DNS administrator. If you have a very small network in which information is maintained dependably, you may choose to have your DNS namespace administered by a different organization that specializes in DNS administration, such as your government or an Internet Service Provider (ISP). In this case, the other organization will host and administer your DNS zone data for you or integrate your hosts with an existing DNS zone hosted in their network. Once your network expands beyond a small number of hosts, you will want to begin administering DNS yourself in order to better serve the name resolution needs of your expanding network.

Setting up a DNS server typically involves configuring the DNS server with DNS zones to administer the DNS domain names in your network, adding DNS resource records for the hosts in your network to your DNS zones, and delegating administration for these zones by creating a delegation from the parent DNS server previously authoritative for a domain name to the child DNS server that is accepting responsibility for a domain name. Lastly, a DNS server administrator should maintain the integrity of DNS zone data by securing the DNS servers in the network. You can also set up a DNS server from the command line. For more information, see DNS tools. For more information about setting up DNS, see DNS How To....

**To configure a DNS server**

1. Open DNS.
2. If needed, add and connect to the applicable server in the console.
3. In the console tree, click the applicable DNS server.

   **Where?**

   - DNS/*Applicable DNS server*

4. On the **Action** menu, click **Configure a DNS server**.
5. Follow the instructions in the Configure a DNS Server Wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DNS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DNS**.
- If the DNS server is running locally, you do not need to perform step 2.
- The Configure a DNS Server Wizard allows you to specify zones, root hints, and forwarders.
- If you are setting up DNS for your intranet and you want your computers to connect to the Internet also, configure the

root hints with the IP addresses of the DNS servers located at your ISP.

- When you finish configuring the server, you will need to complete additional tasks, such as configuring your network hosts to use this DNS server as their preferred DNS server, enabling dynamic update for the zones on this DNS server, or adding resource records to its zones.

**To add a resource record to a zone**

1. Open DNS.
2. In the console tree, right-click the applicable zone and click **Other New Records**.
3. In **Select a resource record type** list box, select the type of resource record you want to add.
4. Click **Create Record**.
5. In **New Resource Record**, enter the information needed to complete the resource record.
6. After you specify all of the necessary information for the resource record, click **OK** to add the new record to the zone.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DNS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DNS**.
- Add a resource record for every host in your network that will use DNS. If you have configured your DNS zones to accept dynamic updates, and your network hosts support dynamic update and are configured to use this DNS server as their preferred DNS server, then your network hosts will add their resource records automatically.
- For more information about the different types of resource records you can add, see Resource records reference.

**To create a zone delegation**

1. Open DNS.
2. In the console tree, right-click the applicable subdomain, and then click **New Delegation**.
3. Follow the instructions provided in the New Delegation Wizard to finish creating the new delegated domain.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open DNS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DNS**.
- All domains (or subdomains) that appear as part of the applicable zone delegation must be created in the current zone prior to performing delegation as described here. As necessary, use the DNS console to first add domains to the zone before completing this procedure. For more information, see Delegating zones.

**To secure a DNS server**

1. Open DNS.

2. In the console tree, right-click the applicable DNS server, and then click **Properties**.

3. On the **Interfaces** tab, ensure that the DNS server is listening to the correct interfaces.

4. On the **Advanced** tab, select the **Secure cache against pollution** check box.

5. If this DNS server will not perform recursive resolution, then select the **Disable recursion** check box.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open DNS, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **DNS**.

- If a DNS zone is stored in Active Directory, you can also secure that DNS zone and its resource records by using the security features of Active Directory.

- By default, a DNS zone is only permitted to allow zone transfers from the DNS servers that are listed in the DNS zone properties.

- By default, the DNS service listens for DNS message communications on all IP addresses that are configured for the server computer.

- Server IP addresses that are added here need to be statically managed. If you later change or remove addresses specified here from the TCP/IP configurations maintained at this server, update this list accordingly.

- The **Secure cache against pollution** check box is selected by default.

- If you disable recursion on this DNS server, you cannot use this DNS server to answer recursive queries from DNS clients or to list this DNS server as a DNS forwarder. Disable recursion on DNS servers that only perform iteration with other DNS servers.

- By disabling recursive resolution on this DNS server, you can prevent a Denial of Service (DoS) attack in which a malicious user attempts to have this DNS server respond to recursive queries for a domain in a DNS zone under the malicious user's control.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Setting up TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up TCP/IP**

By default, computers running Windows Server 2003 operating systems are configured as Dynamic Host Configuration Protocol (DHCP) clients, which means they can accept leases from any available DHCP server. TCP/IP computers (hosts) on a DHCP network automatically obtain TCP/IP configurations from DHCP servers that are located elsewhere on that network. This is the most common scenario for mid-sized and large TCP/IP networks. For more information about DHCP, see DHCP.

In certain cases, you will need to configure TCP/IP for static addressing. Configuring TCP/IP for static addressing is the process of manually assigning unique, permanent addresses to network devices, and providing static address information about other network resources (for example, DHCP servers, routers, and default gateways). If you are setting up a computer to run on a network that does not have a DHCP server, but that does provide Windows Internet Name Service (WINS), you will need to configure TCP/IP to use WINS. For more information about WINS, see WINS.

Some of the most common tasks for setting up TCP/IP are configuring TCP/IP for static addressing, and configuring TCP/IP to use WINS. You can also set up TCP/IP from the Managing TCP/IP from the command line. For more information about other tasks for setting up TCP/IP, see TCP/IP How To....

**To configure TCP/IP for static addressing**

1. Open Network Connections.
2. Right-click the network connection you want to configure, and then click **Properties**.
3. On the **General** tab (for a local area connection) or the **Networking** tab (for all other connections), click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. Click **Use the following IP address**, and do one of the following:
   - For a local area connection, in **IP address**, **Subnet mask**, and **Default gateway**, type the IP address, subnet mask, and default gateway addresses.
   - For all other connections, in **IP address**, type the IP address.
5. Click **Use the following DNS server addresses**.
6. In **Preferred DNS server** and **Alternate DNS server**, type the primary and secondary DNS server addresses.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If your network does not have a DNS server, you can skip steps 5 and 6.

**To configure TCP/IP to use WINS**

1. Open Network Connections.

2. Right-click the network connection you want to configure, and then click **Properties**.

3. On the **General** tab (for a local area connection) or the **Networking** tab (for all other connections), click **Internet Protocol (TCP/IP)**, and then click **Properties**.

4. Click **Advanced**, click the **WINS** tab, and then click **Add**.

5. In **TCP/IP WINS server**, type the IP address of the WINS server, and then click **Add**.

6. Repeat steps 4 and 5 for each WINS server IP address you want to add, and then click **OK**.

7. To enable the use of the Lmhosts file to resolve remote NetBIOS names, select the **Enable LMHOSTS lookup** check box. This option is enabled by default.

8. To specify the location of the file that you want to import into the Lmhosts file, click **Import LMHOSTS**, and then select the file in the **Open** dialog box.

9. To enable or disable NetBIOS over TCP/IP, do the following:

   - To enable the use of NetBIOS over TCP/IP, click **Enable NetBIOS over TCP/IP**.

   - To disable the use of NetBIOS over TCP/IP, click **Disable NetBIOS over TCP/IP**.

   - To have the DHCP server determine whether NetBIOS over TCP/IP is enabled or disabled, click **Default**. For more information, see Notes.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- If you are using a DHCP server to allocate WINS server IP addresses, you do not need to add WINS server addresses.

- You can no longer configure the NetBIOS scope ID on the **WINS** tab (previously available in Windows NT 4.0). To configure the NetBIOS scope ID, set the following registry value to the name of the scope ID that you want to use:

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\NetBT\Parameters\ScopeID**

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Setting user and group security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting user and group security**

In order to secure a computer and its resources, you must decide what tasks and actions users or groups of users can perform. The tasks and actions that a user or group of users can perform are determined by the user rights that you assign to them. For example, if a trusted member of the Users group needed to monitor the security log, you could grant the user the "Manage auditing and security log" user right instead of adding the user to a more privileged group, such as the Administrators group. Similarly, you can secure an object, such as a file or folder, by assigning permissions.

Some of the most common tasks are assigning user rights on your local computer, assigning user rights throughout your organization, and setting file and folder permissions. For more information about other tasks for setting user and group security, see Access Control How To....

**To assign user rights on your local computer**

1. Open Local Security Settings.
2. In the console tree, click **User Rights Assignment**.

   **Where?**

   - Security Settings/Local Policies/User Rights Assignment
3. In the details pane, double-click the user right that you want to modify.
4. Do one of the following, and then click **OK**.

   - To add a user or group, click **Add a User or Group**. In **Select Users or Groups**, type the user name or group name that you want to add, and then click **OK**.
   - To remove a user or group, select the user or group in the list, and then click **Remove**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**To assign user rights throughout your organization**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the Group Policy object for which you want to edit security settings.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click **Edit** to open the Group Policy object you want to edit. Or, click **New** to create a new Group Policy object, and then click **Edit**.

5. In the console tree, click **User Rights Assignment**.

   **Where?**

   - *GroupPolicyObject* [*ComputerName*] Policy/Computer Configuration/Windows Settings/Security Settings/Local Policies/User Rights Assignment

6. In the details pane, double-click the user right that you want to modify.

7. If this security setting has not yet been defined, select the **Define these policy settings** check box.

8. Do one of the following, and then click **OK**.

   - To add a user or group, click **Add a User or Group**. In **Select Users or Groups**, type the user name or group name that you want to add, and then click **OK**.

   - To remove a user or group, select the user or group in the list, and then click **Remove**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- If you are on a server or workstation joined to the domain, you can open Active Directory Users and Computers if you click **Start**, click **Run**, type **mmc**, and then click **OK**. On the File menu, click **Add/Remove Snap-in**, click **Add**, double-click **Active Directory Users and Computers**, click **Close**, and then click **OK**.

- Always test a newly created policy on a test organizational unit before applying it to your network.

- When you change a security setting and click **OK**, that setting will take effect in the next refresh of settings.

- The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.

**To set, view, change, or remove permissions on files and folders**

1. Open Windows Explorer.

2. Right-click the file or folder for which you want to set permissions, click **Properties**, and then click the **Security** tab.

3. Do one of the following:

   - To set permissions for a group or user that does not appear in the **Group or user names** box, click **Add**. Type the name of the group or user for which you want to set permissions, and then click **OK**.

   - To change or remove permissions from an existing group or user, click the name of the group or user.

4. Do one of the following:

- To allow or deny a permission, in the **Permissions for *User or Group*** box, select the **Allow** or **Deny** check box.
- To remove the group or user from the **Group or user names** box, click **Remove**.

### Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- In the Windows Server 2003 family, the Everyone group no longer includes Anonymous Logon.
- You can set file and folder permissions only on drives formatted to use NTFS.
- If the check boxes under **Permissions for *User or Group*** are shaded or if the **Remove** button is unavailable, then the file or folder has inherited permissions from the parent folder. For more information, see How inheritance affects file and folder permissions.
- When adding a new user or group, by default, this user or group will have **Read & Execute**, **List Folder Contents**, and **Read** permissions.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Troubleshooting Strategies

Updated: January 21, 2005

# Troubleshooting Stop messages: general strategies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting Stop messages: general strategies**
This topic describes a general method for troubleshooting Stop messages or unexpected shutdowns. For more information, see the following:

- For information about specific Stop messages, see Troubleshooting specific Stop messages.
- For articles about specific Stop messages, see Search the Knowledge Base at the Microsoft Web site.
- For information about support options, see Support resources.
- For information about troubleshooting specific technologies or components (for example, disks and file systems), see the *Windows Server 2003 Technical Reference* at the Microsoft Windows Server System Web site.

You can use the System Information tool to gather important information about system settings, problem devices, and hardware resources. For more information, see System Information.

**Important**

- To ensure system stability, install the latest service pack that is appropriate for your system (follow service pack instructions) and use only signed drivers. For more information, see Windows Update at the Microsoft Web site. For a description of the different ways you can use Windows Update, see Windows Update.

Follow these steps for any Stop error that does not display identifying text or specific troubleshooting steps:

1. Use the Windows Online Crash Analysis tool at the Microsoft Web site. You can use this tool to send error reports to Microsoft and track their status by using your Microsoft Passport information. You can access the Online Crash Analysis Web site by using the Error Reporting service or by using your Web browser. When it is enabled, the Error Reporting service monitors your system for kernel and user mode faults that are related to operating system components and applications. With kernel-mode reporting, you can obtain more information about the problem or condition that caused the Stop error. For more information, see System and program error reporting overview.

2. Use the File Signature Verification tool, which identifies unsigned drivers and incompatible system files on your computer. The system files and device driver files that are provided with the Windows Server 2003 family have a Microsoft digital signature, which indicates that the files are original, unaltered system files or that they have been approved by Microsoft for use with Windows. For more information, see Using File Signature Verification.

3. If the Stop message is caused by a driver problem, you can use Device Manager to roll back to a previous version of the driver. For more information, see Roll back to the previous version of a driver. You may need to disable any newly installed drivers.

4. Using a recent version of virus-protection software, check for viruses on your computer. If a virus is found, perform the steps required to eliminate it from your computer. See your antivirus software documentation for these steps.

5. You can search the Knowledge Base for updated information on Stop messages. See Search the Knowledge Base at the Microsoft Web site, and then follow the instructions on the page. When typing keywords, use the Stop message number (for example, **stop 0x0000000A**).

   For more information about articles, troubleshooting wizards, and items that you can download, see Updated technical information.

6. If you can start the operating system, check the System Log in Event Viewer for additional information that might help

determine the device or driver that is causing the problem. Many Stop messages produce specific events that you can search for, such as Event ID 1001 (generated by various Stop messages) and Event ID 6008 (usually caused by an unexpected shutdown or a computer that does not restart correctly). To display a description of an event, in Event Viewer, double-click the event. For more information about Event Viewer, see Event Viewer.

You can search the Knowledge Base for updated information on Event IDs. See Search the Knowledge Base at the Microsoft Web site, and then follow the instructions on the page.

7. If you cannot start your computer, try starting it in Last Known Good Configuration or in Safe Mode, and then remove or disable newly added programs or drivers. For information about how to start your computer in Safe Mode, see Start the computer in Safe Mode. For more information about how to start your computer in Last Known Good Configuration, see Start the computer using the last known good configuration.

   **Important**

   - When you use Last Known Good Configuration, system setting changes made after the last successful startup are lost.

8. Remove any newly installed hardware (RAM, adapters, hard disks, modems, and so on).

9. Ensure that you have updated drivers for your hardware devices. Also, ensure that you have the latest system BIOS (for x86-based or x64-based computers) or the correct firmware (for Itanium architecture-based computers). The device or hardware manufacturers can assist you in obtaining these items.

10. Run the system diagnostics supplied by your computer manufacturer, especially the memory check.

11. Confirm that your hardware is designed for the Windows Server 2003 family by clicking the appropriate link in Support resources.

12. If Safe Mode and other startup options do not work, you can consider using the Recovery Console. This method is recommended only if you are an advanced user who can use basic commands to identify and locate problem drivers and files. In addition, you must be an administrator to use the Recovery Console. For more information, see Recovery Console overview.

# Troubleshooting compatibility issues

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting compatibility issues**
What problem are you having?

- An application stops responding, quits, or behaves improperly.
- Hardware does not function properly.

**An application stops responding, quits, or behaves improperly.**
**Cause:** The version of the application is not compatible with this version of Windows.

**Solution:** Start the Program Compatibility Wizard to detect and test compatibility settings. To start the Program Compatibility Wizard, click **Start**, click **Run**, and then type **hcp://system/compatctr/compatmode.htm**.

**See also:** Accessing information about compatibility; Troubleshooting specific Stop messages

**Cause:** The display settings are not correct.

**Solution:** Some older games and applications may require a 256-color quality or 640 x 480 screen resolution to function properly. Use the **Display Properties** dialog box to change the display settings. To open Display, click **Start**, click **Control Panel**, and then double-click **Display**.

**Note**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**Hardware does not function properly.**
**Cause:** The hardware is not compatible with this release, or it needs to be updated to work with this release.

**Solution:** To confirm that your hardware is designed for the Windows Server 2003 family, see the compatibility information in Support resources.

**See also:** Hardware compatibility

**Notes**

- For the latest information about products that are designed for the Windows Server 2003 family, see Hardware compatibility information in the Windows Catalog at the Microsoft Web site.
- For more information about the Designed for Windows logo program, see Designed for Windows at the Microsoft Web site.

# Troubleshooting audio, imaging, and CD-burning peripheral devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting audio, imaging, and CD-burning peripheral devices**
What problem are you having?

- The audio device does not work.
- The imaging device does not work.
- The CD-burning device does not work.

**The audio device does not work.**
**Cause:** If you receive the following message: "The service cannot be started, either because it is disabled or because it has no enabled devices associated with it," the device requires that the Windows Audio service be enabled. By default, the Windows Audio service required by this peripheral device is started only on computers running Windows Server 2003, Standard Edition.

**Solution:** If sound is required, start this service, and then set **Startup type** to **Automatic**.

Most peripheral devices are supported by drivers on the installation CD for the Windows Server 2003 family. If the CD does not list a driver for your device, look for an update from the device manufacturer or from Windows Update. To check if your hardware is compatible, see Support resources.

**See also:** Start, stop, pause, resume, or restart a service; Configure how a service is started

**Note**

- The hardware drivers for this peripheral device cannot be updated unless the Windows Audio service is started.

**The imaging device does not work.**
**Cause:** If you receive the following message: "The service cannot be started, either because it is disabled or because it has no enabled devices associated with it," the device requires that the Windows Image Acquisition (WIA) service be enabled. By default, the Windows Image Acquisition (WIA) service required by this peripheral device is disabled.

**Solution:** If imaging is required, start this service, and then set **Startup type** to **Manual**.

Most peripheral devices are supported by drivers on the installation CD for the Windows Server 2003 family. If the CD does not list a driver for your device, you can look for an update from the device manufacturer or from Windows Update. To check if your hardware is compatible, see Support resources.

**See also:** Start, stop, pause, resume, or restart a service; Configure how a service is started

**Note**

- The hardware drivers for this peripheral device cannot be updated unless the Windows Image Acquisition (WIA) service is started.

**The CD-burning device does not work.**
**Cause:** The IMAPI CD-Burning COM Service required by this peripheral device is disabled.

**Solution:** If CD burning is required, start this service and set **Startup type** to **Manual**, and then restart the server.

Most peripheral devices are supported by drivers on the installation CD for the Windows Server 2003 family. If the CD does not list a driver for your device, you can look for an update from the device manufacturer or from Windows Update. To check if your hardware is compatible, see Support resources.

**See also:** Start, stop, pause, resume, or restart a service; Configure how a service is started

**Note**

- With some third-party software, you may be able to burn CDs without starting the IMAPI CD-Burning COM Service.

# Using Event Viewer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Event Viewer**

You can use Event Viewer to monitor events that are recorded in the Application, Security, and System logs. By using the event logs in Event Viewer, you can gather information about hardware, software, and system problems. You can also monitor security events. For more information, see Event Viewer.

# Using the Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Shutdown Event Tracker**

Shutdown Event Tracker provides a simple and standard mechanism that you can use to consistently document the reasons for shutting down or restarting your computer. You can then use this information to analyze the root causes of shutdowns and to develop a more complete understanding of your system environment. For more information, see Shutdown Event Tracker.

# Using online resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using online resources**

The Microsoft Web site contains support information, including the latest downloads and Knowledge Base articles written by support professionals at Microsoft:

- Product Support Services. Search frequently asked questions (FAQs) by product, browse the product support newsgroups, and contact Microsoft Support.
- Search the Knowledge Base. Search the Microsoft Knowledge Base of technical support information and self-help tools for Microsoft products.
- Windows Server Community. The official online community for enthusiasts of the Windows server operating systems.
- Windows Deployment and Resource Kits. Find information about the *Windows Deployment and Resource Kits* that are available for Windows products.
- Windows Resource Kits--Web Resources. Find information about and resources for a variety of Windows topics.
- Microsoft TechNet. Search for troubleshooting information, service packs, patches, and downloads for your system.

# Troubleshooters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooters**
Troubleshooters are tools that walk you through technical problems that might occur with your computer. For more information, see the following:

- Using troubleshooters

# Quick Guide for Finding Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quick guide for finding tools**

This section provides links to topics and tools for carrying out basic administrative tasks:

- Checklists Provided in Windows Server 2003 Help
- Best practices: pointers to recommendations and tips
- New ways to do familiar Windows tasks
- Configuring Roles for Your Server
- Troubleshooting A-Z
- Step-by-step guides for deployment
- Windows interface administrative tool reference A-Z
- Command-line reference A-Z
- Windows Resource Kit Tools Help
- Install Windows Support Tools

**Notes**

- For information about Microsoft® Visual Basic®, Scripting Edition, (VBScript) for system administrators, see "Scripting Solutions for System Administrators" at the Microsoft Windows Resource Kits Web site.
- For information about scripting, see "Scripting for the Enterprise" at the Microsoft Windows Resource Kits Web site.

# Checklists Provided in Windows Server 2003 Help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

A checklist describes the steps required to set up, configure, or implement a Windows Server 2003, Enterprise Edition, component. Each step refers you to background information or instructions that are needed to complete the step. To perform a task, find the component in the following table and click the checklist.

Windows Server 2003, Enterprise Edition, offers all the features of Windows Server 2003, Standard Edition, as well as enhanced memory support, support for additional processors, and clustering. To learn more about memory support, see Enterprise Memory Architecture. To find checklists for Network Load Balancing clusters and server clusters, see Clustering in the following table.

| Component | Checklist |
|---|---|
| Active Directory | Active Directory Checklists |
| Backing up and restoring data | Checklists for Backing Up and Restoring Data |
| Certificate Services | Checklist: Creating a certification hierarchy with an offline root certification authority<br>Checklist: Configuring certificate autoenrollment |
| Clustering | Checklist: Enabling and configuring Network Load Balancing<br>Checklists: Creating Server Clusters<br>Checklists: Installing Server Cluster Resources<br>Checklist: Preparation for upgrading a cluster<br>Checklist: Preparation for installing a cluster |

# New ways to do familiar Windows tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

Many components have changed names or locations since Windows NT 4.0 and Windows 2000. To find the new way to do a task, click the letter that the name of the component starts with, and then click the name of the component.

# Configuring Roles for Your Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring roles for your server**
The Configure Your Server Wizard provides a central location from which you can install or remove the server roles available on a server running Windows Server 2003. After installing a server role you can use Manage Your Server to manage that role.

Manage Your Server provides a central location from which you can manage the server roles installed through the Configure Your Server Wizard. Manage Your Server starts automatically the first time you log on to your server computer with administrative credentials.

- Server roles
- Typical setup for a first server
- File server role: Configuring a file server
- Print server role: Configuring a print server
- Application server role: Configuring an application server
- Mail server role: Configuring a mail server
- Terminal server role: Configuring a terminal server
- Remote access/VPN server role: Configuring a remote access/VPN server
- Domain controller role: Configuring a domain controller
- DNS server role: Configuring a DNS server
- DHCP server role: Configuring a DHCP server
- Streaming media server role: Configuring a streaming media server
- WINS server role: Configuring a WINS server
- To remove a server role

**Note**

- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Step-by-step guides for deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Step-by-step guides for deployment**
The Microsoft Web site provides tutorials that you can use to learn about and deploy the operating system. These technical walkthroughs provide step-by-step instructions and illustrations for installing and configuring key features.

You can access the Step-by-Step Guides at the Microsoft Web site.

The following list includes some of the topics that you can find in these guides:

**Infrastructure**

- Building a common network infrastructure

**Active Directory**

- Setting up additional domain controllers
- Delegating control of objects
- Managing Active Directory
- Managing replication topology
- Using LDAP and VBScript to manage Active Directory
- Extending Active Directory using the Schema and display specifiers

**Management services**

- Understanding Group Policy
- Managing remote installation of the operating system
- Managing application deployments for groups of users and computers
- Managing user data and user settings

**Security services**

**Setting up and configuring certificates**

- Setting up a certification authority
- Configuring a domain to trust an external certification authority
- Managing Certificate Services
- Obtaining and managing certificates
- Configuring automatic certificate requests

**Using certificates**

- Requesting certificates using Web pages
- Mapping certificates to user accounts to be used on a Web site

**Additional security features**

- Configuring local security policy on individual computers
- Managing security in an enterprise network
- Encrypting files
- Using Kerberos V5
- Encrypting IP network traffic using Internet Protocol security (IPSec)

**File and print services**

- Creating logical views of directories and files

**Clustering**

- Installing a typical two-node cluster on Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition

# Command-line reference A-Z

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Command-line reference A-Z**
To find information about a command, on the A-Z menu, click the letter that the command starts with, and then click the command name.

In addition to the tools installed with the Windows Server 2003 family there are over 40 support tools that you can install directly from the product CD. You can use these tools to diagnose and resolve computer problems. For more information about these support tools and how to install them, see Install Windows Support Tools.

For more information about changes to the functionality of MS-DOS commands, new command-line tools, command shell functionality, configuring the command prompt, and automating command-line tasks, see Command-line reference.

You must run command-line tools at the prompt of the Cmd.exe command interpreter. To open Command Prompt, click **Start**, click **Run**, type **cmd**, and then click **OK**. To view help at the command line, at the command prompt, type:

*CommandName* **/?**

As a security best practice, consider using an account without administrative credentials to perform routine, nonadministrative tasks. To perform only specific tasks with an account with administrative credentials, you can use the Runas command.

# Windows Resource Kit Tools Help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Resource Kit Tools Help**

**Important**

- Some of the links on this page are to English-only content on the Web, regardless of the language of your operating system. In addition, if you install a Microsoft® Windows® Deployment or Resource Kit on a non-English operating system or on an operating system with a Multilingual User Interface Pack (MUI), you will see some English content mixed with non-English content in Help and Support Center. This behavior should be expected if you browse through tools documentation in the Tools By Category listing in the Tools Center in Help and Support Center or if you search anywhere in Help and Support Center by a tool name.

Windows Resource Kit Tools Help includes documentation on tools designed to help system administrators and IT professionals deploy, support, and maintain Windows Server 2003 family operating systems.

You can use Windows Resource Kit Tools to manage the Active Directory® directory service, administer security features, work with the registry, automate recurring jobs, and perform many other important tasks.

Windows Resource Kit Tools are not part of the Windows operating system. You must install them separately.

For information about Windows Resource Kit Tools and Tools Help, or to browse additional Windows Deployment and Resource Kit documentation on the Web, go to the Windows Deployment and Resource Kits Web site.

# Administration and Scripting Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administration and scripting tools**
This section covers:

- Management Strategies and Tools
- Command-line reference
- Configuration and Management Tools
- Remote Administration Tools
- Monitoring and Status Tools
- Scheduling and Automation Tools
- Scripting Tools

# Management Strategies and Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Management Strategies and Tools**
Windows Server 2003 family operating systems contain a rich set of tools and features that you can use to manage your Windows environment.

For information about the technologies, issues, and methods to consider when deciding which tools to use to perform management tasks, see Management strategies and tools overview.

To find the tool or feature you can use to perform a specific task, see Using Management Tools and Features.

# Management strategies and tools overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Management strategies and tools overview**
When deciding to use a tool or feature available in the Microsoft® Windows Server 2003 family operating systems, it is helpful to have an understanding of:

- The technology or feature set a tool is based on, or part of
- Whether you can perform a task using a graphical user interface (GUI)-based tool, command-line tool, or script
- How security and remote administration issues apply to your daily and long-term IT operations goals and objectives.

Adding the scope and limitations of your IT environment and corporate business goals to your analysis of this information, you can make optimal choices about which tools to use.

**Management technologies and feature sets**
Most of the tools and features available in Windows Server 2003 family operating systems are based on, or are a subset of, the following technologies and feature sets. For more information about each technology or feature set, see its corresponding link under **Overview**.

| Technology or feature set | Overview |
|---|---|
| Microsoft® Active Directory directory service | Active Directory Overview |
| Group Policy | Group Policy overview |
| Microsoft® IntelliMirror management technologies | IntelliMirror |
| Microsoft Management Console (MMC) | MMC overview |
| Terminal Services | Terminal Services overview |
| Windows Management Instrumentation (WMI) | Windows Management Instrumentation overview |

**Choosing a management method**
You can perform management tasks using one, some, or all three of the following types of management tools:

- graphical user interface (GUI)-based
- command-line
- script or script-based

You can perform many of the same tasks using any of these methods, but based on your network environment and management goals and objectives, there might be advantages to using one type of tool over another.

**Advantages to using GUI-based tools**

- You can use Microsoft Management Console (MMC) Consoles to group the tools you use most often so that you can view and modify your client, server, and network components and services from a single location.
- You are less likely to type a command and related parameters incorrectly because you configure tasks through a GUI.
- You do not need to remember a lot of syntax and parameters--again, there is less opportunity to make mistakes.

**Advantages to using command-line tools**

- You can more easily automate a variety of management tasks.
- You have more options to customize a task because a number of parameters might be available to use with the command-line tool.

**Advantages to using scripts or script-based tools**

- You can customize a task or set of tasks down to the last detail.
- You can use scripts to fully automate a task or set of tasks.
- You can run a script from either a GUI-based or command-line tool

For more information about creating and using scripts, see the "System Administration Scripting Guide" at the Microsoft Windows Resource Kits Web site.

**Issues important to system administrators**
As more and more business is done over the Internet and from remote locations, security and remote administration will continue to be among the most important considerations in managing your Windows environment. For more information about these issues, click the corresponding links under **Overview**.

| **Issue** | **Overview** |
|---|---|
| Security | Security overview |
| Remote Administration | Remote administration overview |

# Using Management Tools and Features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using management tools and features**

Each of the following topics represents day-to-day activities you perform to manage your Windows environment. Within each activity are common tasks related to the activity, with corresponding links to more information about both graphical user interface (GUI)-based tools and command-line tools available in Windows Server 2003 family operating systems.

- Automating processes and tasks
- Deploying and managing applications
- Managing the Active Directory directory service
- Managing computers
- Managing disks and data
- Managing network services
- Managing printers and faxes
- Managing security
- Managing servers
- Monitoring and controlling services on computers

# Automating processes and tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automating processes and tasks**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for automating processes and tasks, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| Automate routine or repetitive tasks. | Using batch files |
| Assign scripts to define settings for a group of users. | Group Policy (pre-GPMC) |
| Assign tasks that will be performed whenever a user logs on to a particular computer, such as mapping network drivers, starting background processes, and initializing user environment variables. | Logon Scripts |
| Run a group of commands in batch mode against a specified computer; save a configuration script in a text file for archival purposes, or to help you configure other computers. | Netsh overview |
| Schedule any script, program or document to run at a scheduled time. | Task Scheduler |
| Write a management script or batch file to automate administrative tasks. | Windows Management Instrumentation Command-line |
| Run scripts by clicking a script file on the Windows desktop or by typing the name of a script file at the command prompt. | Windows Script Host |
| Synchronize time on the computers in your network. | Windows Time Service |

For more information about automating installations, see "Automating and Customizing Installations" at the Microsoft Windows Resource Kits Web site.

For more information about creating and using scripts, see the "System Administration Scripting Guide" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for automating processes and tasks, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
|---|---|
| Call one batch program from another without stopping the parent batch program. | Call |
| Choose from among a set of user option keys such as Yes, No and Continue in a batch program. | Choice |
| Redirect command output from the command line to the Clipboard. | Clip |
| Recalls commands, edits command lines, and creates macros. | Doskey |

| | |
|---|---|
| End localization of environment changes in a batch file, restoring environment variables to their values before the matching **setlocal** command. | Endlocal |
| Create a custom event in a specified event log. | Eventcreate |
| List the events and event properties from one or more event logs. | Eventquery.vbs |
| Display and configure event triggers on local or remote computers. | Eventtriggers |
| Exit the current batch script or the Cmd.exe program (that is, the command interpreter) and return to the program that started Cmd.exe or to the Program Manager. | Exit |
| Run a specified command for each file in a set of files. | For |
| Select files in a folder or tree for batch processing. | Forfiles |
| Set the system environment variable %ERRORLEVEL% to the value associated with the specified Windows operating system. | Gettype |
| Within a batch program, directs the operating system to a label; The operating system then processes the commands that begin on the next line. | Goto |
| Perform conditional processing in batch programs. | If |
| Sets the command path in the PATH environment variable, which is the set of directories used to search for executable files. Used without parameters, **path** displays the current command path. | Path |
| Suspend the processing of a batch program and display a message that prompts the user to press any key to continue. | Pause |
| Change the current directory to the directory stored by the **pushd** command. | Popd |
| Store the name of the current directory for use by the **popd** command before changing the current directory to the specified directory. | Pushd |
| Include comments (remarks) in a batch file or in your configuration files. | Rem |
| Communicate with the Service Controller and installed services; retrieve or set control information about services. | SC |
| Schedule commands and programs to run periodically or at a specific time; manage the Task Scheduler service | Schtasks |
| Display, set, or remove environment variables. | Set |
| Start localization of environment variables in a batch file. | Setlocal |
| Set environment variables in the local or system environment, without requiring programming or scripting. | Setx |
| Change the position of batch parameters in a batch file. | Shift |
| Pause the command processor for the specified number of seconds. Timeout is typically used in batch files. | Timeout |
| Diagnose problems occuring with Windows Time. | W32tm |
| Synchronize multiple computers across a network. | waitfor |
| Locate and display all files that match the given parameter; by default, the search is done along the current directory and in the PATH environment variable. | Where |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Deploying and managing applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying and managing applications**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for deploying and managing applications, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| Create a specific desktop configuration of installed applications for a group of users; manage desktop configurations for a group of users. | Group Policy (pre-GPMC) |
| Set up and manage an Internet Information Services (IIS) server to host Web applications and services. | Internet Information Services |
| Track and maintain software licenses. | Administering and tracking licenses |
| Create, save, and open administrative tools (in the form of snap-ins) that manage hardware, software and network components of a local or remote computer, or multiple computers. | Microsoft Management Console |
| Set up remote computers with installation images, without requiring the installation compact disc. | Remote Installation Services |
| Install and remove software; modify, repair, and advertise existing applications. | Windows Installer |
| Download and install updates on your computer, such as security fixes, critical updates, the latest Help files, and device drivers. | Windows Update |

For more information about deploying applications to servers and client computers, see "Planning Server Deployments" at the Microsoft Windows Resource Kits Web site.

For more information about automating and customizing installations, see "Automating and Customizing Installations" at the Microsoft Windows Resource Kits Web site.

For more information about software installation tools, see "Part Two: Change and Configuration Management" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for deploying and managing applications, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
|---|---|
| Create and manage backup copies of the Internet Information Services (IIS) configuration (metabase and schema) of a remote or local computer. | lisback.vbs: IIS backup management script |
| Import or export all or selected elements of an Internet Information Services (IIS) metabase on a local or remote computer. | liscnfg.vbs: IIS configuration script |
| Create, delete, list, start, stop, or pause FTP sites on local or remote servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | lisftp.vbs: IIS FTP site management script |

| | |
|---|---|
| Create, delete, or display virtual directories on FTP sites of servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | IISFtpdr.vbs: IIS FTP directory script |
| Create or delete virtual directories of Web sites on servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | Iisvdir.vbs: IIS virtual directory script |
| Create, delete, list, start, stop, or pause Web sites on servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | Iisweb.vbs: IIS Web site management script |
| Install, modify, and perform operations in conjunction with Windows Installer. | Msiexec (command-line options) |
| Manage Remote Installation Services on a server. | Risetup |
| Communicate with the Service Controller and installed services; retrieve or set control information about services. | SC |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing the Active Directory directory service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing the Active Directory directory service**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing the Active Directory directory service, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| Administer Active Directory. | Administering Active Directory |
| Deploy Active Directory. | Deploying Active Directory |
| Create a specific desktop configuration of installed applications for a group of users, and manage desktop configurations for a group of users. | Group Policy (pre-GPMC) |
| Secure and manage user accounts and groups stored locally on your computer. | Local Users and Groups |
| Set up your directory structure. | Introduction to Active Directory |

For more information about deploying Active Directory, see "Part 1: Designing and deploying directory services" at the Microsoft Windows Resource Kits Web site.

For more information about managing Active Directory, see the "Directory services guide" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing the Active Directory directory service, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
|---|---|
| Import or export data from the Active Directory directory service using files that store data in the comma-separated variable (CSV) format. | CSVDE |
| Restore default Group Policy objects to their original state (after initial installation). | Dcgpofix |
| Manage objects and information about those objects in Active Directory. | Directory service command-line tools |
| Display Group Policy settings and Resultant Set of Policy (RSOP) for a user or computer. | Gpresult |
| Refresh local and Active Directory-based Group Policy settings, including security settings. | Gpupdate |

| | |
|---|---|
| Create, modify, or delete directory objects on computers running Windows Server 2003 family operating systems or Windows XP Professional; extend the schema, export Active Directory user and group information to other applications or services, or populate Active Directory with data from other directory services. | LDIFDE |
| Manage the Active Directory database. | Ntdsutil |
| Administer phone books. | Pbadmin |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing computers**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing computers, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| On a single local or remote computer: create and manage shared resources, view a list of users who are connected to the computer, or view device configurations and add new device drivers. | Computer Management |
| Use a graphical view of the hardware that is installed on your computer; if necessary, update the drivers for hardware devices, modify hardware settings and troubleshoot problems. | Device Manager |
| Monitor security and other events that occur on a local or remote computer, including hardware and software-generated events, and system problems. | Event Viewer |
| Create a specific desktop configuration for a group of users (for example, programs available to users, programs that appear on the user's desktop, Start menu options). | Group Policy (pre-GPMC) |
| Install hardware and manage hardware-related issues. | Hardware |
| Secure and manage user accounts and groups stored locally on a computer. | Local Users and Groups |
| Create, save, and open administrative tools (in the form of snap-ins) that manage hardware, software, and network components of a local or remote computer, or multiple computers. | Microsoft Management Console |
| Manage how a computer connects to the network. | Network Connections Overview |
| Connect computers to printers. | Netsh overview |
| View or edit configuration information on a computer. | The Registry |
| On local or remote computers: display system configuration information, such as hardware configurations, computer components, installed software, and driver information. | System Information |
| View and change system properties on a local or remote computer. | System Properties |
| Manage user profiles. | User profiles overview |
| Manage a single or multiple local or remote computers in a single command. | Windows Management Instrumentation Command-line |
| Synchronize time on the computers in your network. | Windows Time Service |

For more information about deploying computers, see "Part 1: Client Deployments" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing computers, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
| --- | --- |
| Configure, query, or change Boot.ini file settings. | Bootcfg |
| Manage Terminal Services. | Terminal Services change commands |
| Display or change the identification number of an active console code page. | Chcp |
| Install or removes a Connection Manager service profile. | Cmstp |
| Displays the current system date setting. Used without parameters, **date** displays the current system date setting and prompts you to type a new date. | Date |
| Display properties for all installed device drivers. | Driverquery |
| Create a custom event in a specified event log. | Eventcreate |
| List the events and event properties from one or more event logs. | Eventquery.vbs |
| Display and configure event triggers on local or remote computers. | Eventtriggers |
| Display a comprehensive view of the hardware, system components, and software environment on the local computer. | Msinfo32 |
| Display and configure the virtual memory paging file on a computer. | Pagefileconfig.vbs |
| Detect floating point division error (if present) in the Pentium chip, disable floating point hardware, or start floating point emulation. | Pentnt |
| Control the power settings on a computer. | Powercfg |
| Check Terminal Services status information. | Terminal Services query commands |
| Automate the connection process for any Microsoft client. | Rasdial |
| Add, change, or displays registry subkey information and values in registry entries. | Reg |
| Register .dll files as command components in the registry. | Regsvr32 |
| Reset (delete) a session from a terminal server. | Reset session |
| Run commands on remote computers running the Rexec service (daemon); authenticates a user name on a remote computer before executing a command. | Rexec |
| Run commands on remote computers running the RSH service or daemon. | Rsh |
| Communicate with the Service Controller and installed services; retrieve or set control information about services. | SC |
| Shut down or restart a local or remote computer. | Shutdown |
| Install a limited set of optional components. | Sysocmgr |
| Display detailed configuration information about a computer and its operating system, including operating system configuration, security information, product ID, and hardware properties, such as RAM, disk space, and network cards. | Systeminfo |
| Scan and verify the versions of all protected system files after you restart your computer. | System File Checker (sfc) |

| | |
|---|---|
| Set up or disable the telephony application programming interface (TAPI) client. | Tcmsetup |
| Administer a local or a remote computer running Telnet Server. | Telnet Command-line Reference for Telnet Server |
| Administer Terminal Services. | Terminal Services commands |
| Display or set the system time. | Time |
| Import assignment information from an Extensible Markup Language (XML) file into the TAPI server security file (Tsec.ini); you can also use this command to display the list of TAPI providers and the lines devices associated with each of them, validate the structure of the XML file without importing the contents, and check domain membership. | Tsecimp |
| Displays the Windows XP version number. | Ver |
| Diagnose problems occuring with Windows Time. | W32tm |
| Install or upgrade to a product in the Windows Server 2003 family. | Winnt32 |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing disks and data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing disks and data**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing disks and data, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| Back up and restore data. | Backup overview |
| Set properties for storage devices. | Computer Management |
| Analyze local volumes and consolidate fragmented files and folders on your hard disk. | Disk Defragmenter |
| Manage hard disks and the volumes they contain. | Disk Management |
| Monitor and limit disk space use on NTFS volumes. | Disk Quotas |
| Manage files and folders. | Managing Files and Folders |
| Work with network files and program even when you are not connected to the network. | Offline Files overview |
| Extend disk space on your server without adding more hard disks. | Remote Storage |
| Track a computer's removeable storage media and manage the hardware libraries that contain them. | Removable Storage |
| View the contents of network folders as they existed at points of time in the past. | Shadow Copies for Shared Folders |

For more information about managing disks and data, see "Part One: Managing Data and Devices" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing disks and data, and the command-line tools you use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
|---|---|
| Display or modify file name extension associations. | Assoc |
| Display, set, or remove the read-only, archive, system, and hidden attributes assigned to files or directories. | Attrib |
| Display the name of the current directory or changes the current folder. | Chdir |
| Create and display a status report for a disk based on the file system; correct errors on the disk. | chkdsk |
| Display or specify whether automatic system checking is scheduled to be run on a FAT, FAT32, or NTFS volume when the computer is started. | Chkntfs |
| Display or alter the encryption of folders and files on NTFS volumes. | Cipher |

| | |
|---|---|
| Compare the contents of two files or sets of files byte by byte on the same drive or on different drives, or in the same directory or in different directories. | Comp |
| Display and alter the compression of files or directories on NTFS partitions. | Compact |
| Convert FAT and FAT32 volumes to NTFS. | Convert |
| Copy one or more files from one location to another. | Copy |
| Clean specified profiles of wasted space and, if user-specific file associations are disabled, remove these associations from the registry. | Cprofile |
| Locate and consolidate fragmented boot files, data files, and folders on local volumes. | Defrag |
| Delete specified files. | Del |
| Manage a distributed file system. | Dfscmd |
| Display a list of a directory's files and subdirectories. | Dir |
| Compare the contents of two floppy disks. | Diskcomp |
| Copy the contents of the floppy disk in the source drive to a formatted or unformatted floppy disk in the destination drive. | Diskcopy |
| Manage objects (disks, partitions, or volumes) by using scripts or direct input. | DiskPart |
| Expand one or more compressed files. | Expand |
| Compare two files and display the differences between them. | Fc |
| Used in conjunction with the command redirection pipe character (\|), a command filter is a command within a command that reads the command's input, transforms the input, and then writes the output. Filter commands help you sort, view, and select parts of a command output. Filter commands divide, rearrange, or extract portions of the information that passes through them. | Using filters |
| Searches for a specific string of text in a file or files. After searching the specified file or files, **find** displays any lines of text that contain the specified string. | Find |
| Searches for patterns of text in files using regular expressions. | Findstr |
| Enable or disable flat temporary folders. | Flattemp |
| Format the disk in the specified volume to accept Windows files. | Format |
| Check to see if the specified amount of disk space is available before continuing with an installation process. | Freedisk |
| Perform many FAT and NTFS file system related tasks, such as managing reparse points, managing sparse files, or dismounting a volume. | Fsutil |
| Displays or modifies file types used in file name extension associations. Used without parameters, **ftype** displays the file types that have open command strings defined. | Ftype |
| Replace locked operating system files. | Inuse |
| Create, change, or delete the volume label (that is, the name) of a disk. | Label |
| Manage File Server for Macintosh servers, volumes, directories, and files. | Macfile |
| Creates a directory or subdirectory. | Mkdir |
| Create, delete, or list a volume mount point. **Mountvol** is a way to link volumes without requiring a drive letter. | Mountvol |
| Move one or more files from one directory to a specified directory. | Move |

| | |
|---|---|
| Back up disks and data. | Ntbackup |
| Query, display, or disconnect open files or files opened by network users; enable or disable the system Maintain Objects List global flag. | Openfiles |
| Copy files between a Windows Server 2003 family, or Windows XP computer and a system running **rshd**, the remote shell service (daemon). | Rcp |
| Remove (delete) a directory. | Rd |
| Recover readable information from a bad or defective disk. | Recover |
| Change the name of a file or a set of files. | Rename (ren) |
| Replace files in the destination directory with files in the source directory that have the same name; add unique file names to the destination directory. | Replace |
| Remove (delete) a directory. | Rmdir (Rd) |
| Manage media resources using Removable Storage | Rsm |
| Manage Remote Storage. | Rss |
| Read input, and sort data; write the results to the screen, to a file, or to another device. | Sort |
| Associate a path with a drive letter. | Subst |
| Display the directory structure of a path or of the disk in a drive graphically. | Tree |
| Displays the contents of a text file. Use the **type** command to view a text file without modifying it. | Type |
| Display the disk volume label and serial number, if they exist. | Vol |
| Displays current volume shadow copy backups and all installed shadow copy writers and providers in the command window. The Windows Server 2003 family version of this command contains more parameters than the one that is in Windows XP. | Vssadmin |
| Locate and display all files that match the given parameter. | Where |
| Copy files and directories, including subdirectories. | Xcopy |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing network services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing network services**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing network services, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| **Task** | **Tool or feature** |
|---|---|
| Manage availability and scalability of objects on your network. | Availability and Scalability |
| Set up and configure a DHCP or DNS server. | Configuring Roles for Your Server |
| Configure communication links for network connections, modems, and wireless networking. | Configuring Communication Links |
| Configure communication services for telephony. | Configuring Communication Services |
| Enable dynamic allocation of IP addresses and other related configuration details for clients on your network, by administering the DHCP service. | DHCP |
| Administer the Domain Name System (DNS) service. DNS enables client computer to resolve DNS domain names of network objects. Once domain names are resolved on your computer, you can access resources offered by other computers on your network or other networks, such as the Intranet. | DNS |
| Configure and administer Internet and E-mail services. | Internet and E-mail Services |
| Configure Internet Protocol Security. | Internet Protocol Security (IPSec) |
| Manage bandwidth issues, such as Quality of Service (QoS) and Windows Asynchronous Transfer Mode (ATM) Services. | Managing Bandwidth |
| Choose and manage remote connections and methods through routing and remote access, Connection Manager, Connection Point Services, virtual private networks, and Internet Authentication Service. | Managing Remote Connections |
| Create, save, and open administrative tools (in the form of snap-ins) that manage hardware, software, and network components of a local or remote computer, or multiple computers. | Microsoft Management Console |
| Set up, configure and manage network connections. | Network Connections |

| | |
|---|---|
| Display information about your computer, operating system, network, and network adapters; perform standard tests for network connectivity. | Using Network Diagnostics |
| Gather information about network traffic status. | Network Monitor |
| Obtain status information about network hosts such as servers, workstations, or routers, bridges, and hubs from a centrally-located computer on network using TCP/IP. | SNMP |
| Enable Windows-based computers to connect and share information with other Microsoft and non-Microsoft systems. | TCP/IP Core Networking Service |
| Resolve names for computer and groups on a network using the NetBIOS naming protocol. | WINS |

For more information about deploying network services, see "Deploying Network Services" at the Microsoft Windows Resource Kits Web site.

For more information about managing network services, see the "Networking Guide" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing network services, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| **Task** | **Command-line tool** |
|---|---|
| Display and modify entries in the Address Resolution Protocol (ARP) cache | Arp |
| Monitor connections and addresses that are registered by the ATM Call Manager on an asynchronous transfer mode (ATM) network; display statistics for incoming and outgoing calls on ATM adapters. | Atmadm |
| Transfer files to and from a computer running a File Transfer Protocol (FTP) server service such as Internet Information Services. | Ftp |
| Display the media access control (MAC) address and list of network protocols associated with each address for all network cards in each computer, either locally or across a network. | Getmac |
| Display the host name portion of the full computer name of the computer. | Hostname |
| Display all current TCP/IP network configuration values or refresh Dynamic Host Configuration Protocol (DHCP) and Domain Name System (DNS) settings. | Ipconfig |
| Display or modify information about the routing tables used by the IPX protocol. | Ipxroute |
| Send files over an infrared link. | Irftp |
| Display the configuration of a multicast router to aid in the troubleshooting of multicast forwarding and routing problems | Using the IP multicasting utilities |
| Display NetBIOS over TCP/IP (NetBT) protocol statistics, NetBIOS name tables for both the local computer and remote computers, or the NetBIOS name cache. | Nbtstat |
| Check network status and other configuration information. | Net services overview |
| Display or modify the network configuration of a local or remote computer that is currently running. | Netsh overview |
| Display active TCP connections, ports on which the computer is listening, Ethernet statistics, the IP routing table, IPv4 statistics (for the IP, ICMP, TCP, and UDP protocols), and IPv6 statistics (for the IPv6, ICMPv6, TCP over IPv6, and UDP over IPv6 protocols). | Netstat |

| | |
|---|---|
| Manage network load balancing. | Nlb |
| Display information that you can use to diagnose Domain Name System (DNS) infrastructure. . | Nslookup |
| Obtain information about network latency and network loss at intermediate hops between a source and destination; send multiple Echo Request messages to each router between a source and destination over a period of time and then compute results based on the packets returned from each router. | Pathping |
| Verify IP-level connectivity to another TCP/IP computer by sending Internet Control Message Protocol (ICMP) Echo Request messages. | Ping |
| Display and modify the entries in the local IP routing table. | Route |
| Manage TCP/IP. | TCP/IP utilities and services |
| Transfer files to and from a remote computer, typically a computer running UNIX, that is running the Trivial File Transfer Protocol (TFTP) service or daemon. | Tftp |
| Determine the path taken to a destination by sending Internet Control Message Protocol (ICMP) Echo Request or ICMPv6 messages to the destination with incrementally increasing Time to Live (TTL) field values. | Tracert |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing printers and faxes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing printers and faxes**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing printers and faxes, and the tools you can use to perform them. For more information, click the corresponding link under "Tool or feature."

| Task | Tool or feature |
|---|---|
| Enable network users to send and receive faxes through remote fax printer connections. | Fax Service Manager |
| Install, connect to, and manage printers. | Printing |

For more information about printing, see "Network Printing" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing printers and faxes, and the command-line tools you can use to perform them. For more information, click the corresponding link under "Command-line tool."

| Task | Command-line tool |
|---|---|
| Start or stop the File Server for Macintosh service or the Print Server for Macintosh service. | Services for Macintosh commands |
| Display the status of a print queue on a computer running Line Printer Daemon (LPD). | Lpq |
| Send a file to a computer running Line Printer Daemon (LPD) in preparation for printing. | Lpr |
| Send a text file to a printer. | Print |
| Configure or display configuration information about a printer. | Prncnfg.vbs |
| Add, delete, or list printer drivers. | Prndrvr.vbs |
| Pause, resume, cancel, or lists print jobs. | Prnjobs.vbs |
| Add, delete, or list printers or printer connections; set or display the default printer. | Prnmngr.vbs |
| Create, delete, or list standard TCP/IP printer ports, in addition to displaying and changing port configuration. | Prnport.vbs |
| Print a test page; pause or resume a printer, or clear a printer queue. | Prnqctl.vbs |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing security**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing security, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| Secure a computer by granting users or groups specific user rights, or assign permissions to an object to enable users or groups to perform specific actions on that object. | Access Control |
| Set up an auditing policy to record user or system activity in specified event categories. | Auditing Security Events |
| Confirm the identity of any user trying to log on to a domain or access network resources. | Authentication |
| Grant access to assigned user roles related to job function. | Authorization Manager |
| Encrypt files and directories that are stored on a disk. | Encrypting File System |
| Verify and authenticate the validity of each party involved in an electronic transaction through the use of public key cryptography. | Public Key Infrastructure |
| Create, apply, and edit the security for your local computer, organizational unit, or domain. | Security Configuration Manager |
| Understand security. | Security overview |
| Identify software and control its ability to run on your local computer, organizational unit, domain, or site. | Software Restriction Policies |

For more information about deploying security, see "Part 2: Deploying Distributed Security Services" at the Microsoft Windows Resource Kits Web site.

For more information about managing security, see "Part One: Security" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing security, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
|---|---|
| Display or modify discretionary access control list (DACL) files. | Cacls |
| Request certificates from a certification authority (CA). | Certreq |
| Process and display certification authority (CA) configuration information, configure Certificate Services, back up and restore CA components, and verify certificates, key pairs, and certificate chains. | Certutil |

| | |
|---|---|
| Create, list or delete stored user names and passwords or credentials. | Cmdkey |
| Enable a user to run specific tools and programs with different permissions than the user's current logon provides. | Runas |
| Configure and analyze system security by comparing your current configuration to at least one template. | Secedit |
| Recover access to a file that previously was denied by making the administrator owner of the file. | Takeown |
| Display domain or computer name, user name, group names, logon identifier and privileges for the user currently logged on. | Whoami |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Managing servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing servers**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for managing your server, and the tools you can use to perform them. For more information, click the corresponding link under **Tool or Feature**.

| Task | Tool or feature |
|---|---|
| Add and manage roles for your server. | Configuring Roles for Your Server |
| Install and upgrade the operating system. | Installing and Upgrading the Operating System |

For more information about deploying servers, see "Part 2: Server Deployments" at the Microsoft Windows Resource Kits Web site.

For more information about managing servers, see the "Server Management Guide" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for managing your server, and the command-line tools you can use to perform them. For more information, click the corresponding link under **Command-line tool**.

| Task | Command-line tool |
|---|---|
| Connect to, configure and manage server clusters. | Cluadmin |
| Create a new cluster or administer an existing cluster. | Cluster |
| Create and manage backup copies of the Internet Information Services (IIS) configuration (metabase and schema) of a remote or local computer. | Iisback.vbs: IIS backup management script |
| Import or export all or selected elements of an Internet Information Services (IIS) metabase on a local or remote computer. | Iiscnfg.vbs: IIS configuration script |
| Create, delete, list, start, stop, or pause FTP sites on local or remote servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | Iisftp.vbs: IIS FTP site management script |
| Create, delete, or display virtual directories on FTP sites of servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | IISFtpdr.vbs: IIS FTP directory script |
| Create or delete virtual directories of Web sites on servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | Iisvdir.vbs: IIS virtual directory script |

| | |
|---|---|
| Create, delete, list, start, stop, or pause Web sites on servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. | Iisweb.vbs: IIS Web site management script |
| Start or stop the File Server for Macintosh service or the Print Server for Macintosh service. | File and print server for Macintosh |
| Create, modify, or delete directory objects on computers running Windows Server 2003 operating systems or Windows XP Professional; extend the schema, export Active Directory user and group information to other applications or services, or populate Active Directory with data from other directory services. | LDIFDE |
| Manage a server running Remote Installation Services. | Risetup |
| Communicate with the Service Controller and installed services; retrieve or set control information about services. | SC |
| Display detailed configuration information about a computer and its operating system, including operating system configuration, security information, product ID, and hardware properties, such as RAM, disk space, and network cards. | Systeminfo |
| Install or upgrade to a product in the Windows Server 2003 family. | Winnt32 |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Monitoring and controlling services on computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring and controlling services on computers**

- Using the Windows interface
- Using command-line tools

**Using the Windows interface**

The following table lists some of the most common tasks for monitoring and controlling services, and the tools you can use to perform them. For more information, click the corresponding link under "Tool or feature".

| Task | Tool or feature |
|---|---|
| Collect performance data automatically from local or remote computers, and package data so that it can be viewed by System Monitor or exported to a spreadsheet or database for further analysis and report generation. | Performance Logs and Alerts overview |
| Track how often users shut down or restart their computers. | Shutdown Event Tracker |
| Display system configuration information for local and remote computers, including hardware configurations, computer components, software and drivers. | System Information |
| Collect and view extensive data about the usage of hardware resources and the activity of system services on your computer or other computers on the network. | System Monitor overview |
| View and change system properties on a local or remote computer. | System Properties |
| Monitor key indicators of your computer's performance. | Task Manager overview |
| Synchronize time on the computers in your network. | Windows Time Service |

For more information about monitoring and controlling services on computers, see "Part Four: Operating System Services" at the Microsoft Windows Resource Kits Web site.

**Using command-line tools**

The following table lists some of the most common tasks for monitoring and controlling services, and the command-line tools you can use to perform them. For more information, click the corresponding link under "Command-line tool."

| Task | Command-line tool |
|---|---|
| Configure the translation of events to traps, trap destinations, or both based on information in a configuration file. | Evntcmd |
| Register new Performance counter names and Explain text for a service or device driver; saves or restore counter settings and explain text. | Lodctr |
| Manage and schedule performance counter and event trace log collections on local and remote computers. | Logman |
| Display system status, change system settings, or reconfigure ports or devices. | Mode |
| Display a comprehensive view of the hardware, system components, and software environment on the local computer. | Msinfo32 |

| | |
|---|---|
| Open a Performance console configured with the System Monitor Active-X control and the Performance Logs and Alerts Service snap-in in the Microsoft Management Console. | Perfmon |
| Extract performance counters from performance counter logs into other formats, such as text-TSV (for tab-delimited text), text-CSV (for comma-delimited text), binary-BIN, or SQL. | Relog |
| Communicate with the Service Controller and installed services; retrieve or set control information about services. | SC |
| Display detailed configuration information about a computer and its operating system, including operating system configuration, security information, product ID, and hardware properties, such as RAM, disk space, and network cards. | Systeminfo |
| End one or more tasks or processes. | Taskkill |
| Display a list of applications, services, and the Process ID (PID) currently running on either a local or a remote computer. | Tasklist |
| Process event trace logs or real-time data from instrumented event trace providers, and generate trace analysis reports and CSV (comma-delimited) files for the events generated. | Tracerpt |
| Display performance counter data. | Typeperf |
| Remove performance counter names and explain text for a service or device driver from the system registry. | Unlodctr |
| Diagnose problems occurring with Windows Time. | W32tm |

For more information about the command shell, see Command shell overview. For information about tools used to manage the command-prompt window, see Manage the command-prompt window. For an alphabetical list of all of the command-line tools, see Command-line reference A-Z.

# Command-Line Reference

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Command-line reference**
You can use Command-line reference to familiarize yourself with new and enhanced command-line tools, to configure your command prompt, to learn about the command shell, and to automate command-line tasks by using batch files or scripting tools such as CScript and WMIC.

- For information about functionality that has been changed or is no longer available in the Microsoft® Windows Server 2003 family, see New ways to do familiar command-line tasks.
- For a list of new command-line tools, see New command-line tools.
- For a complete list of command-line tools, see Command-line reference A-Z.
- For general background information, see Command shell overview.
- For help with configuring the command prompt, see Configure the command prompt.

# New ways to do familiar command-line tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The Windows Server 2003 family retains and enhances almost all MS-DOS functionality. The following tables explain:

- Changes to the functionality of MS-DOS commands.
- MS-DOS commands that are no longer available in the Windows Server 2003 family.
- MS-DOS commands that are no longer available on Windows Server 2003, Datacenter Editionor Windows Server 2003, Enterprise Edition.

**Changes toMS-DOScommands**

The following table lists changes to the functionality of MS-DOS commands.

| Command | Changed features |
|---|---|
| Chcp | Changes code pages for all Command Prompt windows. |
| Diskcomp | Command-line options **/1** and **/8** are not supported. |
| **diskperf** | No longer needed to act upon a server computer. You can still use **diskperf** for remote administration. |
| Diskcopy | Command-line option **/1** is not supported. |
| Doskey | Available for all character-based programs that accept buffered input. **Doskey** has been improved by a series of enhancements. |
| Format | Supports 1.44 MB floppy drive only. 20.8 MB floptical (magneto-optical) drive is no longer supported. Command-line options **/b**, **/s**, **/u**, **/1**, **/4**, and **/8** are no longer supported. |
| Label | The caret (^) and ampersand (&) symbols can be used in a volume label. |
| Mode | The **mode lpt***N*[**:**][**cols**=*c*][**lines**=*N*] and **mode lpt***N*[**:**][*c*][**,**[*N*]] syntaxes are no longer supported. |
| Print | Command-line options **/b**, **/c**, **/m**, **/p**, **/q**, **/s**, **/t**, and **/u** are not supported. |
| Prompt | New character combinations enable you to add ampersands ($a), parentheses ($c and $f), and spaces ($s) to your prompt. |
| recover | Recovers files only. |
| rmdir | New **/s** command-line option deletes directories containing files and subdirectories. |
| Sort | Does not require TEMP environment variable. File size is unlimited. |
| Xcopy | New **/g** command-line option creates decrypted destination files. |

**MS-DOScommands not supported in the Windows Server 2003 family**

The following MS-DOS commands are not supported in the Windows Server 2003 family.

| Command | New procedure or reason for obsolescence |
|---|---|
| **assign** | Not supported. |
| **backup** | Not supported. |

| | |
|---|---|
| **choice** | Not supported. |
| **ctty** | Not supported. |
| **dblspace** | Not supported. |
| **deltree** | The **rmdir /s** command deletes directories containing files and subdirectories. For more information about the **rmdir** command, see Rmdir. |
| **dosshell** | Function is now inherent. |
| **drvspace** | Not supported. |
| **emm386** | Function is now inherent. |
| **fasthelp** | Not supported. Use the **help** command at the command prompt. For more information about the **help** command, see Help. For a complete list of command-line tools, see Command-line reference A-Z. |
| **fdisk** | Not supported. Use the **diskpart** command, which enables you to manage disks, partitions, or volumes. For more information about the **diskpart** command, see DiskPart. |
| **include** | Multiple configurations of the MS-DOS subsystem are not supported. |
| **interlnk** | Not supported. |
| **intersrv** | Not supported. |
| **join** | Increased partition size and an improved file system eliminate the need to join drives. |
| **memmaker** | MS-DOS subsystem memory usage is automatically optimized. |
| **menucolor** | Multiple configurations of the MS-DOS subsystem are not supported. |
| **menudefault** | Multiple configurations of the MS-DOS subsystem are not supported. |
| **menuitem** | Multiple configurations of the MS-DOS subsystem are not supported. |
| **mirror** | Not supported. |
| **msav** | Not supported. |
| **msbackup** | Use the **ntbackup** command for computers with tape drives, or the **xcopy** command for computers without tape drives. For more information about the **ntbackup** command, see Ntbackup. For more information about the **xcopy** command, see Xcopy. |
| **mscdex** | It is unnecessary to configure the MS-DOS subsystem to use CD-ROM drives. The Windows Server 2003 family provides access to CD-ROM drives for the MS-DOS subsystem. |
| **msd** | Use the System Information snap-in. To start System Information, click **Start**, click **Run**, and then type **msinfo32**. |
| **numlock** | Not supported. |
| **power** | Not supported. |
| **restore** | Not supported. |
| **scandisk** | Not supported. Use the **chkdsk** command, which enables you to create and display a status report for a disk based on the file system. Chkdsk also lists and corrects errors on the disk. For more information about the **chkdsk** command, see chkdsk. |
| **smartdrv** | Caching for the MS-DOS subsystem is automatic. |
| **submenu** | Multiple configurations of the MS-DOS subsystem are not supported. |

| | |
|---|---|
| **sys** | Windows Server 2003 family operating systems will not fit on a standard 1.2 MB or 1.44 MB floppy disk. |
| **undelete** | Not supported. |
| **unformat** | Not supported. |
| **vsafe** | Not supported. |

**MS-DOScommands no longer available on Windows Server 2003, Datacenter Edition or Windows Server 2003, Enterprise Edition**
The following 16-bit MS-DOS subsystem commands are not available on Windows Server 2003, Datacenter Editionor Windows Server 2003, Enterprise Edition.

| Command | Function |
|---|---|
| **append** | Enables programs to open data files in specified folders as if these files were in the current folder. |
| **debug** | Starts Debug.exe, a program that you can use to test and debug MS-DOS executable files. |
| **edit** | Starts MS-DOS Editor, which creates and changes ASCII text files. |
| **edlin** | Starts Edlin.exe, a line-oriented text editor with which you can create and change ASCII files. |
| **exe2bin** | Converts .exe (executable files) to binary format. |
| **expand** | Expands one or more compressed files. |
| **fastopen** | Windows XP and the Windows Server 2003 family of products do not use this command. It is included only to preserve compatibility with existing MS-DOS files, but it has no effect at the command line because the functionality is automatic. |
| **forcedos** | Starts the specified program in the MS-DOS subsystem. This command is necessary only for those MS-DOS programs that are not recognized as MS-DOS programs by the Windows Server 2003 family. |
| **graphics** | Loads a program into memory that allows you to print on a printer the displayed contents of the screen when you are using a color or graphics adapter. |
| **loadfix** | Ensures that a program is loaded above the first 64KB of conventional memory, and then runs the program. |
| **loadhigh (lh)** | Loads a program into the upper memory area (UMA). Loading a program into the UMA leaves more room in conventional memory for other programs. |
| **mem** | Displays information about allocated memory areas, free memory areas, and programs that are currently loaded into memory in the MS-DOS subsystem. |
| **nlsfunc** | Loads information specific to country/region. Windows XP and the Windows Server 2003 family of products do not use this command. It is included only to preserve compatibility with existing MS-DOS files, but it has no effect at the command line because the functionality is automatic. |
| **setver** | Sets the MS-DOS version number that the MS-DOS subsystem reports to a program. |
| **share** | Windows XP and the Windows Server 2003 family of products do not use this command. It is included only to preserve compatibility with existing MS-DOS files, but it has no effect at the command line because the functionality is automatic. |

# New command-line tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New command-line tools**

The following table lists the new Windows Server 2003 family command-line tools.

| Command | Features |
|---|---|
| Adprep | Prepares Windows 2000 domains and forests for an upgrade to Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; or Windows Server 2003, Datacenter Edition. |
| Bootcfg | Configures, queries, or changes Boot.ini file settings. |
| choice | Prompts the user to make a choice in a batch program by displaying a prompt and pausing for the user to choose from a set of user-option keys. |
| Clip | Redirects command output from the command line to the Clipboard. |
| Cmdkey | Creates, lists, and deletes stored user names and passwords or credentials. |
| Defrag | Locates and consolidates fragmented boot files, data files, and folders on local volumes. |
| DiskPart | Manages disks, partitions, or volumes. |
| Driverquery | Queries for a list of drivers and driver properties. |
| Dsadd | Adds a computer, contact, group, organization unit, or user to a directory. |
| Dsget | Displays selected attributes of a computer, contact, group, organizational unit, server or user in a directory. |
| Dsmod | Modifies an existing user, computer, contact, group or organizational units in a directory. |
| Dsmove | Moves any object from its current location in the directory to a new location, as long as the move can be accommodated within a single domain controller, and renames an object without moving it in the directory tree. |
| Dsquery | Queries and finds a list of computers, groups, organizational units, servers, or users in the directory by using specified search criterion. |
| Dsrm | Deletes an object of a specific type or any general object from the directory. |
| Eventcreate | Enables an administrator to create a custom event in a specified event log. |
| Eventquery.vbs | Lists the events and event properties from one or more event logs. |
| Eventtriggers | Displays and configures event triggers on local or remote machines. |
| Expand | Expands one or more compressed files. |
| Forfiles | Selects files in a folder or tree for batch processing. |
| Freedisk | Checks for available disk space before continuing with an installation process. |
| Fsutil | Manages reparse points, managing sparse files, dismounting a volume, or extending a volume. |
| Getmac | Obtains the media access control (MAC) address and list of network protocols. |

| | |
|---|---|
| Gettype | Sets the system environment variable %ERRORLEVEL% to the value associated with the specified Windowsoperating system. |
| Gpresult | Displays Group Policy settings and Resultant Set of Policy (RSoP) for a user or a computer. |
| Helpctr | Starts Help and Support Center. |
| Iisapp.vbs: IIS application query script | Reports the process identifiers (PIDs) of currently running W3pwp.exe processes serving a particular application pool. |
| Iisback.vbs: IIS backup management script | Creates and manages backup copies of the Internet Information Services (IIS) configuration (metabase and schema) of a remote or local computer. |
| Iiscnfg.vbs: IIS configuration script | Imports and exports all or selected parts of the configuration of Internet Information Services (IIS) on a local or remote computer. |
| Iisext.vbs: IIS Web service extension script | Configures and manages Web service extensions, applications, and individual files on servers running Windows Server 2003 with Internet Information Services (IIS) 6.0. |
| Iisftp.vbs: IIS FTP site management script | Creates, deletes, and lists FTP sites on servers that are running Internet Information Services (IIS) 6.0. Also, starts, stops, pauses, and continues FTP sites. |
| IISFtpdr.vbs: IIS FTP directory script | Creates and deletes virtual directories of FTP sites on servers that are running Internet Information Services (IIS) 6.0. |
| Iisvdir.vbs: IIS virtual directory script | Creates and deletes virtual directories of Web sites on servers that are running Internet Information Services (IIS) 6.0. |
| Iisweb.vbs: IIS Web site management script | Creates, deletes, and lists Web sites on servers that are running Internet Information Services (IIS) 6.0. Also, starts, stops, pauses, and continues the Web sites. |
| Inuse | Replaces locked operating system files. |
| Logman | Manages and schedules performance counter and event trace log collections on local and remote systems. |
| Nlb | Replaces Wlbs.exe for managing and controlling network load balancing operations. |
| Nlbmgr | Configures and manages Network Load Balancing clusters and all cluster hosts from a single computer. |
| Openfiles | Queries, displays, or disconnects open files. |
| Pagefileconfig.vbs | Displays and configures the paging file Virtual Memory settings of a system. |
| Perfmon | Enables you to open a Performance console configured with settings files from Windows NT 4.0 version of Performance Monitor. |
| Prncnfg.vbs | Configures or displays configuration information about a printer. |
| Prndrvr.vbs | Adds, deletes, and lists printer drivers from local or remote print servers. |
| Prnjobs.vbs | Pauses, resumes, cancels, and lists print jobs. |
| Prnmngr.vbs | Adds, deletes, and lists printers or printer connections, in addition to setting and displaying the default printer. |
| Prnport.vbs | Creates, deletes, and lists standard TCP/IP printer ports, in addition to displaying and changing port configuration. |
| Prnqctl.vbs | Prints a test page, pauses or resumes a printer, and clears a printer queue. |
| Relog | Extracts performance counters from performance counter logs into other formats, such as text-TSV (for tab-delimited text), text-CSV (for comma-delimited text), binary-BIN, or SQL. |

| | |
|---|---|
| Rss | Enables Remote Storage, which is used for extending server disk space. |
| SC | Retrieves and sets information about services. Tests and debugs service programs. |
| Schtasks | Schedules commands and programs to run periodically or at a specific time. Adds and removes tasks from the schedule, starts and stops tasks on demand, and displays and changes scheduled tasks. |
| setx | Sets environment variables in the local or system environment, without requiring programming or scripting. |
| Shutdown | Shuts down or restarts a local or remote computer. |
| Systeminfo | Queries the system for basic system configuration information. |
| Takeown | Allows an administrator to recover access to a file that previously was denied by making the administrator the owner of the file. |
| Taskkill | Ends one or more tasks or processes. |
| Tasklist | Displays a list of applications, services, and the Process ID (PID) currently running on either a local or a remote computer. |
| Timeout | Pauses the command processor for the specified number of seconds. |
| Tracerpt | Processes event trace logs or real-time data from instrumented event trace providers and allows you to generate trace analysis reports and comma-separated value files (.csv) for the events generated. |
| Tsecimp | Imports assignment information from an Extensible Markup Language (XML) file into the TAPI server security file (Tsec.ini). |
| Typeperf | Writes performance counter data to the command window or to a supported log file format. |
| waitfor | Synchronizes multiple computers across a network by using signals. |
| Where | Locates and displays all files that match the given parameter. |
| Whoami | Returns domain name, computer name, user name, group names, logon identifier, and privileges for the user who is currently logged on. |
| Windows Management Instrumentation Command-line (WMIC) tool | Eases the use of Windows Management Instrumentation (WMI) and systems managed through WMI. |

# Command-line reference A-Z

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Command-line reference A-Z**
To find information about a command, on the A-Z menu, click the letter that the command starts with, and then click the command name.

In addition to the tools installed with the Windows Server 2003 family there are over 40 support tools that you can install directly from the product CD. You can use these tools to diagnose and resolve computer problems. For more information about these support tools and how to install them, see Install Windows Support Tools.

For more information about changes to the functionality of MS-DOS commands, new command-line tools, command shell functionality, configuring the command prompt, and automating command-line tasks, see Command-line reference.

You must run command-line tools at the prompt of the Cmd.exe command interpreter. To open Command Prompt, click **Start**, click **Run**, type **cmd**, and then click **OK**. To view help at the command line, at the command prompt, type:

*CommandName* **/?**

As a security best practice, consider using an account without administrative credentials to perform routine, nonadministrative tasks. To perform only specific tasks with an account with administrative credentials, you can use the Runas command.

# Command shell overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Command shell overview**

The command shell is a separate software program that provides direct communication between the user and the operating system. The non-graphical command shell user interface provides the environment in which you run character-based applications and utilities. The command shell executes programs and displays their output on the screen by using individual characters similar to the MS-DOS command interpreter Command.com. The Windows server operating system command shell uses the command interpreter Cmd.exe, which loads applications and directs the flow of information between applications, to translate user input into a form that the operating system understands.

You can use the command shell to create and edit batch files (also called scripts) to automate routine tasks. For example, you can use scripts to automate the management of user accounts or nightly backups. You can also use the command-line version of Windows Script Host, CScript, to run more sophisticated scripts in the command shell. For more information, see Run Windows Script Host. You can perform operations more efficiently by using batch files than you can by using the user interface. Batch files accept all commands that are available at the command line. For more information about batch files and scripting, see Using batch files.

You can customize the command prompt window for easier viewing and to increase control over how you run programs. For more information about customizing the command prompt window, see Configure the command prompt.

**Using command syntax**

Syntax appears in the order in which you must type a command and any parameters that follow it. The following example of the **xcopy** command illustrates a variety of syntax text formats:

**xcopy** *Source* [*Destination*] [**/w**] [**/p**] [**/c**] [**/v**] [**/q**] [**/f**] [**/l**] [**/g**] [**/d**[**:***MM-DD-YYYY*]] [**/u**] [**/i**] [**/s** [**/e**]] [**/t**] [**/k**] [**/r**] [**/h**] [{**/a** | **/m**}] [**/n**] [**/o**] [**/x**] [**/exclude:***File1*[**+**[*File2*]][**+**[*File3*]] [{**/y** | **/-y**}] [**/z**]

The following table explains how to interpret the different text formats.

**Formatting legend**

| Format | Meaning |
|---|---|
| Italic | Information that the user must supply |
| Bold | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

**Using multiple commands and conditional processing symbols**

You can run multiple commands from a single command line or script using conditional processing symbols. When you run multiple commands with conditional processing symbols, the commands to the right of the conditional processing symbol act based upon the results of the command to the left of the conditional processing symbol. For example, you might want to run a command only if the previous command fails. Or, you might want to run a command only if the previous command is successful.

You can use the special characters listed in the following table to pass multiple commands.

| Character | Syntax | Definition |
|---|---|---|
| **&** [**...**] | *Command1* **&***Command2* | Use to separate multiple commands on one command line. Cmd.exe runs the first command, and then the second command. |

| | | |
|---|---|---|
| **&&** [...] | *Command1* **&&***Command2* | Use to run the command following **&&** only if the command preceding the symbol is successful. Cmd.exe runs the first command, and then runs the second command only if the first command completed successfully. |
| **\|\|** [...] | *Command1* **\|\|** *Command2* | Use to run the command following **\|\|** only if the command preceding **\|\|** fails. Cmd.exe runs the first command, and then runs the second command only if the first command did not complete successfully (receives an error code greater than zero). |
| **( )** [...] | **(** *Command1* **&** *Command2***)** | Use to group or nest multiple commands. |
| **;** or **,** | *Command1 Parameter1***;***Parameter2* | Use to separate command parameters. |

**Notes**

- The ampersand (&), pipe (|), and parentheses ( ) are special characters that must be preceded by the escape character (^) or quotation marks when you pass them as arguments.
- If a command completes an operation successfully, it returns an exit code of zero (0) or no exit code. For more information about exit codes, see Using the Windows Deployment and Resource Kits.

**Nesting command shells**

You can nest command shells within Cmd.exe by opening a new instance of Cmd.exe at the command prompt. By default, each instance of Cmd.exe inherits the environment of its parent Cmd.exe application. By nesting instances of Cmd.exe, you can make changes to the local environment without affecting the parent application of Cmd.exe. This allows you to preserve the original environment of Cmd.exe and return to it after you terminate the nested command shell. The changes you make in the nested command shell are not saved.

To nest a command shell, at the command prompt, type:

**cmd**

A message similar to the following appears:

```
Microsoft (R) Windows Server 2003, Standard Edition (TM)(C) Copyright 1985-2002 Microsoft Corp.
```

To close the nested command shell, type **exit**.

You can localize changes even further in an instance of Cmd.exe (or in a script) by using the **setlocal** and **endlocal** commands. **Setlocal** creates a local scope and **endlocal** terminates the local scope. Any changes made within the **setlocal** and **endlocal** scope are discarded, thereby leaving the original environment unchanged. You can nest these two commands to a maximum of 32 levels. For more information about the **setlocal** and **endlocal** commands, see Setlocal and Endlocal.

**Using environment variables with Cmd.exe**

The Cmd.exe command-shell environment is defined by variables that determine the behavior of the command shell and the operating system. You can define the behavior of the command-shell environment or the entire operating system environment by using two types of environment variables, system and local. System environment variables define the behavior of the global operating system environment. Local environment variables define the behavior of the environment of the current instance of Cmd.exe.

System environment variables are preset in the operating system and available to all Windows server operating system processes. Only users with administrative credentials can change system variables. These variables are most commonly used in logon scripts.

Local environment variables are only available when the user for whom they were created is logged on to the computer. Local variables set in the **HKEY_CURRENT_USER**hive are valid only for the current user, but define the behavior of the global operating system environment.

The following list describes the various types of variables in descending order of precedence:

1. Built-in system variables
2. System variables found in the **HKEY_LOCAL_MACHINE** hive

3. Local variables found in the **HKEY_CURRENT_USER** hive

4. All environment variables and paths set in the Autoexec.bat file

5. All environment variables and paths set in a logon script (if present)

6. Variables used interactively in a script or batch file

In the command shell, each instance of Cmd.exe inherits the environment of its parent application. Therefore, you can change the variables in the new Cmd.exe environment without affecting the environment of the parent application.

The following table lists the system and local environment variables for the Windows server operating system.

| **Variable** | **Type** | **Description** |
|---|---|---|
| %ALLUSERSPROFILE% | Local | Returns the location of the All Users Profile. |
| %APPDATA% | Local | Returns the location where applications store data by default. |
| %CD% | Local | Returns the current directory string. |
| %CMDCMDLINE% | Local | Returns the exact command line used to start the current Cmd.exe. |
| %CMDEXTVERSION% | System | Returns the version number of the current Command Processor Extensions. |
| %COMPUTERNAME% | System | Returns the name of the computer. |
| %COMSPEC% | System | Returns the exact path to the command shell executable. |
| %DATE% | System | Returns the current date. Uses the same format as the **date /t** command. Generated by Cmd.exe. For more information about the **date** command, see Date. |
| %ERRORLEVEL% | System | Returns the error code of the most recently used command. A non zero value usually indicates an error. |
| %HOMEDRIVE% | System | Returns which local workstation drive letter is connected to the user's home directory. Set based on the value of the home directory. The user's home directory is specified in Local Users and Groups. |
| %HOMEPATH% | System | Returns the full path of the user's home directory. Set based on the value of the home directory. The user's home directory is specified in Local Users and Groups. |
| %HOMESHARE% | System | Returns the network path to the user's shared home directory. Set based on the value of the home directory. The user's home directory is specified in Local Users and Groups. |
| %LOGONSERVER% | Local | Returns the name of the domain controller that validated the current logon session. |
| %NUMBER_OF_PROCESSORS% | System | Specifies the number of processors installed on the computer. |
| %OS% | System | Returns the operating system name. Windows 2000 displays the operating system as Windows NT. |
| %PATH% | System | Specifies the search path for executable files. |
| %PATHEXT% | System | Returns a list of the file extensions that the operating system considers to be executable. |
| %PROCESSOR_ARCHITECTURE% | System | Returns the chip architecture of the processor. Values: x86 or IA64 (Itanium-based). |
| %PROCESSOR_IDENTFIER% | System | Returns a description of the processor. |
| %PROCESSOR_LEVEL% | System | Returns the model number of the processor installed on the computer. |

| | | |
|---|---|---|
| %PROCESSOR_REVISION% | System | Returns the revision number of the processor. |
| %PROMPT% | Local | Returns the command prompt settings for the current interpreter. Generated by Cmd.exe. |
| %RANDOM% | System | Returns a random decimal number between 0 and 32767. Generated by Cmd.exe. |
| %SYSTEMDRIVE% | System | Returns the drive containing the Windows Server operating system root directory (that is, the system root). |
| %SYSTEMROOT% | System | Returns the location of the Windows Server operating system root directory. |
| %TEMP% and %TMP% | System and User | Returns the default temporary directories that are used by applications available to users who are currently logged on. Some applications require TEMP and others require TMP. |
| %TIME% | System | Returns the current time. Uses the same format as the **time /t** command. Generated by Cmd.exe. For more information about the **time** command, see Time. |
| %USERDOMAIN% | Local | Returns the name of the domain that contains the user's account. |
| %USERNAME% | Local | Returns the name of the user who is currently logged on. |
| %USERPROFILE% | Local | Returns the location of the profile for the current user. |
| %WINDIR% | System | Returns the location of the operating system directory. |

**Setting environment variables**

Use the **set** command to create, change, delete, or display environment variables. The **set** command alters variables in the current shell environment only.

To view a variable, at a command prompt, type:

**set** *VariableName*

To add a variable, at a command prompt, type:

**set***VariableName***=***Value*

To delete a variable, at a command prompt, type:

**set** *VariableName* **=**

You can use most characters as variable values, including white space. If you use the special characters <, >, |, &, or ^, you must precede them with the escape character (^) or quotation marks. If you use quotation marks, they are included as part of the value because everything following the equal sign is taken as the value. Consider the following examples:

- To create the variable value **new&name**, type:

  **set varname=new^&name**

- To create the variable value **"new&name"**, type:

  **set varname="new&name"**

- If you type **set varname=new&name** at the command prompt, an error message similar to the following appears:

  ```
  "'name' is not recognized as an internal or external command, operable program or
  batch file."
  ```

Variable names are not case-sensitive. However, **set** displays the variable exactly as you typed it. You can combine uppercase and lowercase letters in your variable names to make your code more readable (for example, UserName).

**Notes**

- The maximum individual environment variable size is 8192bytes.
- The maximum total environment variable size for all variables, which includes variable names and the equal sign, is 65,536KB.

**Substituting environment variable values**

To enable the substitution of variable values at the command line or in scripts, enclose the variable name in percent signs (that is, **%***VariableName***%**). By using percent signs, you ensure that Cmd.exe references the variable values instead of making a literal comparison. After you define variable values for a variable name, enclose the variable name in percent signs. Cmd.exe searches for all instances of the variable name and replaces it with the defined variable value. For example, if you create a script that contains different values (for example, user names) and you want to define the USERNAME environment variable for each user with these values, you can write one script using the variable USERNAME enclosed in percent signs. When you run this script, Cmd.exe replaces %USERNAME% with the variable values, which eliminates the need to perform this task manually for each user. Variable substitution is not recursive. Cmd.exe checks variables once. For more information about variable substitution, see For and Call.

# Configure the command prompt

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the command prompt**

1. Open Command Prompt.
2. Click the upper-left corner of the Command Prompt window, and then click **Properties**.
3. Click the **Options** tab.
4. In **Command History**, type or select **999** in **Buffer Size**, and then type or select **5** in **Number of Buffers**.
5. In **Edit Options**, select the **Quick Edit Mode** and **Insert Mode** check boxes.
6. Click the **Layout** tab.
7. In **Screen Buffer Size**, type or select **2500** in **Height**.
8. Do any of the following optional tasks:
   - In **Screen Buffer Size**, increase **Width**.
   - In **Window Size**, increase **Height**.
   - In **Window Size**, increase **Width**.
   - Clear the **Let system position window** check box, and then, in **Window Position**, change the values in **Left** and **Top**.
9. In the **Apply Properties** dialog box, click **Save properties for future windows with same title**.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To open **Command Prompt Properties** from the keyboard, press ALT+SPACEBAR+P.
- By selecting the **Quick Edit Mode** check box, you enable copy and paste from the Command Prompt window. To copy, select the text in the Command Prompt window with your left mouse button, and then right-click. To paste, either at the command prompt or in a text file, right-click.
- By increasing the screen buffer size to 999, you enable scrolling through the Command Prompt window.
- By increasing the number of buffers to five, you increase the number of lines in the Command Prompt window to 5000.
- To enable or disable file and directory name completion on a computer or user logon session, run Regedit.exe and set the following **REG_DWORD** value:

  **HKEY_LOCAL_MACHINE\Software\Microsoft\Command Processor\CompletionChar\REG_DWORD**

To set the **REG_DWORD** value, use the hexadecimal value of a control character for a particular function (for example, **0×9** is TAB and **0×08** is BACKSPACE). User-specified settings take precedence over computer settings, and command-line options take precedence over registry settings. For more information about file and directory name completion, see Related Topics.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configuration and Management Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuration and management tools**
This section covers:

- Control Panel
- Group Policy
- Resultant Set of Policy
- Computer Management
- Local Users and Groups
- The Registry
- Windows Management Instrumentation Command-line
- Windows Management Instrumentation Control
- Windows Management Instrumentation Tester
- Microsoft Management Console

# Control Panel

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Control Panel**
Control Panel provides a set of special-purpose administrative tools that you can use to configure the Windows, applications, and services environment. Control Panel includes default items that you can use for common tasks (for example, Display and Add Hardware). User-installed applications and services can also insert icons into Control Panel.

There are two view options for Control Panel: Category View and Classic View. Category View displays Control Panel icons according to the type of task that the user wants to perform. Classic View displays Control Panel icons in a view that is familiar to users of previous versions of Windows.

For more information about setting view options for Control Panel, see:

- To set Control Panel to Classic View
- To set Control Panel to Category View

For more information about Control Panel icons, see:

- Windows interface administrative tool reference A-Z: Accessibility Options
- Windows interface administrative tool reference A-Z: Add Hardware
- Windows interface administrative tool reference A-Z: Add or Remove Programs
- Windows interface administrative tool reference A-Z
- Windows interface administrative tool reference A-Z: Date and Time
- Windows interface administrative tool reference A-Z: Display
- Windows interface administrative tool reference A-Z: Folder Options
- Windows interface administrative tool reference A-Z: Fonts
- Windows interface administrative tool reference A-Z: Game Controllers
- Windows interface administrative tool reference A-Z: Internet Options
- Windows interface administrative tool reference A-Z: Keyboard
- Windows interface administrative tool reference A-Z: Licensing (Control Panel)
- Windows interface administrative tool reference A-Z: Mouse
- Windows interface administrative tool reference A-Z: Network Connections
- Windows interface administrative tool reference A-Z: Phone and Modem Options
- Windows interface administrative tool reference A-Z: Power Options
- Printers and Faxes

- Specify regional and language options and user's name during Setup
- Windows interface administrative tool reference A-Z: Scanners and Cameras
- Windows interface administrative tool reference A-Z: Task Scheduler
- Windows interface administrative tool reference A-Z: Sounds and Audio Devices
- Windows interface administrative tool reference A-Z: Speech
- Stored User Names and Passwords
- Windows interface administrative tool reference A-Z: System

**Note**

- To add Control Panel to My Computer, on the **Tools** menu in Control Panel, click **Folder Options**, click the **View** tab, and then, under **Advanced settings**, select the **Show Control Panel in My Computer** check box.

# Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy**

You can use Group Policy to manage features included with the Microsoft® Windows Server 2003 family, such as Group Policy Software Installation, Administrative Templates, Folder Redirection, Remote Installation Services, Security Settings, Scripts (Startup/Shutdown and Logon/Logoff) and Internet Explorer Maintenance.

To use Group Policy without the Group Policy Management Console (GPMC), see Group Policy (pre-GPMC).

To use Group Policy with the Group Policy Management Console, see Group Policy Management.

Microsoft makes available new procedures, and new and updated tools online. For the latest information about Group Policy and tools that you can use to manage Group Policy, see Group Policy at the Microsoft Web site.

# Group Policy (pre-GPMC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy**

You can use Group Policy to define policy settings that are applied to computers or users.

- Before you use Group Policy, see Checklist: Implementing Group Policy.
- To find features that have been moved in the Microsoft® Windows Server 2003 family, see New ways to do familiar Group Policy tasks (pre-GPMC).
- For tips about using Group Policy, see Group Policy Best Practices (pre-GPMC).
- For help with specific tasks, see Group Policy How To... (pre-GPMC).
- For general background information, see Group Policy Concepts.
- For problem-solving instructions, see Troubleshooting Group Policy.

# Checklist: Implementing Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Implementing Group Policy**

| | Step | References |
|---|---|---|
| | Review key concepts about Group Policy. | Group Policy overview; Group Policy settings overview |
| | Open Group Policy Object Editor. | Open Group Policy Object Editor; Ways to open Group Policy Object Editor |
| | Create a new Group Policy object or edit an existing Group Policy object. | Create a new Group Policy object; Edit a Group Policy object |
| | Configure Group Policy settings. | Software Settings; Windows Settings; Use Administrative Templates |
| | (Optional) Link a Group Policy object to a site, domain, or organizational unit. | Link a Group Policy object to a site, domain, or organizational unit |
| | (Optional) Set Group Policy Software Installation options. | Group Policy Software Installation overview; Set Group Policy Software Installation defaults; Use Group Policy to work with Applications; Set Application Properties |
| | (Optional) Configure Folder Redirection to redirect special folders. | Folder Redirection; Use Folder Redirection |

# New ways to do familiar Group Policy tasks (pre-GPMC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

Windows NT 4.0 introduced the System Policy Editor, which you could use to create a system policy to control user actions and the work environment and to enforce system configuration settings for all computers that run Windows NT 4.0. Policy settings define the various components of the desktop environment, including the applications that are available to users, the applications that appear on users' desktops, and the options that are displayed on the **Start** menu.

Group Policy and its extensions, included with Windows XP Professional, Windows XP 64-bit Edition (Itanium), and the Windows Server 2003 family, replace many of the tools that you are familiar with in Windows NT 4.0.

The following table lists common tasks for configuring policy. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Set policies on users and computers in a site | Not applicable | Group Policy, accessed through Active Directory Sites and Services |
| Set policies on users and computers in a domain | System Policy Editor (Poledit.exe) | Group Policy, accessed through Active Directory Users and Computers |
| Set policies on users and computers in an organizational unit | Not applicable | Group Policy, accessed through Active Directory Users and Computers |
| Link a Group Policy object to a site, domain, or organizational unit | Not applicable | Group Policy, accessed through Active Directory Users and Computers |
| Use security groups to filter the scope of policy | Not applicable | Permissions on the **Security** tab in the Group Policy object's properties dialog box. |
| Manage software | For an administrator, Systems Management Server. For a user, Add/Remove programs in Control Panel. | Systems Management Server and the three Group Policy Software Installation and Maintenance tools:<br>• Group Policy Software Installation overview, an extension to the Group Policy Object Editor snap-in<br>• Windows Installer<br>• Add or Remove Programs in Control Panel |
| Create a safe user interface for editing the registry | Windows NT 4.0 Administrative Templates for System Policy Editor | Administrative Templates for Group Policy<br>For an explanation of how the role of .adm files has changed in the Windows Server 2003 family, see The role of Administrative Templates. |

| | | |
|---|---|---|
| Perform general administrative tasks | Administrative wizards, User Manager, and Server Manager | Microsoft Management Console (MMC) snap-ins: Active Directory Users and Computers, Active Directory Sites and Services, and Open Group Policy Object Editor and its extensions. |

The following table lists a common task for configuring Folder Redirection in Group Policy. The user interface for performing this task is different in this version of Windows from the way it was in Windows 2000. For more information about additional changes to Group Policy, see New Group Policy features (pre-GPMC).

| **If you want to** | **In Windows 2000 use** | **In this version of Windows use** |
|---|---|---|
| Redirect a special folder to a shared network directory with a Universal Naming Convention (UNC) path that is personalized to the user | A UNC path that incorporates *UserName*, for example, *ServerName**ShareName**UserName*\My Documents | The special folder's properties dialog box, as described in Redirect special folders to the root directory |

# Group Policy Best Practices (pre-GPMC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- Best practices for Group Policy objects
- Best practices for Group Policy Software Installation
- Best practices for Folder Redirection

# Best practices for Group Policy objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Group Policy objects**

**Do not process policy settings that are not configured.**

- If a Group Policy object contains only settings that are set to **Not Configured**, you can avoid processing these settings by disabling User Configuration or Computer Configuration. This expedites the startup and logon processes for those users and computers that are subject to the Group Policy object. For more information, see Disable the User Configuration settings in a Group Policy object, Disable the Computer Configuration settings in a Group Policy object, User Configuration and Computer Configuration.

- To prevent an entire Group Policy object from affecting a site, domain, or organizational unit, see Unlink a Group Policy object from a site, domain, or organizational unit and Disable a Group Policy object link. With these procedures, you can enable or re-link the Group Policy object.

- If you never want to use a certain Group Policy object again, see Delete a Group Policy object.

**Use Block Policy inheritance and No Override sparingly.**

- Routine use of these features makes it difficult to troubleshoot policy. If you must use them, see Block policy inheritance and Prevent a Group Policy object from being overridden.

**Do not use the same name for different Group Policy objects.**

- By using the same name for two different Group Policy objects, you do not cause Group Policy to function incorrectly, but you might cause confusion. For more information, see Group Policy objects.

### Caution

- If you type a name for a Group Policy object that is longer than 255 characters, the name is truncated without warning to 255 characters.

**Minimize the number of WMI Filters used with Group Policy objects.**

- The more WMI Filters that are applied to a Group Policy object, the longer it will take to process the object.

**Filter policy based on security group membership.**

- Users who do not have an access control entry (ACE) directing that a particular Group Policy object be applied to them can avoid the associated logon delay, because the Group Policy object is not processed for those users.

- Filtering can only be done by using membership in security groups. For more information, see Filter the scope of Group Policy according to security group membership.

- To see the ACEs, click the **Security** tab in the **Properties** dialog box for a Group Policy object.

**Override user-based Group Policy with computer-based Group Policy only when necessary.**

- Override user-based Group Policy with computer-based Group Policy only if you want the desktop configuration to be the same regardless of who logs on. The mechanism for doing this is called loopback, an advanced Group Policy setting that is useful in certain closely managed environments, such as laboratories, classrooms, public kiosks, and reception

areas. The **User Group Policy loopback processing mode** policy setting is located in Group Policy Object Editor. For more information, see Order of processing settings.

**Use Group Policy rather than System Policy.**

- Use System Policy only to manage computers that run an operating system that is earlier than Windows 2000 or if you need to manage desktops for multiple users on a stand-alone computer. For more information, see Migration Issues.

**Avoid assigning Group Policy objects across domains.**

- The processing of Group Policy objects slows the startup and logon processes if Group Policy is obtained from another domain.

**Do not set File System policy on a drive or directory, such as Sysvol, that is replicated by the NTFS file replication system (FRS).**

- Settings that are under File System in Group Policy Object Editor can cause excessive replication and can waste network bandwidth. For more information, see File System security settings.

**Do not link a Group Policy object to the same organizational unit more than once.**

- When more than one link for the same organizational unit is applied to a single object, the client-side Group Policy extension may interpret the links differently and produce unexpected resultant set of policy.

  For more information, see Link a Group Policy object to a site, domain, or organizational unit and Unlink a Group Policy object from a site, domain, or organizational unit.

# Best practices for Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Group Policy Software Installation**

**Understand the difference between Group Policy Software Installation and Systems Management Server.**

- For simple software installation and deployment scenarios, Group Policy provides Group Policy Software Installation. For more information, see Group Policy Software Installation. For software installation scenarios where scheduling, inventory, reporting, status, and support for installation across a wide area network (WAN) is required, use Systems Management Server (SMS).

**Specify application categories for your organization.**

- Using categories makes it easier for users to find an application in Add or Remove Programs in Control Panel. You can define application categories, such as Sales Applications, Accounting Applications, and so on. For more information, see Specify categories for applications to be managed.

**Verify that Windows Installer packages are correctly transformed before they are published or assigned.**

- Transforms are applied to packages at the time of assignment or publication. Transforms (.mst files) are customizations that are applied to Windows Installer packages. A transform is applied at the time of assignment or publication, not at the time of installation. In practical terms, this means that you should verify that the **Modifications** tab in the package **Properties** dialog box is set up the way that you want it before you click **OK**. If you neglect to do this, and you assign or publish a transformed package before you have completely configured it, you can remove the software and republish or reassign it, or you can upgrade the software with a completely transformed version. For more information, see Remove a managed application, Upgrade an application, and Add or remove modifications for an application package.

**Assign or publish just once per Group Policy object.**

- It is recommended that a Windows Installer package be used to assign an application or to publish an application no more than once in the same Group Policy object. For example, if you assign Microsoft Office to the computers that are affected by a Group Policy object, do not assign or publish it to the users who are affected by the Group Policy object. For more information, see Assign an application and Publish an application.

**Take advantage of authoring tools.**

- Developers who are familiar with the files, registry entries, and other requirements that are necessary for an application to work properly can author native Windows Installer packages by using tools that are available from various software vendors.

**Repackage existing software.**

- You can use commercially available tools to create Windows Installer packages for software that does not include natively authored .msi files. These tools work by comparing a computer's state before and after installation. For best results, install them on a computer that is free of other application software (clean installation).

**Assign or publish applications at a high level in the Active Directory hierarchy.**

- Because Group Policy settings apply by default to child Active Directory containers, it is efficient to assign or publish applications by linking a Group Policy object to a parent organizational unit or domain. Use security descriptors (ACEs) on the Group Policy object for finer control over who receives the software. For more information, see Filter the scope of Group Policy according to security group membership.

**Use required, rather than optional, upgrades.**

- For the correct upgrade procedures, both required and optional, see Upgrade an application.
- The **Upgrades** tab for a package in Group Policy Software Installation has a **Required upgrade for existing packages** check box. It is recommended that you select this check box. If two users use the application on one computer, and one user upgrades the application and the other does not, both versions of the application exist on the computer. Some applications do not support this configuration.
- Authenticated Users need the Read and Apply Group Policy ACE to be able to install applications from the software distribution point.
- Administrators need Full Control to manage software.

**Use Group Policy Software Installation properties for widely scoped control.**

- By using Group Policy Software Installation, you save administrative keystrokes when you assign or publish a large number of packages with similar properties in a single Group Policy object. For example, when all of the software is published and it all comes from the same software distribution point. For specific procedures, see Set Options for Group Policy Software Installation.

**Use Windows Installer package properties for fine control.**

- Use this method for assigning or publishing a single package. For specific procedures, see Use Group Policy to work with Applications.

# Best practices for Folder Redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Folder Redirection**

**Accept the default settings.**

- In general, accept the default Folder Redirection settings.

**Allow the system to create the folders.**

- If you create the folders yourself, they will not have the correct permissions.
- If you must, or already have, created the folders, the information in the "Folder Redirection permissions" section in the Folder Redirection Help topic might not apply.

**Do not redirect My Documents to the home directory unless you have already deployed home directories in your organization.**

- Redirection to the home directory offers less security than standard folder redirection, and it is offered only for backward compatibility. For more information, see Folder Redirection and Redirect My Documents to the home directory.

**If you redirect My Documents to the home directory, and if your users log on to the domain through Terminal Server clients, do not specify a separate Terminal Services Home Directory.**

- The properties dialog box for a user in Active Directory has a **profile** tab, where the **Home Folder** can be set, and also a **Terminal Services profile** tab, where the **Terminal Services Home Directory** can be set. If these network folders are different, logging on to the terminal server causes the profile Home Folder to be copied to the Terminal Services Home Directory. Logging off the terminal server causes copying to occur in the opposite direction. This is probably not the intended behavior, and it might result in delay in the logon and logoff processes for users. For more information, see Redirect My Documents to the home directory.

**Enable client-side caching.**

- This is especially important for users with portable computers. For information about how to configure Folder Redirection and Offline Files to work together, see Folder Redirection.
- Always enable the **Synchronize all offline files before logging off** Group Policy setting in the Group Policy Object Editor under \Computer Configuration (or User Configuration)\Administrative Templates\Network\Offline Files. By enabling this setting, you ensure that offline files are fully synchronized and that all of the files in the user's redirected folder are available when the user is working offline. If this setting is not enabled, the system performs only a cursory synchronization, and as a result only recently used files are cached.

  **Note**

  - On client computers running Windows XP Professional and Windows Server 2003 operating systems, redirected folders are automatically cached to client-side caching. In Windows 2000, you must enable this feature.

**Use fully qualified universal naming convention (UNC) paths.**

- Although you can use paths like C:\FolderName, it is not recommended because the path might not exist on the target computer. Use fully qualified UNC paths.

  **Caution**

- UNC paths that are longer than 260 characters are truncated. If the path is truncated, redirection fails.

**Always place the My Pictures folder in the My Documents folder.**

- My Pictures can be redirected independently of My Documents, or it can follow My Documents (to remain its subfolder whenever My Documents is redirected), as it does by default. The default behavior is recommended unless you have a specific reason (such as server scalability) for separating My Pictures from My Documents.

**Consider the impact of policy removal.**

- Consider the behavior of your Folder Redirection policies at the time of policy removal, as described in the table of policy removal considerations in Folder Redirection. Changing the redirection option to **Not configured** does not redirect the folder to the user's local profile location. It will continue to be redirected to the previous location. If you want to return the folder to the local user profile location, use the **Redirect to the local user profile** policy setting, as described in Redirect special folders to the local profile location.

# Group Policy How To... (pre-GPMC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Open Group Policy Object Editor
- Work with Group Policy Objects
- Work with Group Policy Object Properties
- Use Administrative Templates
- Use Startup, Shutdown, Logon, and Logoff Scripts
- Use Group Policy Software Installation
- Use Folder Redirection
- Configure Group Policy
- Delegate Control of Group Policy

# Open Group Policy Object Editor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Open Group Policy Object Editor**

- Open Group Policy from Active Directory Users and Computers
- Open Group Policy from Active Directory Sites and Services
- Open Group Policy as an MMC snap-in

# Open Group Policy from Active Directory Users and Computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open Group Policy Object Editor from Active Directory Users and Computers**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

   **Where?**

   - Active Directory Users and Computers/*domain/organizational unit/child organizational unit*

3. Click **Properties**, and then click the **Group Policy** tab.
4. Do one of the following:

   - To edit an existing Group Policy object, click the Group Policy object in the list, and then click **Edit**.
   - To create a new Group Policy object, click **New**, type a name for the new Group Policy object, and then click **Edit**.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- You can open Group Policy Object Editor in several ways, depending on the action that you want to perform and the object to which you want to apply Group Policy.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Open Group Policy as an MMC snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open Group Policy Object Editor as an MMC snap-in**

1. Open Microsoft Management Console.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. On the **Standalone** tab, click **Add**.
4. In the **Available Standalone Snap-ins** list, click **Group Policy Object Editor**, and then click **Add**.
5. In the **Select Group Policy Object** dialog box, click **Local Computer** to edit the local Group Policy object, or click **Browse** to find the Group Policy object that you want to edit.
6. Click **Finish**, click **Close**, and then click **OK**. Group Policy Object Editor opens the Group Policy object for you to edit.

## Notes

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- If you want to save a Group Policy Object Editor console and choose which Group Policy object opens in it from the command line, select the **Allow focus of the Group Policy Snap-in to be changed when launching from the command line** check box in the **Select Group Policy Object** dialog box.
- You can open Group Policy Object Editor in several ways, depending on the action that you want to perform and the object to which you want to apply Group Policy.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Group Policy Objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with Group Policy objects**

- Edit a Group Policy object
- Edit the local Group Policy object
- Create a new Group Policy object
- Delete a Group Policy object
- Link a Group Policy object to a site, domain, or organizational unit
- Block policy inheritance
- Unlink a Group Policy object from a site, domain, or organizational unit
- Disable a Group Policy object link
- Prevent a Group Policy object from being overridden

# Edit a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a Group Policy object**

1. Open the Group Policy object that you want to edit.
2. In the console tree, double-click the folders to view the policies in the details pane.
3. In the details pane, double-click a policy to open the **Properties** dialog box, and then change the policy settings.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- You must have Read and Write permissions for a Group Policy object to open it.
- Because changes to a Group Policy object take place immediately, you might want to disable the Group Policy object while you are editing it. For information about disabling a Group Policy object, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a new Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new Group Policy object**

1. Do one of the following:

   - To create a Group Policy object that is linked to a domain or to an organizational unit, open Active Directory Users and Computers.

   - To create a Group Policy object that is linked to a site, open Active Directory Sites and Services.

2. In the console tree, right-click the site, domain, or organizational unit to which you want the newly created Group Policy object to be linked.

   The Group Policy object will be stored in the current domain, that is, the domain that contains the domain controller that is being used by Active Directory Users and Computers or Active Directory Sites and Services.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **New**, type a name for the Group Policy object, and then click **Close**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.

- The newly created Group Policy object is linked by default to the site, domain, or organizational unit that you select when you create the Group Policy object,and its settings apply to that site, domain, or organizational unit. If you want to unlink the Group Policy object from that site, domain, or organizational unit, see Related Topics.

**Information about functional differences**

# Delete a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a Group Policy object**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain, or right-click any organizational unit in the domain.
3. Click **Properties**, and then click the **Group Policy** tab.
4. To find all the Group Policy objects that are stored in the domain, click **Add**.
5. In the **Add a Group Policy Object Link** dialog box, click the **All** tab, right-click the Group Policy object that you want to delete, and then click **Delete**.
6. Click **Yes**, click **Cancel**, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- When you delete a Group Policy object, any sites, domains, or organizational units to which it is linked are no longer affected by it. You might want to disable the Group Policy object instead. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Link a Group Policy object to a site, domain, or organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To link a Group Policy object to a site, domain, or organizational unit**

1. Do one of the following:

   - To link to a domain or an organizational unit, open Active Directory Users and Computers.
   - To link to a site, open Active Directory Sites and Services.

2. In the console tree, right-click the site, domain, or organizational unit to which you want the Group Policy object to be linked.
3. Click **Properties**, and then click the **Group Policy** tab.
4. To add the Group Policy object to the **Group Policy Object Links** list, click **Add**. This opens the **Add a Group Policy Object Link** dialog box.
5. Click the **All** tab, click the Group Policy object that you want, and then click **OK**.
6. In the properties dialog box for the site, domain, or organizational unit, click **OK**.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- You can link a Group Policy object to specify that its settings are applied to users and computers in the site, domain, or organizational unit and that its settings are applied to users and computers in Active Directory containers that inherit policy settings from the site, domain, or organizational unit.

# Block policy inheritance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To block policy inheritance**

1. To block policy inheritance in a domain or organizational unit, open Active Directory Users and Computers.
2. In the console tree, right-click the domain, or organizational unit in which you want to block Group Policy inheritance, and then click **Properties**.
3. Click the **Group Policy** tab, select the **Block Policy inheritance** check box, and then click **OK**. This option is recommended, and it is selected by default.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- The **Block Policy inheritance** option blocks Group Policy objects that apply higher in the Active Directory hierarchy of domains, and organizational units. It does not block Group Policy objects if they have **No Override** enabled.
- The **Block Policy inheritance** option is set only on domains, and organizational units, but not on individual Group Policy objects.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Unlink a Group Policy object from a site, domain, or organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To unlink a Group Policy object from a site, domain, or organizational unit**

1. Do one of the following:

   - To unlink a Group Policy object from a domain or organizational unit, open Active Directory Users and Computers.
   - To unlink a Group Policy object from a site, open Active Directory Sites and Services.

2. In the console tree, right-click the site, domain, or organizational unit from which you want to unlink the Group Policy object.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click the Group Policy object that you want to unlink, and then click **Delete**.
5. In the **Delete** dialog box, click **Remove the link from the list**, and then click **OK**.

### Important

- If you click **Remove the link and delete the Group Policy object permanently** in the **Delete** dialog box, all sites, domains, and organizational units to which the Group Policy object is linked will no longer have those Group Policy settings applied to them, and the Group Policy object will be deleted.

### Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- Unlinking prevents the Group Policy object from affecting that site, domain, or organizational unit.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable a Group Policy object link

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable a Group Policy object link**

1. Do one of the following:

    - To disable a Group Policy object link to a domain or organizational unit, open Active Directory Users and Computers.
    - To disable a Group Policy object link to a site, open Active Directory Sites and Services.

2. In the console tree, right-click the site, domain, or organizational unit to which the Group Policy object is linked, and then click **Properties**.
3. Click the **Group Policy** tab.
4. Right-click the Group Policy object link that you want to disable, click **Disabled**, and then click **Yes**. This switches the Disabled state to Active, and a check appears in the **Disabled** column.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- When you disable a Group Policy object link, the settings in the Group Policy object no longer apply to users or computers in the site, domain, or organizational unit to which the Group Policy object was linked; and they no longer apply to users and computers in child Active Directory containers that inherit those Group Policy settings.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Prevent a Group Policy object from being overridden

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prevent a Group Policy object from being overridden**

1. Do one of the following:

   - For a Group Policy object that is linked to a domain or organizational unit, open Active Directory Users and Computers.

   - For a Group Policy object that is linked to a site, open Active Directory Sites and Services.

2. In the console tree, right-click the site, domain, or organizational unit to which the Group Policy object is linked.

3. Click **Properties**, and then click the **Group Policy** tab.

4. In the **Group Policy Object Links** list, right-click the Group Policy object link that you want to enforce, click **No Override**, and then click **OK**. A check mark appears in the **No Override** column.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.

- If you set **No Override** on a Group Policy object link, the Group Policy settings are enforced on all users or computers in the site, domain, or organizational unit and on all users and computers in Active Directory containers that inherit Group Policy from it.

- Group Policy settings that are enforced by using **No Override** cannot be blocked.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with Group Policy object properties**

- Filter the scope of Group Policy according to security group membership
- Find the sites, domains, and organizational units to which a Group Policy object is linked
- Disable the User Configuration settings in a Group Policy object
- Disable the Computer Configuration settings in a Group Policy object

# Filter the scope of Group Policy according to security group membership

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To filter the scope of Group Policy according to security group membership**

1. Open the Group Policy object whose scope you want to filter.

2. In the console tree, right-click the icon or name of the Group Policy object, and then click **Properties**.

3. Click the **Security** tab, and then click the security group through which you want to filter this Group Policy object. If you want to change the list of security groups through which to filter this Group Policy object, use the **Add** and **Remove** buttons to add or remove security groups.

4. In the **Permissions** box for the selected security group, select or clear the appropriate check boxes to set permissions as shown in the following table, and then click **OK**.

| Your intention | Permissions | Result |
|---|---|---|
| Members of this security group have this Group Policy object applied to them. | Set **Apply Group Policy** to **Allow**.<br><br>Set **Read** to **Allow**. | This Group Policy object applies to members of this security group, unless they are members of at least one other security group that has **Apply Group Policy** set to **Deny**, or **Read** set to **Deny**, or both. |
| Members of this security group are exempt from this Group Policy object. | Set **Apply Group Policy** to **Deny**.<br><br>Set **Read** to **Deny**. | This Group Policy object never applies to members of this security group, regardless of the permissions these members have in other security groups. |
| Membership in this security group is irrelevant to whether the Group Policy object should be applied. | Set **Apply Group Policy** to neither **Allow** nor **Deny**.<br><br>Set **Read** to neither **Allow** nor **Deny**. | This Group Policy object applies to members of this security group if and only if they have both **Apply Group Policy** and **Read** set to **Allow** as members of at least one other security group. They also must not have **Apply Group Policy** or **Read** set to **Deny** as members of any other security group. |

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Object Editor, see Related Topics.

- Group Policy objects are applied only to sites, domains, and organizational units. Group Policy settings affect only the users and computers that they contain. In particular, Group Policy objects are not linked to security groups.

- The location of a security group in Active Directory has no relation to, and no effect on, filtering through that security group as described in this procedure.

- If a user or computer is not contained in a site, domain, or organizational unit that is subject to a Group Policy object, either directly through a link or indirectly through inheritance, there is no combination of permissions on any security group that can cause those Group Policy settings to affect that user or computer.

- Filtering at the Group Policy object level, as described in this procedure, causes the Group Policy object to be processed or not processed as a whole. The Group Policy Software Installation and Folder Redirection extensions use security groups to refine control beyond the Group Policy object level. Except for Folder Redirection and Group Policy Software Installation, security groups are not used to filter individual settings, or subsets, of a Group Policy object. For control over individual settings, edit or create a Group Policy object instead.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Find the sites, domains, and organizational units to which a Group Policy object is linked

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find the sites, domains, and organizational units to which a Group Policy object is linked**

1. Open the Group Policy object.
2. In the console tree, right-click the icon or name of the Group Policy object, and then click **Properties**.
3. Click the **Links** tab, and then click **Find Now**. The sites, domains, and organizational units to which the Group Policy object is linked are listed in the **Sites, Domains or Organizational Units found** box.

## Notes

- To open Group Policy Object Editor, see Related Topics.
- If the Group Policy object is linked to more than one domain, you can limit your search for organizational units to one domain at a time by using the **Domain** list.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Administrative Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Administrative Templates**

- Add or remove an Administrative Template (.adm file)
- Use the view provided by Administrative Templates
- Filter the view provided by Administrative Templates

# Add or remove an Administrative Template (.adm file)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add or remove an Administrative Template (.adm file)**

1. Open the Group Policy object that you want to edit.
2. In the console tree, right-click **Administrative Templates**.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Administrative Templates

3. Click **Add/Remove Templates**.
4. Do one of the following:

   - To add a template, click **Add**. In the **Policy Templates** dialog box, click the template that you want to add, and then click **Open**.
   - To remove a template, in the **Current Policy Templates** list, click the template, and then click **Remove**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- Because the role of Administrative Templates in the Windows Server 2003 family is different from Windows NT 4.0, the use of Windows NT 4.0 .adm files on client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems is not recommended.

  If you do use the older .adm files to create namespaces in the Group Policy console, you can control whether the Windows NT 4.0 System Policy settings are visible in the details pane. To do this, in the console tree, click **Administrative Templates**. On the **View** menu, click **Filtering**, and then select or clear the **Only show policy settings that can be fully managed** check box. By selecting this check box, you cause System Policy settings to not be visible in the details pane. You can also use the Group Policy setting **Enforce Show Policies Only** to do this.

  **Where?**

  - *Group Policy object*/User Configuration/Administrative Templates/System/Group Policy

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use the view provided by Administrative Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use the view provided by Administrative Templates**

1. Open Group Policy Object Editor.
2. In the console tree, click the folder under Administrative Templates that contains the policy settings that you want to set.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Administrative Templates/*policy folder*

3. At the bottom of the details pane, click the **Extended** tab.
4. In the **Setting** column, click the name or icon for a setting to read a description of the setting.
5. To change that setting from its default (not configured) state, double-click the name or icon for the setting.
6. On the **Setting** tab, click one of the buttons described in the following table.

| Button | Result |
|---|---|
| **Not Configured** | The registry is not modified. |
| **Enabled** | The registry reflects that the policy setting is selected. |
| **Disabled** | The registry reflects that the policy setting is not selected. |

7. Select any other available options that you want on the **Setting** tab, and then click **OK**.
8. To view and set other settings in the current folder, click **Previous Setting** or **Next Setting**.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- In Group Policy Object Editor, there are two Administrative Templates branches. Settings for **HKEY_LOCAL_MACHINE** are under Computer Configuration, and settings for **HKEY_CURRENT_USER** are under User Configuration.
- If computer policy conflicts with user policy, computer policy generally takes precedence. Application authors can disregard that convention, however, and if they do, Group Policy cannot enforce it.
- The **Extended** tab feature displays the text that explains the policy setting and indicates which versions of Windows are supported as clients for the setting. If you prefer a view of the policy setting without the explanatory text, click the **Standard** tab.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Ways to open Group Policy Object Editor

# Filter the view provided by Administrative Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To filter the view provided by Administrative Templates**

1. Open Group Policy Object Editor.
2. In the console tree, click **Administrative Templates**, or click a folder under Administrative Templates that contains the policy settings that you want to filter.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Administrative Templates/*policy folder*

3. On the **View** menu, click **Filtering**.
4. Select the **Filter by Requirements information** check box.
5. In the list box, select the check boxes for the categories that you want to make visible.
6. To hide settings that are not configured, select the **Only show configured policy settings** check box. If you do this, only enabled or disabled settings will be visible.
7. To hide Windows NT 4.0 system policy settings, select the **Only show policy settings that can be fully managed** check box. This option is recommended, and it is selected by default.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- This filtering procedure is useful if there are too many Administrative Templates settings at one time in Group Policy Object Editor. This filtering only selects which settings are visible in the console. It does not affect whether the settings apply to users or computers, and it is not the same as filtering the scope of Group Policy according to security group membership.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign computer startup scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign computer startup scripts**

1. Open Group Policy Object Editor.
2. In the console tree, click **Scripts (Startup/Shutdown)**.

   **Where?**

   - *Group Policy object*/Computer Configuration/Windows Settings/Scripts (Startup/Shutdown)

3. In the details pane, double-click **Startup**.
4. In the **Startup Properties** dialog box, click **Add**.
5. In the **Add a Script** dialog box, do the following:

   - In **Script Name**, type the path to the script, or click **Browse** to search for the script file in the Netlogon shared folder on the domain controller.
   - In **Script Parameters**, type any parameters that you want, the same way as you would type them on the command line. For example, if your script includes parameters called //logo (display banner) and //I (interactive mode), type **//logo //I**.

6. In the **Startup Properties** dialog box, specify the options that you want as follows:

   - **Startup Scripts for *Group Policy object*--**Lists all the scripts that are currently assigned to the selected Group Policy object. If you assign multiple scripts, the scripts are processed in the order that you specify. To move a script up in the list, click it, and then click **Up**. To move a script down in the list, click it, and then click **Down**.
   - **Add--**Opens the **Add a Script** dialog box, where you can specify any additional scripts to use.
   - **Edit--**Opens the **Edit Script** dialog box, where you can modify script information, such as name and parameters.
   - **Remove--**Removes the selected script from the **Startup Scripts** list.
   - **Show Files--**Displays the script files that are stored in the selected Group Policy object.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- Startup scripts are run as Local System, and they have the full rights that are associated with being able to run as Local System.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign computer shutdown scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign computer shutdown scripts**

1. Open Group Policy Object Editor.
2. In the console tree, click **Scripts (Startup/Shutdown)**.

   **Where?**

   - *Group Policy object*/Computer Configuration/Windows Settings/Scripts (Startup/Shutdown)

3. In the details pane, double-click **Shutdown**.
4. In the **Shutdown Properties** dialog box, click **Add**.
5. In the **Add a Script** dialog box, do the following:

   - In **Script Name**, type the path to the script, or click **Browse** to search for the script file in the Netlogon shared folder on the domain controller.
   - In **Script Parameters**, type any parameters that you want, the same way as you would type them on the command line. For example, if your script includes parameters called //logo (display banner) and //I (interactive mode), type **//logo //I**.

6. In the **Shutdown Properties** dialog box, specify the options that you want as follows:

   - **Shutdown Scripts for *Group Policy object*--**Lists all the scripts that are currently assigned to the selected Group Policy object. If you assign multiple scripts, the scripts are processed in the order that you specify. To move a script up in the list, click it, and then click **Up**. To move a script down in the list, click it, and then click **Down**.
   - **Add--**Opens the **Add a Script** dialog box, where you can specify any additional scripts to use.
   - **Edit--**Opens the **Edit Script** dialog box, where you can modify script information, such as name and parameters.
   - **Remove--**Removes the selected script from the **Shutdown Scripts** list.
   - **Show Files--**Displays the script files that are stored in the selected Group Policy object.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- Shutdown scripts are run as Local System, and they have the full rights that are associated with being able to run as Local System.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign user logon scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign user logon scripts**

1. Open Group Policy Object Editor.
2. In the console tree, click **Scripts (Logon/Logoff)**.

   **Where?**

   - *Group Policy object*/User Configuration/Windows Settings/Scripts (Logon/Logoff)

3. In the details pane, double-click **Logon**.
4. In the **Logon Properties** dialog box, click **Add**.
5. In the **Add a Script** dialog box, do the following:

   - In **Script Name**, type the path to the script, or click **Browse** to search for the script file in the Netlogon shared folder on the domain controller.
   - In **Script Parameters**, type any parameters that you want, the same way as you would type them on the command line. For example, if your script includes parameters called //logo (display banner) and //I (interactive mode), type **//logo //I**.

6. In the **Logon Properties** dialog box, specify the options that you want as follows:

   - **Logon Scripts for *Group Policy object*--**Lists all the scripts that are currently assigned to the selected Group Policy object. If you assign multiple scripts, the scripts are processed in the order that you specify. To move a script up in the list, click it, and then click **Up**. To move a script down in the list, click it, and then click **Down**.
   - **Add--**Opens the **Add a Script** dialog box, where you can specify any additional scripts to use.
   - **Edit--**Opens the **Edit Script** dialog box, where you can modify script information, such as name and parameters.
   - **Remove--**Removes the selected script from the **Logon Scripts** list.
   - **Show Files--**Displays the script files that are stored in the selected Group Policy object.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign user logoff scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign user logoff scripts**

1. Open Group Policy Object Editor.
2. In the console tree, click **Scripts (Logon/Logoff)**.

   **Where?**

   - *Group Policy object*/User Configuration/Windows Settings/Scripts (Logon/Logoff)

3. In the details pane, double-click **Logoff**.
4. In the **Logoff Properties** dialog box, click **Add**.
5. In the **Add a Script** dialog box, do the following:

   - In **Script Name**, type the path to the script, or click **Browse** to search for the script file in the Netlogon shared folder on the domain controller.
   - In **Script Parameters**, type any parameters that you want, the same way as you would type them on the command line. For example, if your script includes parameters called //logo (display banner) and //I (interactive mode), type **//logo //I**.

6. In the **Logoff Properties** dialog box, specify the options the you want as follows:

   - **Logoff Scripts for *Group Policy object*--**Lists all the scripts that are currently assigned to the selected Group Policy object. If you assign multiple scripts, the scripts are processed in the order that you specify. To move a script up in the list, click it, and then click **Up**. To move a script down in the list, click it, and then click **Down**.
   - **Add--**Opens the **Add a Script** dialog box, where you can specify any additional scripts to use.
   - **Edit--**Opens the **Edit Script** dialog box, where you can modify script information, such as name and parameters.
   - **Remove--**Removes the selected script from the **Logoff Scripts** list.
   - **Show Files--**Displays the script files that are stored in the selected Group Policy object.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- Logoff scripts are run as User, not Administrator, and their rights are limited accordingly.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Group Policy Software Installation**

- Open Group Policy Software Installation
- Set Options for Group Policy Software Installation
- Use Group Policy to work with Applications
- Set Application Properties
- Add or remove modifications for an application package

# Open Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open Group Policy Software Installation**

1. Open Group Policy Object Editor.
2. To assign software applications to computers, in the console tree double-click **Computer Configuration**. To assign or publish software applications to users, in the console tree double-click **User Configuration**.
3. Double-click **Software Settings**, and then click **Software installation**.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Software Settings/Software installation

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set Options for Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set options for Group Policy Software Installation**

- Set Group Policy Software Installation defaults
- Specify automatic installation options based on file name extension
- Specify categories for applications to be managed

# Set Group Policy Software Installation defaults

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set Group Policy Software Installation defaults**

1. Open Group Policy Software Installation.

2. In the console tree, right-click **Software installation**.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Software Settings/Software installation

3. Click **Properties**, and on the **General** tab specify the following options:

   - In **Default package location**, specify the default software distribution point.

   - In **New packages**, specify how to add new packages to user settings. By default, packages can either be published or assigned. (To computers, they can only be assigned). If you want to select these options for each package, click **Display the Deploy Software dialog box**. For even more control on a per-package basis, click **Advanced**.

   - In **Installation user interface options**, click **Basic** or **Maximum**, depending on how apparent you want the installation process to be to the users.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Software Installation, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify automatic installation options based on file name extension

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify automatic installation options based on file name extension**

1. Open Group Policy Software Installation.

2. In the console tree, right-click **Software installation**.

   **Where?**

   - *Group Policy object*/Computer Configuration (or User Configuration)/Software Settings/Software installation

3. Click **Properties**, and then click the **File Extensions** tab.

4. On the **File Extensions** tab, specify the following options:

   - **Select file extension--**Displays a list of all available file name extensions for the managed software. When an extension is selected, all applications in Active Directory that are associated with the selected file name extension are displayed in the **Application precedence** list box. For example, for an .htm extension, many applications can be associated, such as Microsoft Word, Microsoft Internet Explorer, Netscape Communicator, and so on.

   - **Application precedence--**Lists all the applications that are associated with the selected file name extension. By default, the application with the highest precedence is at the top of the list.

   - **Up--**Moves the selected application higher in the precedence list. The application at the top of the list is automatically installed if a document with the selected file name extension is invoked before the application has been installed. The **Up** button is unavailable when the selected application is at the top of the list.

   - **Down--**Moves the selected application lower in the priority list. The **Down** button is unavailable when the selected application is at the bottom of the list.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Software Installation, see Related Topics.

- When you upgrade an application, turn off the autoinstall option for the older version.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify categories for applications to be managed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify categories for applications to be managed**

1. Open Group Policy Software Installation.
2. In the console tree, right-click **Software installation**.

   **Where?**

   - *Group Policy object*\Computer Configuration (or User Configuration)\Software Settings\Software installation

3. Click **Properties**, and then click the **Categories** tab.
4. To create or change the list of categories under which programs appear in Add or Remove Programs in Control Panel, do any of the following:

   - To create a new category, click **Add**, and then type the new category name. If you do not have permission to add categories, this button is unavailable.
   - To modify an existing category, click the category that you want to modify, click **Modify**, and then change the text of the selected category. If you do not have permission to edit categories, this button is unavailable.
   - To remove a category from the **Categories** list, click the category name, and then click **Remove**. If you do not have permission to edit categories, this button is unavailable.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.
- The changes that you make to the application categories apply throughout the domain in which this Group Policy object is stored.
- To perform this procedure, you must be a domain administrator or have equivalent rights.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Group Policy to work with Applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with applications**

- Assign an application
- Publish an application
- Upgrade an application
- Remove a managed application

# Assign an application

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign an application**

1. Open Group Policy Software Installation.
2. In the console tree, right-click **Software installation**, point to **New**, and then click **Package**.

   **Where?**

   - *Group Policy object*\Computer Configuration (or User Configuration)\Software Settings\Software installation

3. In the **Open** dialog box, click the Windows Installer package, and then click **Open**.
4. In the **Deploy Software** dialog box, click **Assigned**, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.
- The **Open** dialog box shows the packages that are located at a software distribution point that you specify as the default. For instructions on how to set the default software distribution point, see Related Topics.
- If the Windows Installer package is located on a different shared network directory, navigate to the correct software distribution point in the **Open** dialog box, click the package, and then click **Open**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Publish an application

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To publish an application**

1. Open Group Policy Software Installation.
2. Right-click in the details pane, point to **New**, and then click **Package**.
3. In the **Open** dialog box, click the Windows Installer package to be published, and then click **Open**.
4. In the **Deploy Software** dialog box, click **Published**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.
- Packages can be published only to users, not to computers.
- The **Open** dialog box shows the packages that are located at a software distribution point that you specify as the default. For instructions on how to set the default software distribution point, see Related Topics.
- If the Windows Installer package is located on a different shared network directory, navigate to the correct software distribution point in the **Open** dialog box, click the package, and then click **Open**.
- The application is available for users to install either by using Add or Remove Programs in Control Panel or by opening a file with a file name extension that you have associated with the application. For information about how to associate a file name extension with an application, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Upgrade an application

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade an application**

1. Open Group Policy Software Installation.
2. In the details pane, right-click the new Windows Installer upgrade package (that is, not the package to be upgraded).
3. Click **Properties**, and then click the **Upgrades** tab.
4. Click **Add** to create or add to the list of packages that you want to upgrade with the new upgrade package.
5. In the **Add Upgrade Package** dialog box, under **Choose a package from**, do one of the following:
   - Click **Current Group Policy object (GPO)**.
   - Click **A specific GPO**, click **Browse**, and then click the Group Policy object that you want to upgrade.
6. Review the list of packages under **Package to upgrade**, which lists all of the other packages that are assigned or published within the selected Group Policy object.
7. Click the package that you want to upgrade, and then do one of the following:
   - To replace an application with a completely different application (perhaps an application from a different vendor), click **Uninstall the existing package, then install the upgrade package**.
   - To install a newer version of the same product while retaining the user's application preferences, document type associations, and so on, click **Package can upgrade over the existing package**.
8. (Optional) To make the upgrade mandatory, on the **Upgrades** tab, select the **Required upgrade for existing packages** check box.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- Before you can perform this procedure, you must first assign or publish the upgrade package.
- Depending on the Group Policy object, the list of packages under **Package to upgrade** might have zero or more entries.
- If this is an upgrade under Computer Configuration in the Group Policy console tree, the **Required upgrade for existing packages** check box is selected and unavailable because packages can only be assigned to computers, not published.
- To open Group Policy Software Installation, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a managed application

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a managed application**

1. Open Group Policy Software Installation.
2. In the details pane, right-click the application that you want to remove, point to **All Tasks**, and then click **Remove**.
3. In the **Remove Software** dialog box, click one of the following removal methods:
   - To specify that the application is removed the next time a user logs on or restarts the computer, click **Immediately uninstall the software from users and computers**.
   - To specify that users can continue to use the application if they have already installed it, click **Allow users to continue to use the software, but prevent new installations**. If users have removed the application or if they have never installed it, they will not be able to install it.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit installation options for applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit installation options for applications**

1. To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

2. Open Group Policy Software Installation.

3. In the details pane, right-click the application for which you want to set installation options, and then click **Properties**.

4. In the properties dialog box for the application, click the **Deployment** tab.

5. On the **Deployment** tab, click one of the following options under **Deployment type**:

   - **Published--**Users in the selected site, domain, or organizational unit can install the application by using either Add or Remove Programs in Control Panel or file activation.

   - **Assigned--**Users in the selected site, domain, or organizational unit receive this application the next time that they log on (for assignment to users) or when the computer restarts (for assignment to computers).

6. Under **Deployment options**, select the check boxes for the following options that you want:

   - **Auto-install this application by file extension activation--**Select this option if you want to use the application precedence for the file name extension as it is determined on the **File Extensions** tab in the **Software installation Properties** dialog box. If the application is not already installed, selecting this option causes the application to be installed when the user opens a file with this file association, for example, by double-clicking the file.

   - **Uninstall this application when it falls out of the scope of management--**Select this option if you want the application to be removed when users log on, or when computers start up, if they move to a site, domain, or organizational unit for which the application is not deployed.

   - **Do not display this package in Add or Remove Programs in Control Panel--**This option removes the most obvious method for users to uninstall the application. This may be useful from time to time during the software life cycle.

   - **Install this application at logon--**This option fully installs the application using the package defaults. It does not merely advertise the application to the user by means of a shortcut. Note that the package defaults themselves might call for installation of all features or of only some features.

7. Under **Installation user interface options**, click one of the following options:

   - **Basic--**Only progress bars and errors are displayed.

   - **Maximum--**The entire user interface that is supported by the package is displayed.

8. If you want to set the following advanced options, click **Advanced**:

   - **Ignore language when deploying this package--**Select this check box if you are installing an application whose

language differs from the language of the operating system.

- **Remove existing installs of this product for users, if the product was not installed by Group Policy-based Software Installation--**This option might be useful, for example, if company policy does not allow users to install applications from their own compact discs.

- **Make this 32-bit X86 application available to Win64 machines--**Specifies whether the 32-bit application should be assigned or published to 64-bit computers.

- **Include OLE class and product information--**Specifies whether to deploy information about COM components with the package so that software on the client can install them from Active Directory as needed, in a manner similar to activation by file extension.

### Notes

- To open Group Policy Software Installation, see Related Topics.

- The **Advanced Deployment Options** dialog box, which appears when you click **Advanced**, provides advanced diagnostic information, which can be useful for troubleshooting. The following table lists and describes this information.

| Field | Data |
|---|---|
| Product code | A globally unique identifier (GUID) representing the product |
| Deployment Count | The number of times the package has been deployed in this Group Policy object |
| Script name | The full network path, including GUIDs, to the application assignment script (.aas file) |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify application categories for Add or Remove Programs in Control Panel

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify application categories for Add or Remove Programs in Control Panel**

1. Open Group Policy Software Installation.
2. In the details pane, double-click the managed application for which you want to set categories.
3. In the properties dialog box for the application, click the **Categories** tab.
4. On the **Categories** tab, do any of the following:
   - To associate an application category that has been defined for your organization with this application, click a category in the **Available categories** list, and then click **Select**.
   - To remove a category that is associated with this application, click a category in the **Selected categories** list, and then click **Remove**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.
- The categories that you set in this dialog box generally pertain to published applications only, because assigned applications do not appear in Add or Remove Programs in Control Panel. The application appears in the selected categories in Add or Remove Programs, which the user can use to install the application.
- This procedure is not used to create or remove categories, but only to associate applications with existing categories. To manage the categories themselves, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the autoinstall option for an application

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the autoinstall option for an application**

1. Open Group Policy Software Installation.
2. In the console tree, click **Software installation**.

**Where?**

- *Group Policy object*\Computer Configuration (or User Configuration)\Software Settings\Software installation

1. In the details pane, right-click the application that you want to be installed automatically when the user tries to open a file with the associated extension.
2. Click **Properties**, and then click the **Deployment** tab.
3. Under **Deployment options**, select the **Auto-install this application by file extension activation** check box, and then click **OK**. This option is recommended, and it is selected by default.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.
- When you upgrade an application, turn off the autoinstall option for the older version.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set permissions for Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions for Group Policy Software Installation**

1. Open the Group Policy object that you want to edit.
2. In the console tree, right-click the icon or name of the Group Policy object, and then click **Properties**.
3. Click the **Security** tab, and in the **Group or user names** box, click the security group for which you want to set permissions.
4. Do any of the following:
   - To change the set of security groups that have permissions on this Group Policy object, click **Add** or **Remove** to add or remove security groups.
   - If the security group represents administrators (who manage software for users and computers in the organization), in the **Permissions** box for the selected security group, select the **Allow** check box for Full Control, and then click **OK**.
   - If the security group represents users (who use software that is assigned or published by an administrator), in the **Permissions** box for the selected security group, select the **Allow** check box for both Apply Group Policy and Read, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- The permissions that you set in this procedure pertain only to the Group Policy object. In addition, the network must have a shared folder (a software distribution point) containing the packages to be installed. Administrators must have Full Control of the software distribution point, and users must have Read permission. For information about permissions and how to set them, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add or remove modifications for an application package

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add or remove modifications for an application package**

1. Open Group Policy Software Installation.
2. In the console tree, right-click **Software installation**, point to **New**, and then click **Package**.

**Where?**

- *Group Policy object*\Computer Configuration (or User Configuration)\Software Settings\Software installation

1. In the **Open** dialog box, click the Windows Installer package, and then click **Open**.
2. In the **Deploy Software** dialog box, click **Advanced**, and then click **OK**.
3. In the properties dialog box for the package, click the **Modifications** tab.
4. Do any of the following:
   - To add modifications, click **Add**. In the **Open** dialog box, browse to the transform file (.mst), and then click **Open**.
   - To remove modifications, on the **Modifications** tab, click the modification that you want to remove, and then click **Remove**. Repeat this step until you have removed each modification that you do not want.
5. When you are sure that the modifications are configured the way you want them, click **OK**.

   **Important**

   - Do not click **OK** until you have finished configuring the modifications. When you click **OK**, the package is assigned or published immediately. If the modifications are not properly configured, you will have to uninstall the package or upgrade the package with a correctly configured version.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Software Installation, see Related Topics.
- The **Open** dialog box shows the packages that are located at a software distribution point that you specify as the default. For instructions on how to set the default software distribution point, see Related Topics.
- If the Windows Installer package is located on a different shared network directory, navigate to the correct software distribution point in the **Open** dialog box, click the package, and then click **Open**.
- Modifications (.mst files) are applied to Windows Installer packages (which have the .msi extension) in an order that you specify. This order must be determined before the application is assigned or published.
- You can add multiple modifications, which are also called transforms. The transforms are applied in the order that you

specify in the **Modifications** list, from top to bottom. To rearrange the list, click a transform in the list, and then click **Move Up** or **Move Down**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Folder Redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Folder Redirection**

- Redirect Special Folders to the Same Location for All Users
- Redirect Special Folders to Different Locations Based on Security Group Membership

# Redirect Special Folders to the Same Location for All Users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Redirect special folders to the same location for all users**

- Redirect My Documents to the home directory
- Redirect special folders to the root directory
- Redirect special folders to a specific path
- Redirect special folders to the local profile location

# Redirect My Documents to the home directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To redirect My Documents to the home directory**

1. Open a Group Policy object that is linked to the site, domain, or organizational unit that contains the users whose My Documents folders you want to redirect.

2. In the console tree, double-click **Folder Redirection** to display My Documents.

   **Where?**

   - *Group Policy object*\User Configuration\Windows Settings\Folder Redirection\My Documents

3. Right-click **My Documents**, and then click **properties**.

4. On the **Target** tab, in **Setting**, click **Basic - Redirect everyone's folder to the same location**.

5. Under **Target folder location**, click **Redirect to the user's home directory**, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Object Editor, see Related Topics.

- This option is intended only for organizations that have already deployed home directories and that want to maintain compatibility with their existing home directory environment.

- If you redirect My Documents to the home directory, domain administrators have full control over the user's My Documents folder. This is the case even if you select the **Grant the user exclusive rights to My Documents** check box on the **Settings** tab in the **My Documents properties** dialog box.

- Redirection to the home directory requires a client computer running Windows XP Professional, Windows XP 64-bit Edition (Itanium), or a Windows Server 2003 operating system. It does not work for Windows NT clients, Windows 2000 clients, or Windows XP Home Edition clients.

- In redirection of the home directory, security is not checked, and permissions are not changed. Folder Redirection assumes that the administrator has set directory security correctly. This relaxed security is why redirection to the home directory is only recommended if it is needed for backward compatibility.

- In home directory redirection, no ownership checks are made. Normally, folder redirection fails if a user is not the owner of the folder to which he or she is being redirected. Because redirection to the home directory is intended for use in a legacy environment, this ownership check is skipped.

- Users must have the home directory property set correctly on their user object in Active Directory. The client computer finds the path for the user's home directory from the user object in Active Directory at logon time. Users who are affected by Folder Redirection policy must have this path set correctly, or folder redirection will fail.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Redirect special folders to the root directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To redirect special folders to the root directory**

1. Open a Group Policy object that is linked to the site, domain, or organizational unit that contains the users whose special folders you want to redirect.

2. In the console tree, double-click **Folder Redirection** to display the special folder that you want to redirect.

   **Where?**

   - *Group Policy object*\User Configuration\Windows Settings\Folder Redirection

3. Right-click the special folder that you want to redirect (for example, **Desktop** or **My Documents**), and then click **Properties**.

4. On the **Target** tab, in **Setting**, click **Basic - Redirect everyone's folder to the same location**.

5. Under **Target folder location**, click **Create a folder for each user under the root path**.

6. In **Root Path**, type a Universal Naming Convention (UNC) path (for example, **\\servername\sharename**), and then click **OK**.

7. In the properties dialog box for the special folder, click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Object Editor, see Related Topics.

- The user name and folder name are appended to the UNC path automatically.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Redirect special folders to a specific path

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To redirect special folders to a specific path**

1. Open a Group Policy object that is linked to the site, domain, or organizational unit that contains the users whose special folders you want to redirect.

2. In the console tree, double-click **Folder Redirection** to display the special folder that you want to redirect.

   **Where?**

   - *Group Policy object name*\User Configuration\Windows Settings\Folder redirection

3. Right-click the special folder that you want to redirect (for example, **Desktop** or **My Documents**), and then click **Properties**.

4. On the **Target** tab, in **Setting**, click **Basic - Redirect everyone's folder to the same location**.

5. Under **Target folder location**, click **Redirect to the following location**.

6. In **Root Path**, type a UNC path (for example, *****ServerName******ShareName*), or type a locally valid path (for example, **C:***FolderName*).

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Object Editor, see Related Topics.

- In most cases, you want to redirect special folders to the root directory rather than to a specific location, as described in this procedure. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Redirect special folders to the local profile location

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To redirect special folders to the local profile location**

1. Open a Group Policy object that is linked to the site, domain, or organizational unit that contains the users whose special folders you want to redirect.

2. In the console tree, double-click **Folder Redirection** to display the special folder that you want to redirect.

   **Where?**

   - *Group Policy object*\User Configuration\Windows Settings\Folder Redirection

3. Right-click the special folder that you want to redirect (for example, **Desktop** or **My Documents**), and then click **Properties**.

4. On the **Target** tab, in **Setting**, click **Basic - Redirect everyone's folder to the same location**.

5. Under **Target folder location**, click **Redirect to the local user profile location**, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Object Editor, see Related Topics.

- This procedure is useful for returning redirected folders to their original, default location.

- If you change the setting to **No administrative policy specified** on the **Target** tab of the properties dialog box for a special folder, you do not cause the special folder to be redirected back to its default location.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Redirect special folders to different locations based on security group membership**

- Redirect My Documents to the home directory based on security group membership
- Redirect special folders to the root directory based on security group membership
- Redirect special folders to a specific path based on security group membership
- Redirect to the local profile location based on security group membership

# Redirect My Documents to the home directory based on security group membership

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To redirect My Documents to the home directory based on security group membership**

1. Open a Group Policy object that is linked to the site, domain, or organizational unit that contains the users whose My Documents folders you want to redirect.

2. In the console tree, double-click **Folder Redirection** to display My Documents.

   **Where?**

   - *Group Policy object*\User Configuration\Windows Settings\Folder Redirection\My Documents.

3. Right-click **My Documents**, and then click **properties**.

4. On the **Target** tab, in **Setting**, click **Advanced - Specify locations for various user groups**.

5. Click **Add**.

6. In the **Specify Group and Location** dialog box, under **Security Group Membership**, type the name of the security group, or click **Browse** to search for it.

7. Under **Target Folder Location**, click **Redirect to the user's home directory**, and then click **OK**.

8. In the **My Documents properties** dialog box, click **OK**.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.

- To open Group Policy Object Editor, see Related Topics.

- This option is intended only for organizations that have already deployed home directories and that want to maintain compatibility with their existing home directory environment.

- If you redirect My Documents to the home directory, domain administrators have full control over the user's My Documents folder. This is the case even if you select the **Grant the user exclusive rights to My Documents** check box on the **Settings** tab in the **My Documents properties** dialog box.

- Redirection to the home directory requires a client computer running Windows XP Professional, Windows XP 64-bit Edition (Itanium), or a Windows Server 2003 operating system. It does not work for Windows 2000 clients, Windows NT clients, or Windows XP Home Edition clients.

- In home directory redirection, security is not checked, and permissions are not changed. Folder Redirection assumes that the administrator has set directory security correctly. This relaxed security is why redirection to the home directory is only recommended if it is needed for backward compatibility.

- In home directory redirection, no ownership checks are made. Normally, folder redirection fails if a user is not the owner of the folder to which he or she is being redirected. Because redirection to the home directory is intended for use in a

legacy environment, this ownership check is skipped.

- Users must have the home directory property set correctly on their user object in Active Directory. The client computer finds out the path for the user's home directory from the user object in Active Directory at logon time. Users who are affected by Folder Redirection policy must have this path set correctly, or folder redirection will fail.

# Configure Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure Group Policy**

- Extend the functionality of Group Policy
- Refresh Group Policy immediately
- Set permissions on a Group Policy object
- Set the Group Policy refresh rate for computers
- Set other policies for Group Policy

# Extend the functionality of Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To extend the functionality of Group Policy**

1. Open Group Policy Object Editor as an MMC snap-in.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. Click the **Extensions** tab, click the snap-ins that you want to extend, click the extensions that you want to add, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set permissions on a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions on a Group Policy object**

1. Open Group Policy Object Editor.
2. In the console tree, right-click the icon or the name of the Group Policy object for which you want to set permissions, and then click **Properties**.
3. Click the **Security** tab, and then specify the following options:
   - **Add--**Opens the **Select Users, Computers, or Groups** dialog box, where you can specify the users and groups for whom you want to assign permissions.
   - **Remove--**In the **Group or user names** box, removes selected users or groups and their associated permissions from this object.
   - **Permissions for Authenticated Users--**Lists the standard permissions that you can allow or deny to users, for example, Full Control, Read, Write, and so on.
   - **Advanced--**Use this option to set special permissions, auditing information, and owner information for the selected object.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- You can only set permissions on a nonlocal Group Policy object.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the Group Policy refresh rate for computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the Group Policy refresh rate for computers**

1. Open Group Policy Object Editor.
2. In the console tree, click **Group Policy**.

   **Where?**

   - *Group Policy object*\Computer Configuration\Administrative Templates\System\Group Policy

3. In the details pane, double-click **Group Policy refresh interval for computers**.
4. On the **Setting** tab, click **Enabled**.
5. In the **Minutes** boxes, type or click the number of minutes for the refresh interval and random offset, and then click **OK**.
6. In the details pane, double-click **Turn off background refresh of Group Policy**.
7. On the **Setting** tab, click **Disabled**, and then click **OK**.

**Notes**

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- By default, the System.adm file is installed in Computer Configuration\Administrative Templates so that you can view these options. For information about how to add or remove an Administrative Templates file like System.adm, see Related Topics.
- Client computers request policy from a domain controller when any of the following events occur:
  - A computer starts up.
  - A user logs on.
  - An application requests a refresh through the **RefreshPolicy()** application programming interface (API).
  - The user requests an immediate refresh.
  - One of the Group Policy refresh interval policies is enabled, and the interval has transpired.
  - Policy is not imposed by the domain controller; it is requested by the client computer.
- The minimum setting for the Group Policy refresh interval (zero minutes) actually takes about seven seconds between requests for a refresh. Very short refresh interval settings should not be used in a production environment, except briefly for testing.

- Group Policy Software Installation and Folder Redirection are not affected by policy refreshes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set other policies for Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set other policies for Group Policy**

1. Open Group Policy Object Editor.
2. Do one of the following:
   - To edit a computer policy, in the console tree click **Group Policy**.
   - **Where?**
   - *Group Policy object*/Computer Configuration/Administrative Templates/System/Group Policy
   - To edit a user policy, in the console tree click **Group Policy**.
   - **Where?**
   - *Group Policy object*/User Configuration/Administrative Templates/System/Group Policy
3. In the details pane, double-click the icon or the name of the policy that you want to set.
4. On the **Setting** tab, select the options that you want, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Administrators security group, the Enterprise Administrators security group, or the Group Policy Creator Owners security group.
- To open Group Policy Object Editor, see Related Topics.
- By default, the most common Administrative Templates are displayed. You can add Administrative Templates by right-clicking the Administrative Templates folder, and then clicking **Add/Remove Templates**. For more information, see Add or remove an Administrative Template (.adm file).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate Control of Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Delegate control of Group Policy**

- Delegate Group Policy object editing
- Delegate creation of Group Policy objects
- Delegate Group Policy object linking

# Delegate Group Policy object editing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate Group Policy object editing**

1. Open Group Policy Object Editor.
2. In the console tree, right-click the icon or name of the Group Policy object, and then click **Properties**.
3. Do any of the following:
   - To add a user or group of users, click the **Security** tab, and then click **Add**. Type the name of the user or group of users, and then click **OK**.
   - To give a user or group Group Policy object editing permissions, in **Permissions for Authenticated Users**, select the check boxes that correspond to the permissions you want to give. When you are finished, click **OK**.
   - If you do not want to apply the policy to a user or group of users, under **Permissions for Authenticated Users**, clear the **Allow** check box for Apply Group Policy. When you are finished, click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Admins group or the Enterprise Admins group.
- To open Group Policy Object Editor, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate creation of Group Policy objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate creation of Group Policy objects**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.
3. In the **Name** column in the details pane, double-click **Group Policy Creator Owners**.
4. In the **Group Policy Creator Owners Properties** dialog box, click the **Members** tab.
5. Click **Add**, type the name of the user or group of users, and then click **OK**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Admins group or the Enterprise Admins group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- By default, only domain administrators, enterprise administrators, Group Policy Creator Owners, and the operating system can create new Group Policy objects. If the domain administrator wants a nonadministrator or a group to be able to create Group Policy objects, that user or group can be added to the Group Policy Creator Owners security group. When a user who is not an administrator, but who is a member of the Group Policy Creator Owners group, creates a Group Policy object, that user becomes the creator and owner of the Group Policy object; therefore, that user can edit the Group Policy object. Being a member of the Group Policy Creator Owners group gives the user full control of only those Group Policy objects that the user creates or those Group Policy objects that are explicitly delegated to that user. It does not give the nonadministrator user any additional rights over other Group Policy objects for the domain--these users are not granted rights over Group Policy objects that they did not create.
- When an administrator creates a Group Policy object, the Domain Admins group becomes the Creator Owner of the Group Policy object.
- When you delegate this task to nonadministrators, also consider delegating the ability to manage the links for a specific organizational unit. The reason for this is that, by default, nonadministrators cannot manage links, and the inability to manage links prevents them from being able to use Active Directory Users and Computers to create a Group Policy object.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate Group Policy object linking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate Group Policy object linking**

1. Open Active Directory Users and Computers.
2. Right-click the organizational unit to which you want to delegate the right to link Group Policy objects, and then click **Delegate Control**.
3. In the Delegation of Control Wizard, click **Next**, and then click **Add**.
4. In the **Select Users, Computers, or Groups** dialog box, enter the object name to select, and then click **OK**, and then click **Next**.
5. On the Task to Delegate page, in **Delegate the following common tasks**, select the **Manage Group Policy links** check box, and then click **Next**.
6. Click **Finish**.

## Notes

- To complete this procedure, you must be logged on as a member of the Domain Admins group or the Enterprise Admins group.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- To open Group Policy Object Editor, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Group Policy overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy overview**

To begin using Group Policy immediately, see Ways to open Group Policy Object Editor.

Group Policy settings define the various components of the user's desktop environment that a system administrator needs to manage, for example, the programs that are available to users, the programs that appear on the user's desktop, and options for the **Start** menu. To create a specific desktop configuration for a particular group of users, use Group Policy Object Editor. Group Policy settings that you specify are contained in a Group Policy object, which is in turn associated with selected Active Directory® objects--sites, domains, or organizational units.

Group Policy applies not only to users and client computers, but also to member servers, domain controllers, and any other Microsoft® Windows® 2000 computers within the scope of management. By default, Group Policy that is applied to a domain (that is, applied at the domain level, just above the root of Active Directory Users and Computers) affects all computers and users in the domain. Active Directory Users and Computers also provides a built-in Domain Controllers organizational unit. If you keep your domain controller accounts there, you can use the Group Policy object Default Domain Controllers Policy to manage domain controllers separately from other computers.

Group Policy includes policy settings for User Configuration, which affect users, and for Computer Configuration, which affect computers. For more information, see User Configuration and Computer Configuration.

With Group Policy you can do the following:

- **Manage registry-based policy with Administrative Templates.** Group Policy creates a file that contains registry settings that are written to the User or Local Machine portion of the registry database. User profile settings that are specific to a user who logs on to a given workstation or server are written to the registry under **HKEY_CURRENT_USER** (HKCU), and computer-specific settings are written under **HKEY_LOCAL_MACHINE** (HKLM). For procedural information, see Use Administrative Templates. For technical details, see "Implementing Registry-based Policy" at the Microsoft Web site.

- **Assign scripts.** This includes such scripts as computer startup, shutdown, logon, and logoff. For more information, see Use Startup, Shutdown, Logon, and Logoff Scripts.

- **Redirect folders.** You can redirect folders, such as My Documents and My Pictures, from the Documents and Settings folder on the local computer to network locations. For more information about Folder Redirection, see Use Folder Redirection.

- **Manage applications.** With Group Policy you can assign, publish, update, or repair applications by using Group Policy Software Installation. For more information, see Use Group Policy Software Installation.

- **Specify security options.** To learn about setting security options, see Security Settings extension to Group Policy.

**Group Policy objects that exist by default**

Each computer that runs Windows 2000, Microsoft® Windows® XP Professional , or Windows Server 2003 operating systems has exactly one Group Policy object stored locally. This local Group Policy object contains a subset of the settings that are available in nonlocal Group Policy objects. For more information, see Local Group Policy.

By default, when Active Directory is set up, two nonlocal Group Policy objects are created:

- Default Domain Policy is linked to the domain, and it affects all users and computers in the domain (including computers that are domain controllers) through policy inheritance. For more information, see Policy inheritance.

- Default Domain Controllers Policy is linked to the Domain Controllers organizational unit, and it generally only affects domain controllers, because computer accounts for domain controllers are kept exclusively in the Domain Controllers organizational unit.

### Caution

- If you move a domain controller outside of the Domain Controllers organizational unit, the default Domain Controllers policy is no longer applied. If you need to keep a domain controller in a different organizational unit, link the default Domain Controllers policy to that organization unit.

#### How and when Group Policy is applied

To view a detailed chronology for the application of policy, see Order of events when starting up and logging on.

#### User and computer policy

User policy settings are located under User Configuration in Group Policy, and they are obtained when a user logs on. Computer policy settings are located under Computer Configuration, and they are obtained when a computer starts. For more information, see User Configuration and Computer Configuration.

Users and Computers are the only types of Active Directory objects that receive policy. Specifically, policy does not apply to security groups. Instead, for performance reasons, security groups are used to filter the policy by means of an Apply Group Policy access control entry (ACE), which can be set to **Allow** or **Deny** or left unconfigured. For more information, see Filter the scope of Group Policy according to security group membership.

#### Order of application

Policies are applied in this order:

1. The unique local Group Policy object.
2. Site Group Policy objects, in administratively specified order.
3. Domain Group Policy objects, in administratively specified order.
4. Organizational unit Group Policy objects, from largest to smallest organizational unit (parent to child organizational unit) and in administratively specified order at the level of each organizational unit.

For more information, see Order of processing settings.

By default, policies that are applied later overwrite previously applied policies when the policies are inconsistent. If the policies are not inconsistent, however, earlier and later policies both contribute to the effective policy. For more information, see Group Policy Precedence.

#### Filtering policy by security group membership

A security group ACE on a Group Policy object can be set to **Not configured** (no preference), **Allowed**, or **Denied**. **Denied** takes precedence over **Allowed**. For more information, see Filter the scope of Group Policy according to security group membership.

#### Blocking policy inheritance

Policies that would otherwise be inherited from higher sites, domains, or organizational units can be blocked at the site, domain, or organizational unit level. For more information, see Block policy inheritance.

#### Enforcing policy from above

You can set policies that would otherwise be overwritten by policies in child organizational units to **No Override** at the Group Policy object level. For more information, see Prevent a Group Policy object from being overridden.

### Notes

- Policies set to **No Override** cannot be blocked.
- The **No Override** and **Block** options should be used sparingly. Casual use of these advanced features complicates troubleshooting. For tips about using Group Policy, see Troubleshooting Group Policy and Group Policy Best Practices (pre-GPMC).

# Group Policy settings overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy settings overview**
With Group Policy settings, you can define the configuration of a user's desktop environment. Settings are available for Computer Configuration and User Configuration. In addition to client computers and users, you can apply these settings to member servers and domain controllers within the scope of an Active Directory forest.

**Administrative Templates folder**
The Administrative Templates folders are available under Computer Configuration and User Configuration in Group Policy Object Editor. These folders contain registry settings. For more information, see Administrative Templates.

The following table contains links to Help for all of the registry settings included in the five default Administrative Templates.

| For these settings | Open this Administrative Template | Reference |
|---|---|---|
| System settings that control features such as desktop, network connections, shared folders, and Control Panel. | System (System.adm) | Group Policy settings for Windows 2000, Windows XP, and the Windows Server 2003 family |
| Internet Explorer settings that control features such as security zones, proxy settings, search, and temporary Internet files. | Internet Explorer (Inetres.adm) | Group Policy settings for Internet Explorer |
| Windows Media Player settings that control features such as proxy settings, codec, and network buffering. This tool is not available on the Itanium-based versions of the Windows operating systems. This tool is not available on the x64-based versions of the Windows operating systems. | Windows Media Player (Wmplayer.adm) | Group Policy settings for Windows Media Player |
| NetMeeting settings to control features such as application sharing, audio, video, and chat. This tool is not available on the Itanium-based versions of the Windows operating systems. This tool is not available on the x64-based versions of the Windows operating systems. | NetMeeting (Conf.adm) | Group Policy settings for NetMeeting v3.01 |
| Windows Update settings that control features such as automatic software updates through the Internet. | Windows Update (Wuau.adm) | Group Policy settings for Windows Update |

**Software Settings folder**
The Software Settings folders are available under Computer Configuration and the User Configuration in Group Policy Object Editor. The Computer Configuration\Software Settings folder contains software settings that apply to all users who log on to the computer. This folder contains software installation settings, and it might contain other settings that are placed there by independent software vendors. The User Configuration\Software Settings folder contains software settings that apply to users regardless of which computer they log on to. This folder also contains software installation settings, and it might contain other settings that are placed there by independent software vendors. For more information, see Software Settings.

**Windows Settings folder**
The Windows Settings folders are available under Computer Configuration and User Configuration in Group Policy Object Editor. The Computer Configuration\Windows Settings folder contains Windows settings that apply to all users who log on to the computer. This folder also contains the following items: Security Settings and Scripts. The User Configuration\Windows Settings folder contains Windows settings that apply to users regardless of which computer they log on to. This folder also contains the following items: Folder Redirection, Security Settings, and Scripts. For more information, see Windows Settings.

**Security Settings folder**
The Security Settings folders are available under Computer Configuration and User Configuration in Group Policy Object Editor. Security settings or security policies are rules that you configure on a computer or multiple computers that protect

resources on a computer or network. With security settings you can specify the security policy of an organizational unit, domain, or site. To view a complete list and detailed information about security settings, see Security Setting Descriptions. To specify security settings on a local computer, see Local Security Policy. For more information, see Security Settings extension to Group Policy.

# Understanding Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Group Policy**
This section covers:

- New Group Policy features (pre-GPMC)
- Group Policy objects
- Policy inheritance
- Storage of Group Policy objects
- User Configuration
- Computer Configuration
- Administrative Templates
- Software Settings
- Fast Logon Optimization
- Windows Settings
- Folder Redirection
- Windows Management Instrumentation (WMI) Filters
- Startup, shutdown, logon, and logoff scripts
- Group Policy Software Installation
- Group Policy Precedence

# New Group Policy features (pre-GPMC)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features**

The Windows 2000 change and configuration management technologies have been improved in the Windows Server 2003 family. For information about specific user interface changes in the Windows Server 2003 family, see New ways to do familiar Group Policy tasks (pre-GPMC).

Following is a list of the new features included with Group Policy in the Windows Server 2003 family:

- **Administrative Templates**

  There are over 220 new administrative policies than were previously available on Windows 2000. There is a new supported keyword in .adm files that tells you which versions of Windows are supported as clients for the setting. For more information, see "Implementing Registry-based Policy" at the Microsoft Web site. There is also a new Administrative Templates Web view that uses the supported keyword to show you which operating systems are supported clients for individual settings. For information about how to use the Web view, see Use the view provided by Administrative Templates. For more information about Administrative Templates, see Administrative Templates.

  Administrative Templates online Help is now included with Windows. The following table contains links to the .adm Help files.

| .adm file | Policy settings |
|---|---|
| System.adm | Open Help for System Settings |
| Wmplayer.adm | Open Help for Windows Media Player settings |
| Inetres.adm | Open Help for Internet Explorer settings |
| Conf.adm | Open Help for NetMeeting settings |

- **Command-line tools**

  The new **gpudate** command replaces the Windows 2000 command **secedit /refreshpolicy**. For more information, see Gpupdate.

  The Windows 2000 Resource Kit command **gpresult** has been enhanced, and it is now included with Windows XP Professional, Windows XP 64-bit Edition (Itanium), and the Windows Server 2003 family. For more information, see Gpresult.

- **Folder Redirection**

  It is now easier to use Folder Redirection. It is no longer necessary to type variables such as *UserName* as part of the redirection path. There is a new option for redirecting My Documents to a user's home directory. This is for use in environments where home directories are already deployed. For more information, see Use Folder Redirection.

- **Group Policy Software Installation**

  Group Policy Software Installation now has an advanced deployment option to enable or disable availability of 32-bit programs to 64-bit computers. With another new advanced option, you can enable or disable (default) publication of OLE class information about a software package. As an administrator, you also have an option that forces assigned applications to be installed at deployment time. For more information, see Edit installation options for applications.

- **Resultant Set of Policy**

Resultant Set of Policy (RSoP) is a new tool that you can use to plan for and troubleshoot policy. For more information, see Resultant Set of Policy.

- **Support across forests**

  Group Policy features are now supported in multiple forest environments allowing authenticated access to resources in separate, networked environments. You can manage and enforce policy objects for user and computer objects in remote trusted forests and analyze policies using Resultant Set of Policy. For more information, see Group Policy features that are supported across forests and Accessing resources across forests.

# Group Policy objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy objects**

Policy settings are stored in Group Policy objects. Group Policy Object Editor can be thought of as an application whose document type is the Group Policy object, just as a word processor might use .doc or .txt files.

There are two kinds of Group Policy objects: local and nonlocal. Local Group Policy objects are stored on individual computers. Only one local Group Policy object exists on a computer, and it has a subset of the settings that are available in a nonlocal Group Policy object. Local Group Policy object settings can be overwritten by nonlocal settings if they are in conflict; otherwise, both groups of settings apply. For more information, see Local Group Policy.

Nonlocal Group Policy objects, which are stored on a domain controller, are available only in an Active Directory environment. They apply to users and computers in the site, domain, or organizational unit with which the Group Policy object is associated. For more information, see Storage of Group Policy objects.

# Policy inheritance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policy inheritance**

In general, Group Policy is passed down from parent to child containers within a domain, which you can view by using Active Directory Users and Computers. Group Policy is not inherited from parent to child domains, for example, from wingtiptoys.com to sales.wingtiptoys.com. Active Directory Domains and Trusts, which you can use to manage relationships of this type, is not related to Group Policy.

If you assign a specific Group Policy setting to a high-level parent container, that Group Policy setting applies to all containers beneath the parent container, including the user and computer objects in each container. However, if you explicitly specify a Group Policy setting for a child container, the child container's Group Policy setting overrides the parent container's setting.

If a parent organizational unit has policy settings that are not configured, the child organizational unit does not inherit them. Policy settings that are disabled are inherited as disabled. In addition, if a policy setting is configured (enabled or disabled) for a parent organizational unit and the same policy setting is not configured for a child organizational unit, the child inherits the parent's enabled or disabled policy setting.

If a policy setting that is applied to a parent organizational unit and a policy setting that is applied to a child organizational unit are compatible, the child organizational unit inherits the parent policy setting, and the child's setting is also applied.

If a policy setting that is configured for a parent organizational unit is incompatible with the same policy setting that is configured for a child organizational unit (because the setting is enabled in one case and disabled in the other), the child does not inherit the policy setting from the parent. The policy setting in the child is applied.

**Blocking inheritance**

You can block policy inheritance at the domain or organizational-unit level by opening the properties dialog box for the domain or organizational unit and selecting the **Block Policy inheritance** check box. For more information, see Block policy inheritance.

**Enforcing inheritance**

You can enforce policy inheritance by setting the **No Override** option on a Group Policy object link.

When you select the **No Override** check box, you force all child policy containers to inherit the parent's policy, even if that policy conflicts with the child's policy and even if **Block Inheritance** has been set for the child.

You can set **No Override** on a Group Policy object link by opening the properties dialog box for the site, domain, or organizational unit and making sure that the **No Override** check box is selected. For more information, see Prevent a Group Policy object from being overridden.

### Notes

- Policies that are set to **No Override** cannot be blocked.
- It is recommended that **No Override** and **Block** be used sparingly. Casual use of these advanced features makes troubleshooting more complicated. For more information, see Troubleshooting Group Policy and Group Policy Best Practices (pre-GPMC).

# Storage of Group Policy objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Storage of Group Policy objects**
Each computer that runs Windows XP Professional, Windows XP 64-bit Edition (Itanium), or the Windows Server 2003 operating systems, has exactly one local Group Policy object (GPO). It is stored in *systemroot*\System32\GroupPolicy.

Group Policy objects, other than the local Group Policy object, are virtual objects. The policy setting information of a GPO is actually stored in two locations: the Group Policy container and the Group Policy template. The Group Policy container is an Active Directory container that stores GPO properties, including information on version, GPO status, and a list of components that have settings in the GPO. The Group Policy template is a folder structure within the file system that stores Administrative Template-based policies, security settings, script files, and information regarding applications that are available for Group Policy Software Installation. The Group Policy template is located in the system volume folder (Sysvol) in the \Policies subfolder for its domain. For more information about the local Group Policy object, see Local Group Policy.

**Group Policy container**
The Group Policy container is a directory service object. It includes subcontainers for computer and user Group Policy information. The Group Policy container contains the following data:

- **Version information--**Used to verify that the information is synchronized with Group Policy template information.
- **Status information--**Indicates whether the Group Policy object is enabled or disabled for this site, domain, or organizational unit.
- **List of components--**Specifies which extensions to Group Policy have settings in the Group Policy object.

The Group Policy container stores information for Group Policy Software Installation and for Folder Redirection, which are extensions of the Group Policy Object Editor. For more information, see Group Policy Software Installation overview and Folder Redirection.

**Group Policy template**
The Group Policy template is a folder of domain controllers for the storage domain of the Group Policy object. A typical Group Policy template folder might look like the following example:

*systemroot*\Sysvol\SYSVOL\Streetmarket.com\Policies\

{34975054-fd77-df75-54fe-074936850457}

**Subfolders of the Group Policy template**
The Group Policy template folder contains subfolders, including, but not limited to, the following:

- **Adm--**Contains all the .adm files for this Group Policy template.
- **Scripts--**Contains all the scripts and related files for this Group Policy template.
- **User--**Includes a Registry.pol file that contains the registry settings that are to be applied to users. When a user logs on to a computer, this Registry.pol file is downloaded and applied to the **HKEY_CURRENT_USER** portion of the registry. The User folder contains an Applications subfolder.
- **User\Applications--**Contains the application advertisement script files (.aas) that are used by the operating system-based installation service. These files are applied to users.
- **Machine--**Includes a Registry.pol file that contains the registry settings that are to be applied to computers. When a computer initializes, this Registry.pol file is downloaded and applied to the **HKEY_LOCAL_MACHINE** portion of the registry. The Machine folder contains an Applications subfolder.
- **Machine\Applications--**Contains the .aas files that are used by the operating system-based installation service. These

files are applied to computers.

# User Configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User Configuration**

You can use User Configuration in Group Policy to set policies that apply to users, regardless of which computer they log on to.

User Configuration typically contains subitems for Software Settings, Windows Settings, and Administrative Templates, but because you can add or remove extensions from Group Policy Object Editor, the exact set of subitems that you see might be different. For more information about these subitems, see Software Settings, Windows Settings, and Administrative Templates.

# Computer Configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computer Configuration**
With Computer Configuration in Group Policy, you can set policies that are applied to computers, regardless of who logs on to the computers.

Computer Configuration typically contains Software Settings, Windows Settings, and Administrative Templates. However, because you can add or remove extensions in Group Policy Object Editor, what you see might be slightly different.

For more information about these subitems, see Software Settings, Windows Settings, and Administrative Templates.

# Administrative Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative Templates**
Administrative Templates provide policy information for the items that appear under the Administrative Templates folder in the console tree of the Group Policy Object Editor.

**Administrative Template .adm files**
An .adm file consists of a hierarchy of categories and subcategories that together define how the policy settings appear. It also contains the following information:

- Registry locations that correspond to each setting.
- Options or restrictions in values that are associated with each setting.
- For many settings, a default value.
- Explanations of what each setting does.
- The versions of Windows that support each setting.

The Administrative Templates for Group Policy contain all registry-based policy information. User configurations are saved in **HKEY_CURRENT_USER** (HKCU), and computer configurations are saved in **HKEY_LOCAL_MACHINE** (HKLM). HKCU and HKLM place registry information that is specific to Group Policy under \Software\Policies or under \Software\Microsoft\Windows\CurrentVersion\Policies. Therefore, there are five areas of the registry that contain Group Policy registry settings.

Administrative Templates offer these new features:

- A description of each policy setting in Administrative Templates appears in searchable online Help.

| Administrative Template | Description |
|---|---|
| System.adm | System settings |
| Inetres.adm | Internet Explorer settings |
| Wmplayer.adm | Windows Media Player settings.<br>This tool is not available on the Itanium-based versions of the Windows operating systems.<br>This tool is not available on the x64-based versions of the Windows operating systems. |
| Conf.adm | NetMeeting settings.<br>This tool is not available on the Itanium-based versions of the Windows operating systems.<br>This tool is not available on the x64-based versions of the Windows operating systems. |
| Wuau.adm | Windows Update settings. |

- A supported keyword in the .adm files that tells you which versions of Windows are supported as clients for the setting. For information about the supported keyword, see "Implementing Registry-based Policy" at the Microsoft Web site.
- A Web view that shows the explain text of each setting and the new supported information. For information about how to use the Web view, see Use the view provided by Administrative Templates.
- The ability to filter settings from the view to reduce screen clutter when you are using Administrative Templates. For

information about how to use this new feature, see Filter the view provided by Administrative Templates.

If you plan to create entries for Administrative Templates, populate the namespace by using the following naming convention, which is also used in the registry: *CompanyName**product**version* (or *CompanyName**product&version*). For example, the operating system settings for Windows are in \Microsoft\Windows.

For information about adding an .adm file, see Add or remove an Administrative Template (.adm file). For more information about Administrative Templates, see Administrative Templates included with this version of Windows and The role of Administrative Templates.

**Registry.pol files**

The Administrative Templates extension of Group Policy saves information in Registry.pol files. These files contain the customized registry settings that you specify (by using Group Policy) that are to be applied to the computer or user portion of the registry:

- One of the Registry.pol files contains registry settings that are specific to the **HKEY_LOCAL_MACHINE** key; it is stored in the GPT\Machine folder.

- The other Registry.pol file contains registry settings that are specific to the **HKEY_CURRENT_USER** key; it is stored in the GPT\User subdirectory.

# Software Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Software Settings**

Software Settings are available under both User Configuration and Computer Configuration in the console tree of Group Policy Object Editor.

Computer Configuration\Software Settings is for software settings that apply to all users who log on to the computer. This folder contains the Software installation subitem, and it might contain other subitems that are placed there by independent software vendors.

User Configuration\Software Settings is for software settings that apply to users regardless of which computer they log on to. This folder also contains the Software installation subitem, and it might contain other subitems that are placed there by independent software vendors.

For more information about the Computer Configuration and User Configuration folders, see User Configuration and Computer Configuration. For more information about the Software installation subitem, see Group Policy Software Installation overview.

# Fast Logon Optimization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Fast Logon Optimization**

The Fast Logon Optimization feature is set by default for both domain and workgroup members. This results in the asynchronous application of policy when the computer starts up and when the user logs on. This application of policy is similar to a background refresh. It can reduce the length of time it takes for the logon dialog box to appear and the length of time it takes for the desktop to become available to the user.

You can change the default setting by using the Group Policy MMC snap-in. This feature is enabled by default, but you can disable it by using the following policy: Administrative Templates\System\Logon**Always wait for the network at computer startup and logon**.

Policies are processed according to the criteria listed in the following table.

| Default policy process for clients | At startup | At logon | At policy refresh |
|---|---|---|---|
| Windows 2000 | Sync | Sync | Async |
| Windows Server 2003 family | Sync | Sync | Async |
| Windows XP Professional and Windows XP 64-bit Edition (Itanium) | Async | Async | Async |

**Notes**

- Logon Optimization will not be enabled and policies will be processed synchronously when a user is logging on for the first time, the user has a roaming profile, the user has a HomeDir, and the user has a logon script specified in the User object. Folder Redirection and Group Policy Software Installation require a synchronous application of policy. Under these conditions, computer startup can still be asynchronous. However, since logon is synchronous, logon does not exhibit optimization.

- Client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems support Fast Logon Optimization in any domain environment.

# Windows Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Settings**

Windows Settings are available under both User Configuration and Computer Configuration in the console tree of Group Policy Object Editor.

Computer Configuration\Windows Settings is for windows settings that apply to all users who log on to the computer. It includes two subitems: Security Settings and Scripts.

User Configuration\Windows Settings is for windows settings that apply to users regardless of which computer they log on to. It includes three subitems: Folder Redirection, Security Settings, and Scripts.

For more information about the Computer Configuration and User Configuration folders, see User Configuration and Computer Configuration. For more information about the settings in the Windows Settings subitems, see Security Settings extension to Group Policy, Startup, shutdown, logon, and logoff scripts, and Folder Redirection.

# Folder Redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Folder Redirection**

In Group Policy Object Editor, you can use Folder Redirection to redirect certain special folders to network locations. Special folders are those folders, such as My Documents and My Pictures, that are located under Documents and Settings. Folder Redirection is located under User Configuration in the console tree of Group Policy Object Editor.

There are several basic options for Folder Redirection. For each basic option, there is an advanced version of that option. The advanced version provides for finer control by allowing redirection that is based on security group membership. For more information about specific procedures, see Use Folder Redirection. The following table describes the different folder redirection options that are available to you.

| Special folder | Notes |
|---|---|
| Application Data | A Group Policy setting controls the behavior of Application Data when client-side caching is enabled. Look in User Configuration\Administrative Templates\Network\Offline Files in the console tree of Group Policy Object Editor. |
| Desktop | Desktop can be redirected independently of all the other special folders. |
| My Documents | My Documents is the default location in the shell for users to save their documents and pictures. |
| My Documents\My Pictures | My Pictures can be redirected independently of My Documents, or it can be made to follow My Documents (to remain its subfolder whenever My Documents is redirected), as it does by default. The default behavior is recommended unless you have a specific reason (such as server scalability) for separating My Pictures from My Documents. If these folders are separated, a shortcut takes the place of the My Pictures folder in My Documents. |
| Start Menu | When Start Menu is redirected, its subfolders always follow. |

**Caution**

- When creating a shared folder redirection directory, limit access to only those users that need access. Redirected folders can contain personal information such as confidential documents and EFS certificates, care should be taken to protect access to the shared folder. Restrict access to the shared folder to only those users that need access. You can also create a security group for users that require permissions for a particular shared folder, and limit access to only those users.

  When creating the shared folder, hide it by putting a **$** after the share name. This hides the shared folder from casual browsers, and it will not be visible in My Network Places.

**Advantages of redirecting My Documents**

Some of the following benefits pertain to redirecting any folder, but redirecting My Documents can be particularly advantageous because this folder tends to become large over time.

- When roaming user profiles are used, only the network path to the My Documents folder is part of the roaming user profile, not the My Documents folder. Therefore, its contents do not have to be copied back and forth between the client computer and the server each time the user logs on or off, and the process of logging on or off can be much faster than it was in Windows NT 4.0.

- Even if a user logs on to various computers on the network, his or her documents are always available.

- Offline File technology gives users access to My Documents even when they are not connected to the network. This is particularly useful for people who use portable computers. For more information, see Make a file or folder available offline.

- Data that is stored in a shared network folder can be backed up as part of routine system administration. This is safer

because it requires no action on the part of the user.

- As an administrator, you can use Group Policy to set disk quotas, limiting the amount of space that is taken up by users' special folders.

- Data that is specific to a user can be redirected to a different hard disk on the user's local computer from the hard disk that holds the operating system files. This makes the user's data safer if the operating system is reinstalled.

For tips about using Folder Redirection, see Best practices for Folder Redirection.

**Granting exclusive rights to special folders**

The **Settings** tab in each folder's properties dialog box contains a check box labeled **Grant the user exclusive rights to My Documents**. If you select this check box, the user and the local system have full control over the folder, and no one else, not even the administrator, has any rights to it. If you clear this check box, no changes are made to the permissions on the folder. Whatever permissions are in effect by default remain in effect.

**Policy removal considerations with regard to Folder Redirection**

The following table summarizes what happens to redirected folders and their contents when the Group Policy object no longer applies.

| Move the contents of the special folder to the new location setting | Policy Removal option | Results when policy is removed |
|---|---|---|
| **Enabled** | **Redirect the folder back to the user profile location when policy is removed** | • The special folder returns to its user profile location.<br>• The contents are copied, not moved, back to the user profile location.<br>• The contents are not deleted from the redirected location.<br>• The user continues to have access to the contents, but only on the local computer. |
| **Disabled** | **Redirect the folder back to the user profile location when policy is removed** | • The special folder returns to its user profile location.<br>• The contents are not copied or moved to the user profile location.<br>**Caution**<br>• If the contents of a folder are not copied to the user profile location, the user cannot see them.<br>• |

| | | |
|---|---|---|
| Either **Enabled** or **Disabled** | **Leave the folder in the new location when policy is removed** | • The special folder remains at its redirected location.<br>• The contents remain at the redirected location.<br>• The user continues to have access to the contents at the redirected folder. |

**Folder Redirection and Offline Files**

The Offline Files technology applies to any mounted or mapped drive that contains documents or data that a user might want to use offline. Offline Files does not depend on Folder Redirection. It is set up and configured on shared network servers separately from the Folder Redirection snap-in. Offline Files enables the user to do useful work even when the user is not connected to the network, for example, on a portable computer or in the event of router failure. For more information, see Offline Files.

If you use redirected folders of any type, it is recommended that you set up Offline Files as described in the following table.

| Special Folder | Offline File configuration |
|---|---|
| My Documents | Autocaching for documents (or manual caching for documents, if you want users to have to manually make files and folders available for offline use) |
| My Pictures | Autocaching for documents (or manual caching for documents, if you want users to have to manually make files and folders available for offline use) |
| Application Data | Autocaching for programs |
| Desktop | Autocaching for programs if the desktop is Read Only |
| Start Menu | Autocaching for programs |

**Folder Redirection permissions**

This is an advanced topic. If you let Folder Redirection create folders for you, which is the recommended procedure, correct permissions are set automatically. Usually, knowledge of these permissions is not necessary. However, there are two reasons the permissions might be of interest:

- Sometimes, even though it is not recommended, administrators create the redirected folders before Folder Redirection creates them. The following table shows what permissions have to be set for Folder Redirection to work.
- Redirection of My Documents to the home directory provides more relaxed security than standard folder redirection. The following table shows what security is in effect in the standard case.

**NTFS permissions required for the root folder**

| User account | Folder Redirection defaults | Minimum permissions needed |
|---|---|---|
| Creator/owner | Full Control, this folder, subfolders, and files | Full Control, this folder, subfolders, and files |
| Administrators | No permissions | No permissions |
| Everyone | No permissions | No permissions |
| Local System | Full Control, this folder, subfolders, and files | Full Control, this folder, subfolders, and files |

| | | |
|---|---|---|
| Security group of users who need to put data on the shared network server | N/A | List Folder/Read Data, Create Folders/Append Data - **This folder only** |

**Share-level (SMB) permissions required for the root folder**

| User Account | Folder Redirection defaults | Minimum permissions needed |
|---|---|---|
| Everyone | Full Control | No permissions (Use security group) |
| Security group of users who need to put data on the shared network server | N/A | Full Control |

**NTFS permissions required for each user's redirected folder**

| User account | Folder Redirection defaults | Minimum permissions needed |
|---|---|---|
| *UserName* | Full Control, owner of folder | Full Control, owner of folder |
| Local System | Full Control | Full Control |
| Administrators | No permissions | No permissions |
| Everyone | No permissions | No permissions |

# Windows Management Instrumentation (WMI) Filters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation (WMI) Filters**

Group Policy provides policy setting information to the WMI Common Information Model (CIM)-compliant object repository (CIMON database). With WMI Filters, you can specify a WMI-based query to filter the effect of a Group Policy object in the CIMON database. WMI Filters can be written and customized using the WMI Query Language (WQL).

For more information, see WMI Overview.

# Startup, shutdown, logon, and logoff scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Startup, shutdown, logon, and logoff scripts**

Group Policy Object Editor includes two extensions for script deployment:

- **Scripts (Startup/Shutdown)--**You can use this extension, which is located under Computer Configuration\Windows Settings in the console tree of Group Policy Object Editor, to specify scripts that are to run when the computer starts up or shuts down. These scripts run as Local System.

- **Scripts (Logon/Logoff)--**You can use this extension, which is located under User Configuration\Windows Settings in the console tree of Group Policy Object Editor, to specify scripts that are to run when the user logs on or logs off the computer. These scripts run as User, not as Administrator.

For more information, see Use Startup, Shutdown, Logon, and Logoff Scripts.

The Windows Server 2003 family includes Windows Script Host, a language-independent scripting host for 32-bit Windows platforms that includes both Visual Basic Scripting Edition (.vbs) and JScript (.js) scripting engines. You can use Windows Script Host to run .vbs and .js scripts directly on the Windows desktop or in the command console, without the need to embed these scripts in an HTML document.

For more information about Windows Script Host, see Windows Script Host overview. To learn about Windows Script Host and the Object Model and to obtain script samples, see the "Windows Script" at the Microsoft Web site.

# Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy Software Installation**
This section covers:

- Group Policy Software Installation overview
- Managing Group Policy Software Installation
- Add or Remove Programs in Control Panel
- File types that you use with Group Policy Software Installation

# Group Policy Software Installation overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy Software Installation overview**

With Group Policy Software Installation, a software management feature, you can manage software throughout its life cycle within the organization. Group Policy Software Installation works in conjunction with Group Policy and Active Directory. It is one of three Group Policy Software Installation and Maintenance components, which are described in the following table.

| Component | Role |
|---|---|
| Group Policy Software Installation (an extension of Group Policy Object Editor) | Used by administrators to manage software |
| Windows Installer | Installs software that is packaged in Windows Installer files |
| Add or Remove Programs in Control Panel | Used by users to manage software on their own computers. For more information, see Add or Remove Programs in Control Panel. |

Group Policy Software Installation helps you specify how applications are installed and maintained within your organization. With Group Policy Software Installation, you can manage an application within a Group Policy object, which is in turn associated with a particular Active Directory container--either a site, a domain, or an organizational unit. Applications can be managed in one of two modes: assigned or published.

For tips about using Group Policy Software Installation, see Best practices for Group Policy Software Installation. To begin using Group Policy Software Installation right away, see Open Group Policy Software Installation. For more information, see Group Policy Software Installation.

**Assigning to users**

When you assign an application to a user, the application is advertised to the user the next time the user logs on to a workstation. The application advertisement follows the user, regardless of which physical computer he or she actually uses. The application is installed the first time that the user activates the application on the computer, either by selecting the application on the **Start** menu or by activating a document that is associated with the application. For more information, see Assign an application.

You assign an application when you want everyone to have the application on his or her computer. For example, suppose that you want all users in a marketing department to have Microsoft Excel on their computers. A Group Policy object manages every user in marketing. When you assign Excel within the marketing Group Policy object, Excel is advertised on every marketing user's computer. When an assigned application is advertised, it is not actually installed on the computer. In this case, the application advertisement installs only enough information about Excel to make the Excel shortcuts appear on the **Start** menu and to make the necessary file associations (.xls) appear in the registry.

When these users log on to their computers, Excel appears on their **Start** menu. When they select Excel on the **Start** menu for the first time, Excel installs. A user can also install an advertised application by opening a document that is associated with the application, either by file name extension or by COM-based activation. If a user who has not yet activated Excel from the **Start** menu clicks an Excel spreadsheet to open it, Excel installs and the spreadsheet opens.

A user can delete an assigned application, but the assigned application is advertised again the next time the user logs on. It installs the next time a user selects it on the **Start** menu.

**Assigning to computers**

When you assign an application to the computer, the application is advertised and the installation is performed when it is safe to do so. Typically, this happens when the computer starts up, so that there are no competing processes on the computer. For more information, see Assign an application.

**Publishing to users**

When you publish an application to users, the application does not appear as installed on the users' computers. No shortcuts are visible on the desktop or on the **Start** menu, and no changes are made to the local registry on the users' computers. Instead, published applications store their advertisement attributes in Active Directory. Information, such as the application's name and file associations, is exposed to the users in the Active Directory container. The application is then available for the user to install by using Add or Remove Programs in Control Panel or by clicking a file that is associated with the application,

such as an .xls file for Microsoft Excel. For more information, see Publish an application and Add or Remove Programs in Control Panel.

You publish an application when you want the application to be available to people who are managed by the Group Policy object, in case a user wants the application. With published applications, it is up to each person to decide whether or not to install the published application.

For example, if you publish Microsoft Image Composer to users who are managed by the marketing Group Policy object, and a marketing user wants to install Image Composer, the user can go to Add or Remove Programs in Control Panel and install the application. If users do not install Image Composer by using Add or Remove Programs, and if the .jpg file name extension for the image document is associated with Image Composer, Image Composer can be installed for users when they first open any .jpg document.

**Application assignment scripts**

Application assignment scripts are one of the file types that are often encountered in Group Policy Software Installation. For every published or assigned application in a particular Group Policy object, an application assignment script (.aas file) is generated and stored in that domain's Group Policy object. These script files contain the advertisement information about the application configuration. For more information, see File types that you use with Group Policy Software Installation.

**The user's view of software installation**

At the user's computer, system components--including Winlogon, the shell, object linking and embedding (OLE), the Lightweight Directory Access Protocol (LDAP) client, and the local registry--provide the user's view of software installation. Winlogon is the privileged agent that applies software installation policy. The shell and the OLE are enhanced to be Active Directory-aware and to communicate with Windows Installer to perform setup actions. The LDAP client provides the capability to search and query Active Directory.

By using Add or Remove Programs, users can browse for and install software from Active Directory in a managed environment or from local media (in a nonmanaged environment or, if policy permits, from local media in a managed environment).

# Managing Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Group Policy Software Installation**
Administrators generally complete the following phases to manage software for their organization: preparation, management, and removal. For tips about using Group Policy Software Installation, see Best practices for Group Policy Software Installation. For more general information, see Group Policy Software Installation overview.

**Preparation**
Before you can use Group Policy Software Installation, you should have a Windows Installer package (.msi) for the program that you want to install. The package is often supplied with the software. If a program does not have a Windows Installer package, you must generate one. Other utilities are available for repackaging a program that you plan to install. You can then use transforms to further customize a package. Transforms, which have the .mst extension, are sometimes called modifications. For more information, see Add or remove modifications for an application package and File types that you use with Group Policy Software Installation.

The next step is to create a shared network directory, called a software distribution point, that contains the packages (.msi files), any transforms (.mst files), and the program files and components. Administration is simpler if packages and program files are kept together, although this is not absolutely necessary. (Packages and transforms do have to be kept together.) As an administrator, you might also benefit from using distributed file systems to help manage these software distribution points.

Finally, verify that users can read from the software distribution point and write to the target of the installation, particularly if the program is written to a network file server.

### Note

- You can still deploy applications that do not have an .msi file by using a .zap setup file. For more information, see File types that you use with Group Policy Software Installation.

**Management**
You can use Group Policy Software Installation to manage programs within your organization. You can assign programs to either computers or users, or you can publish programs to users.

Program assignment and publishing to users have the following software life cycle phases:

- **Evaluation phase--**For evaluation purposes, you might want to have only a few users try out and evaluate the new program. During this phase, the old version of the program is the default version, and the majority of users are still using it. A new user installs the assigned or published version. This is often called a pilot. The pilot is a good time to experiment with Group Policy Software Installation options, such as assigning an application and publishing an application, which is less forceful. You can also try setting the autoinstall option for an application, so that the software is installed when the user attempts to open a file with an extension that you have associated with the application. You can also try the **Basic** or **Maximum** options for the installation user interface, which you can set by using the procedure Set Group Policy Software Installation defaults. These options control the level of visibility of the installation process to the user.

  For more information, see Assign an application, Publish an application, and Set the autoinstall option for an application.

- **Rollout phase--**During rollout, you begin making the new program available to more users. The new version of the program is now the default, and the majority of the users are using the new version. A new user only has the option to install the new program. You can leave certain users unaffected if upgrading them at this time would affect their work.

**Removal**
As an administrator, you must select one of the following options, which are mutually exclusive, when you remove a program:

- **Immediately uninstall--**This option requires that no one currently uses the program. Those users who still have the program on their computers receive an advertisement that removes the program.

- **Just prevent new installations--**This option allows users to continue using the software that they already have.

For more information, see Remove a managed application.

**Deletion from the server**

When you are sure that an old version of a program is no longer needed by the organization, you can delete the Windows Installer package and the program files and components. You might want to archive the package and the program files and components and then delete the files from the software distribution point.

# Add or Remove Programs in Control Panel

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Add or Remove Programs in Control Panel**
By using Add or Remove Programs in Control Panel, you can perform a number of tasks--primarily, the task of installing an application from local media, such as a CD-ROM or floppy disk; a defined Active Directory location, for an assigned and published application on a corporate network; or the Internet. You can also use Add or Remove Programs to remove or modify an existing application or to repair a damaged application.

Add or Remove Programs also offers the following features:

- Provides users with a single user interface for managing and maintaining their programs.
- Supports the installation of programs when a user has the program package (on local media), as well as installation from either a corporate or an Internet environment.
- Exposes the Windows Installer component while maintaining support for other installation technologies.

For more information, see Add or Remove Programs overview.

# File types that you use with Group Policy Software Installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File types that you use with Group Policy Software Installation**

You can use the file types listed in the following table with Group Policy Software Installation.

For more information about specific Group Policy Software Installation procedures, see Use Group Policy Software Installation. For general information about Group Policy Software Installation, see Group Policy Software Installation.

| File type | File name extension | Description |
|---|---|---|
| Windows Installer packages | .msi | Your software vendor typically provides these files to facilitate installation of a specific application. Keep these files with any other necessary files at the software distribution point for the software that you are managing. |
| Transforms | .mst | Also called modifications, these files customize the installation of a Windows Installer package at the time of assignment or publication. For example, they might specify a subset of a suite of applications. |
| Patches | .msp | Bug fixes, service packs, and similar files can be distributed in this form.<br><br>Patches should not be used for major changes, and their effects are limited in the following ways:<br><br>• They cannot remove components or features.<br><br>• They cannot change product codes.<br><br>• They cannot remove or change the names of shortcuts, files, or registry keys. |
| .zap files | .zap | These files are created with a text editor, such as Notepad. They can only be published (not assigned), and they specify a Setup executable program that appears in Add or Remove Programs in Control Panel for users with administrative rights on the local computer.<br><br>**Note**<br>The correct use of quotation marks in .zap file syntax can be difficult. The following rules apply:<br><br>• The path and name of the Setup executable program must always be wrapped in quotation marks.<br><br>• If there are no command-line arguments, they must be wrapped in two sets of quotation marks.<br><br>Example syntax using an absolute path:<br><br>**SetupCommand=""***ServerName******ShareName******FolderName***\setup.exe""**<br><br>**SetupCommand="***ServerName******ShareName******FolderName***\setup.exe" /***argument*<br><br>Example syntax using a relative path:<br><br>**SetupCommand=""setup.exe""**<br><br>**SetupCommand="setup.exe"/***argument* |

| | | |
|---|---|---|
| Application assignment scripts | .aas | These files contain instructions that are associated with the assignment or publication of a package. |

# Group Policy Precedence

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy precedence**
You can apply Active Directory-based Group Policy by linking Group Policy objects to Active Directory objects (sites, domains, or organizational units). Group Policy settings under User Configuration apply to users, and Group Policy settings under Computer Configuration apply to computers. The locations of the user and computer accounts in Active Directory determine what Group Policy objects are used to supply policy. Note that although some settings are user interface settings--for example, the background bitmap or the ability to use the **Run** command on the **Start** menu--they can also be applied to computers.

Group Policy is cumulative. Child directory service containers inherit policy from parent containers, and Group Policy processing occurs in the following order: local, site, domain, and then successive organizational units, from highest organizational unit (farthest from the user or computer account) to lowest organizational unit (actually containing the user or computer account). This means that if you link a Group Policy object to a high-level parent container (domain or organizational unit), this Group Policy object applies to all containers beneath the parent container, that is, to the user and computer objects in each container. However, if you explicitly enable or disable some Group Policy settings in another Group Policy object that is linked to a child container, the child container's Group Policy object settings override the parent container's Group Policy object settings.

You can enforce Group Policy on child directory containers by setting the **No Override** option on a Group Policy object link. You can also prevent inheritance of Group Policy from parent directory containers by using the **Block Policy inheritance** option on a domain or organizational unit.

**Important**

- **No Override** and **Block Policy inheritance** are advanced options, and they are not recommended for casual use, because they change the default behavior of policy inheritance, as described in the previous paragraph, and this can complicate troubleshooting.

**Note**

- In the event of a conflict, Group Policy settings take precedence over user profile settings.

This section covers:

- Order of events when starting up and logging on
- Order of processing settings
- The role of applications in Group Policy precedence

# Order of events when starting up and logging on

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Order of events when starting up and logging on**

The following sequence shows the order in which computer policy and user policy are applied when a computer starts and a user logs on:

1. Network starts. Remote procedure Call System Service (RPCSS) and Multiple Universal Naming Convention provider (MUP) start.

2. An ordered list of Group Policy objects is obtained for the computer. The list might depend on these factors:

   - Whether the computer is part of a domain and therefore subject to Group Policy through Active Directory.

   - The location of the computer in Active Directory.

   - Whether the list of Group Policy objects has changed. If the list of Group Policy objects has not changed, no processing is done. You can use a policy setting to change this behavior.

3. Computer policy is applied. These are the settings under Computer Configuration from the gathered list. This is synchronous by default and in the following order: local, site, domain, organizational unit, child organizational unit, and so on. No user interface appears while computer policies are processed.

   For details about the order in which settings are processed when user or computer policy is applied, see Order of processing settings.

4. Startup scripts run. This is hidden and synchronous by default; each script must complete or time out before the next one starts. The default time-out is 600 seconds. You can use several policy settings to modify this behavior.

5. The user presses CTRL-ALT-DEL to log on.

6. After the user is validated, the user profile loads; it is governed by the policy settings that are in effect.

7. An ordered list of Group Policy objects is obtained for the user. The list might depend on these factors:

   - Whether the user is part of a domain and therefore subject to Group Policy through Active Directory.

   - Whether loopback is enabled, and the state (**Merge** or **Replace**) of the loopback policy setting.

   - The location of the user in Active Directory.

   - Whether the list of Group Policy objects has changed. If the list of Group Policy objects has not changed, no processing is done. You can use a policy setting to change this behavior.

8. User policy is applied. These are the settings under User Configuration from the gathered list. This is synchronous by default and in the following order: local, site, domain, organizational unit, child organizational unit, and so on. No user interface appears while user policies are processed.

   For details about the order in which settings are processed when user or computer policy is applied, see Order of processing settings.

9. Logon scripts run. Unlike Windows NT 4.0 scripts, Group Policy-based logon scripts are hidden and asynchronous by

default. The user object script runs last in a normal window.

10. The operating system user interface that is prescribed by Group Policy appears.

**Important**

- Three special cases deserve consideration during migration:

    - If the computer account object is in a Windows NT 4.0 domain and the user account object is in Active Directory, only computer (not user) System Policy is processed when the user logs on. Then, user (not computer) Group Policy is processed.

    - If the computer account object is in Active Directory and the user account object is in a Windows NT 4.0 domain, computer (not user) Group Policy is processed during computer startup. When the user logs on, user (not computer) System Policy is processed.

    - If the computer and user accounts of the computer running Windows XP Professional or a Windows Server 2003 operating system are members of a Windows NT 4.0 domain, only System Policy (not Group Policy) for the computer and user is applied when the user logs on.

**Note**

- Several of these events can be modified. You can set policies to:

    - Reverse the synchronized or asynchronized defaults for running scripts and applying policy.

    - Specify when scripts time out. By default, scripts time out after 600 seconds.

    - Change whether scripts are run hidden, minimized, or in a normal window.

# Order of processing settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Order of processing settings**

This section provides details about the order in which Group Policy settings for users and computers are processed. For information about where the processing of policy settings fits into the framework of computer startup and user logon, see steps 3 and 8 in Order of events when starting up and logging on.

Group Policy settings are processed in the following order:

1. **Local Group Policy object--**Each computer has exactly one Group Policy object that is stored locally.

2. **Site--**Any Group Policy objects that have been linked to the site are processed next. Processing is synchronous and in an order that is specified by the administrator.

3. **Domain--**Processing of multiple domain-linked Group Policy objects is synchronous and in an order specified by the administrator.

4. **Organizational units--**Group Policy objects that are linked to the organizational unit that is highest in the Active Directory hierarchy are processed first, then Group Policy objects that are linked to its child organizational unit, and so on. Finally, the Group Policy objects that are linked to the organizational unit that contains the user or computer are processed.

   At the level of each organizational unit in the Active Directory hierarchy, one, many, or no Group Policy objects can be linked. If several Group Policy objects are linked to an organizational unit, their processing is synchronous and in an order that is specified by the administrator.

This order means that the local Group Policy object is processed first, and Group Policy objects that are linked to the organizational unit of which the computer or user is a direct member are processed last, which overwrites the earlier Group Policy objects.

**Exceptions to the default order**

The default order for processing settings is subject to the following exceptions:

- Any Group Policy object that is linked to a site, domain, or organizational unit (not a local Group Policy object) can be set to **No Override** with respect to that site, domain, or organizational unit, so that none of its policy settings can be overridden. When more than one Group Policy object has been set to **No Override**, the one that is highest in the Active Directory hierarchy (or higher in the hierarchy that is specified by the administrator at each fixed level in Active Directory) takes precedence.

  Note that **No Override** and **Disabled** are settings on Group Policy objects links, not on the Group Policy objects. A Group Policy object can be linked several times to the same organizational unit, and **No Override** and **Disabled** can be configured independently on each of the links. (Although multiple links from one Group Policy object to a single organizational unit are seldom useful, this capability illustrates the flexibility of the Group Policy infrastructure.)

  For information about how to set links as **No Override** and **Disabled**, see Prevent a Group Policy object from being overridden and Disable a Group Policy object link.

- At any site, domain, or organizational unit, you can mark Group Policy inheritance selectively as **Block Policy inheritance**. Group Policy object links that are set to **No Override** are always applied, however, and they cannot be blocked.

  The **Block Policy inheritance** setting is applied directly to the site, domain, or organizational unit. It is not applied to Group Policy objects, nor is it applied to Group Policy object links. **Block Policy inheritance** deflects all Group Policy settings that would reach the site, domain, or organizational unit from above (by way of links to parents in the Active Directory hierarchy), no matter what Group Policy objects those settings originate from. However, **Block Policy**

**inheritance** does not deflect Group Policy settings from Group Policy objects that are linked directly to the site, domain, or organizational unit that has **Block Policy inheritance** enabled.

- A computer that is a member of a workgroup processes only the local Group Policy object.

- Loopback is an advanced Group Policy setting that is useful on computers in certain closely managed environments, such as kiosks, laboratories, classrooms, and reception areas. For a description of loopback, click the **Explain** tab after you double-click **User Group Policy loopback processing mode** in the details pane of the Microsoft Management Console (MMC), which is located under Computer Configuration\Administrative Templates\System\Group Policy.

  Loopback provides alternatives to the default method of obtaining the ordered list of Group Policy objects whose User Configuration settings affect a user. By default, a user's settings come from a Group Policy object list that depends on the user's location in Active Directory. The ordered list goes from site-linked to domain-linked to organizational unit-linked Group Policy objects, with inheritance determined by the location of the user in Active Directory and in an order that is specified by the administrator at each level.

  Loopback can be set to **Not Configured**, **Enabled**, or **Disabled**, as can any other Group Policy setting. In the **Enabled** state, loopback can be set to **Merge** or **Replace**.

  - **Loopback with Replace--**In the case of **Loopback with Replace**, the Group Policy object list for the user is replaced in its entirety by the Group Policy object list that is already obtained for the computer at computer startup (during step 2 in Order of events when starting up and logging on). The User Configuration settings from this list are applied to the user.

  - **Loopback with Merge--**In the case of **Loopback with Merge**, the Group Policy object list is a concatenation. The default step 2 list for computers in Order of events when starting up and logging on is appended to the default step 7 list for users, and the user gets the User Configuration settings in the concatenated list. Note that the Group Policy object list that is obtained for the computer is applied later, and therefore it has precedence if it conflicts with settings in the user's list.

# The role of applications in Group Policy precedence

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The role of applications in Group Policy precedence**

The Group Policy infrastructure cannot force applications to use Group Policy. For example, applications that have always looked for registry entries in a particular place that is outside the approved registry trees that are reserved for Group Policy will continue to look there. Group Policy does not copy registry settings from the Group Policy areas to the Windows NT 4.0 System Policy areas, nor does it copy Windows NT 4.0 System Policy settings into the reserved Group Policy areas. For more information, see Windows NT 4.0 system policies and Migration Issues.

Guidelines for writing applications that take advantage of Group Policy are available in the Group Policy Platform SDK that is used by developers. For more information, see "Group Policy" at the Microsoft Web site. Administrators, who need to anticipate the behavior of applications that they do not author, should be aware of the steps taken by properly written applications to obtain the registry data that the applications need.

**Initial state of the registry**

After the computer starts and the user logs on, the Group Policy registry areas are rewritten to hold the cumulative Group Policy settings that are in effect from the local Group Policy object and from Active Directory. If Windows NT 4.0 System Policy is enabled (which is not recommended for client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems, or Windows 2000 clients), other registry areas might also change when the user logs on.

**Order of events**

1. The user starts the application.

2. A typical user-oriented application looks for registry data in the Group Policy reserved area **HKEY_LOCAL_MACHINE\Software\Policies**. If the application finds what it needs, it looks no further.

   However, an application that changes or replaces features at the level of the operating system (such as the **Run** command), and which therefore affects the behavior of applications other than itself, might look in the following Group Policy reserved area: **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies**. If the application finds what it needs, it looks no further.

3. The application looks for **HKEY_LOCAL_MACHINE** registry data outside the Group Policy reserved area, and if it finds what it needs, it looks no further.

4. The application looks for **HKEY_CURRENT_USER** registry data outside the Group Policy reserved area, and if it finds what it needs, it looks no further.

5. The application uses .ini files (not recommended) or default settings.

Newly authored, native Windows XP applications might perform only the first three steps. Applications that use Group Policy under Windows XP, but which remain compatible with earlier versions of Windows, continue to step 4 when they run on older operating systems. Applications that predate Windows 2000 never perform steps 2 and 3. Instead, they go directly to step 4.

The order of this sequence of events implies the following:

- For properly written applications that run on client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems, Group Policy takes precedence over Windows NT 4.0 System Policy. For more information, see Policy inheritance, Order of events when starting up and logging on, and Order of processing settings.

- Older versions of applications, which are not aware of Active Directory and Group Policy, continue to function in Windows XP Professional, Windows XP 64-bit Edition (Itanium), and the Windows Server 2003 family as they did under Windows NT 4.0.

- **HKEY_LOCAL_MACHINE** settings take precedence over **HKEY_CURRENT_USER** settings, as they did under Windows NT 4.0.

# Using Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Group Policy**
This section covers:

- Ways to open Group Policy Object Editor
- Local Group Policy
- Administrative Templates included with this version of Windows
- Advanced methods of extending Group Policy
- Group Policy Permissions
- Group Policy and Network Infrastructure
- Migration Issues
- Managing Group Policy from the command line

# Ways to open Group Policy Object Editor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ways to open Group Policy Object Editor**

You can open Group Policy Object Editor in several ways, depending on the action that you want to perform and the object to which you want to apply Group Policy. The following table lists the ways in which you can open Group Policy Object Editor.

| To apply Group Policy to | Do this |
|---|---|
| Local computer | In Group Policy Object Editor, edit the local Group Policy object, as described in Edit the local Group Policy object. |
| Another computer | Open the local Group Policy object that is stored on the network computer, as described in Open Group Policy as an MMC snap-in, and then browse to the network computer. You must have administrative rights on the network computer. |
| Site | Open Group Policy Object Editor, as described in Open Group Policy from Active Directory Sites and Services, and then link a Group Policy object to the intended site. |
| Domain | Open Group Policy Object Editor as described in Open Group Policy from Active Directory Users and Computers, and then link a Group Policy object to the intended domain. |
| Organizational unit | Open Group Policy Object Editor as described in Open Group Policy from Active Directory Users and Computers, and then link a Group Policy object to the intended organizational unit. You can also link a Group Policy object to an organizational unit that is higher in the Active Directory hierarchy, so that the organizational unit can inherit Group Policy settings. |
| Existing Group Policy object or set of Group Policy objects | Create and save your own custom Microsoft Management Console (MMC). For more information, see Microsoft Management Console. |

You can also open Group Policy Object Editor by clicking **Start**, clicking **Run**, and then typing a command. Or, you can open Group Policy Object Editor at the command prompt in an MS-DOS window. The following table contains some examples of how you might open Group Policy Object Editor from the command line in different situations.

| To edit | At a command line, use this command-line syntax |
|---|---|
| The local Group Policy object on *ThisComputerName* | **gpedit.msc /gpcomputer:"** *ThisComputerName* **"** |
| The local Group Policy object on *ThisComputerName* (specified in the DNS style) | **gpedit.msc /gpcomputer:"** *ThisComputerName.domain.com* **"** |
| Group Policy objects stored in Active Directory | **gpedit.msc /gpobject:"LDAP://CN={31B2F340-016D-11D2-945F-00C04FB984F9},CN=Policies,CN=System,DC=WingTipToys,DC=com"**<br><br>**Note**<br><br>• The GUID for the Group Policy object above is a fictitious example. |

For information about other Group Policy command-line tools, see Managing Group Policy from the command line.

# Local Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local Group Policy**

Each computer running Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), or a Windows Server 2003 operating system has exactly one local Group Policy object. In these objects, Group Policy settings are stored on individual computers, whether or not they are part of an Active Directory environment or a networked environment. For more information, see Security Settings extension to Group Policy, Folder Redirection, and Group Policy Software Installation overview.

Local Group Policy objects contain fewer settings than nonlocal Group Policy objects, particularly under Security Settings. Local Group Policy objects do not support Folder Redirection or Group Policy Software Installation.

Because its settings can be overwritten by Group Policy objects that are associated with sites, domains, and organizational units, the local Group Policy object is the least influential object in an Active Directory environment. In a non-networked environment (or in a networked environment that does not have a domain controller), the local Group Policy object's settings are more important, because they are not overwritten by other Group Policy objects.

To edit the local Group Policy object that is stored on your local computer, use the Group Policy Object Editor snap-in. For more information, see Edit the local Group Policy object.

If you want to edit the local Group Policy object that is stored on another computer on the network, open Group Policy as a stand-alone Microsoft Management Console (MMC) snap-in and browse to the Group Policy object that you want. For more information, see Open Group Policy as an MMC snap-in.

The local Group Policy object resides in *systemroot*\System32\GroupPolicy.

Computers that run Windows NT 4.0 or earlier do not have a local Group Policy object, and they do not recognize nonlocal Group Policy. For more information, see Migration Issues.

# Administrative Templates included with this version of Windows

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative Templates included with this version of Windows**

Five Administrative Templates (.adm) files are included with this version of Windows. The following table contains a brief description of each of the .adm files. For more information about .adm files, see Administrative Templates.

| Administrative Template | Description | Help for Administrative Templates policy settings |
|---|---|---|
| System.adm | System settings | System settings |
| Inetres.adm | Internet Explorer settings | Internet Explorer settings |
| Wmplayer.adm | Windows Media Player settings. This tool is not available on the Itanium-based versions of the Windows operating systems. This tool is not available on the x64-based versions of the Windows operating systems. | Windows Media Player settings |
| Conf.adm | NetMeeting settings. This tool is not available on the Itanium-based versions of the Windows operating systems. This tool is not available on the x64-based versions of the Windows operating systems. | NetMeeting settings |
| Wuau.adm | Windows Update settings. | Windows Update settings |

When you add an .adm file to Group Policy, as described in Add or remove an Administrative Template (.adm file), by default only the settings that are contained in the genuine Group Policy trees (the trees that correspond to the reserved Group Policy registry areas) are visible in the console.

If you want to change this default behavior and make not only Group Policy settings but also the older System Policy settings visible, see Filter the view provided by Administrative Templates. Clear the **Only show policy settings that can be fully managed** check box, as described in that procedure. Your ability to clear this check box in the **Filtering** dialog box is subject to the **Enforce Show Policies Only** Group Policy setting.

When you make preference settings appear in Group Policy Object Editor, the icons for these settings are colored red. The icons for true Group Policy settings are colored blue.

**Important**

- It is highly recommended that you do not use System Policy-type .adm files when you manage client computers running Windows 2000 Professional, Windows XP Professional, Windows XP 64-bit Edition (Itanium), or Windows Server 2003 operating systems because this can lead to undesirably persistent registry settings. For more information, see Migration Issues.

# Advanced methods of extending Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Advanced methods of extending Group Policy**
The following table lists advanced methods that you can use to extend Group Policy functionality.

| Method | Advantages | Disadvantages |
|---|---|---|
| For administrators only: Write an .adm file | • Easier than writing an extension to Group Policy.<br>• Everything you need is included in the Windows Server 2003 family.<br>• The .adm files are text files, which you can edit in Notepad.<br>• You can write from scratch or modify existing templates to suit your purpose. | • This option is only suitable for registry-based policies.<br>• The user interface is limited. Finding where to set individual policies might be difficult. |
| For software developers only: Write an extension to Group Policy | • Richer user interface.<br>• The full Group Policy application programming interface (API) is available to the developer.<br>• Not limited to registry-based policies. | • Because writing an extension takes considerable development time, this option is not worthwhile unless it will be used widely or often.<br>• Requires software development kit (SDK) material that is not included with the Windows Server 2003 family. |

**Creating custom .adm files**
You can consider creating custom .adm files if the supplied template, System.adm, is inadequate. However, it is recommended that you use the supplied template.

Administrative Templates propagate registry settings to a large number of computers without requiring you to have detailed knowledge of the registry. In the Windows Server 2003 family, Group Policy is used to set registry-based policies. In Windows NT 4.0, the System Policy Editor (Poledit.exe) was used to set System Policy.

For more information, see "Implementing Registry-based Policy" at the Microsoft Web site.

**Creating Microsoft Management Console extensions**
Developers can create extensions to Microsoft Management Console (MMC) snap-ins to provide program-specific user interfaces for setting Group Policy. For more information, see "Group Policy" at the Microsoft Web site and "MSDN Library" at the Microsoft Web site.

# Group Policy Permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy permissions**

If you want to delegate policy-related tasks to other people, including nonadministrators, see Delegate Control of Group Policy.

This section covers:

- Default permissions
- Policy for Microsoft Management Console

# Default permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Default permissions**

The following table describes the default permissions on Group Policy objects.

| Security group | Default settings |
|---|---|
| Authenticated users | Read, Apply Group Policy (AGP) |
| Local system | Full Control (includes AGP) |
| Domain administrators | Read, Write, Create Child, Delete Child, AGP |
| Administrators | Read, Write, Create Child, AGP |
| Group Policy Creator Owners | Read, Write, AGP |

By default, the Group Policy object Default Domain Policy cannot be deleted by any administrator. The purpose of this restriction is to prevent the accidental deletion of this Group Policy object, which contains important and required settings for the domain. If Default Domain Policy must be deleted for some reason, the Delete permission must be given explicitly to the intended group. This is an advanced access control entry (ACE) on the Group Policy object. For more information, see Set permissions for Group Policy Software Installation.

# Policy for Microsoft Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Policy for Microsoft Management Console**

There are several Group Policy settings in one of the default Administrative Templates files, System.adm, that govern the use of the Microsoft Management Console (MMC). You can delegate administrative rights by saving previously configured consoles. For more information, see Delegate Control of Group Policy. You can find MMC policy settings in Group Policy Object Editor. You can then double-click each item for which you want to set an administrative Group Policy setting that governs the use of that item in MMC.

For more information, see Microsoft Management Console, Group Policy Permissions, and Configure Group Policy.

# Group Policy and Network Infrastructure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy and network infrastructure**
This section covers:

- Group Policy features that are supported across forests
- Group Policy in multiplatform networks
- Group Policy in replicated environments
- Group Policy over slow links
- Group Policy on sites

# Group Policy features that are supported across forests

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy features that are supported across forests**

The Windows Server 2003 family introduces a powerful set of new features that enable you to authenticate and authorize access to resources from separate, networked forests. With full trusts established between forests, you can manage Group Policy throughout Active Directory regardless of the forest, which provides greater flexibility especially in large organizations. For more information about accessing resources across forests in Active Directory, see Accessing resources across forests. For more information on forest trusts, see Forest trusts.

Following is a list of the Group Policy features that are supported across forests:

- **Interactive logon**

  The following table lists the interactive logon tasks that are supported across forests.

| Task | Support across the domain? | Support across domains in the same forest? | Support interactive logon across forests? |
|---|---|---|---|
| Apply policy to a user object | Yes | Yes | Yes |
| Apply policy to a computer object | Yes | Yes | Yes |
| Support Group Policy loopback processing | Yes | Yes | Yes |

  For example, User1 is located in forestA and computer1 is located in forestB. User1 goes to forestB and logs into computer1. In this scenario, computer policy is applied to computer1 from forestB, user policy is applied to user1 on computer1 from forestA. Site policy might be applied depending on the subnet to which computer1 belongs.

  For interactive logon across forests with loopback processing, Group Policy objects with loopback enabled for merge or replace are applied across forests under the same logon model as specified for interactive logon. For more information about loopback, see Order of processing settings.

- **Network logon**

  The following Group Policy extensions are supported for network logon across forests:

  - Software distribution points located in another forest
  - Logon scripts on a shared network directory in another forest.
  - Roaming user profiles stored on a shared network directory in another forest. For more information, see Using roaming user profiles.
  - Redirected folders stored on a file share in another forest. For more information, see Folder Redirection.

- **Delegation**

  Delegation across forests is supported for managing Group Policy links. Other tasks such as creating, deleting, or modifying Group Policy objects across forests is not supported.

# Group Policy in multiplatform networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy in multiplatform networks**
Many networks include computers with different operating systems and versions. To allow administrators the greatest control, Group Policy and its extensions can be applied to computers running Windows 2000 Professional, Windows 2000 Server, Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems.

For client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems that are operating in networks with Windows 2000 Active Directory, the following features and limitations apply:

- **Fast Logon Optimization**

  The Windows Server 2003 family provides a Fast Logon Optimization feature. This results in the asynchronous application of policy when the computer starts up and when the user logs on. This feature is supported for client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems that are operating in any environment. This feature is not available to Windows 2000 clients. For more information, see Fast Logon Optimization.

- **Administrative Templates**

  The Windows Server 2003 family supports all registry policy settings available in Windows 2000. In addition, the Windows Server 2003 family has 212 new registry settings. These new policy settings only apply to client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems. If specified for Windows 2000 clients, the settings are ignored. You can deploy new .adm files provided with Windows XP Professional and Windows Server 2003 operating systems from Windows 2000 Active Directory. For more information, see Administrative Templates.

- **Folder Redirection**

  The Windows Server 2003 family contains a new Folder Redirection with a simplified user interface. You can configure folder redirection for client computers running Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems. With client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems, you can redirect folders to a HomeDir or redirect a folder back to a local profile. These options cannot be applied to Windows 2000 clients. For more information, see Folder Redirection.

- **Roaming User profiles**

  This feature contains new registry policy settings to prevent Roaming User profile changes from propagating to the server, allow only local user profiles, and add Administrators security group to Roaming User profiles. These features can only be applied to client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems. Users can roam between client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems and Windows 2000 clients, however, only policies that can be applied to each platform will be used. For more information, see Using roaming user profiles.

- **Security**

  With a software restriction policy, you can identify software on client computers and prevent it from running. Software can be identified by file name, path, URL, and MD5 Hash. This policy must be configured in a Group Policy object from the security settings snap-in from a client computer running Windows XP Professional, Windows XP 64-bit Edition (Itanium), or Windows Server 2003 operating systems. This feature is not supported for Windows 2000 clients. For more information, see Security Settings extension to Group Policy.

- **Group Policy Software Installation**

The Windows Server 2003 family contains numerous enhancements to the Group Policy Software Installation user interface. In addition, this version of Windows also support the deployment of 32-bit MSI applications to client computers running Windows XP 64-bit Edition (Itanium), 64-bit versions of Windows Server 2003, Enterprise Edition, and 64-bit versions of Windows Server 2003, Datacenter Edition. You cannot install 64-bit applications on 32-bit clients. Although Group Policy provides a robust solution for software installation and distribution, Microsoft Systems Management Server is the preferred solution for enterprise software planning, distribution, and management. For more information, see Group Policy Software Installation.

- **WMI filtering**

  With WMI Filters, you can specify a WMI-based query to filter the application of a Group Policy object. WMI Filters are written using WMI query language (WQL). WMI Filters only apply to client computers running Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems. WMI Filters associated with a Group Policy object will be ignored by Windows 2000 clients.

# Group Policy in replicated environments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy in replicated environments**

In a domain that contains more than one domain controller, Active Directory information takes time to propagate from one domain controller to another. This topic describes the replication mechanism as it relates to Group Policy.

By default, Group Policy objects are created or edited only on the domain controller that is holding the primary domain controller (PDC) emulator operations master token. This token moves from one domain controller to another over time, as Active Directory information is replicated to keep the domain controllers synchronized.

An organizational unit must be replicated to the domain controller that is holding the token before the Group Policy object that is created there can be linked to it, which allows the Group Policy settings to be applied. If you use Active Directory Users and Computers, you can create an organizational unit on any domain controller. These considerations are more significant if the intradomain links are slow. For more information, see Group Policy over slow links and Group Policy on sites.

**Options governing selection of a domain controller**

When you click the name of the Group Policy object in the console tree of Group Policy Object Editor, the **View** menu contains a command called **DC Options**. This command opens the **Options for domain controller selection** dialog box, where you can specify a domain controller to use for editing Group Policy. The options in this dialog box are as follows:

- **The one with the Operations Master token for the PDC emulator--**This is the default and preferred option, and it is the best option from the standpoint of data safety.

- **The one used by the Active Directory snap-ins--**This option uses the same domain controller as the utility from which the Group Policy Object Editor was invoked, if Group Policy was started this way.

- **Use any available domain controller--**This option allows Group Policy Object Editor to choose any available domain controller. This is the least safe option, because different administrators could theoretically edit a Group Policy object simultaneously, with an indeterminate outcome. On the other hand, when you use this option, it is likely that a domain controller in the local site will be selected. If only one administrator can administer Group Policy on a large domain with several sites, the performance gain might be worthwhile.

**Domain controller selection set through Group Policy**

In addition to the **DC Options** command, there is also a Group Policy setting for domain controller selection. This is part of the System.adm Administrative Template that is loaded into Group Policy Object Editor by default. You can find this Group Policy setting in Group Policy Object Editor under User Configuration\Administrative Templates\System\Group Policy. You can double-click **Group Policy domain controller selection** in the details pane, and then click the appropriate setting in the list.

# Group Policy over slow links

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy over slow links**

If the computer is a member of the domain that the Routing and Remote Access server belongs to or is trusted to, you can apply Group Policy remotely. This is true whether you are logging on through Routing and Remote Access or logging on with cached credentials, and then establishing a Routing and Remote Access connection.

Group Policy is not applied to computers that are members of a workgroup or of a foreign domain (a domain that does not contain the computer and that is not in a trust relationship with the computer's domain). Although the connection may still be made, access to domain resources may be adversely affected because of mismatched Internet Protocol security (IPSec).

By default, registry-based policies are always applied, and they cannot be turned off. Security settings are also applied by default, but all other settings are not applied. For all but the registry settings, the default behavior can be switched to apply or not apply.

A remote access connection is not necessarily a slow link, nor is a local area network (LAN) necessarily a fast link. By default, the fast or slow status of a link is based on a test ping to the server. If it takes less than 2000 milliseconds (two seconds), it is considered a fast link. If it takes more time, it is considered a slow link. You can set this value by using the Group Policy setting **Slow network connection time-out for user profiles**, which is located under Computer Configuration\Administrative Templates\System\User Profiles.

Several other Group Policy settings that are related to slow links appear in this folder as well. Also, check the Group Policy setting **Group Policy slow link detection**, which is located under Computer Configuration\Administrative Templates\System\Group Policy.

For more information, see Group Policy in replicated environments and Group Policy on sites. For a more information about slow link detection, see "Group Policy" at the Microsoft Web site.

# Group Policy on sites

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy on sites**

Group Policy objects that are applied to Active Directory site objects affect all computers in the site. Directory information is replicated and available among all the domain controllers in the site and to any domain controllers in sites for which a site link has been established. Therefore, any Group Policy object that is linked to a site is applied to all computers in that site, without regard to which domain (in the forest) contains the computers.

This allows multiple domains within a forest to receive the same Group Policy object (and included policies), although the Group Policy object exists only as a stored entity on a single domain and it must be read from that domain when the affected clients read their site-linked Group Policy.

If child domains are set up across wide area network (WAN) boundaries, the site setup should take this into account. If it does not, the computers in a child domain access a site-linked Group Policy object across a WAN link. This increases the processing time for Group Policy.

For more information, see Group Policy in replicated environments and Group Policy over slow links.

**Note**

- Group Policy is not usually applied to sites. It is usually applied to domains and organizational units. For more information, see Ways to open Group Policy Object Editor.

# Migration Issues

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Migration issues**
This section covers:

- Client operating systems
- The role of Administrative Templates
- The role of System Policy Editor
- Windows NT 4.0 system policies

# Client operating systems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Client operating systems**

This section describes several operating system issues regarding clients for policy.

- Windows Server 2003 family

  Group Policy fully supports client computers that run Windows Server 2003 operating systems. These servers can either be ordinary member servers of Active Directory or domain controllers. Group Policy fully supports both types of computers.

- Windows 2000 Server

  Computers that run Windows 2000 Server can either be ordinary member servers of Active Directory or domain controllers. Group Policy fully supports both types of computers.

- Windows XP Professional and Windows 2000 Professional

  Group Policy fully supports client computers that run Windows XP Professional, Windows XP 64-bit Edition (Itanium) and Windows 2000 Professional.

- Windows 95, Windows 98, and Windows Millennium Edition

  It is recommended that Windows 95, Windows 98 and Windows Millennium Edition clients run System Policy Editor (Poledit.exe) on the local computer. This ensures that the Config.pol file that is created is compatible with those operating systems. Copy the resultant Config.pol file to the SysVol folder of the domain controller. Group Policy does not apply.

- Windows NT 4.0 Workstation and Windows NT 4.0 Server

  These clients continue to be fully supported by Windows NT 4.0 System Policy. You can use System Policy Editor (Poledit.exe) to write Windows NT 4.0 .adm files. System Policy Editor can be obtained from a Windows NT 4.0 CD. Windows NT 4.0 does not use Active Directory. Because computers that run Windows NT 4.0 do not have local Group Policy objects, Group Policy does not apply. For more information, see Local Group Policy.

- Windows XP Home Edition, Windows NT 3.51, Windows 3.1, and MS-DOS

  Group Policy does not apply to these operating systems.

# The role of Administrative Templates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The role of Administrative Templates**
In the Windows Server 2003 family, Administrative Templates use the .adm file name extension, as they did in Windows NT 4.0. However, their role is slightly different.

**Role in earlier versions of Windows**
In earlier versions of Windows, Administrative Templates were ANSI-encoded text files. They created a namespace within System Policy Editor for convenient editing of the registry. Administrative Templates provided a friendlier user interface than the Registry Editor (Regedit.exe). They also added a degree of safety by exposing only the registry keys that are explicitly mentioned in the .adm file.

**Role in the Windows Server 2003 family**
The Windows Server 2003 family of products include several .adm files, which are listed in Administrative Templates included with this version of Windows. You can also write additional .adm files. The new version of the .adm language is a superset of the previous version--older templates can create a user interface in Group Policy, but new templates cannot create a user interface in System Policy Editor. For more information on the new .adm language, see "Implementing Registry-based Policy" at the Microsoft Web site.

The Windows Server 2003 family supports Unicode-based .adm files.

For information about using Windows NT 4.0 .adm files in a Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), or Windows Server 2003 family environment, see Windows NT 4.0 system policies.

# The role of System Policy Editor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The role of System Policy Editor**

Although System Policy Editor (Poledit.exe) is mostly replaced by Group Policy, it is still useful under some circumstances. If you are upgrading from earlier versions of Windows, see Migration Issues.

- **Management of computers that run Windows 95 or Windows 98--**System Policy Editor must be run locally on computers that run Windows 98 or Windows 95 to create Config.pol files that are compatible with the local operating system.

- **Management of computers that run Windows NT 4.0 Workstation and Windows NT 4.0 Server--**These computers also need their own .pol file: NTconfig.pol.

- **Management of stand-alone computers--**A Windows 2000 computer that is not joined to any domain is not subject to nonlocal Group Policy through Active Directory. The only Group Policy that applies to such a computer is local Group Policy, which contains settings for all users of that computer. For more information on local Group Policy, see Local Group Policy. To provide settings for multiple users, use System Policy Editor to write a Registry.pol file. Only the Windows 2000 version of System Policy Editor is compatible with Windows 2000.

Although earlier versions of System Policy Editor worked only with ASCII-encoded .adm files, the Windows 2000 version also supports Unicode-encoded .adm files.

For client computers running Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), and Windows Server 2003 operating systems, use Group Policy instead. For tips about using Group Policy, see Group Policy Best Practices (pre-GPMC).

# Windows NT 4.0 system policies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows NT 4.0 system policies**
If a Windows NT 4.0 client computer is upgraded to Windows XP Professional, Windows XP 64-bit Edition (Itanium), or a Windows Server 2003 operating system, the computer receives only Computer Configuration Group Policy, not Windows NT 4.0 computer System Policy. The policy that is received by the user who logs on is User Configuration Group Policy, if the user account is in Active Directory. If the user account is managed by a Windows NT 4.0 domain controller, the user receives Windows NT 4.0 user System Policy. For more information, see Computer Configuration and User Configuration.

Policies that are included with Windows 2000, Windows XP Professional, Windows XP 64-bit Edition (Itanium), and the Windows Server 2003 family set registry keys and values only in one of these four reserved trees:

- **HKEY_LOCAL_MACHINE\Software\Policies**
- **HKEY_CURRENT_USER\Software\Policies**
- **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies**
- **HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Policies**

The first two trees are preferred. All four trees are secure, and they cannot be modified by a user who is not an administrator. When Group Policy changes for any reason, these trees are wiped clean and the new policies are rewritten. Windows NT 4.0 policies do not respect these special trees, and they can write to any part of the registry. After such a policy is applied, it persists until the value is intentionally reversed, either by a counteracting Windows NT 4.0 policy or by editing the registry.

**Caution**

- It is possible, using the procedure to add or remove an Administrative Template (.adm file), for Administrative Templates to be added to Group Policy that set registry values outside the approved Group Policy trees, although the Windows Server 2003 family does not include any such .adm file. Choosing to install Windows NT 4.0 .adm files can lead to undesirable persistent registry settings. For more information, see Administrative Templates and Add or remove an Administrative Template (.adm file).

  If you must use the procedure in this manner, see the information about the **Only show policy settings that can be fully managed** check box in Filter the view provided by Administrative Templates and the information about the **Enforce Show Policies Only** Group Policy setting in Add or remove an Administrative Template (.adm file).

# Managing Group Policy from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Group Policy from the command line**
In addition to using Group Policy Object Editor, you can use command-line tools to manage Group Policy. For example, you can use **gpresult** to see what policy is in effect and to troubleshoot problems. You can use **gpupdate** to refresh policy immediately and to specify certain options at the command line.

For more information about Group Policy command-line tools, see the following:

- Gpresult
- Gpupdate

### Notes

- **Gpupdate** replaces the Windows 2000 command **secedit /refreshpolicy**.
- To start Group Policy Object Editor from the command line, see Ways to open Group Policy Object Editor.

# Group Policy Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

**Important**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

For more information about Group Policy, see the Microsoft Group Policy home page on the Microsoft Web site.

**Related Windows tools and online Help topics**

You can use the following tools with Group Policy:

- **IntelliMirror--**IntelliMirror is a set of powerful features for change and configuration management. IntelliMirror ensures that users' data, software, and personal settings are available when they move from one computer to another, and persist when their computers are connected to the network. IntelliMirror features are a subset of Group Policy, which in turn requires the Active Directory directory service. Not all of the tools associated with IntelliMirror technologies are available on all versions of Windows. Of those tools that are available on computers running Windows Server 2003 operating systems, not all of them are appropriate for managing Windows computers. For more information, see IntelliMirror and Help for specific tools.

- **Resultant Set of Policy (RSoP)--**Resultant Set of Policy (RSoP) is an addition to Group Policy that makes it easier to implement and troubleshoot policy. RSoP is a query engine that polls existing policies--and also planned policies--and then reports the results of those queries. It polls existing policies based on site, domain, domain controller, and organizational unit. RSoP gathers this information from the CIMOM database (commonly referred to as "WMI"). For more information, see Resultant Set of Policy.

- **User profiles--**On computers running Windows Server 2003 operating systems, user profiles automatically create and maintain the desktop settings for each user's work environment on the local computer. A user profile is created for each individual user when logging on to a computer for the first time. You set a profile path from the **Profile** tab of a User object in Active Directory. For more information, see User Profiles.

- **Windows Installer--**Windows Installer is an integral part of IntelliMirror, and a core component of the Windows Group Policy-based change and configuration management technology. By using the IntelliMirror technologies, Group Policy, and change and configuration management, you can approve certain applications, specifying that all configuration operations on those applications (installation, removal, and repair) run as the local system account. For more information, see Windows Installer.

# Troubleshooting Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**

An important part of troubleshooting Group Policy problems is to consider dependencies between components. For example, Group Policy Software Installation relies on Group Policy, and Group Policy relies on Active Directory. Active Directory relies on proper configuration of network services. When trying to fix problems that appear in one component, it is generally helpful to check whether components, services, and resources on which the component relies are working correctly. Event logs are useful for tracking problems that are caused by this type of hierarchical dependency.

What problem are you having?

- I need to know what policy settings are in effect.
- I want to refresh policy.
- I want to check basic network connectivity.
- I want to enable logging.
- I need help with the individual Group Policy settings that are included in Administrative Templates.
- I cannot open a Group Policy object in Group Policy Object Editor even though I have Read access to it.
- When I try to edit a Group Policy object, I get the "Failed to open the Group Policy object" error.
- When I try to edit a Group Policy object, I get the "Missing Active Directory Container" error.
- When I try to edit a Group Policy object, I get the "Snap-in failed to initialize" error.
- Group Policy is not being applied to users and computers in a security group that contains those users and computers, even though a Group Policy object is linked to an organizational unit that contains that security group.
- Group Policy is not affecting users and computers in a site, domain, or organizational unit.
- Group Policy is not affecting users and computers in an Active Directory container.
- Group Policy is not taking effect on the local computer.
- Software that you assigned to a computer is not available on the computer.
- Software that you assigned or published to a user is not available on the user's computer.
- Published applications do not appear in Add or Remove Programs in Control Panel.
- Document activation of a published application does not cause the application to install.
- The user receives an error message such as "The feature you are trying to install cannot be found in the source directory."
- The user receives an error message such as "This product is not installed" or "Feature ID not registered."
- After removal of an application, the shortcuts for the application continue to appear on the user's desktop.
- A user receives an error message such as "Another installation is already in progress."

- The user opens an already installed application, and Windows Installer starts.
- A user receives error messages such as "Active Directory will not allow the package to be deployed" or "Cannot prepare package for deployment."
- When I click one of the Group Policy Software Installation icons in the console tree of Group Policy Object Editor, I get the error message "Snap-in failed to initialize."
- I accidentally deleted default Group Policy objects.
- I accidentally deleted the domain controllers Sysvol directory or parts of the Sysvol directory that contain default Group Policy objects.
- I configured policies and I am now being denied access.

**I need to know what policy settings are in effect.**
**Solution:** To see what policy is in effect, use Resultant Set of Policy (RSoP) or **gpresult**.

You can also get a report on policy from Help and Support Center by following these steps:

1. Click the **Start** button, and then click **Help and Support**.
2. Click **Support**.
3. Under **See Also**, click **Advanced System Information**.
4. Under **Advanced System Information**, click **View Group Policy settings applied**.

The report includes the following:

- User name and domain
- Computer name and domain
- When User Settings and Computer Settings were last applied
- Folder redirection details
- Logon, logoff, startup and shutdown scripts
- Installed software
- Administrative Templates
- Security Settings
- Connection and proxy settings for IE Maintenance

**See also:** Resultant Set of Policy; Gpresult

**I want to refresh policy.**
**Solution:** Use **gpupdate** to refresh policy immediately. With **Gpupdate** you can specify certain options at the command line. **Gpupdate** replaces and improves on the Windows 2000 command **secedit /refreshpolicy**. Some policy items, such as computer-assigned software, require a reboot to take effect, however. User-assigned software requires the user to log on and log off.

**See also:** Gpupdate; Refresh Group Policy immediately

**I want to check basic network connectivity.**
**Solution:** Try to ping a domain controller.

Verify that DNS is working properly.

**See also:** Ping; DNS; About Network Connections; Configure a connection to a remote network; Using local area connections; Test a TCP/IP configuration by using the ping command

**I want to enable logging.**
**Solution:** Set a registry key that causes Group Policy diagnostic logging to be written to a file named Userenv.log on the client computer.

You can also set a registry key that enables verbose logging to the event log so that you can see it with Event Viewer.

**See also:** Registry Editor; Event Viewer; "Monitoring Group Policy with Log Files" and "Verbose Logging to Event Log" sections in "Troubleshooting Group Policy" at the Microsoft Web site

**I need help with the individual Group Policy settings that are included in Administrative Templates.**
**Solution:** This information is included in Help.

**See also:** Administrative Templates included with this version of Windows

**I cannot open a Group Policy object in Group Policy Object Editor even though I have Read access to it.**
**Cause:** As an administrator, you must have Full Control of the Group Policy object to open it in Group Policy Object Editor.

**Solution:** Verify that you are a member of a security group with Full Control on the Group Policy object. For example, a domain administrator can manage Active Directory-based Group Policy. An administrator on a computer can edit the local Group Policy object on that computer.

**When I try to edit a Group Policy object, I get the "Failed to open the Group Policy object" error.**
**Cause:** This usually is due to a networking problem, specifically, a problem with the domain name system (DNS) configuration.

**Solution:** Verify that DNS is working properly.

**See also:** DNS

**When I try to edit a Group Policy object, I get the "Missing Active Directory Container" error.**
**Cause:** This is caused by Group Policy attempting to link a Group Policy object to an organizational unit that it cannot find. The organizational unit might be deleted, or it might be created on another domain controller but not replicated to the domain controller that you are using.

**Solution:** Limit the number of administrators who can make structural changes to Active Directory, or who can edit a Group Policy object, at any one time. Allow changes to replicate before making changes that affect the same organizational unit or Group Policy object.

**When I try to edit a Group Policy object, I get the "Snap-in failed to initialize" error.**
**Cause:** This may be happen if Group Policy cannot find framedyn.dll.

**Solution:** If you use installation scripts, verify that your scripts place the *systemroot*\system32\wbem directory in the system path. By default, *systemroot*\system32\wbem is in the system path already; therefore, you are not likely to encounter this issue if you do not use installation scripts.

**Group Policy is not being applied to users and computers in a security group that contains those users and computers, even though a Group Policy object is linked to an organizational unit that contains that security group.**
**Cause:** This is correct behavior. Group Policy affects only the users and computers that are contained in sites, domains, and organizational units. Group Policy objects are not applied to security groups.

**Solution:** Link Group Policy objects to sites, domains, and organizational units only. The location of a security group in Active Directory is unrelated to whether Group Policy applies to the users and computers in that security group.

**See also:** Filter the scope of Group Policy according to security group membership

**Group Policy is not affecting users and computers in a site, domain, or organizational unit.**
**Cause:** Group Policy settings can be prevented, intentionally or inadvertently, from affecting users and computers in several ways. A Group Policy object can be disabled so that it does not affect users, computers, or both. It also must be linked directly to an organizational unit that contains the users and computers, or it must be linked to a parent domain or organizational unit,

so that the Group Policy settings apply through inheritance.

When multiple Group Policy objects apply, they are processed in this order: local, site, domain, organizational unit. By default, settings that are applied later have precedence. In addition, Group Policy can be blocked at the level of any organizational unit, or it can be enforced through a setting of **No Override** that is applied to a particular Group Policy object link.

Finally, the user or computer must belong to one or more security groups that have the appropriate permissions set.

**Solution:** Do the following:

- Verify that the intended policy is not being blocked.
- Verify that no overriding policy that is set at a higher level of Active Directory has been set to **No Override**.
- If **Block** and **No Override** are both used, **No Override** takes precedence.
- Verify that the user or computer is not a member of any security group for which the Apply Group Policy access control entry (ACE) is set to **Deny**.
- Verify that the user or computer is a member of at least one security group for which the Apply Group Policy access control entry (ACE) is set to **Allow**.
- Verify that the user or computer is a member of at least one security group for which the Read access control entry (ACE) is set to **Allow**.

**See also:** Policy inheritance; Filter the scope of Group Policy according to security group membership

**Group Policy is not affecting users and computers in an Active Directory container.**
**Cause:** Group Policy objects cannot be linked to Active Directory containers other than sites, domains, and organizational units.

**Solution:** Link a Group Policy object to an organizational unit that is a parent to the Active Directory container. Then, by default, those settings are applied to the users and computers in the container through inheritance.

**See also:** Filter the scope of Group Policy according to security group membership

**Group Policy is not taking effect on the local computer.**
**Cause:** Local policies are the weakest. Any Active Directory-based policy can overwrite them.

**Solution:** Check to see what Group Policy objects are being applied through Active Directory and if those Group Policy objects have settings that are in conflict with the local settings.

**Software that you assigned to a computer is not available on the computer.**
**Cause:** The client computer has not been restarted.

**Solution:** Restart the client computer.

**Software that you assigned or published to a user is not available on the user's computer.**
**Cause:** The user has not logged off and then logged on.

**Solution:** Have the user log off and then log on.

**Published applications do not appear in Add or Remove Programs in Control Panel.**
**Cause:** Several causes are possible:

- Group Policy is not applied.
- Active Directory cannot be accessed.
- Users do not have any published applications in the Group Policy objects that apply to them.
- The client is running Terminal Server.

**Solution:** Investigate each possibility in turn. Note that Group Policy Software Installation is not supported for Terminal Server clients.

**Document activation of a published application does not cause the application to install.**
**Cause:** As an administrator, you did not set autoinstall.

**Solution:** Set autoinstall.

**See also:** Set the autoinstall option for an application

**The user receives an error message such as "The feature you are trying to install cannot be found in the source directory."**
**Cause:** This could be caused by network or permissions problems.

**Solution:** Verify that the network is working correctly.

**See also:** Set permissions for Group Policy Software Installation

**The user receives an error message such as "This product is not installed" or "Feature ID not registered."**
**Cause:** This could be caused by a user with a roaming user profile logging on to two computers simultaneously, which is an unsupported use of roaming user profiles.

**Solution:** Have the user log off one computer before logging on to another. That way, the application shortcuts will be updated and valid on the second computer, and they will not give error messages.

**After removal of an application, the shortcuts for the application continue to appear on the user's desktop.**
**Cause:** The user has created shortcuts, and Windows Installer does not recognize them.

**Solution:** The user must remove the shortcuts manually.

**A user receives an error message such as "Another installation is already in progress."**
**Cause:** An uninstallation might be taking place in the background, with no user interface presented to the user, or perhaps the user has inadvertently triggered two installations simultaneously, which is not supported.

**Solution:** The user can try again later.

**The user opens an already installed application, and Windows Installer starts.**
**Cause:** An application might be undergoing automatic repair, or a user-required feature is being added.

**Solution:** No action is required.

**A user receives error messages such as "Active Directory will not allow the package to be deployed" or "Cannot prepare package for deployment."**
**Cause:** The package might be corrupted, or there might be a networking problem.

**Solution:** Use an uncorrupted package. Investigate the possibility of network problems and take appropriate action.

**When I click one of the Group Policy Software Installation icons in the console tree of Group Policy Object Editor, I get the error message "Snap-in failed to initialize."**
**Cause:** This may be happen if Group Policy Software Installation cannot find framedyn.dll.

**Solution:** If you use installation scripts, verify that your scripts place the *systemroot*\system32\wbem directory in the system path. By default, *systemroot*\system32\wbem is in the system path already; therefore, you are not likely to encounter this issue if you do not use installation scripts.

**I accidentally deleted default Group Policy objects.**
**Cause:** This can happen when you delete Group Policy objects from Active Directory Users and Computers.

**Solution:** Use **dcgpofix** to restore default Group Policy objects to their original state.

**See also:** Dcgpofix

**I accidentally deleted the domain controllers Sysvol directory or parts of the Sysvol directory that contain default Group Policy objects.**
**Cause:** This can happen when you delete directories from the system root.

**Solution:** Restore the Sysvol directory. Use the Dcgpofix command-line tool to restore default Group Policy objects to their original state. It is very important to backup the Sysvol directory with a regularly scheduled backup procedure.

**See also:** Dcgpofix

**I configured policies and I am now being denied access.**

**Cause:** This can happen in default Group Policy objects when setting File system security policy on the Sysvol directory or setting excessive security for domain administrator policies.

**Solution:** Logon as Administrator and use the Dcgpofix command-line tool to restore default domain and domain controller Group Policy objects to their original state.

**See also:** Dcgpofix

# Group Policy Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy Management**
The Group Policy Management Console snap-in provides a single user interface through which to manage Group Policy across an enterprise. The Group Policy Management Console consists of a Microsoft Management Console (MMC) snap-in and a set of scriptable interfaces for managing Group Policy.

- Before you use Group Policy Management Console, see Checklist: Using the Group Policy Management Console.
- To find ways to perform common tasks using Group Policy Management Console, see New ways to do familiar tasks using GPMC.
- For help with specific tasks, see GPMC How To....
- For general background information, see GPMC Concepts.

# Checklist: Using the Group Policy Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Using the Group Policy Management Console**

This section shows recommended steps to start using Group Policy Management Console (GPMC).

| Step | Reference |
|---|---|
| Check system requirements for GPMC | You need Windows Server 2003 or Windows XP Professional Service Pack 1 (SP1) to install GPMC. Some features require a Windows Server 2003 domain controller. For details, see Deployment considerations for Group Policy. |
| Install GPMC | Follow the GPMC installation instructions from the Microsoft Web site or installation media where you obtained the installer package (GPMC.msi). Run GPMC.msi, read and accept the End User License Agreement (EULA), and finish the installation. |
| Check for last-minute issues | Consult the release notes that were installed with GPMC, in the **%systemroot%\Program Files\GPMC** folder. |
| Start GPMC | Open GPMC. For step-by-step instructions, see Start Group Policy Management Console. |

# New ways to do familiar tasks using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common Group Policy tasks. Using Group Policy Management Console (GPMC), the procedures for performing these tasks are different from the way you performed these tasks in the past, without the Group Policy Management snap-in. Previously Administrators used Active Directory Users and Computers and Active Directory Sites and Services to manage Group Policy. Now you use GPMC to perform all Group Policy-related tasks.

| If you want to | On a computer without GPMC | With Group Policy Management snap-in |
|---|---|---|
| Create a Group Policy object (GPO) and a link to it | On the **Group Policy** tab for a site, domain, or organizational unit, click **New**. | In GPMC, right-click the relevant site, domain, or organizational unit and then click **Create and link a GPO here**. For more information, see Create or delete a Group Policy object and Link a Group Policy object using GPMC. |
| Create an unlinked GPO | Navigate to the **Group Policy** properties tab for a site, domain, or organizational unit, click **Add**. On the **All** tab, right-click, and then click **New**. | In GPMC, navigate to **Group Policy Objects**, right-click it, and then click **New**. For more information, see Create or delete a Group Policy object. |
| Edit a GPO | Navigate to the **Group Policy** properties tab for a site, domain, or organizational unit, select the GPO, and then click **Edit**. This opens Group Policy Object Editor. | In GPMC, navigate to **Group Policy Objects**, right-click the GPO, and then click **Edit**. For more information, see Edit a Group Policy object from GPMC.<br>**Note**<br>• Group Policy Object Editor MMC snap-in is still used to edit GPOs and is opened when you click **Edit** in GPMC. |
| Link an existing GPO to a site, domain, or organizational unit | Navigate to the **Group Policy** properties tab for a site, domain, or organizational unit, click **Add**, and then select a GPO. | In GPMC, navigate to a site, domain, or organizational unit, right-click it, and then click **Link an existing GPO here**. For more information, see Link a Group Policy object using GPMC. |
| Use security groups to filter the scope of policy | Edit the access control entry (ACE) permission option for **Apply Group Policy** on the **Security** tab in the **Properties** dialog box for the GPO. | In GPMC, click a GPO or GPO Link, select the **Scope** tab, and then use the **Add** and **Remove** buttons to control the groups, users, and computers on which the GPO applies. For more information, see Filter using security groups. |
| Delegate permissions on GPOs | Navigate to the properties of a GPO, click **Permissions for Authenticated Users**, and select the check boxes that correspond to the permissions you want to give. | In GPMC, click the GPO, click the **Delegation** tab, and then click the **Add** or **Remove buttons**. For more information, see Delegate Group Policy tasks. |
| Determine Resultant Set of Policy with Group Policy Results (logging mode) | In Resultant Set of Policy snap-in, right-click **Resultant Set of Policy**, and then click **Generate RSoP Data**. Select **Logging Mode** in the Resultant Set of Policy Wizard. | In GPMC, right-click **Group Policy Results**, and then click **Group Policy Results Wizard**. For more information, see Determine Resultant Set of Policy with Group Policy Results. |
| Simulate Resultant Set of Policy using Group Policy Modeling | In Resultant Set of Policy snap-in, right-click **Resultant Set of Policy**, and then click **Generate RSoP Data**. Select **Planning Mode** in the Resultant Set of Policy Wizard. | In GPMC, right-click **Group Policy Modeling**, and then click **Group Policy Modeling Wizard.** For more information, see Simulate Resultant Set of Policy using Group Policy Modeling. |

| | | |
|---|---|---|
| Add a WMI filter | Navigate to the Properties of a Group Policy object, and click the **WMI Filter** tab. | In GPMC, right-click **WMI Filters** and click **New**. For more information, see Create, import, export, copy, and paste WMI filters. |

# GPMC How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Start Group Policy Management Console
- Create or delete a Group Policy object
- Edit a Group Policy object from GPMC
- Add a forest, site, or domain to the Group Policy Management Console
- Search for a Group Policy object
- Specify a domain controller
- View, print, and save a report of Group Policy object settings
- Determine Resultant Set of Policy with Group Policy Results
- Simulate Resultant Set of Policy using Group Policy Modeling
- Set Group Policy Management Console user interface options
- Back Up, Restore, Copy, and Import
- Control Group Policy Object Scope
- Delegate Group Policy tasks
- Use Script and Command Line Methods

# Start Group Policy Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Group Policy Management console**

- To open Group Policy Management, click **Start,** click **Control Panel,** click **Administrative Tools,** and then click **Group Policy Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create or delete a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create or delete a Group Policy object**

1. Open Group Policy Management.
2. Depending upon whether you want to create or delete, use one of the following procedures:
   - Create
   - Create and link
   - Delete

**Create**

1. In the console tree, right-click **Group Policy Objects** in the forest and domain in which you want to create a Group Policy object (GPO).

   **Where?**

   *Forest name*/Domains/*Domain name*/Group Policy Objects

2. Click **New**.
3. In the **New GPO** dialog box, specify a name for the new GPO, and then click **OK**.

**Create and link**

1. In the console tree, right-click the *domain name* in the forest in which you want to create and link a Group Policy object (GPO).

   **Where?**

   *Forest name*/Domains/*Domain name*

2. Click **Create and Link a GPO Here**.
3. In the **New GPO** dialog box, specify a name for the new GPO, and then click **OK**.

**Delete**

1. In the console tree, double-click **Group Policy Objects** in the forest and domain containing the Group Policy object (GPO) that you want to delete.

   **Where?**

   *Forest name*/Domains/*Domain name*/Group Policy Objects

2. Right-click the GPO, and then click **Delete**.
3. When prompted to confirm the deletion, click **OK**.

**Notes**

- To create a GPO, you must have GPO creation privileges. By default only domain administrators, enterprise administrators, and members of the Group Policy creator owners group can create Group Policy objects. To delegate GPO creation permissions to additional groups and users, go to **Group Policy Objects** in the desired domain and click the Delegation tab.

- To delete a GPO, you must have **Edit Settings**, **Delete**, **Modify Security** permissions for the GPO.

- When you use this procedure to create a GPO, no links are created to the GPO, but you can add links within the same forest by right-clicking any domain, site, or organizational unit, and then clicking **Link Existing GPO**. Alternatively, you can both create and link a GPO by right-clicking any domain or organizational unit and then clicking **Create and Link a GPO Here**.

- When you delete a GPO, Group Policy Management attempts to delete all links to that GPO in the domain of the GPO. However, to delete a link to a GPO, you must have permission to link Group Policy objects for the organizational unit or domain. If you do not have rights to delete a link, the GPO will be deleted, but the link will remain. Links from other domains and sites are not deleted. The link to a deleted GPO appears in Group Policy Management as **Not Found**. To delete **Not Found** links, you must either have permission on the site, domain or organizational unit containing the link, or ask someone with sufficient rights to delete it.

- Group Policy objects are distinguished in the Active Directory by GUID, and it is theoretically possible for more than one GPO to have the same friendly name. The Group Policy Management snap-in prevents the creation of Group Policy objects with duplicate friendly names, but the Group Policy infrastructure does not enforce uniqueness of friendly names. Therefore, it is possible for duplication of friendly names to occur if you use legacy tools to create Group Policy objects, if replication is slow, or if you use a script to perform operations on Group Policy objects.

- You cannot delete the Default Domain Controllers policy or the Default Domain policy.

- Before deleting a GPO, you can check for cross-domain links by navigating to the **Scope** tab of the GPO you want to delete and, in the **Display links in this location** box, selecting **Entire Forest**. You can then select all links, right click the selection, and click **Delete link**. This procedure ensures that cross-domain links are deleted before you delete the GPO.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Group Policy Management Console Overview
Start Group Policy Management Console

# Edit a Group Policy object from GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a Group Policy object**

1. Open Group Policy Management.

2. In the console tree, double-click **Group Policy Objects** in the forest and domain containing the Group Policy object (GPO) that you want to edit.

   **Where?**

   - *Forest name*/Domains/*Domain name*/Group Policy Objects

3. Right-click the GPO, and then click **Edit**.

4. In the **Group Policy Object Editor** console, edit the settings as appropriate.

   **Important**

   - Avoid editing the default domain policy. If you need to apply Group Policy settings to the entire domain, create a new GPO, link it to the domain, and create the settings in that GPO.

   - The default domain policy and default domain controllers policy are vital to the health of any domain. You should not edit the Default Domain Controller policy or the Default Domain policy, except in the following cases:

     It is recommended that account policy be set in the Default Domain Policy.

     If you install applications on domain controllers that require modifications to User Rights or Audit Policies, the modifications must be made in the Default Domain Controllers Policy.

## Notes

- To edit a GPO, you must have **edit** permissions for the GPO that you want to edit.

- To edit IPSec policy settings from within a GPO, you must be a member of the domain administrators group. Otherwise, you can only assign or unassign an existing IPSec policy.

- You can also edit a GPO by clicking any link to the GPO in the console tree and following the above steps. When using Group Policy Object Editor to edit the settings in the GPO, any changes that you make are global to the GPO, so they will impact all locations where the GPO is linked.

- To edit the local Group Policy object, you must open it by clicking **Start**, clicking **Run**, typing **gpedit.msc**, and then clicking **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Group Policy Management Console Overview
Start Group Policy Management Console

# Add a forest, site, or domain to the Group Policy Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Add a forest, site, or domain to the Group Policy Management Console**

1. Open Group Policy Management.
2. Depending upon whether you want to add a forest, site, or domain, use one of the following procedures:
   - Forest
   - Domain
   - Site

**Forest**

1. In the console tree, right-click **Group Policy Management**, and then click **Add Forest**.
2. In the **Add Forest** dialog box, type the DNS or NetBIOS name of any domain in the forest, and then click **OK**.

   You can specify either the DNS name or the NetBIOS name of any domain in the forest. If you specify a NetBIOS name, you must confirm that the NetBIOS name corresponds to the DNS name of the domain.

   The forest is added to Group Policy Management Console, along with the domain that you specified.

**Domain**

1. In the console tree, double-click the forest in which you want to add a domain, right-click **Domains**, and then click **Show Domains**.
2. In the **Show Domains** dialog box, select the check box next to each domain to add in Group Policy Management Console and then click **OK**.

**Site**

1. In the console tree, double-click the forest in which you want to add a site, right-click **Sites**, and then click **Show Sites**.
2. In the **Show Sites** dialog box, select the check box next to each site to add to Group Policy Management Console and then click **OK**.

## Notes

- Adding a forest to Group Policy Management does not create a new forest in Active Directory. This function simply allows you to view and manage an existing forest using Group Policy Management Console. Likewise, adding a domain or site to Group Policy Management does not actually create a new domain or site in Active Directory.
- When you add a forest, the forest displayed in Group Policy Management is named after the forest root domain for that forest. By default, Group Policy Management shows a single domain in the forest, which is the domain that you specified in the **Add forest** dialog box. To show other domains, you must add them.

- By default, sites do not appear in the console. Sites are shown only if you explicitly add them.

- Because Group Policy is not inherited across domains, domains are always shown as peers of one another, regardless of their actual relationship.

- You can use the **Add Forest** function to add externally trusted domains, even if you do not have forest trust with the entire forest. You must, however, have trust between the domain you want to add and the domain of your user object. In the **Add Forest** dialog box, enter the name of the externally trusted domain that you want to add.

- When you close Group Policy Management Console, it preserves the current list of forests, domains, and sites shown.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Start Group Policy Management Console

# Search for a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To search for a Group Policy object**

1. Open Group Policy Management.

2. In the console tree, double-click the forest containing the domain that you want to search for a Group Policy object (GPO), double-click **Domains**, right-click the domain, and then click **Search**.

3. In the **Search for Group Policy Objects** dialog box, in the **Search for GPOs in this domain** box, select a domain or **All domains shown in this forest**.

4. In the **Search item** box, select the type of object on which you want to base your search.

   If you select **Security Group**, the **Select User, Computer, or Group** dialog box appears. Specify the appropriate object type, location of the object, and object name, and then click **OK**.

   You can choose **GPO-links** on the **Search item** dropdown menu to find unlinked GPOs and GPOs linked across domains.

5. In the **Condition** box, select the condition that you want to use in the search.

6. In the **Value** box, select or specify the value that you want to use to filter the search, and then click **Add**.

7. Repeat steps 4 through 6 until you complete the definition of all search criteria, and then click **Search**.

   The search is based on the intersection of the criteria specified, so a GPO must meet all criteria specified for it to be returned in the results.

8. When search results are returned, do one of the following:

   - To save the search results, click **Save results** and then, in the **Save GPO Search Results** dialog box, specify the file name for the saved results, and then click **Save**.

   - To navigate to a GPO found in the search, double-click the GPO in the search results list.

   - To clear the search results, click **Clear**.

9. Repeat steps 3 through 8 until you have completed all required searches, and then click **Close**.

### Notes

- You can also open the search dialog box by by right-clicking a forest and then clicking Search. In this case, the Search for GPOs in this domain box defaults to **All domains shown in this forest**.

- If a setting is enabled, and then all the settings in that extension are removed, there can be false-positive search for certain types of settings. This happens because the GPO has the extension listed as active. The extensions with this behavior are Security Settings, Software Installation, Folder Redirection, Internet Explorer Maintenance, and Encrypting File System (EFS).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Start Group Policy Management Console

# Specify a domain controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a domain controller**

1. Open Group Policy Management.
2. In the console tree, take one of the following actions, depending on whether you want to change the domain controller for a domain or a site:
   - If you want to change the domain controller for a domain, double-click the forest that contains the domain for which you want to change the domain controller, double-click **Domains**, right-click the domain, and then click **Change Domain Controller**.
   - If you want to change the domain controller for a site, double-click the forest that contains the sites for which you want to change the domain controller, right-click **Sites**, and then click **Change Domain Controller**. In the **Look in this domain** list of the **Change Domain Controller** dialog box, select the domain in which the domain controller resides.
3. To change the domain controller for either a site or a domain, do one of the following:
   - To choose the primary domain controller, select **The domain controller with the Operations Master token for the PDC emulator**, and then click **OK**.
   - To choose any available domain controller, select **Any available domain controller**, and then click **OK**.
   - To choose any available domain controller running Windows Server 2003 or later, select **Any available domain controller running Windows Server 2003 or later**, and then click **OK**.
   - To choose a specific domain controller, select **This domain controller**, select a domain controller from the list, and then click **OK**.

## Notes

- All operations performed in the domain, including operations on Group Policy objects (GPOs), security groups, and organizational units in this domain use the domain controller you specify using the **Change Domain Controller** function.
- All operations performed on links to sites use the domain controller that you specify for the sites, but all operations on Group Policy objects (GPOs) use the domain controller you specify for the domain in which the GPO resides.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Group Policy Management Console Overview
Start Group Policy Management Console

# View, print, and save a report of Group Policy object settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view, print, and save a report of Group Policy object settings**

1. Open Group Policy Management.
2. In the console tree, double-click the forest containing the domain or organizational unit which contains the Group Policy object (GPO) you want to work with, and then select the GPO.
3. Click the **Settings** tab to view reports in GPMC.
4. If you want to print or save the report, right-click the settings report in the results pane and do one of the following:
   - Select **Print** to print the report.
   - Select **Save Report** to save the report.

## Notes

- To customize the information displayed in a report, click **show** or **hide** to display only the data you want to view or print.
- On computers with Internet Explorer Enhanced Security Configuration enabled a prompt appears when you attempt to view reports in the Group Policy Management Console (GPMC) snap-in. This happens because the reports contain a script that allows you to expand and collapse sections of the reports using **Show** and **Hide**. To use the show and hide functionality in these reports, you must add the about:security_MMC.exe site to the Trusted sites zone in Internet Explorer. This site represents all Web pages that are hosted inside MMC. You can do this by clicking **Add** on the **Internet Explorer** prompt. This opens the **Trusted sites** dialog box with the correct entry (about:security_mmc.exe) for the page being called by GPMC. Select **Add** and then **Close** on the **Trusted sites** dialog box to add this site to the Trusted sites zone. If the about:security_mmc.exe site is not added to the Trusted sites zone, the reports appear fully expanded and you cannot collapse the report.
- To view a description of a setting in Administrative Templates, click the setting name in the report. This feature is only available for settings in the Administrative Templates section of the report.
- From within Group Policy Management, it is not possible to use the keyboard to navigate inside an HTML report. To navigate inside the HTML save the report to a file and then use Internet Explorer to view the report. The reports have been designed to support keyboard navigation when viewed directly in Internet Explorer.
- To view a saved report directly in a Web browser, you must use Internet Explorer 6 or Netscape 7. Netscape 7 does not support functionality that enables you to show or hide data in reports.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Determine Resultant Set of Policy with Group Policy Results

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Determine Resultant Set of Policy with Group Policy Results**

1. Open Group Policy Management.
2. In the console tree, double-click the forest in which you want to create a Group Policy Results query, right-click **Group Policy Results**, and then click **Group Policy Results Wizard**.
3. In the **Group Policy Results Wizard**, click **Next** and enter the appropriate information.
4. After completing the wizard, click **Finish**.
5. If you want to print or save the report, right-click the settings report in the results pane and do one of the following:
   - Select **Print** to print the report.
   - Select **Save Report** to save the report.

### Notes

- To access Group Policy Results data for a user or computer, you must have **Read Group Policy Results data** permission on the domain or organizational unit that contains the user or computer, or you must be a member of a local Administrator's group on the targeted computer.
- To customize the information displayed in a report, click **show** or **hide** to display only the data you want to view or print.
- On computers with Internet Explorer Enhanced Security Configuration enabled a prompt appears when you attempt to view reports in the Group Policy Management Console (GPMC) snap-in. This happens because the reports contain a script that allows you to expand and collapse sections of the reports using Show and Hide. To enable the Show and Hide functionality in these reports, you must add the about:security_MMC.exe site to the Trusted sites zone in Internet Explorer. This site represents all Web pages that are hosted inside MMC. You can do this by clicking **Add** on the **Internet Explorer** prompt. This opens the **Trusted sites** dialog box with the correct entry (about:security_mmc.exe) for the page being called by GPMC. Select **Add** and then **Close** on the **Trusted sites** dialog box to add this site to the Trusted sites zone. If the about:security_mmc.exe site is not added to the Trusted sites zone, the reports appear fully expanded and you cannot collapse the report.
- From within Group Policy Management, it is not possible to use the keyboard to navigate inside an HTML report. To navigate inside the HTML save the report to a file and then use Internet Explorer to view the report. The reports have been designed to support keyboard navigation when viewed directly in Internet Explorer.
- If you open a previously saved console, and want to save a Group Policy Modeling or Group Policy Results report in XML, the report must be regenerated using the **Rerun query** option.
- To view a saved report directly in a Web browser, you must use Internet Explorer 6 or Netscape 7. Netscape 7 does not support functionality that enables you to show or hide data in reports.
- The functionality provided by Group Policy Results was previously referred to as Resultant Set of Policy - logging mode in Windows XP.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Simulate Resultant Set of Policy using Group Policy Modeling

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To simulate Resultant Set of Policy using Group Policy Modeling**

1. Open Group Policy Management.
2. In the console tree, double-click the forest in which you want to create a Group Policy Modeling query, right-click **Group Policy Modeling**, and then click **Group Policy Modeling Wizard**.
3. In the **Group Policy Modeling Wizard**, click **Next** and enter the appropriate information.
4. When finished, click **Finish**.
5. If you want to print or save the report, right-click the settings report in the results pane and do one of the following:
   - Select **Print** to print the report.
   - Select **Save Report** to save the report.

**Notes**

- To create a Group Policy Modeling query, you must have the **Perform Group Policy Modeling analyses** permission on the domain or organizational unit that contains the objects on which you want to run the query.
- **Group Policy Modeling** is only available if at least one domain controller in the forest is running Windows Server 2003.
- To customize the information displayed in a report, click **show** or **hide** to display only the data you want to view or print.
- On computers with Internet Explorer Enhanced Security Configuration enabled a prompt appears when you attempt to view reports in the Group Policy Management Console (GPMC) snap-in. This happens because the reports contain a script that allows you to expand and collapse sections of the reports using Show and Hide. To enable this Show and Hide functionality in these reports, you must add the about:security_MMC.exe site to the Trusted sites zone in Internet Explorer. This site represents all Web pages that are hosted inside MMC. You can do this by clicking **Add** on the **Internet Explorer** prompt. This opens the **Trusted sites** dialog box with the correct entry (about:security_mmc.exe) for the page being called by GPMC. Select **Add** and then **Close** on the **Trusted sites** dialog box to add this site to the Trusted sites zone. If the about:security_mmc.exe site is not added to the Trusted sites zone, the reports appear fully expanded and you cannot collapse the report.
- In Windows Server 2003 without Group Policy Management installed, Group Policy Modeling was referred to as Resultant Set of Policy (RSoP) planning mode.
- From within Group Policy Management, it is not possible to use the keyboard to navigate inside an HTML report. To navigate inside the HTML save the report to a file and then use Internet Explorer to view the report. The reports have been designed to support keyboard navigation when viewed directly in Internet Explorer.
- If you open a previously saved console, and want to save a Group Policy Modeling or Group Policy Results report in XML, the report must be regenerated using the **Rerun query** option.
- To view a saved report directly in a Web browser, you must use Internet Explorer 6 or Netscape 7. Netscape 7 does not support functionality that enables you to show or hide data in reports.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set Group Policy Management Console user interface options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set Group Policy Management Console user interface options**

1. Open Group Policy Management.
2. On the **View** menu, click **Options**.
3. Choose a type of view option from the list below:
   - Columns
   - Reporting
   - General

**Columns**

1. In the **Options** dialog box, click the **Columns** tab.
2. Select a table from the **Table location** drop down box.
3. In **Columns displayed in this order**, add a check next to each column that should be displayed.
4. Select a column and use the **Move Up** and **Move Down** buttons to set the order of columns.
5. Repeat steps 2 through 4 for each table in the **Table location** drop down box you want to change, and then click **OK**.
6. You can optionally check **Save customized column order and sizes** to make column order and size selections persistent. This setting is checked by default.

**Reporting**

1. In the **Options** dialog box, click the **Reporting** tab.
2. Select one of the following options.
   - To specify that Group Policy Managemetn Console (GPMC) should use the local adm files,select **Default**. If an .adm file is not found locally, and then GPMC will look in the Group Policy objects (GPO) folder in the sysvol folder.
   - To specify a custom location that takes precedence over the default locations, select **Custom**, and then enter the location where .adm files are stored.

     **Notes**

   - Group Policy Management Console (GPMC) uses files with an .adm extension to display the friendly names of policy settings when generating HTML reports for GPOs, Group Policy Modeling, and Group Policy Results. These options let you control the location from which GPMC reads these .adm files.
   - When searching for a given .adm file, GPMC uses the .adm file that is first found based on the search order described above, regardless of time stamp.

- If you add or modify an .adm file in an existing location, you need to restart GPMC in order for GPMC to pick up the change in the .adm file when displaying HTML reports. (You do not need to restart GPMC if you switch between the **Default** and **Custom** option buttons, or change the custom location used for .adm files, and click **OK**.)

- GPMC never copies the .adm file to the sysvol folder, unlike the Group Policy Object Editor.

**General**

1. In the **Options** dialog box, click the **General** tab.

2. Select from the following options.

   - To display only forests or domains with two-way trusts to the user's domain, select **Enable trust checking**. This setting is checked by default.

   - To show domain name controller names in parentheses after each domain in GPMC, select **Show domain controllers after domain names**.

   - To display a confirmation dialog box to distinguish between GPOs and GPO links each time a GPO or GPO link is selected in GPMC, select **Show confirmation dialog box to distinguish between GPOs and GPO links**. This setting is checked by default.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Back Up, Restore, Copy, and Import

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Back Up, Restore, Copy, and Import**

- Back up a Group Policy object using GPMC
- Restore a backed-up Group Policy object using GPMC
- Copy a Group Policy object using GPMC
- Import a Group Policy object using GPMC
- Create a migration table

# Back up a Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To back up a Group Policy object**

1. Open Group Policy Management.

2. In the console tree, double-click **Group Policy Objects** in the forest and domain containing the Group Policy object (GPO) that you want to back up.

   **Where?**

   - *Forest name*/Domains/*Domain name*/Group Policy Objects

3. To backup a single GPO, right-click the GPO, and then click **Back Up**. To backup all GPOs in the domain, right-click **Group Policy Objects** and click **Back Up All**.

4. In the **Backup Group Policy Object** dialog box, in the **Location** box, enter the path to the location at which you want to store the GPO backup(s), or click **Browse**, locate the folder in which you want to store the GPO backup(s), and then click **OK**.

5. In the **Description** box, type a description for the GPO(s) that you want to back up, and then click **Backup**. If you are backing up multiple GPOs, the description will apply to all GPOs you back up.

6. After the operation completes, click **OK**.

   **Important**

   - To secure backed up GPOs, ensure that only authorized administrators have permission to access the folder to which you are exporting the GPO.

## Notes

- You must have **Read** permissions on the GPO and **Write** permissions on the folder containing the GPO backup to perform this procedure.

- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restore a backed-up Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore a backed-up Group Policy object**

1. Open Group Policy Management.
2. In the console tree, in the forest and domain containing the Group Policy object (GPO) that you want to restore, locate **Group Policy Objects**.

   **Where?**

   - *Forest name*\Domains*Domain name*\Group Policy Objects.

3. Do one of the following:

   - To restore a previous version of an existing GPO
   - To restore a deleted GPO

**To restore a previous version of an existing GPO**

1. Double-click **Group Policy Objects**, right-click the GPO which you want to restore, and then click **Restore from Backup**.
2. When the **Restore Group Policy Object Wizard** appears, follow the instructions and provide the appropriate information about the GPO that you want to restore, and then click **Finish**.
3. After the **Restore Group Policy Object Wizard** completes the restore operation, click **OK**.

**To restore a deleted GPO**

1. Right-click **Group Policy Objects** and then choose **Manage Backups**.
2. In the **Manage Backups** dialog box, in the **Backup location** box, type the path to the backup folder. You can also use **Browse** to locate the backup folder.
3. In the **Backed up GPOs** box, select the GPO that you want to restore from the list of GPO backups shown, and then click **Restore**.
4. When prompted to confirm the restore operation, click **OK**.

## Notes

- You must have **Edit, delete, and modify security** permissions on the GPO and **Read** permissions on the folder containing the GPO backup to restore an existing GPO.
- You must have privileges to **create** GPOs in the domain and **Read** permissions on the file system location of the backed up GPO to restore a GPO that has been deleted.
- You can also restore an existing or deleted GPO using the **Manage backups** function by right-clicking **Domains** or **Group Policy Objects**.

- The **Manage Backups** dialog box can be used to restore either an existing or deleted GPO. The **Manage Backups** dialog box can be opened either by right-clicking **Domains** or **Group Policy Objects** in a given domain. When **Manage Backups** is opened by right clicking **Group Policy Objects**, only GPO backups from that domain are shown. In contrast, when **Manage Backups** is opened by right clicking **Domains**, all GPO backups are shown, regardless of domain.

- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Copy a Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a Group Policy object**

1. Open Group Policy Management.
2. In the console tree, right-click the Group Policy object (GPO) that you want to copy, and then click **Copy**.

   **Where?**

   - *Forest name*/Domains/*Domain name*/Group Policy Objects/*Group Policy object name*

3. Do one of the following:

   - To create a copy of the GPO in the same domain as the source GPO, right-click **Group Policy Objects**, click **Paste**, specify permissions for the new GPO in the **Copy GPO** box, and then click **OK**.
   - To create a copy of the GPO in a different domain, double-click the destination domain, right-click **Group Policy Objects**, and then click **Paste**. Answer all the questions in the cross-domain copying wizard that appears, and then click **Finish**.

## Notes

- You must have privileges to create GPOs in the destination domain to complete this procedure.
- For copy operations to another domain or forest, you may need to specify a migration table to update references to security principals and UNC paths in the source GPO to new values in the destination GPO. For more information about migration tables see "Migration Tables," "The migration table editor," and "Create a migration table" in Related Topics.
- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import a Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a Group Policy object**

1. Open Group Policy Management.
2. In the console tree, double-click **Group Policy Objects** in the forest and domain containing the Group Policy object (GPO) into which you want to import settings.

   Where?

   - *Forest name*
   - Domains
   - *Domain name*
   - Group Policy Objects
3. Right-click the GPO, and then click **Import Settings**.
4. Follow the instructions in the **Import Settings Wizard**, and then click **Finish**.

## Notes

- You must have **Edit** permissions on the GPO into which you want to import settings to complete this procedure.
- When importing settings from a backed up GPO in another domain or forest, if the GPO settings contain references to UNC paths or security principals, you may need to update these references to new values in the destination GPO. You can specify a migration table during the import operation to update the references to security principals and UNC paths in the destination GPO. For more information about migration tables see "Migration Tables," "The migration table editor," and "Create a migration table" in Related Topics.
- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a migration table

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a migration table**

1. Open Group Policy Management.

2. In the console tree, double click the forest from which you want to create a migration table.

3. Right-click **Domains** and then click **Open Migration Table Editor**

   - or -

   Right-click **Group Policy Objects**, and then click **Open Migration Table Editor**.

4. Specify a source you want to include in the migration table by doing the following:

   a. Under **Source Name**, type the source name or right-click the cell and click **Browse** to find and then specify the object type, location and name.

      If you enter the source name manually, you must type the exact name of the User, Computer, Group or UNC Path referenced in the source GPO. For example, **TestDomain\PolicyAdmins** or **\\server1\publicshare.** The type of the source name must match the source type specified in the migration table.

      Security principals can be specified using any of the following formats:

      UPN. For example, someone@testdomain.com.

      SAM. For example, testdomain\someone.

      DNS. For example, testdomain.com\someone.

      Free text. For example, someone. You must specify the type as Free Text or SID in this case.

      SID. For example, S-1-11-111111111-111111111-1111111111-1112. You must specify the type as Free Text or SID in this case.

   b. Under **Source Type** specify the type of source in the cell adjacent to the source name cell by using the drop down list and selecting the appropriate type. If you have used **Browse** to find the source name, the source type is entered by default.

   c. Under **Destination Name**, type the destination name or right-click the cell adjacent to the source name and source type cells, and then do one of the following:

      Click **Browse** to find a user, computer or group

      - or -

      Point to **Set Destination**, and then click the appropriate selection. You cannot use the **No Destination** option for UNC paths.

5. Repeat step 4 for each source you want to include in the migration table.

6. On the menu, click **File**, and then click **Save**.

7. Specify the location where you want to save the migration table, and then click **Save**.

**Notes**

- You can use the migration table editor to check that destination entries can be resolved. This is important to know before you copy or import a GPO, because if there are unresolvable destination entries in the migration table, then the copy or import operation might fail. To validate your migration table, from the **Tools** menu, click **Validate**.

- You can auto-populate a migration table by scanning one or more GPOs or backup GPOs to extract all references to security principals and UNC paths, and automatically enter these items into the table as source name entries.

  **To auto-populate a migration table from a GPO:**

  1. From the **Tools** menu, click **Auto-populate from GPO**.

  2. In the **Look in this domain** box, select the domain that contains the GPO.

  3. In the **Group Policy objects** box, click the GPO or GPOs from which you want to populate the migration table, check **Include security principals from the DACL on the GPO during scan** if appropriate, and then click **OK**.

  **To auto-populate a migration table from a backup GPO:**

  1. From the **Tools** menu, click **Auto-populate from Backup**.

  2. In the **Backup location** box, type the path to the folder that contains the backup GPO, or click **Browse** to locate the folder.

  3. In the **Backed up GPOs** box, select one or more backed up GPOs, check **Show only the latest version of each GPO** or **Include security principals from the DACL on the GPO during scan** if appropriate, and then click **OK**.

  To complete the migration table for either scenario, you only need to adjust the destination values. By default, the destination name for each entry will be set to **Same as source** when you use either of the Populate options.

- Performing this task does not require you to have administrative credentials.

- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Control Group Policy Object Scope

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Control Group Policy Object Scope**

- Link a Group Policy object using GPMC
- Link a WMI filter to a Group Policy object
- Filter using security groups
- Create, import, export, copy, and paste WMI filters.
- Enforce a Group Policy object link using GPMC
- Block inheritance using GPMC
- Get user settings from the machine account (loopback processing)
- Disable a Group Policy object link using GPMC
- Disable the User or Computer settings in a Group Policy object using GPMC

# Link a Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To link a Group Policy object**

1. Open Group Policy Management.
2. In the console tree, locate the site, domain or organizational unit to which you want to link a Group Policy object (GPO)

   Where?

   - *Forest name*
   - Domains or *Sites*
   - *Site name*, *Domain name* or *organizational unit name*
3. Do one of the following:

   - To link an existing GPO, right-click the domain or organizational unit within the domain, and then click **Link an Existing GPO**. In the **Select GPO** dialog box, click the GPO which you want to link, and then click **OK**.
   - To link a new GPO, right-click the domain or organizational unit within a domain, and then click **Create and Link a GPO Here**. In the **Name** box, type a name for the new GPO, and then click **OK**.

## Notes

- To link an existing GPO to a site, domain, or organization unit, you must have **Link GPOs** permission on that site, domain, or organizational unit. By default, only Domain Administrators and Enterprise Administrators have this privilege for domains and organizational units, and only Enterprise Administrators and Domain Administrators of the forest root domain have this privilege for sites.
- To create and link a GPO, you must have **Link GPOs** permissions on the desired domain or organizational unit, and you must have permission to create GPOs in that domain. By default, only Domain Administrators, Enterprise Administrators, and Group Policy Creator owners have permission to create GPOs.
- The **Create and Link a GPO Here** option is not available for sites, because it is unclear in which domain to create the GPO. The user must first create a GPO in any domain in the forest, and then use the **Link an Existing GPO** option to link it to the site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Filter using security groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To filter using security groups**

1. Open Group Policy Management.
2. In the console tree, double-click **Group Policy Objects**, which contains the Group Policy object (GPO) to which you want to apply security filtering (console tree location is: *Forest name*/Domains/*Domain name*/Group Policy Objects).
3. Click the GPO.
4. In the results pane, on the **Scope** tab, click **Add**.
5. In the **Enter the object name to select** box, type the name of the group, user, or computer that you want to add to the security filter. Click **OK**.

   If **Authenticated Users** appears in the **Security Filtering** section of the **Scope** tab, select this group and click **Remove**. This will ensure that only members of the group or groups you added in step 5 can receive the settings in this GPO.

## Notes

- You must have **Edit settings, delete, and modify security** permissions on the GPO to perform these procedures.
- The settings in a GPO will apply only to users and computers that are contained in the domain, organizational unit, or organizational units where the GPO is linked, and that are specified in, or are members of a group that are specified in **Security Filtering**. You can specify multiple groups, users or computers in the security filter for a single GPO.
- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Link a WMI filter to a Group Policy object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To link a WMI filter to a Group Policy object**

1. Open Group Policy Management.
2. In the console tree, double-click **Group Policy Objects** in the forest and domain containing the Group Policy object (GPO) to which you want to link a WMI filter.

   **Where?**

   *Forest name*/Domains/*Domain name*/Group Policy Objects

3. Click the GPO.
4. In the results pane, on the **Scope** tab, under **WMI Filtering**, select a WMI filter from the drop-down list box.
5. When prompted to confirm the selection, click **Yes**.

**Notes**

- You can also link a WMI filter to a GPO using one of the following methods:

  1. In the console tree, find the WMI filter you want to link to a GPO.

     **Where?**

     *Forest name*/Domains/*Domain name*/WMI Filters/*WMI filter name*

  2. Do one of the following:

     Click the WMI filter.

     In the details pane, on the **General** tab, under **GPOs that use this WMI filter**, right-click, and then click **Add**.

     Under **Group Policy objects**, click the GPO for which you want to link the WMI filter, and then click **OK**.

     -or-

     In the console tree, drag and drop the WMI filter to the GPO you want to link it to.

- To link a WMI filter to a GPO, you must have Edit permissions on a GPO.
- Only one WMI filter can be linked to a GPO. If you try to link a WMI filter to a GPO that already has another WMI filter linked to it, you will be asked whether you want to replace the old filter with the new one.
- You can only link a WMI filter to a GPO in the same domain.
- **WMI Filters** (as well as **WMI Filtering** on the **Scope** tab for GPOs) is only available if at least one domain controller in the domain is running Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create, import, export, copy, and paste WMI filters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create, import, export, copy, and paste WMI filters**

- To create a WMI filter
- To import a WMI filter
- To export a WMI filter
- To copy and paste a WMI filter

**To create a WMI filter**

1. Open Group Policy Management.
2. In the console tree, right-click **WMI Filters** in the forest and domain in which you want to create a WMI filter.

   **Where?**

   *Forest name*/Domains/*Domain name*/WMI Filters

3. Click **New**.
4. In the **New WMI Filter** dialog box, type a name for the new WMI Filter in the **Name** box, type a description of the filter in the **Description** box.
5. Click **Add**.
6. In the **WMI Query** dialog box, either leave the default namespace (root\CIMv2) or enter another namespace by doing one of the following:

   - In the **Namespace** box, type the name of the namespace that you want to use for the WMI query.
   - Click **Browse**, select a namespace from the list, and then click **OK**.

7. Type a WMI query in the **Query** box, and then click **OK**.
8. To add more queries, repeat steps 5 through 7 to add each query.
9. After adding all queries, click **Save**.

**Notes**

- You must have privileges to create WMI filters in the domain in which you want to create the filter. By default the Domain Administrators, Enterprise Administrators, and Group Policy Creator Owners groups have this permission.
- **WMI Filters** is only available if at least one domain controller in the domain is running Windows Server 2003. The same is true for **WMI Filtering** on the **Scope** tab for Group Policy objects (GPOs).
- To delete a WMI filter, in the console tree, right-click the WMI filter and then click **Delete**. When asked to confirm

whether you want to delete the WMI filter, click **Yes**.

**Where?**

*Forest name*/Domains/*Domain name*/WMI Filters/*WMI filter name*

#### To import a WMI filter

1. Open Group Policy Management.

2. In the console tree, right-click **WMI Filters** in the forest and domain into which you want to import a WMI filter.

   **Where?**

   *Forest name*/Domains/*Domain name*/WMI Filters

3. Click **Import**.

4. In the **Import WMI Filter** dialog box, enter the .mof file that contains the WMI filter you want to import, and then click **Open**.

5. In the **Import WMI Filter** dialog box, specify the appropriate information in the **Name** and **Description** boxes, and then do one of the following:

   - To import the WMI filter without changing it, click **Import**.

   - To change the WMI filter and then import it, click **Edit**, make the appropriate changes to the namespace or query, click **OK**, and then click **Import**.

### Notes

- You must have privileges to create WMI filters in the domain in which you want to create the filter to complete this procedure. By default the Domain Administrators, Enterprise Administrators, and Group Policy Creator Owners groups have this permission.

- **WMI Filters** is only available if at least one domain controller in the domain is running WindowsServer 2003. The same is true for **WMI Filtering** on the **Scope** tab for Group Policy objects (GPOs).

- Importing a WMI filter creates a new filter instead of modifying an existing filter.

#### To export a WMI filter

1. Open Group Policy Management.

2. In the console tree, find the WMI filter that you want to export.

   **Where?**

   *Forest name*/Domains/*Domain name*/WMI Filters/*WMI filter name*

3. Right-click the WMI filter that you want to export, and then click **Export**.

4. In the **Export WMI filter** dialog box, select a secure file system location from the **Save in** drop-down list box, enter a name for the filter that you want to export, and then click **Save**.

   **Important**

- To secure exported WMI filters, ensure that only authorized administrators have permission to access the folder to which you are exporting the filter.

- To maximize security, you should store WMI filters in a secure file system location on servers running Windows 2000 Server or Windows Server 2003.

### Notes

- **WMI Filters** is only available if at least one domain controller in the domain is running Windows Server 2003. The same is true for **WMI Filtering** on the **Scope** tab for Group Policy objects (GPOs).

- You can also export a WMI filter by clicking **WMI Filters** and, in the results pane, clicking the **Contents** tab, right-clicking the filter name, and then clicking **Export**.

- Exported WMI filters are stored in the file system as .mof files, which use a general-purpose format for storing various types of WMI data. Group Policy Management can import only .mof files that contain a single WMI filter.

#### To copy and paste a WMI filter

1. Open Group Policy Management.

2. In the console tree, click the WMI filter in the forest and domain containing the WMI filter that you want to copy.

   **Where?**

   *Forest name*/Domains/*Domain name*/WMI Filters/*WMI filter name*

3. Right-click the WMI filter you want to copy, and then click **Copy** to copy the filter to the clipboard.

4. In the destination domain, right-click **WMI Filters**, and then click **Paste**.

### Notes

- You must have privileges to create WMI filters in the domain in which you want to create the filter to complete this procedure. By default the Domain Administrators, Enterprise Administrators, and Group Policy Creator Owners groups have this permission.

- **WMI Filters** is only available if at least one domain controller in the domain is running Windows Server 2003. The same is true for **WMI Filtering** on the **Scope** tab for Group Policy objects (GPOs).

# Enforce a Group Policy object link using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enforce a Group Policy object link**

1. Open Group Policy Management.
2. In the console tree, double-click the forest containing the domain, site, or organizational unit containing the link for which you want to change enforcement of a Group Policy object (GPO) link, and then do one of the following:
   - To enforce a GPO link to a domain, double-click **Domains**, and then double-click the domain containing the GPO link.
   - To enforce a GPO link to an organizational unit, double-click **Domains**, double-click the domain containing the organizational unit, and then double-click the organizational unit (including any parent or child organizational unit) containing the GPO link.
   - To enforce a GPO link to a site, double-click **Sites**, and double-click the site containing the GPO link.
3. Right-click the GPO link, and then click **Enforced** to enable or disable enforcement. A check mark next to **Enforced** indicates that the link is enforced.

## Notes

- You must have **Link GPOs** permission for the domain, site, or organizational unit containing the GPO link to complete this procedure.
- To determine whether a GPO link is enforced, you can also click the GPO link and look at the information in the **Links** section of the **Scope** tab.
- You can also enforce a GPO link by clicking on the GPO link in the console tree, right-clicking the link under **Links** on the **Scope** tab in the results pane, clicking **Enforced** to enable or disable enforcement for the link, and then clicking **OK**.
- **Enforced** is referred to as **No Override** on computers where Group Policy Management Console has not been installed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Block inheritance using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To block inheritance**

1. Open Group Policy Management.
2. In the console tree, double-click the forest containing the domain or organizational unit for which you want to block inheritance for Group Policy object (GPO) links, and then do one of the following:
   - To block inheritance of the GPO links of an entire domain, double-click **Domains**, and then right-click the domain.
   - To block inheritance for an organizational unit, double-click **Domains**, double-click the domain containing the organizational unit, and then right-click the organizational unit.
3. Click **Block Inheritance**.

## Notes

- You must have **Link GPOs** permission for the domain or organizational unit to complete this procedure.
- If a domain or organizational unit is set to block inheritance, it will appear with a blue exclamation mark in the console tree.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Get user settings from the machine account (loopback processing)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To get user settings from the machine account (loopback processing)**

1. Open Group Policy Management.
2. In the console tree, double-click the forest containing the domain or organizational unit which contains the computer accounts.
3. Double-click the domain or organization unit.
4. Right-click a Group Policy object (GPO) that is linked to the domain or organizational unit, and then click **Edit**. This opens Group Policy Object Editor. If there is no existing GPO, use the **Create and Link a GPO Here** option.
5. In the results pane of the Group Policy Object Editor, double-click **User Group Policy loopback processing mode**.

   Where?

   - *GPO name*
   - Computer Configuration
   - Administrative Templates
   - System
   - Group Policy
   - User Group Policy loopback processing mode
6. Click **Enabled**, and then in the **Mode** box, select either **Merge** or **Replace**. Click **OK**.

### Notes

- You must have **Edit** permissions on the GPO to perform this procedure.
- The Loopback option applies to all GPOs applied to a given computer. It cannot be specified on a per GPO basis.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable a Group Policy object link using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable a Group Policy object link**

1. Open Group Policy Management.
2. In the console tree, double-click the forest containing the domain, site, or organizational unit containing the Group Policy object (GPO) link that you want to disable, and then do one of the following:
   - To disable a GPO link to a domain, double-click **Domains**, and then double-click the domain containing the GPO link.
   - To disable a GPO link to an organizational unit, double-click **Domains**, double-click the domain containing the organizational unit, and then double-click the organizational unit (including any parent or child organizational unit) containing the GPO link.
   - To disable a GPO link to a site, double-click **Sites**, and double-click the site containing the GPO link.
3. Right-click the GPO link. A check mark next to **Link Enabled** indicates that the link is currently enabled.
4. Click **Link Enabled** to remove the check mark and disable the link.

## Notes

- You must have **Link GPOs** permission for the domain, site, or organizational unit containing the GPO link to complete this procedure. If you do not have **Link GPOs** permission, **Link Enabled** is unavailable.
- To determine whether a GPO link is enabled, you can also click the GPO link and look at the information in the **Links** section of the **Scope** tab.
- You can also disable a GPO link by clicking on the GPO link in the console tree, right-clicking the link under **Links** on the **Scope** tab in the results pane, clicking **Link Enabled** to enable or disable the link, and then clicking **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable the User or Computer settings in a Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable the user or computer settings for a Group Policy object**

1. Open Group Policy Management.
2. In the console tree, double-click the forest containing the domain or organizational unit which contains the Group Policy object (GPO).
3. Double-click the domain or organizational unit.
4. Right-click the GPO that contains the user or computer settings you want to disable, point to **GPO Status**, and then do one of the following:
   - Click **User settings disabled** to disable user settings for the GPO. A check mark next to **User settings disabled** indicates that user settings are disabled.
   - Click **Computer settings disabled** to disable computer settings for the GPO. A check mark next to **Computer settings disabled** indicates that computer settings are disabled.

## Notes

- You must have **Edit** permission on the GPO to complete this procedure.
- You can also modify GPO Status from the **Details** tab of a GPO.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate Group Policy tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Delegate Group Policy tasks**

- Delegate creation of Group Policy objects using GPMC
- Delegate an individual Group Policy object using GPMC
- Delegate policy-related permissions on a domain, OU, or site using GPMC
- Delegate creation of WMI filters using GPMC
- Delegate an individual WMI filter using GPMC

# Delegate creation of Group Policy objects using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate creation of Group Policy objects**

1. Open Group Policy Management.
2. In the console tree, click **Group Policy Objects** in the forest and domain for which you want to delegate creation rights for Group Policy objects (GPOs).

   **Where?**

   - *Forest name*/Domains/*Domain name*/Group Policy Objects

3. In the results pane, click the **Delegation** tab, and then do one of the following.

   - To add a new group or user, using the Group Policy Creator Owners group
   - To add a new group or user to have the same permissions as the Group Policy Creator Owners Group
   - To remove creation rights from a group or user

**To add a new group or user, using the Group Policy Creator Owners group**

1. In the **Groups and Users** list box, double-click **Group Policy Creator Owners**.
2. In the **Group Policy Creator Owners** properties dialog box, select the **Members** tab, and click **Add**.
3. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects for which you want to delegate creation rights, and then click **OK**.
4. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object for which you want to delegate creation rights, and then click **OK**.
5. In the **Enter the object name to select** box, enter the name of the object to which you want to delegate creation rights by doing one of the following:

   - If you know the name, type it, and then click **OK**.
   - To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.

**To add a new group or user to have the same permissions as the Group Policy Creator Owners group**

1. Click **Add**.
2. In the **Select User, Computers, or Groups** dialog box, click **Object Types**, select the types of objects to which you want to delegate creation rights for GPOs, and then click **OK**.
3. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object to which you want to delegate creation rights, and then click **OK**.

4. In the **Enter the object name to select** box, enter name of the object to which you want to delegate creation rights by doing one of the following:

    - If you know the name, type it, and then click **OK**.

    - To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.

**To remove creation rights from a group or user**

1. Do one of the following:

    - To remove a name from the **Groups and users** list box, delete the name of the group or user, and then click **Remove**.

    - To remove a member of Group Policy Creator Owners group, double-click **Group Policy Creator Owners**, click the **Members** property tab, select the name to be removed, and then click **Remove**.

2. When prompted to confirm the removal of the delegation privilege, click **Yes**, and then click **OK**.

## Notes

- You must be a member of the Domain Administrators or Enterprise Administrators to complete this procedure.

- You can also remove a group or user from the permissions list by right-clicking the name of the group or user in the **Groups and users** list box on the **Delegation** tab, and then clicking **Remove**.

- If you want to delegate permissions to groups and users in the same domain as the GPOs, it is recommended that you add them to the Group Policy Creator Owners group since this is the original method that was available in Windows 2000. However, you cannot add groups or users from another domain to the Group Policy Creator Owners group.

- To delegate GPO creation permissions to groups or users in another domain, you must explicitly grant that group GPO creation permissions (without using Group Policy Creator Owners group). Alternatively you can create a domain local group in the domain where you want to delegate GPO creation permission and grant that group permission to create GPOs. Then add members to this domain local group from other domains as needed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Delegate an individual Group Policy object using GPMC

# Delegate an individual Group Policy object using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate an individual Group Policy object**

1. Open Group Policy Management.

2. In the console tree, double-click **Group Policy Objects** in the forest and domain containing the Group Policy object (GPO) for which you want to add or remove permissions.

   **Where?**

   *Forest name*/Domains/*Domain name*/Group Policy Objects

3. Click the GPO.

4. In the results pane, click the **Delegation** tab, and then do one of the following:

   - To delegate permissions for a group or user
   - To change permissions for a group or user
   - To remove permissions for a group or user

**To delegate permissions for a group or user**

1. Click **Add**.

2. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects for which you want to add GPO permissions, and then click **OK**.

3. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object for which you want to add GPO permissions, and then click **OK**.

4. In the **Enter the object name to select** box, enter the name of the object for which you want to add GPO permissions by performing one of the actions in the following table.

   - If you know the name, type it, and then click **OK**.
   - To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.
   - In the **Permissions** box of the **Add Group or User** dialog box, select the appropriate permissions from the drop down list, and then click **OK**.

**To change permissions for a group or user**

1. In the **Groups and users** list box, right-click the name of the group or user for which you want to change permissions, and then click the appropriate permission level: **Read only**, **Edit Settings**, or **Edit, delete, modify security**.

2. When prompted to confirm the change in delegation permissions, click **OK**.

**To remove permissions for a group or user**

1. In the **Groups and users** list box, right-click the name of the group or user for which you want to remove permissions, and then click **Remove**.

2. When prompted to confirm the removal of the delegation privilege, click **OK**.

## Notes

- You must have **Edit settings, delete, and modify security** permissions on the GPO to perform these procedures.

- Groups and users that have **Custom** in the **Allowed Permissions** column in the **Groups and users** list box on the **Delegation** tab have permissions that do not match one of the three standard levels of permissions. To view the permissions for groups with custom permissions or to set custom permissions, click **Advanced**. To change permissions to one of the standard levels, follow the steps above for *change permissions for a group or user*.

- At least one group or user must have **Edit settings, delete, and modify security** permissions on each GPO. You cannot remove a group or user if it is the only group or user on a GPO that has this permission set.

- Permissions inherited from parent containers cannot be removed.

- You can also perform this procedure or a related task by using one or more of the sample scripts included with Group Policy Management. For more information, see "Scripting Group Policy tasks" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate policy-related permissions on a domain, OU, or site using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Delegate policy-related permissions on a domain, organizational unit, or site**

To delegate permissions to link Group Policy objects

1. Open Group Policy Management.
2. In the console tree, do one of the following:
   - To delegate permission to link Group Policy objects (GPOs) to either the domain or an organizational unit, click the domain or the organizational unit (console tree location is: *Forest name*/Domains/*Domain name*/Organizational unit).
   - To delegate permission to link GPOs to a site, click the site (console tree location is: *Forest name*/Sites/*Site name*).
3. In the results pane, click the **Delegation** tab.
4. In the **Permission** drop down list box, select **Link GPOs**, and then specify permissions to link GPOs for a group or user by doing one of the following:
   - To add a new group or user to the permissions list for domains and organizational units
   - To add a new group or user to the permissionslist for sites
   - To change the inheritance of permissions on a domain or organizational unit for a group or user
   - To remove a group or user from the permissions list
   - To delegate permissions for generating Group Policy Modeling data
   - To delegate permissions to read Group Policy Results data

**To add a new group or user to the permissions list for domains and organizational units**

1. On the **Delegation** tab, click **Add**.
2. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects to which you want to delegate permissions for the domain, site, or organizational unit, and then click **OK**.
3. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object to which you want to delegate permissions, and then click **OK**.
4. In the **Enter the object name to select** box, enter name of the object to which you want to delegate permissions by doing one of the following:
   - If you know the name, type it, and then click **OK**.
   - To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box,

click **OK**, and then click **OK**.

5. In the **Add Group or User** dialog box, in the **Permissions** drop down list box, select the level to which you want permissions to apply for this group or user, and then click **OK**.

**To add a new group or user to the permissions list for sites**

1. On the **Delegation** tab, click **Add**.

2. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects to which you want to delegate permissions for the domain, site, or organizational unit, and then click **OK**.

3. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object to which you want to delegate permissions, and then click **OK**.

4. In the **Enter the object name to select** box, enter name of the object to which you want to delegate permissions by doing one of the following:

   - If you know the name, type it, and then click **OK**.

   - To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.

**To change the inheritance of permissions on a domain or organizational unit for a group or user**

- On the **Delegation** tab of the domain or organizational user, in the **Groups and users** list box, right-click the name of the group or user, and then click **This container only** or **This container and children** to specify the level to which you want permissions to apply for this group or user.

**To remove a group or user from the permissions list**

1. On the **Delegation** tab, in the **Groups and users** list box, select the name of the group or user to be removed, and then click **Remove**.

2. When prompted to confirm the removal, click **OK**.

## Notes

- To delegate permissions to Link GPOs to a site, domain or organizational unit, you must have **Modify Permissions** on that site, domain or organizational unit. By default, only Domain Administrators, Enterprise Administrators, have this permission.

- Users and groups with permission to link GPOs to a specific site, domain, or organizational unit can link GPOs, change link order, and set block inheritance on that site, domain, or organizational unit.

- You cannot remove groups and users that inherit permissions from a parent container.

- Some entries in the **Groups and users** list box, such as **System**, do not have an associated property dialog box, so **Properties** is unavailable for these entries.

**To delegate permissions for generating Group Policy Modeling data**

1. Open Group Policy Management.

2. In the console tree, click the domain or organizational unit for which you want to delegate Group Policy Modeling

permissions.

**Where?**

- *Forest name*/Domains/*Domain name*/Organizational unit (if applicable)

3. In the results pane, click the **Delegation** tab.

4. In the **Permission** box, select **Perform Group Policy Modeling analyses**, and then do one of the following:

| | |
|---|---|
| **To add a new group or user to the permissions list** | a. On the **Delegation** tab, click **Add**.<br><br>b. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects to which you want to delegate permissions for the domain, site, or organizational unit, and then click **OK**.<br><br>c. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object to which you want to delegate permissions, and then click **OK**.<br><br>d. In the **Enter the object name to select** box, enter name of the object to which you want to delegate permissions by doing one of the following:<br><br>• If you know the name, type it, and then click **OK**.<br><br>• To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.<br><br>• In the **Add Group or User** dialog box, in the **Permissions** drop down list box, select the level to which you want permissions to apply for this group or user, and then click **OK**. |
| **To change the inheritance for a group or user in the permissions list** | On the **Delegation** tab, in the **Groups and users** list box, right-click the name of the group or user, and then click **This container only** or **This container and children** to specify the level to which you want permissions to apply for this group or user. |
| **To remove a group or user from the permissions list** | a. On the **Delegation** tab, in the **Groups and users** list box, select the name of the group or user to be removed, and then click **Remove**.<br><br>b. When prompted to confirm the removal, click **OK**. |

**Notes**

- To delegate permissions to perform Group Policy Modeling analyses for objects in a domain or organizational unit, you must have **Modify Permissions** on that domain or organizational unit. By default, only Domain Administrators and Enterprise Administrators have this permission.

- You cannot delegate permission to perform Group Policy Modeling analyses for sites.

- In earlier versions of Group Policy, Group Policy Modeling was referred to as Resultant Set of Policy (RSoP) planning mode.

**To delegate permissions to read Group Policy Results data**

1. Open Group Policy Management.

2. In the console tree, click the domain or organizational unit for which you want to delegate permission to read Group Policy Results data.

   **Where?**

   - Group Policy Management Console/*Forest name*/Domains/*Domain name*/Organizational unit (if applicable)

3. In the results pane, click the **Delegation** tab.

4. In the **Permissions** dropdown list, select **Read Group Policy Results data**, and then do one of the following:

| | |
|---|---|
| **To add a new group or user to the permissions list** | a. On the **Delegation** tab, click **Add**.<br>b. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects to which you want to delegate permissions for the domain, site, or organizational unit, and then click **OK**.<br>c. Select the user or group to who permission should be delegated.<br>d. In the **Add Group or User** dialog box, in the **Permissions** drop down list box, select the level to which you want permissions to apply for this group or user, and then click **OK**. |
| **To change inheritance for a group or user in the permissions list** | On the **Delegation** tab, in the **Groups and users** list box, right-click the name of the group or user, and then click **This container only** or **This container and children** to specify the level to which you want permissions to apply for this group or user. |
| **To remove a group or user from the permissions list** | a. On the **Delegation** tab, in the **Groups and users** list box, select the name of the group or user to be removed, and then click **Remove**.<br>b. When prompted to confirm the removal, click **OK**. |

**Notes**

- To delegate permissions to read Group Policy Results data for objects in a domain or organizational unit, you must have **Modify Permissions** on that domain or organizational unit. By default, only Domain Administrators and Enterprise Administrators have this permission.

- You cannot delegate permission to read Group Policy Results data for sites.

- In earlier versions of Group Policy, Group Policy Results was referred to as Resultant Set of Policy (RSoP) logging mode.

# Delegate creation of WMI filters using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate creation of WMI filters**

1. Open Group Policy Management.

2. In the console tree, click **WMI Filters** in the forest and domain in which you want to delegate management permissions for all WMI filters.

   **Where?**

   *Forest name*/Domains/*Domain name*/WMI Filters

3. In the results pane, click the **Delegation** tab, and then do one of the following:

   - To add a new group or user with management permissions on all WMI filters
   - To change the permission levels on all WMI filters for a group or user
   - To remove a group or user from the permissions list for all WMI filters

**To add a new group or user with management permissions on all WMI filters**

1. Click **Add**.

2. In the **Select Users, Computers, or Groups** dialog box, click **Object Types**, select the types of objects to which you want to delegate permissions on all WMI filters, and then click **OK**.

3. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object to which you want to delegate permissions, and then click **OK**.

4. In the **Enter the object name to select** box, enter name of the object to which you want to delegate permissions by doing one of the following:

   a. If you know the name, type it, and then click **OK**.

   b. To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.

5. In the **Add Group or User** dialog box, select the permissions level you want to assign to the group or user, and then click **OK**.

**To change the permission levels on all WMI filters for a group or user**

- In the list box, right-click the name of the group or user, and then click **Creator Owner** or **Full Control** to specify the permissions level you want to assign to the group or user.

**To remove a group or user from the permissions list for all WMI filters**

- In the **Groups and users** list box, select the name of the group or user to have permissions on all WMI filters removed, and then click **Remove**.

- or -

1. If the group or user is a member of another group with these permissions, double-click the group it belongs to. In the property dialog box that appears, click the group or user you want to remove, and then click **Remove**.

2. When prompted to confirm the removal of the delegation privilege, click **OK**.

### Notes

- You must be a domain administrator or Enterprise Administrator to delegate permissions on all WMI filters in a domain.

- Users with Full control permissions can create and control all WMI filters in the domain, including WMI filters created by others. Users with Creator owner permissions can create WMI filters, but can only control WMI filters that they create.

- If you remove Group Policy Creator Owners from the permissions list, users who create Group Policy objects (GPOs) can no longer create WMI filters unless they are explicitly given that permission through membership in another group.

- All users must have Read access to all WMI filters. Otherwise, Group Policy stops processing when it encounters a WMI filter that cannot be read. You cannot use Group Policy Management to remove Read permissions from WMI filters.

- **WMI Filters** is only available if at least one domain controller in the domain is running Windows Server 2003. The same is true for **WMI Filtering** on the **Scope** tab for GPOs.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate an individual WMI filter using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate an individual WMI filter**

1. Open Group Policy Management.
2. In the console tree, click the WMI filter you want to delegate permissions for.

   **Where?**

   *Forest name*/Domains/*Domain name*/WMI Filters/*WMI filter name*

3. In the results pane, click the **Delegation** tab, and then do one of the following:

   - To add a new group or user with management permissions on the WMI filter
   - To change the permissions levels on the WMI filter for a group or user in the permission list
   - To remove a group or user from the permissions list for the WMI filter

**To add a new group or user with management permissions on the WMI filter**

1. Click **Add**.
2. In the **Select User, Computer, or Group** dialog box, click **Object Types**, select the types of objects to which you want to delegate permissions on the WMI filter, and then click **OK**.
3. Click **Locations**, select either **Entire Directory** or the domain or organizational unit containing the object to which you want to delegate permissions, and then click **OK**.
4. In the **Enter the object name to select** box, enter name of the object to which you want to delegate permissions by doing one of the following:

   - If you know the name, type it, and then click **OK**.
   - To search for the name, click **Advanced**, enter the search criteria, click **Find Now**, select the name in the list box, click **OK**, and then click **OK**.

5. In the **Add Group or User** dialog box, in the **Permissions** box, select the permissions level you want to assign to the group or user, and then click **OK**.

**To change the permissions levels on the WMI filter for a group or user in the permission list**

1. In the list box, right-click the name of the group or user, and then click **Edit** or **Full Control** to specify the permissions level you want to assign to that group or user.
2. When prompted to confirm the change, click **OK**.

**To remove a group or user from the permissions list for the WMI filter**

1. In the list box, select the name of the group or user for which you want to have permissions removed, and then click

**Remove**.

2. When prompted to confirm the removal of the delegation privilege, click **OK**.

### Notes

- You must have Full Control permissions on a WMI filter to change its permissions.
- You cannot remove or change inherited permissions for WMI filters.
- All users must have Read access to all WMI filters. Otherwise, Group Policy stops processing when it encounters a WMI filter that cannot be read.
- You cannot use Group Policy Management to remove Read permissions from WMI filters.
- To open Group Policy Management, click **Start,** click **Programs,** click **Administrative Tools,** and then click **Group Policy Management**.
- **WMI Filters** is only available if at least one domain controller in the domain is running Windows Server 2003.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Script and Command Line Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Script and Command Line Methods**

- Run a script for a Group Policy-related task
- Refresh Group Policy settings with GPUpdate.exe
- Determine Resultant Set of Policy with GPResult.exe

# Run a script for a Group Policy-related task

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run a script for a Group Policy related task**

- From the command line, enter the path and name of the script with the appropriate parameters. If cscript is not your default scripting host, be sure to precede this script name with "cscript" and enclose the path name in quotes if it contains spaces.

## Notes

- Group Policy Management Console (GPMC) provides over 30 sample scripts that you can use to perform various administrative tasks. All of the scripts are located in **%programfiles%\gpmc\scripts** directory on any computer where you installed GPMC.
- All of these scripts execute from the command line. Executing a script with the /? switch displays the usage for that script.
- The sample scripts echo output to the command window and must be executed using cscript.exe. If cscript.exe is not your default scripting host, you will need to explicitly specify cscript.exe on the command line. For example, to run the ListAllGPOs.wsf script, type the following at the command line: "cscript ListAllGPOs.wsf".
- You can run "cscript //H:cscript" from a command line to make cscript the default scripting host.
- These sample scripts are based on the COM interfaces that are provided by Group Policy Management Console. The interfaces are documented in the Group Policy Management Console SDK, which is located at **%program%files\gpmc\scripts\gpmc.chm** on any computer where you installed GPMC. The GPMC SDK is also available in the Platform SDK. The GPMC SDK is only available in English.
- You can modify and distribute the sample scripts in accordance with the terms of the End User License Agreement.
- For more information, see Scripting Group Policy tasks using GPMC.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Refresh Group Policy settings with GPUpdate.exe

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To refresh Group Policy settings with GPUpdate**

The **gpupdate** command refreshes local and Active Directory–based Group Policy settings, including security settings on the computer from where it is run. You can use **gpupdate** locally on Windows XP and higher computers to refresh policy immediately. On computers running Windows 2000, this functionality is provided by the using the **secedit** command with the refreshpolicy option.

**Syntax**

**Gpupdate** [**/target:**{**computer**|**user**}] [**/force**] [**/wait:***value*] [**/logoff**] [**/boot**]

**Parameters**

**/target:{computer|user}**

Processes only the *computer* settings or the current *user* settings. By default, both the computer settings and the user settings are processed.

**/force**

Ignores all processing optimizations and reapplies all settings. The Group Policy engine on the client tracks versions of the GPOs that are applied to the user and computer. By default, if none of the GPO versions change and the list of GPOs remains the same, the Group Policy engine will not reprocess policy. This option overrides this optimization and forces the Group Policy engine to reprocess all policy information.

**/wait: *value***

Number of seconds that policy processing waits to finish. The default is 600 seconds. *0* means "no wait"; *-1* means "wait indefinitely."

**/logoff**

Logs off after the refresh has completed. This is required for those Group Policy client-side extensions that do not process on a background refresh cycle but that do process when the user logs on, such as user Software Installation and Folder Redirection. This option has no effect if there are no extensions called that require the user to log off.

**/boot**

Restarts the computer after the refresh has completed. This is required for those Group Policy client-side extensions that do not process on a background refresh cycle but that do process when the computer starts up, such as computer Software Installation. This option has no effect if there are no extensions called that require the computer to be restarted.

**/?**

Displays help at the command prompt.

**Remarks**

- If you make a syntax error, a syntax summary appears that looks similar to this Help topic.

**Examples**

The following examples show how you can use the **gpupdate** command:

- **gpupdate**
- **gpupdate /target:computer**
- **gpupdate /force /wait:**100
- **gpupdate /boot**

**Formatting legend**

| Format | Meaning |
|---|---|

| | |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Determine Resultant Set of Policy with GPResult.exe

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To determine resultant set of policy with GPResult**

Gpresult is a command line tool and must be run from the command prompt. The **gpresult** command displays Resultant Set of Policy (RSOP) for a user or a computer. You can use gpresult to see what policy is in effect and to troubleshoot problems on Windows XP and higher computers.

**Important**

The gpresult.exe that ships with Windows XP and Windows Server 2003 family is completely different than the original version of gpresult.exe that shipped in the Windows 2000 Resource Kit. The newer version cannot be used to view policy information for computers running Windows 2000.

**Syntax**

**Gpresult** [**/s** *computer* [**/u** *domain\user* **/p** *password*]] [**/user** *TargetUserName*] [**/scope** {**user**|**computer**}] [**/v**] [**/z**]

**Parameters**

***/s computer***

Specifies the name or IP address of a remote computer. (Do not use backslashes.) The default is the local computer.

**/u *domain\user***

Runs the command with the account permissions of the user that is specified by *user* or *domain\user*. The default is the permissions of the current logged-on user on the computer that issues the command.

**/p *password***

Specifies the password of the user account that is specified in the **/u** parameter.

**/user *TargetUserName***

Specifies the user name of the user whose RSOP data is to be displayed.

**/scope {user|computer}**

Displays either **user** or **computer** results. Valid values for the **/scope** parameter are **user** or **computer**. If you omit the **/scope** parameter, **gpresult** displays both **user** and **computer** settings.

**/v**

Specifies that the output display verbose policy information.

**/z**

Specifies that the output display all available information about Group Policy. Because this parameter produces more information than the **/v** parameter, redirect output to a text file when you use this parameter (for example, **gpresult /z >policy.txt**).

**/?**

Displays help at the command prompt.

**Remarks**

- Because you can apply overlapping levels of policies to any computer or user, the Group Policy feature generates a resulting set of policies when the user logs on to the network. **Gpresult** displays the resulting set of policies that were enforced on the computer when the specified user logged on.

**Examples**

The following examples show how you can use the **gpresult** command:

**gpresult /user targetusername /scope computer**

**gpresult /s srvmain /u maindom\hiropln /p p@ssW23 /user targetusername /scope USER**

**gpresult /s srvmain /u maindom\hiropln /p p@ssW23 /user targetusername /z >policy.txt**

**gpresult /s srvmain /u maindom\hiropln /p p@ssW23**

**Formatting legend**

| Format | Meaning |
| --- | --- |
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# GPMC Concepts

Updated: January 21, 2005

- Delegation and policy-related permissions

# Domains in Group Policy Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Domains in Group Policy Management Console**
Group Policy Management Console (GPMC) supports management of multiple domains at the same time, with each domain grouped by forest in the console.

For information about GPMC in a multi-forest environment, see Forests in Group Policy Management Console.

**Adding and removing domains**
By default, only a single domain is shown in GPMC. When you first start GPMC using either the pre-configured snap-in (gpmc.msc) or a custom MMC console, GPMC displays the domain that contains the user account you used to start GPMC. When you add a new forest, GPMC displays the domain that was entered in the **Add Forest** dialog box.

You can specify domains in each forest that you want to manage using GPMC by adding and removing the domains shown in the console.

- Adding domains
- Removing domains

**Adding domains**
Under each forest, right-click the **Domains** node and click **Show Domains**. In the **Show Domains** dialog box, select each domain that you want to display in GPMC.

To add domains in another forest, you must first add the new forest that contains that domain.

You can add externally trusted domains, even if you do not have forest trust with the entire forest. By default, you must have two-way trust between the domain you want to add and the domain of your user object. You can also add domains across a one-way trust by disabling the trust detection feature of GPMC, using the **Options** dialog box on the **View** menu. To add externally trusted domains, you must first use the **Add Forest** dialog box to add one domain from a forest that contains the externally trusted domains. Once this forest is added, you can add any domains in that forest that are trusted by right-clicking the Domains node of the forest and clicking **Show Domains**.

For step-by-step instructions, see Add a forest, site, or domain to the Group Policy Management Console.

**Removing domains**
Remove domains from the console by using the **Show Domains** dialog box, available by right-clicking the **Domains** node. In the **Show Domains** dialog box, clear check boxes if you want to remove them from GPMC. You can also right-click an existing domain in the console and click **Remove**.

# Forests in Group Policy Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Forests in Group Policy Management Console**
Group Policy Management Console (GPMC) supports management of multiple forests from within the console, when there is trust between the target forest and the forest of your user object.

### Notes

- GPOs cannot be linked outside a forest.
- GPMC also supports operations such as backup and import, to allow migrating GPOs between untrusted domains in separate forests.

**Adding and removing forests**
When you first open Group Policy Management, it displays only the forest containing the domain of your user account (you, the GPMC user). You can add additional existing forests, as long as there is trust between the forest of your user account and the other forest. Forest trust is a new feature of Windows Server 2003. You can also add externally trusted domains even if there is no forest trust, provided there is an explicit external trust.

You can enable support for adding forests and domains with one way trusts, by turning off the trust detection feature of GPMC, using the Options dialog box on the View menu. By default, GPMC requires two-way trust to the target forest, either via a two-way external trust between domains, or a two way forest trust between the forests.

It is not possible to add a forest to which you have no trust.

In GPMC, each forest shows the following child nodes: **Domains**, **Sites**, and **Group Policy Results**. Forests with the Windows Server 2003 schema will also show **Group Policy Modeling**.

- Adding forests
- Removing forests

**Adding forests**
Add forests one at a time, by right-clicking the Group Policy Management root node and clicking **Add Forest**. You specify either the NetBIOS name or the DNS name of a domain in the forest.

When adding a forest, the forest displayed in Group Policy Management is named after the forest root domain for that forest and includes a single domain, which is the domain that you specified in the **Add forest** dialog box. To show other domains, you can add them by right-clicking the **Domains** node and clicking **Show Domains**.

For step-by-step instructions to add a forest, see Add a forest, site, or domain to the Group Policy Management Console.

**Removing forests**
You remove forests from GPMC one at a time by right-clicking each forest node and clicking **Remove**.

# Backup, Restore, Import, Copy, and Migration Tables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backup, Restore, Import, Copy, and Migration Tables**
With Group Policy Management Console (GPMC) you can back up, restore, import, or copy Group Policy objects (GPOs). When copying or importing GPOs across domains, you can use migration tables to facilitate the copy or import operation.

This section contains the following information:

- Backup using GPMC
- Restore using GPMC
- Import using GPMC
- Copy using GPMC
- Migration tables
- The migration table editor

# Backup using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backup**
Backing up a Group Policy object (GPO) copies the data in the GPO to the file system. The backup function also serves as the export capability for GPOs. A GPO backup can be used to restore the GPO to the backed-up state, or to import the settings in the backup to another GPO. For step-by-step instructions, see Back up a Group Policy object using GPMC.

**What is saved in a backup**
Backing up a GPO saves all information that is stored inside the GPO to the file system. This includes the following information:

- The GPO globally unique identifier (GUID) and domain
- GPO Settings
- The discretionary access control list (DACL) on the GPO
- The WMI filter link, if there is one, but not the filter itself
- Links to IP Security Policies, if any
- XML report of the GPO settings, which can be viewed as HTML from within GPMC
- Date and time stamp of when the backup was taken
- User-supplied description of the backup

**What is not saved in a backup**
Backing up a GPO only saves data that is stored inside the GPO. Data that is stored outside the GPO includes the following information:

- Links to a site, domain or organizational unit
- WMI filter
- IP Security policy

This data is not available when the backup is restored to the original GPO or imported into a new one.

**Managing Backups**
Multiple backups of the same or different GPO can be stored in the same file system location. Each backup is identified by a unique backup ID. The collection of backups in a given file system location can be managed using the **Manage Backups** dialog box in GPMC or through the scriptable interfaces. The **Manage Backups** dialog box is available by right-clicking either the **Domains** node or the **Group Policy Objects** node in a given domain. When you open **Manage Backups** from the Group Policy Objects node, the view is automatically filtered to show only backups of GPOs from that domain. When opened from the **Domains** node, the **Manage Backups** dialog box shows all backups, regardless of which domain they are from.

**Securing GPO backups**
To prevent unauthorized access and tampering, you should store GPO backups in a secure location with strong file system security (using discretionary access control lists, also known as DACLs) so that only authorized administrators have access to the backups.

For additional security, you can store these files on computers running Windows 2000 or later operating systems. This will prevent tampering with the data while in transit over the network. This is because all SMB traffic between computers running Windows 2000 and above is digitally signed by default. Furthermore, mutual authentication is used for communications between computers running Windows 2000 or later, which ensures that the data comes from a trusted source.

# Restore using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restore**

Restoring a Group Policy object (GPO) re-creates the GPO from the data in the backup. A restore operation can be used in both of the following cases: the GPO was backed up but has since been deleted, or the GPO is live and you want to roll back to a known previous state. The end effect is the same in either case, except as noted below in some cases for GPOs that contain software installation settings. A restore operation replaces the following components of a GPO:

- GPO settings
- The Discretionary Access Control List (DACL) on the GPO
- WMI filter links (but not the filters themselves)

The restore operation does not restore objects that are not part of the GPO. This includes:

- Links to a site, domain, or organizational unit. Links are an attribute of the site, domain, or organizational unit, not the GPO. Any existing links in these containers will continue to be used, for example, when restoring an existing GPO to a previous state. However, if you have deleted a GPO and all links to the GPO, you must add these links back after restoring the GPO.
- WMI filters. A GPO only contains a link to the WMI filter. If the WMI filter does not exist at the time of restore, the link will be dropped, otherwise the link will be restored.
- IPSec Policies. A GPO only contains a link to the IPSec policy. If the IPSec policy does not exist at the time of restore, the link will be dropped, otherwise the link will be restored.

GPMC identifies the GPO by its domain and globally unique identifier (GUID). The purpose of a restore operation is to return the GPO to its original state, so the restore operation retains the original GUID even if it is recreating a deleted GPO. This is a key difference between the restore operation and the import or copy operations. You cannot use restore to transfer GPOs to different domains or forests. That capability is provided by import and copy.

GPMC identifies the GPO by its domain and globally unique identifier (GUID), a restore operation retains the original GUID even if it is recreating a deleted GPO. This is a key difference between the restore operation and the import or copy operations. You cannot use restore to transfer GPOs to different domains or forests. That capability is provided by import and copy.

**Restoring a GPO from backup: permissions required**

The permissions necessary to perform a restore of a GPO vary, depending on whether you are restoring an existing GPO or if you are restoring a GPO that has been deleted since it was backed up. Version numbers for the GPO are handled differently as well. The following table summarizes the situation for existing and deleted GPOs:

| GPO state | Permission needed to restore GPO from backup | GPO version number |
|---|---|---|
| Existing GPO | The user must have **Edit settings, delete, and modify** permissions on the GPO, as well as read access to the file system location where the backup is stored. This does NOT require GPO creation rights. | Incremented by 1, which will trigger client refreshes of settings from the GPO. |
| Deleted GPO | The user must have the right to create GPOs in the domain, as well as read access to the file system location where the backup is stored. | Retained unchanged from the backed-up GPO. |

**Restoring GPOs with software installation settings**

When restoring a *deleted* GPO that contains Software Installation settings, some side effects are possible depending on the circumstances under which the GPO is restored.

When restoring a GPO that contains software installation settings, it is possible that:

- Cross-GPO upgrade relationships that upgrade applications in the GPO being restored, if any, are not preserved after restore. A cross-GPO upgrade is one in which the administrator has specified that an application should upgrade another application, and the two applications are not in the same GPO. Note that upgrade relationships are preserved when applications—in the GPO being restored—upgrade applications in other GPOs.

- If the client computer has not yet detected that the GPO has been deleted (either because the user has not logged on again or rebooted since the deletion of the GPO), and the application was deployed with the option to **Uninstall this application when it falls out of scope of management** then the next time the user logs on:

    - Published applications that the user has previously installed will be removed.

    - Assigned applications will be uninstalled before re-installation.

This issue can be avoided if all of the following conditions are met:

- You perform the restore on a Windows Server 2003 domain controller instead of a Windows 2000 domain controller.

- The user performing the restore has permissions to re-animate tombstone objects in the domain.

- The time elapsed between deletion and restoration of the GPO does not exceed the tombstone lifetime specified in Active Directory.

Tombstone re-animation is a new feature of Windows Server 2003 Active Directory. By default, only Domain Admins and Enterprise Admins have this permission but you can delegate this right to additional users at the domain level using the ACL editor.

As a general rule, if you deploy software using Group Policy, it is recommended that you perform the restoration of GPOs that contain application deployments using a domain controller running Windows Server 2003 and that you grant the tombstone re-animation right to the users who will be performing restoration of those GPOs.

For more details on this issue, see the Group Policy Administration with Group Policy Management Console (GPMC) (http://www.microsoft.com/).

Finally, when restoring a GPO that contains software installation settings, if you are using categories to classify applications, the application in the restored GPO will appear in its original category only if the category exists at the time of restoration. Note that the category definition is not part of the GPO.

# Import using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Import**
The Import operation transfers settings into an existing GPO in Active Directory using a backed-up GPO in the file system location as its source. Import operations can be used to transfer settings from one GPO to another GPO within the same domain, to a GPO in another domain in the same forest, or to a GPO in a domain in a different forest. The import operation always places the backed-up settings into an existing GPO. It erases any pre-existing settings in the destination GPO. Import does not require trust between the source domain and destination domain. Therefore it is useful for transferring settings across forests and domains that don't have trust. Importing settings into a GPO does not affect its discretionary access control list (DACL), links on sites domains or organizational units to that GPO, or a link to a WMI filter.

For step-by-step instructions, see Import a Group Policy object using GPMC.

If you have separate test and production forests, with or without trust, it is a good idea to test GPOs in the test forest before importing them into the production forest.

When using import to transfer GPO settings to a GPO in a different domain or different forest, you may want to use a migration table in conjunction with the import operation. A migration table allows you to facilitate the transfer of references to security groups, users, computers, and UNC paths in the source GPO to new values in the destination GPO. For information about migration tables, see Migration tables. For step-by-step instructions on creating a migration table, see Create a migration table.

# Copy using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Copy**
A copy operation allows you to transfer settings from an existing Group Policy object (GPO) in Active Directory directly into a new GPO. The new GPO created during the copy operation is given a new globally unique identifier (GUID) and is unlinked. You can use a copy operation to transfer settings to a new GPO in the same domain, another domain in the same forest, or a domain in another forest. Because a copy operation uses an existing GPO in Active Directory as its source, trust is required between the source and destination domains. Copy operations are suited for moving Group Policy between production environments, and for migrating Group Policy that has been tested in a test domain or forest to a production environment, as long as there is trust between the source and destination domains.

For step-by-step instructions, see Copy a Group Policy object using GPMC.

**Copying** is similar to a backing up followed by importing, but there is no intermediate file system step, and a new GPO is created as part of the copy operation. For information about backup, see Backup using GPMC.

The import operation, by contrast with the copy operation, does not require trust. For information about the import operation, see Import using GPMC.

**Specifying the discretionary access control list (DACL) on the new GPO**
You have two options for specifying the DACL to use on the new GPO:

- Use the default permissions that are used when creating new GPOs.
- Preserve the DACL from the source GPO. For this option, you can specify a migration table, used to facilitate the transfer of references to security groups, users, computers, and UNC paths in the source GPO to new values in the destination GPO. If you specify a migration table for the copy operation, and you choose the option to preserve the DACL from the source GPO, the migration table will apply to any security principals in the DACL. For information on migration tables, see Migration tables.

**Copying within a domain compared with copying to another domain**
Copying a GPO to another domain is slightly different from copying it to the same domain:

When copying a GPO within the same domain, you have a simple choice of two options, just described, for choosing the DACL. However, for copy operations to another domain, GPMC presents a wizard to facilitate the operation. The wizard guides you through the following choices:

- Choice of DACL for the new GPO, as described earlier.
- Specification of migration table, if applicable. A migration table allows you to facilitate the transfer of references to security groups, users, computers, and UNC paths in the source GPO to new values in the destination GPO. For more details, see Migration tables.

When copying a GPO within the same domain, any link to a WMI filter is preserved. However, when copying a GPO to a new domain, the link is dropped because WMI filters can only be linked to GPOs within the same domain.

# Migration tables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Migration tables**

When you copy or import a Group Policy object (GPO) from one domain to another, you can use a migration table to tell Group Policy Management Console (GPMC) how domain-specific data should be treated.

The key challenge when migrating GPOs from one domain to another is that some information in the GPO is actually specific to the domain where the GPO is defined. When transferring the GPO to a new domain, it may not always be desirable, or even possible, to use the exact same settings. Items that can be specific to a domain include references to security principals such as users, groups, and computers as well as UNC paths. The solution is to modify these references in the GPO that are domain-specific, during the import or copy operation, so that the settings in the destination GPO are written with the appropriate information for the destination domain. GPMC supports this capability using migration tables.

A migration table is a file that maps references to users, groups, computers, and UNC paths in the source GPO to new values in the destination GPO. A migration table consists of one or more mapping entries. Each mapping entry consists of a type, source reference, and destination reference. If you specify a migration table when performing an import or copy, each reference to the source entry will be replaced with the destination entry when writing the settings into the destination GPO.

The migration table will apply to any references in the settings within a GPO, whether you are performing an import or copy operation. In addition, during a copy operation, if you choose the option to preserve the discretionary access control list (DACL) on the GPO, the migration table will also apply to both the DACL on the GPO and the DACLs on any software installation settings in the GPO.

Migration tables store the mapping information as XML, and have their own file name extension, .migtable. You can create migration tables using the Migration Table Editor (MTE). The MTE is a convenient tool for viewing and editing migration tables without having to work in, or be familiar with, XML. The MTE is associated with the .migtable extension so that when you double click a migration table, it opens in the MTE. The MTE is installed with GPMC. For information about MTE, see The migration table editor. You can also create and edit migration tables using any XML editor or using the GPMC scripting interfaces.

For more information about using migration tables for importing GPOs from one forest to another, see the white paper, Migrating GPOs Across Domains with GPMC.

**Settings impacted by migration tables**

There are two types of settings that may not transfer well across domains:

- Users, groups, and computers (security principals) that are referenced in the following places: the settings of the GPO, in the ACL for the GPO itself, and the ACL for any software installation settings in the GPO. Security principals do not transfer well for several reasons. For instance, domain local groups are invalid in external domains but other groups are valid if there is trust in place. Even with a trust between domains, it may not always be appropriate to use the exact same group in the new domain. If there is no trust, then none of the security principals in the source domain will be available in the destination domain.

- UNC paths. When you are migrating GPOs across domains that do not have trust, such as from test to production environments, users in the destination domain may not have access to paths in the source domain.

The following items can contain security principals and can be modified using a migration table:

- Security policy settings of the following types:
    - User rights assignment
    - Restricted groups
    - Services
    - File system

    - Registry

- Advanced folder redirection policies.

- The GPO Discretionary Access Control List (DACL), if you choose to preserve it during a copy operation.

- The DACL on software installation objects. This is only preserved if the option to copy the GPO DACL is specified. Otherwise the default DACL is used.

  **Note**

    - Security Principals referenced in Administrative Templates settings cannot be migrated using a migration table.

The following items can contain UNC paths and can be modified using a migration table:

- Folder redirection policies.

- Software installation policies (for software distribution points).

- Pointers to scripts deployed through Group Policy (such as startup and shutdown scripts) that are stored outside the GPO. Note that the script itself is not copied as part of the GPO copy operation, unless the script is stored inside the source GPO.

**Options for specifying migration tables**
Migration tables are specified when performing import and copy operations. There are three options for using migration tables with import and copy:

- Do not use a migration table. This option copies the GPO exactly as it is. All references to security principals and UNC paths are copied identically.

- Use a migration table. This option maps any references in the GPO that are in the migration table. References that are not contained in the migration table are copied as is.

- Use a migration table exclusively. This option requires that all references to security principals and UNC paths that are referenced in the source GPO be specified in the migration table. If a security principal or UNC path is referenced in the source GPO and is not included in the migration table, the import or copy operation fails.

In addition, cross-domain copy operations will apply the migration table to the DACL on the GPO (and any software installation settings) if you choose the option to **Preserve or migrate the existing permissions.**

When performing a copy or import, the wizard scans the source GPO to determine if there are any references to security principals or UNC paths in the GPO. If there are, you have the opportunity to specify a migration table. During cross-domain copy operations, if you specify the option to **Preserve or migrate the permissions on the GPO**, the wizard will always present the opportunity to specify a migration table, because a DACL by definition contains security principals.

**Contents of Migration tables**
A migration table consists of one or more mapping entries. Each mapping entry has three pieces of information: Type, source and destination. The following table describes these categories in more detail.

| | **Description** |
|---|---|

| | |
|---|---|
| **Source Type** | The type of domain-specific information in the domain for the source GPO. Migration tables support the following types:<br>• User<br>• Computer<br>• Domain Local Group<br>• Domain Global Group<br>• Universal Group<br>• UNC Path<br>• Free Text or security identifier (SID). Note: This category is only for use with security principals that are specified as free text and raw SIDs.<br><br>**Note**<br>• Built-in groups such as "Administrators" and "Account Operators" have the same SID in all domains. If references to built-in groups are stored in the GPO using their resolved format (based on the underlying SID), they cannot be mapped using migration tables. However, if references to built-in groups are stored as free text, you can map them using a migration table, and in this case, you must specify source type="Free Text or SID."<br><br>When viewed in an XML editor, the types are represented as follows:<br>• `<Type>User</Type>`<br>• `<Type>Computer</Type>`<br>• `<Type>LocalGroup</Type>`<br>• `<Type>GlobalGroup</Type>`<br>• `<Type>UniversalGroup</Type>`<br>• `<Type>UNCPath</Type>`<br>• `<Type>Unknown</Type>` |

| | |
|---|---|
| **Source Name** | The exact name of the User, Computer, Group or UNC Path referenced in the source GPO. For example, **TestDomain\PolicyAdmins** or **\\server1\publicshare.** The type of the source name must match the source type specified in the migration table.<br><br>Security principals can be specified using any of the following formats:<br><br>● UPN. For example, "someone@example.com".<br><br>● SAM. For example, "example\someone".<br><br>● DNS. For example, "example.com\someone".<br><br>● Free text. For example, "someone". You must specify the type as Unknown Group in this case.<br><br>● SID. For example, S-1-11-111111111-111111111-1111111111-1112. You must specify the type as Free Text or SID in this case. |

| | |
|---|---|
| **Destination Name** | The destination name specifies how the name of the User, Computer, Group or UNC Path in the source GPO should be treated upon transfer to the destination GPO.<br><br>There are four choices:<br><br>1. **Same as source**. Copy without changes. Equivalent to not putting the source value in the migration table at all.<br>  - MTE value: <Same As Source><br>  - XML tag:<br>  `<DestinationSameAsSource />`<br>2. **None**. Removes the User, Computer or Group from the GPO. This option cannot be used with UNC paths.<br>  - MTE value: <None><br>  - XML tag: <DestinationNone /><br>3. **Map by relative name**. For example, map **SourceDomain\Group1** to **TargetDomain\Group1**. This option cannot be used with UNC paths.<br>  - MTE value: <Map by Relative name><br>  - XML tag: `<DestinationByRelativeName />`<br>4. **Explicitly specify value.** In the destination GPO, replace the source value with the exact literal value you specify.<br>  - MTE value:<br>  `<exact name to use in target>`<br>  - XML tag: `<Destination>`*Exact name to use in target domain*`</Destination>`<br><br>Security principals can be specified using any of the following formats:<br><br>- UPN. For example, "someone@example.com".<br>- SAM. For example, "example\someone".<br>- DNS. For example, "example.com\someone".<br>- Free text. For example, "someone".<br><br>Raw SIDs cannot be used for the destination name. |

A sample migration table can be found at **%programfiles%\GPMC\scripts\SampleMigrationTable.migtable**.

**Creating Migration Tables Manually**

Valid migtable files must contain the following entries, which identifies the namespace used by .migtables. If you are creating migtables by hand, you need to add this. Otherwise MTE does this for you.

```
<?xml version="1.0" encoding="utf-16"? >

<MigrationTable xmlns="http://www.microsoft.com/GroupPolicy/GPOOperations/MigrationTable">
```

Each mapping entry appears in the following format:

```
<Mapping>

<Type> Type </Type>

<Source> Source </Source>

<Destination> Destination </Destination>

</Mapping>
```

Migration Tables can also be created using the GPMC scripting interfaces. For example, see the CreateMigrationTable.wsf sample script that is included with GPMC.

# The migration table editor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The Migration Table Editor**

The Migration Table Editor (MTE) is provided with Group Policy Management Console (GPMC) to facilitate the editing of migration tables. Migration tables are used for copying or importing Group Policy objects (GPOs) from one domain to another, in cases where the GPOs include domain-specific information that must be updated during copy or import. For information about migration tables, see Migration tables.

MTE displays three columns of information:

| Source Name | Source Type | Destination Name |
|---|---|---|
| Name of the user, computer, group, or UNC path, referenced in the source GPO. | The type of the reference named in the Source Name column. For example, Domain Global Group. | The new value, after copy or import to the new GPO; or the method used to calculate the new value. |

Note that you do not specify Destination Type. The Destination Type is determined during the import or copy operation by checking the actual reference identified in the Destination Name.

**Migration Table Editor Features**

MTE offers these features:

- You can edit text fields using Cut, Copy, and Paste options, for example when you right-click an item in the **Source Name** column.
- You can add computers, users, and groups, for source and destination names, by using a **Browse** dialog box.
- You can fill in **Source Type** fields by using a drop-down menu.
- MTE provides automatic syntax checking to make sure the XML file is properly populated and also ensures that only compatible entries are entered in the table. For example, \\server1\share1 is not a valid security group name name, and server1 is not a valid UNC path so MTE prompts the user to correct those entries.
- You can validate the overall migration table using MTE, in addition to basic syntax checking using the **Validate Table** option, which is available on the **Tools** menu. The **Validate Table** option checks to ensure:
    - The existence of destination security principals and UNC paths. This is important to know before you copy or import a GPO, because if there are unresolvable entries in the migration table, then the copy or import operation might fail.
    - Source entries with UNC paths do not have destinations of MapByRelative name or NoDestination.
    - Type of the destination entry in the table matches the real type in the destination source.
- You can auto-populate a migration table by scanning one or more GPOs or backups to extract all references to security principals and UNC paths, and then enter these items into the table as source name entries. This capability is provided by the **Populate from GPO** and **Populate from Backup** options available on the **Tools** menu. To complete the migration table, you only need to adjust the destination values. By default, the destination name for each entry will be set to **Same as source** when you use either of the Populate options.

  **Note**

    - With either auto-populate option, when the source GPO or backup contains references to built-in groups such as **Administrators** or **Backup Operators**, these references will not be entered into the migration table if the references are stored in the source GPO or backup in their resolved format [based on security identifier (SID)].

This is because built-in groups have the same SID in all domains and therefore cannot be mapped to new values using a migration table. However, if references to built-in groups are stored as free text, they will be captured by the auto-populate options. In this case, you can map them as long as you specify the source type as "Free Text or SID."

**Accessing Migration Table Editor**

MTE can be opened in the following ways:

- In GPMC, right-click either the **Domains** node in a given forest or the **Group Policy Objects** container in a given domain, and then click **Open Migration Table Editor**.
- In GPMC, when you use wizards to import or copy GPOs that have references to users, groups, computers, or UNC paths, you can open MTE to edit, examine, or create a migration table.
- When you double-click a migration table (.migtable), it opens in MTE.
- You can open MTE from the command line. The executable, mtedit.exe, is located in **Program Files\GPMC**. Example: mtedit table1.migtable /domain:domain1.wingtiptoys.com /DC:DC1.

**Command-line support for Migration Table Editor**

### Syntax

```
Mtedit.exe [/domain:value][/DC:value] [/forest:value][/DisableTrustChecking][filename]
[/?]
```

### Parameters

`/Domain:value`

Specifies the domains to be used with the "Populate from GPO" option. The domain must be specified in DNS format. When used with the /DC parameter, this parameter can be specified multiple times in the order to include multiple domains.

`/DC:value`

Specifies the domain controller to use for the previously specified domain. If no domain controller is specified, any will be used. You can specify either DNS or NetBIOS format for the name of the domain controller.

`/Forest:value`

If specified, the Migration Table Editor will use all domains in the specified forest to populate the Domain list in the Select GPO dialog box used for the "Populate from GPO" option. This parameter can be specified multiple times in the order to include domains from the more than one forest. The forest name must be specified as the DNS name of the forest root domain in the forest.

`/DisableTrustChecking`

If this parameter is not specified, you can only access domains to which you have two-way trust.

`Filename`

Specifies the name of a migration table you want to open in the Migration Table Editor.

`/?`

Displays the usage.

# Delegation and policy-related permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Delegation and policy-related permissions**

With Group Policy Management Console (GPMC), the following tasks can be delegated:

- Create Group Policy objects (GPOs) in a domain.
- Set permissions on a GPO.
- Set policy-related permissions on site, domain or organizational unit.
    - Link GPOs to a given site, domain or organizational unit.
    - Perform Group Policy Modeling analyses on a given domain or organizational unit (but not on a site).
    - Read Group Policy Results data for objects in a given domain or organizational unit (but not on a site).
- Create WMI filters in a domain.
- Set permissions on a WMI filter.

GPMC simplifies delegation by managing the various access control entries (ACEs) required for a task as a single bundle of permission for the task. If you want to see the access control list (ACL) in detail, you can click the **Advanced** button on the **Delegation** tab.

**Delegating creation of GPOs**

Creating GPOs is a user right of the Group Policy Creator Owners (GPCO) group by default but can be delegated to any group or user. There are two methods to grant a group or user this right:

- Add the user or group to membership of the Group Policy Creator Owners (GPCO) group. This was the only method available prior to GPMC.
- Explicitly grant the group or user permission to create GPOs. This method is newly available with GPMC.

You can manage this permission using the **Delegation** tab on the **Group Policy Objects** container for a given domain in GPMC. This tab shows the groups that have permission to create GPOs in the domain, including the GPCO group. From this tab, you can modify the membership of existing groups with this permission, or add new groups.

The ability to grant users permissions to create GPOs without using GPCO was added to facilitate the delegation of GPO creation to users outside the domain. Because the Group Policy Creator Owners group is a domain global group, it cannot contain members from outside the domain. Thus, prior to GPMC, this task could not be delegated to members outside the domain.

It is recommended that for users and groups within the domain, you continue to use the GPCO group to grant them GPO creation rights. If you require that users outside the domain have the ability to create GPOs, then create a new domain local group in the domain ("GPCO - External"), grant that group GPO creation rights in the domain, and then add external domain users to that group.

Adding a user to the membership of GPCO, or granting the user GPO creation permissions directly using the new method available in GPMC, is identical in terms of permissions. Users have the ability to create GPOs in the domain, but do not have permissions on GPOs created by other users. For example, granting a user the ability to create GPOs in the domain does not give the user the ability to edit or delete existing GPOs, or the ability to link the GPO to a site, domain or organizational unit.

For step-by-step instructions, see Delegate creation of Group Policy objects using GPMC.

**Delegating an individual GPO**

There are five permission options on GPOs in GPMC user interface. Each corresponds to a set of individual NT permissions. The correspondence is summarized in the following table.

| Option in GPMC user interface | Corresponding NT permission in ACL Editor |
|---|---|
| Read | Allow **Read** Access on the GPO |
| Edit settings | Allow **Read**, **Write**, **Create Child Objects**, and **Delete Child Objects** |
| Edit, delete, and modify security | Allow **Read**, **Write**, **Create Child Objects**, **Delete Child Objects**, **Delete**, **Modify Permissions**, and **Modify Owner**. This essentially grants full control on the GPO, except that the **Apply Group Policy** permission is not set. |
| Read (from Security Filtering) | This setting cannot be set directly, but appears on the delegation tab if the user has **Read** and **Apply Group Policy** permissions to the GPO. |
| Custom | Any other combination of permissions, including the use of **Deny** will show up as **Custom** in the display. GPMC can only set custom permission sets by clicking the Advanced button and opening the ACL editor. |

Permissions on a GPO are managed from the Delegation tab of that GPO. For step-by-step instructions, see Delegate an individual Group Policy object using GPMC.

**Delegating Group Policy-related permissions on sites, domains, and organizational units**

The ability to link GPOs to a site, domain or organizational unit is a permission that is specific to that site, domain or organizational unit. In GPMC, this permission can be managed using the **Delegation** tab on the site, domain or organizational unit when you click the **Link GPOs** option in the permission drop-down list box. At the individual permission level in Active Directory, this allows **Read** and **Write** access to the gPLink and gPOptions attributes on the site, domain, or organizational unit. By default, only Domain Administrators and Enterprise Administrators have this permission.

Group Policy Modeling allows the user to simulate the resultant set of policy for objects in a domain or organizational unit. In GPMC, this permission can be managed using the **Delegation** tab on the domain or organizational unit when you click the **Perform Group Policy Modeling Analyses** option in the **permission** drop-down list box. This feature is only available to Domain Administrators and Enterprise Administrators by default but can be delegated to other users or groups. At the individual permission level in Active Directory, this delegation is equivalent to granting the user or group the **Generate Resultant Set of Policy (Planning)** permission on the domain or organizational unit. This permission is only available in forests that have the Windows Server 2003 schema or later.

Group Policy Results allows the user to read Resultant Set of Policy logging data for objects in a domain or organizational unit. In GPMC, this permission can be managed using the **Delegation** tab on the domain or organizational unit when you click the **Read Group Policy Results data** option in the **permission** drop-down list box. By default, only users with local administrator rights on the target computer can remotely access Group Policy Results data. However, this right can be delegated to other users or groups. Delegation is performed on a domain or organizational unit. Users with this permission can read Group Policy Results data for any object in that container. This requires the **Generate Resultant Set of Policy (Logging)** permission on the domain or organizational unit. This permission is only available in forests with the Windows Server 2003 schema.

For step-by-step instructions for delegation of linking of GPOs, delegation of Group Policy Modeling analyses, and delegation of Group Policy Results, see Delegate policy-related permissions on a domain, OU, or site using GPMC.

**Delegating creation of WMI filters**

The ability to create WMI filters is a per-domain right. In GPMC, there are two levels of permission for creating WMI filters. **Creator Owner** allows the user to create new WMI Filters in the domain, but does not grant them permissions on WMI filters created by other users. **Full Control** allows the user to create WMI filters, and grants them full control on all WMI Filters in the domain, including new filters that are created after they are granted this right.

When a new WMI filter is created it is stored in the WMIPolicy container in the domain's System container in Active Directory Users and Computers. It is the permissions on the WMIPolicy container that govern the rights a user has to create, edit, and delete WMI Filters.

In GPMC, you can manage these permissions from the **Delegation** tab of the **WMI Filters** container in a given domain.

For step-by-step instructions, see Delegate creation of WMI filters using GPMC.

**Delegating an individual WMI Filter**

GPMC provides the ability to delegate rights on an individual WMI Filter. There are two levels of delegation of an individual WMI filters. **Edit** allows the user or group to edit the WMI Filter. **Full Control** allows the user or group to edit, delete, and modify security on the WMI Filter.

All users have **Read** access to all WMI filters through the Authenticated Users group, because it is required to allow policy processing. GPMC does not allow you to remove read permission.

These permissions are managed using the **Delegation** tab of a WMI filter. For step-by-step instructions, see Delegate an individual WMI filter using GPMC.

# Group Policy objects overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy objects**

Policy settings are stored in Group Policy objects (GPOs). Settings for each GPO are edited using the Group Policy Object Editor. After installation of the Group Policy Management Console (GPMC), Group Policy Object Editor is usually opened from GPMC. For information about Group Policy Object Editor, see Group Policy object editor overview for GPMC. For information about GPMC, see Group Policy Management Console Overview.

There are two kinds of GPOs:

- **Active Directory-based GPOs**. These are stored in a domain and replicate to all the domain controllers for the domain. They are available only in an Active Directory environment. They apply to users and computers in a site, domain, or organizational unit to which the Group Policy object is linked. This is the primary mechanism through which Group Policy is used in an Active Directory environment.

- **Local GPOs**. There is just one local GPO stored on each computer. Local GPOs are the least influential GPOs in an Active Directory environment, and local GPOs have only a subset of the settings found in Active Directory-based GPOs. For information about local GPOs, see Local Group Policy objects overview for GPMC.

**Active Directory-based GPOs**

Active Directory-based GPOs can be linked to a domain, site, or organizational unit to apply their settings.

A GPO can be linked to more than one site, domain or organizational unit.

A site, domain or organizational unit can have more than one GPO linked to it. In that case there are rules that determine which settings prevail in case of conflict. See Group Policy processing and precedence for information about these rules. In the case where multiple GPOs are linked to a particular site, domain, or organizational unit, you can prioritize the order and therefore the precedence with which these GPOs are applied. By default, the last applied configured setting is used. Settings are applied in this order: Local, Site, Domain, and organizational unit. For example, suppose **Add Logoff to the Start Menu** were configured in GPOs as follows:

| The local GPO | Site-linked GPO | Domain-linked GPO | Organizational unit-linked GPOs |
|---|---|---|---|
| Disabled | Not Configured | Disabled | Enabled for the first applied (link order 2) GPO, and Not Configured for the second applied GPO (link order 1) |

In that case Enabled wins, and Logoff will appear on the user's start menu.

GPMC introduces support for copy, import, backup, and restore of GPOs. See Back Up, Restore, Copy, and Import and Backup, Restore, Import, Copy, and Migration Tables for information about GPMC support for these tasks.

For information on modifying the scope of a GPO, see Controlling the Scope of Group Policy Objects using GPMC.

**User settings and computer settings**

GPO settings are divided between **User Configuration**, which holds settings that are applied to users when they log on, and **Computer Configuration**, which holds settings that are applied to computers when they start up (boot). Most settings are found in only one section, but a few, like **Run logon scripts synchronously**, are found in both. If they are found in both, and there is a disagreement, the computer setting is used.

User Configuration and Computer Configuration are further subdivided into a customizable set of MMC extensions to Group Policy. To learn about the default extensions, see Group Policy Object Editor Extensions.

**Changing the status of a GPO**

The status of a GPO is **Enabled** by default. It can be changed to **User settings disabled**, which disables the User Configuration of the GPO, or **Computer settings disabled**, which disables the Computer Configuration of the GPO, or **All settings disabled**, which disables the entire GPO. When a client computer processes a GPO, disabled portions of the GPO are not evaluated.

The status of a GPO is **Enabled** by default. It can be changed to **User settings disabled**, which affects all settings under **User Configuration**, or **Computer settings disabled**, which affects all settings under **Computer Configuration**, or **All settings disabled**, which disabled the entire GPO.

When you change the status of a GPO, all sites, domains and organizational units that get policy from the GPO are affected. Thus, disabling a GPO is more far-reaching than disabling one of it links.

**Notes**

- **Enforce** (previously known as "no override") on a GPO link takes precedence over **Block Inheritance** on a domain or organizational unit.
- If you turn on **Enforced** and turn off **Link Enabled** for a GPO link, then the GPO does not apply.
- **Block Inheritance** does not deflect Group Policy settings from GPOs that are linked directly to the domain or organizational unit that has **Block Inheritance** enabled.

**Default permissions on GPOs**

The default permissions on Group Policy objects are shown in the following table.

| Security group | Default permissions as shown in GPMC |
|---|---|
| Authenticated Users | Security Filtering on GPO Scope tab; "Read (from Security Filtering)" on Delegation tab |
| SYSTEM | Edit settings, delete, modify security |
| Domain Admins | Edit settings, delete, modify security |
| Enterprise Admins | Edit settings, delete, modify security |
| ENTERPRISE DOMAIN CONTROLLERS | Read |

**Note**

- The Enterprise domain controllers group is not granted any permissions on GPOs in a pure Windows 2000 forest that does not have the Windows Server 2003 schema.

The special Group Policy objects **Default Domain Policy** and **Default Domain Controllers Policy** cannot be deleted. The purpose of this restriction is to prevent the accidental deletion of these Group Policy objects, which contain important and required settings for the domain.

# Local Group Policy objects overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local Group Policy objects**
The local Group Policy object (local GPO) is stored on each individual computer, in the hidden **%systemroot%\System32\GroupPolicy** directory. Each computer running a version of Windows Server 2003, Windows 2000, or Windows XP Professional has exactly one local GPO, regardless of whether the computers are part of an Active Directory environment.

**Limitations of the local Group Policy object**
Local GPOs do not support certain extensions, such as Folder Redirection or Group Policy Software Installation. Local GPOs do support many security settings, but the Security Settings extension of the Group Policy Object Editor does not support remote management of local GPOs. Thus, for example, the command line **gpedit.msc /gpcomputer:"Computer1"** will allow you to edit the local GPO on Computer1, but **Security Settings** will not appear.

Local GPOs are always processed, but are the least influential GPOs in an Active Directory environment, because Active Directory-based GPOs have precedence.

For more information about the Group Policy extensions that differ in the local GPO as compared with Active Directory-based GPOs, see Folder redirection overview for GPMC, Software installation overview for GPMC, and Security settings overview for GPMC.

Group Policy Management Console Overview

# Group Policy object editor overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy object editor**
Group Policy Object Editor is an MMC snap-in used to edit the policy settings in Group Policy objects (GPOs).

**Opening Group Policy Object Editor**
In Group Policy Management Console (GPMC), open Group Policy Object Editor by right-clicking a node for a GPO or a GPO link and then clicking **Edit**.

**Note**

- You must have **edit** rights on the GPO in order to open it in Group Policy Object Editor.

**Configuring Group Policy settings**
Group Policy Object Editor consists of two main sections: **User Configuration**, which holds settings that are applied to users (at logon and periodic background refresh) and **Computer Configuration**, which holds settings that are applied to computers (at startup and periodic background refresh). These sections are further divided into the different types of policies that can be set, such as Administrative Templates, Security, or Folder Redirection. For more information about these categories of policy settings, see Group Policy Object Editor Extensions.

You configure Group Policy settings by navigating to the appropriate location in each section. For example, if you want to set an Administrative Templates policy setting in a GPO to prevent users from seeing the Run command, you would need to enable the policy setting **Remove Run Menu from Start Menu**. This is located under **User Configuration\Administrative Templates\Start Menu and Task Bar**. You edit most policy settings by double-clicking the title of the policy setting, which opens a dialog box that provides specific options. In Administrative Templates policy settings, for example, you can choose to enable or disable the policy setting or leave it as not configured. In other areas, such as Security Settings, you can select a check box to define a policy setting and then set available parameters.

The Group Policy Object Editor provides different ways of learning about the function or definition of specific policy settings. In most cases, when you can double click the title of a policy setting, the dialog box contains any relevant defining information about the policy setting. For Administrative Templates policy settings, the Group Policy Object Editor provides explain text directly in the Web view of the console. You also can find this explain text by double-clicking the policy setting and then clicking the **Explain** text tab. In either case, this text shows operating system requirements, defines the policy setting, and includes any specific details about the effect of enabling or disabling the policy setting.

**Managing Multiple Platforms in Group Policy Object Editor**
Because new Administrative Template policy settings have been added that only work on specific versions of the operating system such as Windows XP Professional or Windows Server 2003, the Group Policy Object Editor enables you to view only the Administrative Template policy settings that might be applied in your users' work environment. For example, you may want to edit only policy settings that could be applied on client computers running Windows 2000 Service Pack 3. You can specify these options in the **Filtering** dialog box, available by clicking a node in the Administrative Templates section, clicking the **View** menu and then clicking **Filtering**.

For more information about editing Group Policy objects see:

- Group Policy objects overview for GPMC
- Edit a Group Policy object from GPMC
- Group Policy Object Editor Extensions

To learn how Group Policy tasks differ after you install GPMC, see New ways to do familiar tasks using GPMC.

**Opening Group Policy Object Editor from the command line**
It is sometimes useful to open Group Policy Object Editor from the command line. By specifying the appropriate command line switches, you can automatically connect to a specific machine or GPO.

The following table illustrates the available command-line switches used to open Group Policy Object Editor under different circumstances.

| Command-line parameters | Effect |
|---|---|
| **gpedit.msc** | Edit the local GPO on the local computer. |
| **gpedit.msc /gpcomputer:"Computer1"**<br><br>**Notes**<br><br>• The quotation marks are mandatory.<br><br>• There is no space after **/gpcomputer:** | You can edit the local GPO on Computer1. |
| **gpedit.msc /gpcomputer:"ThisComputer.TailspinToys.com"**<br><br>**Notes**<br><br>• The quotation marks are mandatory.<br><br>• There is no space after **/gpcomputer:** | You can edit the local GPO on Computer1, with the computer specified in the DNS style rather than the NetBIOS style. |
| **gpedit.msc /gpobject:**"LDAP:"LDAP_PATH_TO_GPO"<br><br>**Notes**<br><br>• LDAP path to the GPO is based on the GUID of the GPO, for example: "LDAP://CN={31B2F340-016D-11D2-945F-00C04FB984F9},CN=Policies,CN=System,DC=WingTipToys,DC=com".<br><br>• You can optionally specify the domain controller to use in the LDAP path as the first item in the LDAP path. You can use either a NETBIOS or DNS format for the name of the domain controller. For example, this path would specify that GPEdit could use domain controller named DC13.TailspinToys.com: "LDAP://DC13.TailspinToys.com/CN={31B2F340-016D-11D2-945F-00C04FB984F9},CN=Policies,CN=System,DC=WingTipToys,DC=com". | You can edit an Active Directory–based GPO by passing in the LDAP path to the GPO. |

# Group Policy Object Editor Extensions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy Object Editor Extensions**
Group Policy Object Editor is an MMC snap-in, and like all snap-ins, its functionality can be customized or extended by means of MMC snap-in extensions. When you use Group Policy Object Editor, various extensions are included by default, and are visible in the tree view with icons of their own.

This section contains information about the following Group Policy Object Editor extensions:

- Administrative templates overview for GPMC
- Security settings overview for GPMC
- Software installation overview for GPMC
- Folder redirection overview for GPMC
- Scripts overview for GPMC
- Internet Explorer Maintenance overview for GPMC
- Remote Installation Services overview for GPMC

# Administrative templates overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administrative Templates**

Administrative templates, (or .adm files), enable administrators to control registry settings using Group Policy. These settings appear under the **Administrative Templates** folder for both user configuration and computer configuration in the console tree of the Group Policy Object Editor, and in HTML reports produced by GPMC.

It is important to understand that .adm files are not the actual settings that are deployed to client operating systems. The .adm file is simply a template file (implemented as text file with an .adm extension) that provides the friendly name for the setting and an explanation. This template file is used to populate the user interface. The settings that are deployed to clients are contained in the registry.pol file inside the GPO. On Windows XP and Windows Server 2003, each registry setting contains a "Supported on" tag that indicates which operating system versions support that policy setting. If a setting is specified and deployed to a client operating system that does not support that setting, the settings are ignored. These .adm files are stored in two locations by default: inside GPOs, and in the %windir%\inf folder on the local computer.

Windows includes a predefined set of Administrative template files that define the registry settings that can be configured in a Group Policy object (GPO). The .adm files can be added or removed from the Group Policy Object Editor by right-clicking **Administrative Templates** and clicking **Add/Remove Templates**. Adding or removing .adm files does not affect which policies are processed by the Group Policy engine. It only affects whether a specific Administrative Template policy setting is displayed in the Group Policy Object Editor. For example, if you removed all the .adm files from the GPO via the **Add/Remove Templates** dialog box, no Administrative Template policy settings would be displayed under the Administrative Templates node. This will not affect the policies already stored in the Registry.pol file.

**Contents of .adm files**

An .adm file consists of a hierarchy of categories and subcategories that together define how the policy settings are to appear in the Group Policy Object Editor user interface (UI), and also contains information about which registry locations control the settings.

The following information is included in .adm files:

- Registry locations that correspond to each setting in the Administrative Templates section of the Group Policy Object Editor.
- Options or restrictions in values that are associated with each setting. These are only restrictions for the user interface. There is no checking of value ranges during the actual policy processing.
- Check box, editbox, and other methods of parameter input.
- For many settings, a default value to display.
- Explanations of what each setting does, and about settings that affect and are affected by it, is included in Help text embedded in the .adm file. This information is displayed on an **Explain** tab in Group Policy Object Editor.
- The versions of Windows that support each setting are indicated by use of the **Suppported** keyword.
- Registry location for the setting, hive name, key name, and value name. Type of registry key, whether DWORD, REG_SZ, or other type. Binary data is not supported.

**Standard .adm files included with Windows**

The predefined set of Administrative template files that define the registry settings for controlling various aspects of the operating system are grouped into five .adm files listed below.

A description of each policy setting in Administrative Templates appears in searchable online Help.

| Administrative Template | Description |
|---|---|
| System.adm | System settings |
| Inetres.adm | Internet Explorer settings |
| Wmplayer.adm | Windows Media Player settings. This tool is not available on Windows XP 64-Bit Edition and the 64-bit versions of the Windows Server 2003 family. |
| Conf.adm | NetMeeting settings. This tool is not available on Windows XP Professional, 64-Bit Edition and the 64-bit versions of the Windows Server family. |
| Wuau.adm | Windows Update settings. |

**True Policies or Preferences**
The standard Administrative Templates shipped with Windows only contain true policies, as distinct from preferences. The registry information for true policies is located under \Software\Policies or under \Software\Microsoft\Windows\CurrentVersion\Policies in the HKEY_CURRENT_USER or HKEY_LOCAL_MACHINE hives.

Policy settings that are stored in these specific locations of the registry are known as *true policies*. Storing settings here has the following advantages:

- These trees are secure and cannot be modified by a non-administrator.
- When Group Policy changes, for any reason, these trees are cleaned, and the new policies are then rewritten.

This prevents the behavior that was often present in Windows NT 4.0, whereby System Policies resulted in persistent settings in the user and computer registry. The policy remained in effect until the value was reversed, either by a counteracting policy or by editing the registry. These settings are stored outside the approved registry locations above and are known as *preferences*.

All the policy settings in the standard Administrative Templates shipped with Windows use registry settings in the Policies trees of the registry. This means that they will *not*cause persistent settings in the registry when the GPO that applies to them is no longer in effect.

The Group Policy Object Editor does not show preferences. If you add an .adm file that contains preferences rather than policy settings, you will have to clear the **Only show policy settings that can be fully managed** check box on the **Filtering** dialog box under the **View** menu of Group Policy Object Editor, otherwise the settings will not be visible in the console.

If you plan to create entries for Administrative Templates, populate the namespace by using the following naming convention, which is also used in the registry: *CompanyName**product**version* (or *CompanyName**product&version*). For example, the operating system settings for Windows are in \Microsoft\Windows.

For information about creating custom policy settings in .adm files, see "Implementing Registry-based Policy" at the Microsoft Web site. (http://msdn.microsoft.com/)

**Registry.pol files**
Group Policy Object Editor, when setting Administrative Templates policy settings, saves information in Registry.pol files. These Unicode files contain the customized registry settings that you specify (by using Group Policy) that are to be applied to the computer or user portion of the registry. The Registry.pol files contain the actual Group Policy settings used by the Group Policy engine during processing. They contain instructions to add or delete registry keys, corresponding to the settings specified by the administrator in the Group Policy Object Editor.

- One of the Registry.pol files contains registry settings that are specific to the **HKEY_LOCAL_MACHINE** key. It is stored in the GPT\Machine folder.
- The other Registry.pol file contains registry settings that are specific to the **HKEY_CURRENT_USER** key. It is stored in the GPT\User subdirectory.

Deployment considerations for Group Policy

# Security settings overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security settings**
The Group Policy object editor allows you to edit security settings for users or computers.

Where?

- *Group Policy object name*/Computer (or User) Configuration/Windows Settings/Security Settings

With **Security Settings**, you can require minimum password complexity, control the ability to log on to computers remotely, enable software restriction policies, set IP security, and much more.

**Note**

- Security settings under **Account Policies** for domain user accounts work when the Group Policy object is linked to a domain but are ignored when the Group Policy object is linked to an organizational unit. However, local accounts created on computers affected by the policy will have to follow restrictions defined in the GPO, even when the GPO is linked to an organizational unit.

Where?

- *Group Policy object name*/Computer Configuration/Windows Settings/Security Settings/Account Policies

For information about security settings, see Security Settings extension to Group Policy and Security Setting Descriptions.

For information about specific extensions of Security Settings, see these topics:

- Wireless Networking
- Software Restriction Policies
- Internet Protocol Security (IPSec)
- Encrypting File System
- Public Key Policies

# Software installation overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Software installation**
You can use the Software Installation extension of Group Policy to centrally manage software distribution in your organization. You can assign and publish software for groups of users and computers using this extension.

- Assigning Applications
- Publishing Applications

**Assigning Applications**
When you assign applications to users or computers, the applications are automatically installed on their computers at logon (for user-assigned applications) or startup (for computer-assigned applications.)

When assigning applications to users, the default behavior is that the application will be advertised to the computer the next time the user logs on. This means that the application shortcut appears on the **Start** menu, and the registry is updated with information about the application, including the location of the application package and the location of the source files for the installation. With this advertisement information on the user's computer, the application is installed the first time the user tries to use the application. In addition to this default behavior, Windows XP Professional and Windows Server 2003 clients support an option to fully install the package at logon, as an alternative to installation upon first use. Note that if this option is set, it is ignored by computers running Windows 2000, which will always advertise user-assigned applications.

When assigning applications to computers, the application is installed the next time the computer boots up. Applications assigned to computers are not advertised, but are installed with the default set of features configured for the package. Assigning applications through Group Policy requires that the application setup is authored as a Windows Installer (.msi) package.

**Publishing Applications**
You can also publish applications to users, making the application available for users to install. To install a published application, users can use **Add or Remove Programs** in Control Panel, which includes a list of all published applications that are available for them to install. Alternatively, if the administrator has selected the **Auto-install this application by file extension activation** feature, users can open a document file associated with a published application. For example, double clicking an .xls file will trigger the installation of Microsoft Excel, if it is not already installed. Publishing applications only applies to user policy; you cannot publish applications to computers.

To take advantage of all of the features of Group Policy Software Installation, it is best to use applications that include a Windows Installer (.msi) package. For example, published MSI packages support installation for users who do not have administrative credentials.

However, you can also publish legacy setup programs using a .zap file. These applications will be displayed in **Add or Remove Programs** like any other published application, but typically can only be installed by users with administrative credentials.

A .zap file is a simple text file that describes the path to the setup program, as well as any arguments to be passed on the command line.

A simple example illustrating the syntax of a .zap file is shown below:

```
[Application]
FriendlyName = Microsoft Works 4.5a
SetupCommand = ""\\DeploymentServer\Apps\Works 4.5a\Standard\Setup.exe""
```

**Note**

- When using quotes in zap files, the following rules apply:
    - The path and name of the setup executable must always be quoted.
    - If there are no command-line arguments, they must be quoted twice.

**Additional Information**

Group Policy Software Installation supports a variety of advanced features, such as patching applications and applying transforms at deployment time, as well as filtering based on language, processor architecture, and so on.

For more information about Software Installation, see Software Installation and Maintenance(http://www.microsoft.com/) and Step-by-Step Guide to Software Installation and Maintenance(http://www.microsoft.com/) at the Microsoft Web site.

Group Policy Object Editor Extensions

Group Policy Management Console Overview

# Folder redirection overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Folder redirection**

User settings and user files are normally stored in the local user profile, under the **Documents and Settings** folder. The files in local user profiles are only accessible from the current computer, which makes it difficult for users who use more then one computer to work with their data and synchronize settings between multiple computers. Two different technologies exist to address this problem: Roaming Profiles and Folder Redirection. Both these technologies have their advantages and they can be used separately or together to create a seamless user experience from one computer to another. They also provide additional options for administrators managing user data.

Folder Redirection allows administrators to redirect the path of a folder to a new location. The location can be a folder on the local computer or a directory on a network file share. Users have the ability to work with documents on a server as if the documents were based on a local drive. The documents in the folder are available to the user from any computer on the network. Folder Redirection is located under **Windows Settings** in the console tree of the Group Policy Object Editor.

**Where?**

- *Group Policy object name*/User Configuration/Windows Settings/Folder redirection

There are five folders that can be redirected:

- **My Documents**
- **My Pictures** (Redirection of My Pictures is provided for backward compatibility reasons, and not as a primary feature. You can only redirect the My Pictures folder using the Windows XP or Windows Server 2003 operating system if you are editing GPO that was originally created on Windows 2000 computer and that redirected My Pictures.)
- **Application Data**
- **Desktop**
- **Start Menu** (Only for Terminal Server users.)

**Advantages of Folder Redirection**

- When roaming user profiles are used, only the network path to the folder is part of the roaming user profile, not the folder. Therefore, its contents do not have to be copied back and forth between the client computer and the server each time the user logs on or off, and the process of logging on or off can be much faster.
- Even if a user logs on to various computers on the network, their documents are always available.
- Offline File technology gives users access to the folder even when they are not connected to the network. This is particularly useful for people who use portable computers.
- Data that is stored in a shared network folder can be backed up as part of routine system administration. This is safer because it requires no action on the part of the user.
- As an administrator, you can use Group Policy to set disk quotas, limiting the amount of space that is taken up by users' special folders.
- Data that is specific to a user can be redirected to a different hard disk on the user's local computer from the hard disk that holds the operating system files. This makes the user's data safer in case the operating system has to be reinstalled.
- The Volume Shadowcopy Service feature of Windows Server 2003 can be used by users to recover older copies of the

files in their redirected folders without intervention of technical support personnel.

- Folder Redirection is a secure way to keep user data on a network, provided that the option **Grant the user exclusive rights** is turned on.

#### Selecting a Folder Redirection target

The **Target** tab of the folder's Properties dialog box allows the administrator to select the location of the redirected folder on a network or in local user profile. You can choose between **Basic** and **Advanced** settings. Basic redirection will be applied to all users affected by the GPO. The **Advanced** setting allows you to provide different redirection locations for users based on the users' security group membership. Using either advanced or basic redirection you can set different targets for folder redirection:

- **Create a folder for each user under the root path**. This option will create a folder in the form **\\server\share*User Account Name**Folder Name***. Each user will get a unique path to their redirected folder. This option is not available for the Start Menu folder.

- **Redirect to the following location**. This option will use an explicit path to the redirection location. This can cause multiple users to share the same path to the redirected folder.

- **Redirect to the local user profile location**. This option will move the location of the folder to the local user profile under **Documents and Settings**.

- The My Documents folder has one more option: **Redirect to the user's home directory**. To use this option, the administrator needs to use Active Directory Users and Computers to set the **home directory** attribute on the user objects for each user affected by the policy.

  **Note**

  - The **Redirect to the user's home directory** option causes the value of the **Grant the user exclusive rights** option on the **settings** tab to be ignored.

#### Granting exclusive rights to special folders

The **Settings** tab in the Properties dialog box contains a check box labeled **Grant the user exclusive rights to My Documents**. This option controls permissions on the newly-created redirected folder. If this option is selected, and the target directory doesn't yet exist, Folder Redirection will create the directory and set permissions on this directory to allow only the user and the local system full control over the folder. If this option is selected, and the target directory already exists, then Folder Redirection will verify ownership of the directory. If the directory is owned by someone else, Folder Redirection will fail. Whatever permissions are in effect by default remain in effect. If you clear this check box, no changes are made to the permissions on the folder. Whatever permissions are in effect by default remain in effect. The Start Menu folder can only be redirected with this option turned off.

It is recommended to secure the contents of all folders except the Start Menu by selecting the **Grant the user exclusive rights** option on the **Settings** tab. The Start Menu folder is special in this respect, because redirection of the Start Menu is recommended to be used only for Terminal Server users, with all users sharing the same Start Menu folder. Therefore, the Start Menu folder doesn't have an option to select **Grant the user exclusive rights**.

#### Policy removal considerations with regard to Folder Redirection

The following table summarizes what happens to redirected folders and their contents when the Group Policy object no longer applies.

| Move the contents of the special folder to the new location setting | Policy Removal option | Results when policy is removed |
|---|---|---|

| | | |
|---|---|---|
| **Enabled** | **Redirect the folder back to the user profile location when policy is removed** | • The special folder returns to its user profile location.<br>• The contents are copied, not moved, back to the user profile location.<br>• The contents are not deleted from the redirected location.<br>• The user continues to have access to the contents, but only on the local computer. |
| **Disabled** | **Redirect the folder back to the user profile location when policy is removed** | • The special folder returns to its user profile location.<br>• The contents are not copied or moved to the user profile location.<br>**Caution**<br>• If the contents of a folder are not copied to the user profile location, the user cannot see them. |
| Either **Enabled** or **Disabled** | **Leave the folder in the new location when policy is removed** | • The special folder remains at its redirected location.<br>• The contents remain at the redirected location.<br>• The user continues to have access to the contents at the redirected folder. |

**Important**

- Changing the redirection option to **Not Configured** does not redirect the folder to the local profile, this option means that Folder Redirection no longer controls the location of the folder-if a folder was previously redirected it will continue to be redirected to the previous location. If an administrator wanted to return the folder to the local user profile they should use the **Redirect to the local user profile setting.**

**Folder Redirection and Offline Files**

The Offline Files technology applies to any mounted or mapped drive that contains documents or data that a user might want to use offline. Offline Files does not depend on Folder Redirection. It is set up and configured on shared network servers separately from the Folder Redirection snap-in. Offline Files enables the user to do useful work even when not connected to the network, for example, on a portable computer or in the event of router failure.

If you use redirected folders of any type, it is recommended that you set up Offline Files as described in the following table.

| Special Folder | Offline File configuration |
|---|---|
| My Documents | Autocaching for documents (or manual caching for documents, if you want users to have to manually make files and folders available for offline use) |
| My Pictures | Autocaching for documents (or manual caching for documents, if you want users to have to manually make files and folders available for offline use) |

| | |
|---|---|
| Application Data | Autocaching for programs |
| Desktop | Autocaching for programs if the desktop is Read Only |
| Start Menu | Autocaching for programs |

**Folder Redirection permissions**

It is recommended to let Folder Redirection create folders for you. If you let Folder Redirection create folders for you, correct permissions are set automatically. Usually, knowledge of these permissions is not necessary. However, there are three reasons the permissions might be of interest:

- An administrator must always secure the network file share used for keeping redirected folder data by setting correct share level (SMB) permissions and NTFS file system permissions.

- Sometimes administrators create the redirected folders before Folder Redirection creates them. The directories created by administrators cannot be used together with the **Grant the user exclusive rights** option because Folder Redirection verifies ownership of the directories before allowing the folder to be redirected. The following table shows what permissions have to be set for Folder Redirection to work with the **Grant the user exclusive rights** option turned off.

- Redirection of My Documents to the home directory provides more relaxed security than standard folder redirection. The following table shows what security is in effect in the standard case.

**NTFS permissions required for the root folder**

| **User account** | **Folder Redirection defaults** | **Minimum permissions needed** |
|---|---|---|
| Creator Owner | Full Control, subfolders and files only | Full Control, subfolders and files only |
| Administrators | No permissions | No permissions |
| Everyone | No permissions | No permissions |
| Local System | Full Control, this folder, subfolders, and files | Full Control, this folder, subfolders, and files |
| Security group of users who need to put data on the shared network server | N/A | List Folder/Read Data, Create Folders/Append Data - **This folder only** |

**Share-level (SMB) permissions required for the root folder**

| **User Account** | **Folder Redirection defaults** | **Minimum permissions needed** |
|---|---|---|
| Everyone | Full Control | No permissions (Use security group) |
| Security group of users who need to put data on the shared network server | N/A | Full Control |

**NTFS permissions required for each user's redirected folder**

| **User account** | **Folder Redirection defaults** | **Minimum permissions needed** |
|---|---|---|
| *UserName* | Full Control, owner of folder | Full Control, owner of folder |
| Local System | Full Control | Full Control |
| Administrators | No permissions | No permissions |

| | | |
|---|---|---|
| Everyone | No permissions | No permissions |

Group Policy Management Console Overview

# Scripts overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Scripts**
Group Policy Object Editor includes two extensions for script deployment:

- **Scripts (Startup/Shutdown)—**You can use this extension, which is located under **Computer Configuration\Windows Settings** in the console tree of Group Policy Object Editor, to specify scripts that are to run when the computer starts up or shuts down. These scripts run as Local System.

- **Scripts (Logon/Logoff)—**You can use this extension, which is located under **User Configuration\Windows Settings** in the console tree of Group Policy Object Editor, to specify scripts that are to run when the user logs on or logs off the computer. These scripts run under the account of the user who is logging on or off.

There are five script types:

- Group Policy logon scripts.

- Group Policy logoff scripts.

- Group Policy startup scripts.

- Group Policy shutdown scripts.

- Legacy logon scripts of the style that predates Group Policy. These are specified on the User object.

**Controlling script behavior**
The main administrative template file, system.adm, is present by default, and includes several settings that control how Group Policy processes logon, logoff, startup and shutdown scripts. To see these settings, in the Group Policy Object Editor console tree, click **Scripts**.

**Where?**

- *Group Policy object name*/**Computer** (or **User**) **Configuration**/**Administrative templates**/**System**/**Scripts**

**Notes**

- By default, scripts run invisibly to the user. However, there are policy settings that make logon or logoff scripts run visibly.

- Scripts that run synchronously in order from the top to the bottom of the list shown in the Properties dialog box for scripts of the given type. Logon scripts run asynchronously by default, and there is a policy setting to make them run synchronously. Startup scripts run synchronously by default, and there is a policy setting to make them run asynchronously.

- Whenever possible, it is recommended to use Group Policy scripts rather than legacy-style scripts attached to the user object.

Scripting Group Policy tasks using GPMC

# Internet Explorer Maintenance overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Explorer Maintenance**
Group Policy supports the administration and customization of Microsoft Internet Explorer on computers running Windows 2000, Windows XP, and Windows Server 2003.

Settings for these features can be customized using Group Policy:

**Browser User Interface**
Settings for the user interface and the appearance of the browser are available for the following areas:

- Browser Title
- Custom Logo and Animated Bitmaps
- Toolbar Customization (toolbar background and toolbar buttons)

**Connection Settings**
Settings for the presetting and control of the user's connection settings, such as dial-up and local area network (LAN) connections, are available for the following areas:

- Connection Settings
- Automatic Browser Configuration
- Proxy Settings
- User Agent String

**Custom URLs**
Settings for specifying the URLs that appear on users' browsers, such as the Home page, Search page, and customized Favorites and Links, are available for the following options:

- Favorites and Links
- Important URLs

**Security**
Settings for specifying presetting and controlling user security settings, such as security zones, privacy settings, and content ratings, are available for the following areas:

- Security Zones and Content Ratings
- Authenticode Settings

**Program Associations**
Settings for specifying which Internet programs are used by default for common Internet tasks, such as reading e-mail or viewing newsgroups, are available in the following area:

- Programs

For more information on Internet Explorer Maintenance, see the Internet Explorer Maintenance Help, which is accessible in Windows Server 2003, either from Group Policy Object Editor or, through this link: Internet Explorer Maintenance overview for

GPMC.

**Notes**

- Windows Server 2003 includes a new default security configuration for Internet Explorer, called Internet Explorer Enhanced Security Configuration (ESC). ESC impacts the Security Zones and Privacy settings within the Internet Explorer Maintenance settings of a GPO. The Security Zones and Privacy settings can either be ESC enabled or not. For more details, see Deployment considerations for Group Policy

- If you are running Group Policy Management Console on a computer running Windows XP Professional, Internet Explorer Maintenance Help might not be available. To access the Help, install Windows Help from the Windows Server 2003 installation CD onto a computer running Windows XP Professional.

To customize Internet Explorer before deployment or to administer Internet Explorer on other operating systems, you can use the Profile Manager. The Profile Manager is part of the Internet Explorer Administration Kit (IEAK), which is available in the Windows 2000 and Windows XP Resource Kit and on the Microsoft Windows Web site.

Security settings overview for GPMC

# Remote Installation Services overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services**
Remote Installation Services (RIS) is an optional component of the Windows Server 2003 operating system. It works with other Windows technologies to enable administrators or users to remotely install a copy of the Windows Server 2003, Windows XP Professional, or Windows 2000 operating systems. Administrators use the Remote Installation Services extension of Group Policy only to specify which options are presented to users by the Client Installation Wizard.

Client computers that install an operating system through RIS must be equipped with network cards that either support Pre-boot Execution Environment (PXE), or are supported by the RIS remote boot floppy disk. The client computer starts (boots), connects to the network, and accesses the RIS server to install the operating system. The RIS server queries Active Directory to determine remote installation options defined for the user via policy setting. Based on that result, RIS determines which screens to send to the pre-boot RIS client code for display to the user.

The RIS settings that control what the user sees are visible in the Group Policy Object Editor console tree under the **Remote Installation Services** node.

**Where?**

- *Group Policy object name*/User Configuration/Windows Settings/Remote Installation Services

You can customize these settings using Group Policy Object Editor:

**Automatic Setup**
This option supports the predefinition of the computer name and a location within Active Directory for the client computer accounts.

**Custom Setup**
This option supports user definition of a unique name for a computer and specification of where the computer account is created within Active Directory.

**Restart Setup**
This option restarts an operating system installation attempt if it fails prior to completion.

**Tools**
This option supports user access to tools from the Client Installation Wizard.

For each of the Client Installation Wizard options, the following choices are available:

**Enable**
Users to whom this policy applies are offered the specific option.

**Not Configured**
The policy settings of the parent container apply to the specific option. For example, if you choose **Not Configured** and the administrator for the entire domain has set Group Policy specific to Remote Installation Services, the policy that is set on the domain is applied to all users affected by that policy.

**Disabled**
Users affected by this policy cannot access this installation option.

For more information on Remote Installation Services and the options offered by the Client Installation Wizard, see the Remote Installation Services Help, which is accessible in Windows Server 2003 family, either from Group Policy Object Editor or the **%systemroot%\Windows\Help** folder (RISconcepts.chm).

**Notes**

- Windows XP Professional does not show RIS settings in the Group Policy Object Editor (GPOE) unless the Admin Tools Pack is installed.

- If you are running Group Policy Management Console on a computer running Windows XP Professional, Remote

Installation Services Help is not available by default. To access the Help, install Windows Help from the Windows Server 2003 installation CD onto a computer running Windows XP Professional.

For more information about RIS, see Remote Operating System Installation(http://www.microsoft.com/) on the Microsoft Web site.

Group Policy Object Editor Extensions
Security settings overview for GPMC

# Group Policy replication and domain controller selection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy replication and domain controller selection**

In a domain that contains more than one domain controller, Group Policy information takes time to propagate, or replicate, from one domain controller to another. Low bandwidth network connections between domain controllers slow replication. The Group Policy infrastructure has mechanisms to manage these issues.

Each Group Policy object (GPO) is stored partly in the Sysvol on the domain controller and partly in Active Directory. The Group Policy Management Console (GPMC) and Group Policy Object Editor present and manage the GPO as a single unit. For example, when you set permissions on a GPO in GPMC, GPMC is actually setting permissions on objects in both Active Directory and the Sysvol. It is not recommended that you manipulate these separate objects independently outside of GPMC and the Group Policy Object Editor. It is important to understand that these two separate components of a GPO rely on different replication mechanisms. The file system portion is replicated through the File Replication Service (FRS), independently of the replication handled by Active Directory.

The tools used to manage Active Directory and Group Policy, such as GPMC, the Group Policy Object Editor, and Active Directory Users and Computers all communicate with domain controllers. If there are several domain controllers available, changes made to objects like users, computers, organizational units, and GPOs may take time to appear on other domain controllers. The administrator may see different data depending on the last domain controller on which changes were made and which domain controller they are currently viewing the data from.

For example, if you create a GPO on one domain controller and immediately attempt to link it on another domain controller, the operation could fail. In each domain, GPMC uses the same domain controller for all operations in that domain, in order to avoid any synchronization issues. This includes all operations on GPOs, organizational units, and security groups in that domain. In addition, when the Group Policy Object Editor is opened from GPMC, it will also use the same domain controller in use by GPMC. Finally, GPMC uses the same domain controller for all operations on sites within a given forest. This domain controller for sites is used to read and write information about the links to GPOs that exist on any given site; information regarding the GPO itself is obtained from the domain controller of the domain hosting the GPO. This domain controller is used to read and write information about the links to GPOs that exist on any given site; information regarding the GPO itself is obtained from the domain controller of the domain hosting the GPO.

By default, when you add a new domain to the console, GPMC uses the PDC emulator in that domain to help ensure that all administrators are using the same domain controller. For managing sites, GPMC uses the PDC emulator in the user's domain by default. You can change the default choice of domain controller using the **Change Domain Controller** dialog box in GPMC. If you are located at a remote site with a slow connection to the default domain controller, you may want to do this.

It is important for administrators to consider the choice of domain controller in order to avoid replication conflicts particularly because both Active Directory and FRS use multi-master replication. This is especially important to consider because GPO data resides in both Active Directory and on Sysvol, and two independent replication mechanisms must be used to replicate GPO data to the various domain controllers in the domain. If two administrators are simultaneously editing the same GPO on different domain controllers, it is possible for the changes written by one administrator to be overwritten by another administrator, depending on replication latency.

**Important**

- If multiple administrators manage a common GPO, it is recommended that all administrators use the same domain controller when editing a particular GPO, to avoid collisions in FRS.

**Options governing selection of a domain controller for GPMC**

In GPMC, when you right-click a domain or the sites container and click **Change Domain Controller**, you see a **Change Domain Controller** dialog box. The domain controller options for GPMC are:

- **The one with the Operations Master token for the PDC emulator.** This is the default and preferred option.
- **Use any available domain controller.** This is the least safe option.
- **Use any available domain controller that is running Windows Server 2003 or later.** This option is useful if you are restoring deleted GPOs that contain software installation settings. If possible, it is recommended to perform restoration

of GPOs containing software installation settings on domain controllers running Windows Server 2003. For more information, see Restore using GPMC.

- **This domain controller.** This option allows you to choose a specific domain controller from a list of domain controllers in the domain.

If you are changing the domain controller for a site, you can also choose any available trusted domain from the **Look in this domain** drop-down list box in the **Change Domain Controller** dialog box.

When you open the Group Policy Object Editor from GPMC it always uses the same domain controller that is targeted in GPMC for the domain where that GPO is located.

For step-by-step instructions for choosing a domain controller, see Specify a domain controller.

Group Policy Management Console Overview

# Group Policy processing and precedence

Updated: April 3, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy processing and precedence**
The Group Policy objects (GPOs) that apply to a user (or computer) do not all have the same precedence. Settings that are applied later can override settings that are applied earlier.

**Order of processing settings**
This section provides details about the order in which Group Policy settings for users and computers are processed. For information about where the processing of policy settings fits into the framework of computer startup and user logon, see steps 3 and 8 in Startup and logon, in this topic.

Group Policy settings are processed in the following order:

1. **Local Group Policy object—**Each computer has exactly one Group Policy object that is stored locally. This processes for both computer and user Group Policy processing.

2. **Site—**Any GPOs that have been linked to the site that the computer belongs to are processed next. Processing is in the order that is specified by the administrator, on the **Linked Group Policy Objects** tab for the site in Group Policy Management Console (GPMC). The GPO with the lowest **link order** is processed last, and therefore has the highest precedence.

3. **Domain—**Processing of multiple domain-linked GPOs is in the order specified by the administrator, on the **Linked Group Policy Objects** tab for the domain in GPMC. The GPO with the lowest **link order** is processed last, and therefore has the highest precedence.

4. **Organizational units—**GPOs that are linked to the organizational unit that is highest in the Active Directory hierarchy are processed first, then GPOs that are linked to its child organizational unit, and so on. Finally, the GPOs that are linked to the organizational unit that contains the user or computer are processed.

   At the level of each organizational unit in the Active Directory hierarchy, one, many, or no GPOs can be linked. If several GPOs are linked to an organizational unit, their processing is in the order that is specified by the administrator, on the **Linked Group Policy Objects** tab for the organizational unit in GPMC. The GPO with the lowest **link order** is processed last, and therefore has the highest precedence.

This order means that the local GPO is processed first, and GPOs that are linked to the organizational unit of which the computer or user is a direct member are processed last, which overwrites settings in the earlier GPOs if there are conflicts. (If there are no conflicts, then the earlier and later settings are merely aggregated.)

**Exceptions to the default order of processing settings**
The default order for processing settings is subject to the following exceptions:

- A GPO link may be **enforced**, or **disabled**, or both. By default, a GPO link is neither enforced nor disabled.

- A GPO may have its user settings disabled, its computer settings disabled, or all settings disabled. By default, neither user settings nor computer settings are disabled on a GPO.

- An organizational unit or a domain may have **Block Inheritance** set. By default, **Block Inheritance** is not set.

For information about the above modifications to default behavior, see Managing inheritance of Group Policy.

- A computer that is a member of a workgroup processes only the local Group Policy object.

- Loopback may be enabled. For information about loopback, see Loopback processing with merge or replace.

**Startup and logon**

The following sequence shows the order in which computer policy and user policy are applied when a computer starts and a user logs on:

1. Network starts. Remote Procedure Call System Service (RPCSS) and Multiple Universal Naming Convention Provider (MUP) start. (Windows XP Professional is an exception to this rule. By default, on Windows XP Professional, Group Policy processing does not wait for the network to start. This default behavior can be changed by a policy setting.)

2. An ordered list of GPOs is obtained for the computer. The list might depend on these factors:

   - Whether the computer is part of a domain and therefore subject to Group Policy through Active Directory.

   - The location of the computer in Active Directory.

   - Whether the list of Group Policy objects has changed. If the list of GPOs has not changed, no processing is done. You can use a policy setting to change this behavior.

   - Any enforcements/blocks set by the administrator. An administrator can set a policy at a higher level to always apply, a process called enforcement, previously known as no override. Alternatively, an administrator can set a container to block any policies from higher levels from applying. Note: A policy set by the administrator at a higher level to be enforced will continue to be applied even with a block from above set.

3. Computer policy is applied. These are the settings under Computer Configuration from the gathered list. GPOs are applied in the following order: local, site, domain, organizational unit, child organizational unit, and so on. No notification appears while computer policies are processed. Verbose logging to show notification of computer policies processed can be turned on via policy.

   For details about the order in which settings are processed when user or computer policy is applied, see Order of processing settings, in this topic.

4. Startup scripts run. This is hidden and synchronous by default; each script must complete or time out before the next one starts. The default time-out is 600 seconds. You can use several policy settings to modify this behavior.

**Note**

- Any version of Windows XP Professional provides a fast logon optimization feature. By default, computers with these operating systems do not wait for the network to start when they boot up. After logon, policy is processed in the background once the network is available. This means that at logon and startup, the computer will continue to use the earlier policy settings. Therefore, for settings that can only be applied at boot or logon (such as software installation and folder redirection) more than one logon can be required by the user after the initial change is made to the GPO. This policy is controlled by the setting in **Computer Configuration\Administrative Templates\System\Logon\Always wait for the network at computer startup and logon.** This feature is not available on versions of Windows 2000 or Windows 2003 Server.

1. The user presses CTRL-ALT-DEL to log on.

2. After the user is validated, the user profile loads; it is governed by the policy settings that are in effect.

3. An ordered list of GPOs is obtained for the user. The list might depend on these factors:

   - Whether the user is part of a domain and therefore subject to Group Policy through Active Directory.

   - Whether loopback is enabled, and the state (**Merge** or **Replace**) of the loopback policy setting.

   - The location of the user in Active Directory.

- Any enforcements/blocks set by the administrator. An administrator can set a policy at a higher level to always apply, a process called enforcement, previously known as no override. Alternatively, an administrator can set on a container to block any policies from higher levels from applying. Note: A policy set by the administrator at a higher level to be enforced will continue to be applied even with a block from above set.

4. User policy is applied. These are the settings under User Configuration from the gathered list. GPOs are processed in the following order: local, site, domain, organizational unit, child organizational unit, and so on. No notification appears while user policies are processed. (Notification can be turned on through policy.)

   For details about the order in which settings are processed when user or computer policy is applied, see Order of processing settings, in this topic.

5. Logon scripts run. Unlike Windows NT 4.0 scripts, Group Policy–based logon scripts are hidden and asynchronous by default. The user object script runs last in a normal window. There is also a time-out on logon scripts.

6. The operating system user interface that is prescribed by Group Policy appears.

**Important**

- Three special cases deserve consideration during migration:

  - If the computer account object is in a Windows NT 4.0 domain and the user account object is in Active Directory, System Policy for the computer only (not user) is processed when the user logs on. Then, user (not computer) Group Policy is processed.

  - If the computer account object is in Active Directory and the user account object is in a Windows NT 4.0 domain, computer (not user) Group Policy is processed during computer startup. When the user logs on, System Policy for the user (not computer) is processed.

  - If the computer and user accounts of the computer are members of a Windows NT 4.0 domain, only System Policy (not Group Policy) for the computer and user is applied when the user logs on.

**Note**

- Several of these events can be modified. You can set policies to:

  - Reverse the synchronized or asynchronized defaults for running script.

  - Specify when scripts time out. By default, scripts time out after 600 seconds.

  - Change whether scripts are run hidden, minimized, or in a normal window.

Controlling the Scope of Group Policy Objects using GPMC

# Controlling the Scope of Group Policy Objects using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Controlling the Scope of Group Policy Objects**

The process of targeting Group Policy objects (GPOs) to specific users and computers is referred to as scoping the GPO. In order to apply GPOs to users or computers, you must first link them to sites, domains, or organizational units. In addition, you can change the default order in which GPOs are processed by changing the link order, blocking policy inheritance, enforcing a GPO link (previously known as no override), and disabling a GPO link. After linking GPOs, you have two additional options for applying greater precision: security filtering and WMI filtering on the GPO. Loopback processing allows you to ensure that a consistent set of policies is applied to any user logging on to a particular computer.

This section contains the following information:

- Managing inheritance of Group Policy
- Security filtering using GPMC
- WMI filtering using GPMC
- Loopback processing with merge or replace

# Managing inheritance of Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing inheritance of Group Policy**

To apply the settings of a Group Policy object (GPO) to the users and computers of a domain, site, or organizational unit, you can link that domain site or organizational unit to that GPO. You can add one or more GPO links to each domain, site, and organizational unit in Group Policy Management Console. The settings deployed by GPOs linked to higher containers (parent container) in Active Directory are inherited by default to child containers and combine with any settings deployed in GPOs linked to child containers. If multiple GPOs attempt to set a setting to conflicting values, the GPO with the highest precedence sets the setting. GPO processing is based on a last writer wins model, and GPOs that are processed later have precedence over GPOs that are processed sooner. Group Policy objects are processed according to the following order:

1. The local Group Policy object (LPGO) is applied.
2. GPOs linked to sites.
3. GPOs linked to domains
4. GPOs linked to organizational units. In the case of nested organizational units, GPOs associated with parent organizational units are processed prior to GPOs associated with child organizational units.

Links to a specific site, domain, or organizational unit are applied in reverse sequence based on link order. For example, a GPO with Link Order 1 has highest precedence over other GPOs linked to that container.

You can view the precedence order of GPOs for a given site, domain or organizational unit by navigating to the **Group Policy Inheritance** tab for any site, domain, or organizational unit. Note that when looking on the **Group Policy Inheritance** tab for a domain or organizational unit, GPOs linked to sites are not shown. This is the specific site that a computer is in is not known ahead of time. Also, when viewing a site, the only difference between the **Group Policy Inheritance** tab and the **Linked Group Policy Objects** tab is that the former takes into account the enforcement (described below) attribute.

For more background information about GPO link processing and precedence, including the default order for processing, see Group Policy processing and precedence.

You can further control precedence and how GPO links are applied to specific domains, sites, or organizational units by doing the following:

- Changing the link order
- Blocking Group Policy inheritance
- Enforcing a GPO link
- Disabling a GPO link

**Changing the link order**

Within each domain, site, and organizational unit, the link order controls when links are applied. To change the precedence of a link, you can change the link order, moving each link up or down in the list to the appropriate location. The link with the higher order (with 1 being the highest order) has the higher precedence for a given site, domain, or organizational unit. For example, if you add six GPO links and later decide that you want the last one that you added to have highest precedence, you can move the GPO link to the top of the list.

**Blocking Group Policy inheritance**

You can block policy inheritance for a domain or organizational unit. Using block inheritance prevents GPOs linked to higher sites, domains, or organizational units from being automatically inherited by the child-level. By default, children inherit all GPOs from the parent, but it is sometimes useful to block inheritance. For example, if you want to apply a single set of policies to an entire domain except for one organizational unit, you can link the required GPOs at the domain level (from which all organizational units inherit policies by default), and then block inheritance only on the organizational unit to which the policies

should not be applied.

**Enforcing a GPO link**
You can specify that the settings in a GPO link should take precedence over the settings of any child object by setting that link to Enforced. GPO-links that are enforced cannot be blocked from the parent container. Without enforcement from above, the settings of the GPO links at the higher level (parent) are overwritten by settings in GPOs linked to child organizational units, if the GPOs contain conflicting settings. With enforcement, the parent GPO link always has precedence. By default, GPO links are not enforced. In tools prior to GPMC, "enforced" was known as "No override."

**Disabling a GPO link**
By default, processing is enabled for all GPO links. You can completely block the application of a GPO for a given site, domain, or organizational unit by disabling the GPO link for that domain, site, or organizational unit. Note that this does not disable the GPO itself, and if the GPO is linked to other sites, domains or organizational units, they will continue to process the GPO, if their links are enabled.

For more information about these tasks, see Control Group Policy Object Scope.

### Important

- GPO links set to enforce (no override) cannot be blocked.
- The enforce and block inheritance options should be used sparingly. Casual use of these advanced features complicates troubleshooting.

In addition to using GPO links to apply policies, you can also control how GPOs are applied by using security filters or WMI filters.

**See Also**
**Concepts**
Security filtering using GPMC

# Security filtering using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security filtering**
Security filtering is a way of refining which users and computers will receive and apply the settings in a Group Policy object (GPO). Using security filtering, you can specify that only certain security principals within a container where the GPO is linked apply the GPO. Security group filtering determines whether the GPO as a whole applies to groups, users, or computers; it cannot be used selectively on different settings within a GPO.

In order for the GPO to apply to a given user or computer, that user or computer must have both **Read** and **Apply Group Policy (AGP)** permissions on the GPO, either explicitly, or effectively though group membership.

By default, all GPOs have **Read** and **AGP** both **Allowed** for the Authenticated Users group. The Authenticated Users group includes both users and computers. This is how all authenticated users receive the settings of a new GPO when it is applied to an organizational unit, domain or site. However, you can change these permissions to limit the scope to a specific set of users, groups, or computers within the organizational unit, domain, or site.

Group Policy Management manages these permissions as a single unit, and displays the security filtering for the GPO on the GPO Scope tab. Using Group Policy Management Console (GPMC), you can add and remove groups, users, and computers to be used as security filters for each GPO. In addition, security principals used for security filtering also appear on **Delegation** tab for a GPO as having **Read (from Security Filtering)**, since they have read access to the GPO.

To modify security filtering, you add or remove groups in the Security Filtering section on the Scope tab of a GPO. In practice, you don't have to set the two access control entries (ACEs), because GPMC sets both for you when you set security filtering. For the step-by-step procedure, see Filter using security groups.

In addition, The **Read** and **AGP** permissions are visible separately, and able to be set independently of one another, through the access control list (ACL) editor. In GPMC, the **Security Filtering** section of the **Scope** tab of a GPO shows only whether the GPO will apply. If you want to see the permissions separately, you can open the ACL editor by clicking the **Advanced** button on the **Delegation** tab for the GPO.

**Notes**

- GPOs cannot be linked directly to users, computers, or security groups. They can only be linked to sites, domains and organizational units. However, by using security filtering, you can narrow the scope of a GPO so that it applies only to a single group, user, or computer.

- Granting **Read** and **AGP** is not sufficient to ensure that the GPO is processed for a user or computer. The GPO also has to be linked to a site, domain or organizational unit containing the user or computer, directly or through inheritance.

- A GPO with security filtering set to **Read** and **AGP** doesn't necessarily apply to all security principals that have security filtering. It only applies to them if those user or computer objects are in the container or child container that is linked to the GPO.

- The location of a security group in Active Directory is irrelevant to security group filtering and, more generally, irrelevant to Group Policy processing.

**See Also**
**Concepts**
WMI filtering using GPMC
Managing inheritance of Group Policy

# WMI filtering using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMI filtering**

Windows Management Instrumentation (WMI) filters allow you to dynamically determine the scope of Group Policy objects (GPOs) based on attributes of the target computer.

When a GPO that is linked to a WMI filter is applied on the target computer, the filter is evaluated on the target computer. If the WMI filter evaluates to false, the GPO is not applied (except if the client computer is running Windows 2000, in which case the filter is ignored and the GPO is always applied). If the WMI filter evaluates to true, the GPO is applied.

WMI makes data about a target computer available for administrative use. Such data can include hardware and software inventory, settings, and configuration information. For example, WMI exposes hardware configuration data such as CPU, memory, disk space, and manufacturer, as well as software configuration data from the registry, drivers, file system, Active Directory, the Windows Installer service, networking configuration, and application data.

A WMI filter consists of one or more queries based on this data. If all queries are true, the GPO linked to the filter will be applied. The queries are written using the WMI Query Language (WQL), a SQL-like language. Queries can be combined with AND and OR logical operators to achieve whatever effect the administrator wants. Each query is executed against a particular WMI namespace. When you create a query, you must specify the namespace. The default is root\CIMv2, which is appropriate for most WMI queries.

The WMI filter is a separate object from the GPO in the directory. To apply a WMI filter to a GPO, you link the filter to the GPO. This is shown in the WMI filtering section on the Scope tab of a GPO. Each GPO can have only one WMI filter, however the same WMI filter can be linked to multiple GPOs.

WMI filters, like GPOs, are stored on a per-domain basis. A WMI filter and the GPO it is linked to must be in the same domain.

### Notes

- Client support for WMI filters exists only on Windows XP, Windows Server 2003, and later operating systems. Windows 2000 clients will ignore any WMI filter and the GPO is always applied, regardless of the WMI filter.

- WMI filters are only available in domains that have at least one Windows Server 2003 domain controller. In an environment consisting only of Windows 2000 domains, the WMI filter node in Group Policy Management Console (GPMC) is not shown.

**Using WMI filters with GPMC**

Using GPMC, you can create and delete WMI filters, link and unlink WMI filters, copy and paste WMI filters, import and export WMI filters, and view and edit attributes of WMI filters.

**Sample code**

The following table shows sample code for several WMI filters.

| Criterion | Administrator's intent | WMI filter |
|---|---|---|
| Configuration | Avoid turning on netmon on computers that can have multicasting turned on. | `Select * from Win32_NetworkProtocol where SupportsMulticasting = true` |
| Time zone | Apply policy on all servers located on the East Coast of the United States. | `Root\cimv2 ; Select * from win32_timezone where bias =-300` |
| Hotfix | Apply a policy on computers that have a specific hotfix. | `Root\cimv2 ; Select * from Win32_QuickFixEngineering where HotFixID = 'q147222'` |

| | | |
|---|---|---|
| Software inventory | Assign software only on computers already having either of two software packages. | `Root\cimv2;Select * from Win32_Product where name = "MSIPackage1" OR name = "MSIPackage2"` |
| Operating system | Only target computers running Windows XP Professional. | `Root\CimV2; Select * from Win32_OperatingSystem where Caption = "Microsoft Windows XP Professional"` |
| Resources | Target only machines that have at least 600 megabytes (MB) available. | `Root\CimV2; Select * from Win32_LogicalDisk where FreeSpace > 629145600 AND Description <> "Network Connection"` |
| Make or model | Target Toshiba Tecra models 800 and 810. | `Root\CimV2; Select * from Win32_ComputerSystem where manufacturer = "Toshiba" and Model = "Tecra 800" OR Model = "Tecra 810"` |

# Loopback processing with merge or replace

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Loopback processing with merge or replace**
Loopback is an advanced Group Policy setting that is useful on computers in certain closely managed environments, such as servers, kiosks, laboratories, classrooms, and reception areas. Loopback only works when both the user account and the computer account are in a Windows 2000 or later domain. Loopback does not work for computers joined to a workgroup. Setting loopback causes the User Configuration settings in GPOs that apply to the computer to be applied to every user logging on to that computer, *instead of* (in replace mode) or *in addition to* (in merge mode) the User Configuration settings of the user. This allows you to ensure that a consistent set of policies is applied to any user logging on to a particular computer, regardless of their location in Active Directory. Loopback is controlled by the following setting, **User Group Policy loopback processing mode**, which is located under Computer Configuration\Administrative Templates\System\Group Policy in Group Policy Object Editor (GPMC).

By default, a user's policy settings come from the set of GPOs that are applied to the user object in Active Directory. During Group Policy processing on the client, the Group Policy engine assembles an ordered list of GPOs from the site, domain, and all organizational units for that user object.

Loopback can be set to **Not Configured**, **Enabled**, or **Disabled**. In the **Enabled** state, loopback can be set to **Merge** or **Replace**. In either case the user only receives user-related policy settings.

- **Loopback with Replace—**In the case of **Loopback with Replace**, the GPO list for the user is replaced in its entirety by the GPO list that is already obtained for the computer at computer startup (during step 2 in Group Policy processing and precedence). The User Configuration settings from this list are applied to the user.

- **Loopback with Merge—**In the case of **Loopback with Merge**, the Group Policy object list is a concatenation. The default list of GPOs for the user object is obtained, as normal, but then the list of GPOs for the computer (obtained during computer startup) is appended to this list. Because the computer's GPOs are processed after the user's GPOs, they have precedence if any of the settings conflict.

Managing inheritance of Group Policy

# Resultant set of policy overview for GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resultant Set of Policy**
Resultant set of policy (RSoP) is a feature of Group Policy that makes implementation, troubleshooting, and planning of Group Policy easier. When multiple Group Policy objects (GPOs) apply to a given user or computer, they can contain conflicting policy settings. For most policy settings, the final value of the policy setting is set only by the highest precedent GPO that contains that setting. RSoP helps you understand and identify the final set of policy that is applied as well as settings that did not apply as a result of policy inheritance.

Specifically, Resultant Set of Policy helps you determine the following:

- The final value of the setting that is applied as a result of all the GPOs.
- The final GPO that set the value of this setting (also known as the winning GPO).
- Precedence details that show any other GPOs that attempted to set this setting and the value that each GPO attempted to set for that policy setting.

**Example showing precedence**
Assume that there are three GPOs, GPO-A, GPO-B, and GPO-C, that all apply to the same user. GPO-A has precedence over GPO-B, which has precedence over GPO-C. Each GPO has been configured to set a desktop background. GPO-A sets the value to "Red Moon Desert." GPO-B sets it to "Bliss." GPO-C sets it to "Windows XP." The resultant set of policy data in this example shows that when these three GPOs are applied to a user, the following results occur:

- The background will be set to "Red Moon Desert."
- This background value was set by GPO A because it had highest precedence
- GPO-B attempted to set the background to "Bliss" and GPO-C attempted to set it to "Windows XP". The precedence was GPO-A, followed by GPO-B, followed by GPO-C.

**RSoP in Group Policy Management Console**
The Group Policy Management Console (GPMC) exposes two different resultant set of policy capabilities that are provided by Windows:

- Group Policy Results
- Group Policy Modeling

**Group Policy Results**
This represents the actual policy data that is applied to a given computer and user. It is obtained by querying the target computer and retrieving the RSoP data that was applied to that machine. The Group Policy Results capability is provided by the client operating system and requires Windows XP, Windows Server 2003 or later. Outside of GPMC, Group Policy Results is referred to as RSoP - logging mode.

**Group Policy Modeling**
This is a simulation of what would happen under circumstances specified by an administrator. Group Policy Modeling requires that you have at least one domain controller running Windows Server 2003 because this simulation is performed by a service running on a domain controller that is running Windows Server 2003. With Group Policy Modeling, you can either simulate the RSOP data that would be applied for an existing configuration, or you can perform "what-if" analyses by simulating hypothetical changes to your directory environment and then calculating the RSOP for that hypothetical configuration. For example, you can simulate changes to security group membership, or changes to the location of the user or computer object in Active Directory. Outside of GPMC, Group Policy Modeling is referred to as RSoP - planning mode.

In GPMC, resultant set of policy data is obtained using Group Policy Modeling or Group Policy Results wizards. GPMC provides

an HTML report of the RSoP data. This report shows the final value of the winning settings and the winning GPO that set that value. When you create a Group Policy Modeling or Group Policy Results report, the report is shown in GPMC under the appropriate node. Right-clicking this report and choosing Advanced View opens the RSoP snap-in, which provides additional information, enabling you to verify precedence for a policy setting. The Precedence tab, available from the dialog box for a policy setting, shows all GPOs that attempted to set a particular setting and the value for each GPO.

**RSoP and WMI**

RSoP relies on Windows Management Instrumentation (WMI) for storing and processing information about the policy settings that apply. When Group Policy is processed on a Windows XP or Windows Server 2003 computer, the relevant data is stored in the local WMI repository.

In logging mode, the Group Policy Results feature queries the WMI repository on the target computer, obtains information about the policy settings, and displays it in either the HTML presentation or in RSoP MMC snap-in.

In planning mode, the Group Policy Modeling feature calls the Resultant Set of Policy Provider Service on a domain controller. Administrators use the Group Policy Modeling wizard to specify information about the simulated policy environment such as the target user and computer, membership in security groups, and so forth. The RSOP provider service then simulates the resultant set of policy for this configuration. The results of this simulation are stored to a local WMI database on the domain controller before the information is passed back to GPMC, where it can be easily viewed by the administrator.

# Scripting Group Policy tasks using GPMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Scripting Group Policy tasks**

The Group Policy Management Console (GPMC) provides a comprehensive set of COM interfaces for scripting many Group Policy-related operations. The interfaces are documented in the Group Policy Management Console SDK, which is located at **%programfiles%\gpmc\scripts\gpmc.chm** on any computer where you installed GPMC. (The Group Policy Management Console SDK is only available in English.)

When you install GPMC, a set of sample scripts illustrating the use of these interfaces are installed to the **%programfiles%\gpmc\scripts** directory.

The sample scripts address real-world administrative problems and scenarios. You can perform various tasks such as finding all Group Policy objects (GPOs) in a domain that have duplicate names or generating a list of all GPOs in a domain whose settings are disabled or partially disabled.

**Note**

- Scripted control of individual settings inside a GPO is not provided.

The scripts include examples written in VBScript and JScript. They all have the .wsf extension and are executed through Windows Script Host (WSH), which is included with Windows Server 2003 and other recent versions of Windows. All of the scripts should be executed from the command line. Executing a script with the **/?** switch displays the usage for that script.

The sample scripts echo output to the command window and must be executed using cscript.exe. If cscript.exe is not your default scripting host, you will need to explicitly specify cscript.exe on the command line. For example: "d:\program files\gpmc\scripts>cscript ListAllGPOs.wsf".

**Note**

- You can run "cscript //H:cscript" from a command line to make cscript the default scripting host.

You can modify and distribute the sample scripts in accordance with the terms of the End User License Agreement.

Many of the sample scripts rely on a library of common helper functions contained in the file Lib_CommonGPMCFunctions.js. If you copy these scripts to another location, you must also copy this library file to that location for the script samples to work.

**Scripting samples for Group Policy administrative tasks**

The following table shows the administrative tasks you can perform with sample scripts included with Group Policy Management.

| Administrative task | Script name | Description |
|---|---|---|
| Back up all GPOs in a domain | BackupAllGPOs.wsf | Backs up all GPOs in a domain to the specified folder. |
| Back up a GPO | BackupGPO.wsf | Given a GPO name or a globally unique identifier (GUID), backs up the GPO to the specified folder. |
| Copy a GPO | CopyGPO.wsf | Creates a new GPO and copies the settings from the source GPO into the new destination GPO, given a source GPO name or GUID and a new destination GPO name. |
| Create a policy environment using an XML representation | CreateEnvironmentFromXML.wsf | Reads an XML file that specifies a policy environment; for example, organizational units, GPOs, links, and security groups. The script can either create the environment in a domain by creating the objects, or delete the environment by deleting objects specified in the XML file. |

| | | |
|---|---|---|
| Create a GPO with default options | CreateGPO.wsf | Creates a GPO with the specified name, in the current domain, using the default options. |
| Create a migration table | CreateMigrationTable.wsf | Creates migration tables that can be edited and used to map paths and security principals to new values when importing and copying GPOs across domains. |
| Create an XML representation of a policy environment | CreateXMLFromEnvironment.wsf | Reads an existing policy environment and creates an XML file representing that environment. The XML file captures information about organizational units, GPOs, and GPO links, and security on GPOs. You can use this script in conjunction with the CreateEnvironmentFromXML.wsf script to create a replica of a domain for staging purposes. |
| Delete a GPO | DeleteGPO.wsf | Deletes the specified GPO when given a GPO name or GUID. By default the script deletes links to that GPO within the same domain. |
| Grant Permissions for all GPOs in a Domain | GrantPermissionOnAllGPOs.wsf | Grants a user or group the specified level of permission for all GPOs in the specified domain. |
| Import settings into a GPO | ImportGPO.wsf | Imports the settings from the specified backup to an existing destination GPO in the specified domain. |
| Import multiple GPOs into a domain | ImportAllGPOs.wsf | Creates a new GPO and imports settings into that GPO for each backed-up GPO stored at a specific file system location. |
| Restore a GPO | RestoreGPO.wsf | Restores a backed-up GPO. |
| Restore all GPOs | RestoreAllGPOs.wsf | Restores all GPOs that are stored at a given file system location |
| Grant permissions for GPOs linked to a domain, organizational unit, or site | SetGPOPermissionsBySOM.wsf | Grants a user or group the specified permission type for all GPOs that are linked to a specified domain, organizational unit, or site. You can specify **Read, Apply, Edit, FullEdit,** or **None** for the permission type. |
| Set GPO permissions | SetGPOPermissions.wsf | Sets the permission level for a security principal on a given GPO. You can specify **Read, Apply, Edit, FullEdit,** or **None** for the permission type. |
| Set permissions to create GPOs | SetGPOCreationPermissions.wsf | Grants or removes the ability to create GPOs in a domain for a given security principal. |
| Set policy-related permissions on a given site, domain, or organizational unit | SetSOMPermissions.wsf | Sets policy-related permissions on a given site, domain, or organizational unit. |
| List disabled GPOs | FindDisabledGPOs.wsf | Prints all GPOs in the specified domain that are disabled or partially disabled. |

| | | |
|---|---|---|
| List GPO information | DumpGPOInfo.wsf | Prints the information for a specific GPO, including creation time, modification time, owner, status, version number, security groups that filter the GPO, security groups that have full control, edit, read, or custom permissions, and links. |
| List scope of management information | DumpSOMInfo.wsf | Prints information for a specific site, domain, or organizational unit, including GPO links and policy-related permissions. |
| List GPO by policy extension | FindGPOsByPolicyExtension.wsf | Prints all GPOs in the specified domain for which a specific policy extension is configured; for example, find all GPOs that contain the Software Installation or Folder Redirection policy settings. |
| List GPOs by security group | FindGPOsBySecurityGroup.wsf | Prints all GPOs on which a given security principal has the specified permission or effective permission. You can specify **Read, Apply, Edit,** or **Fulledit** for the permission type. |
| List GPOs with duplicate names | FindDuplicateNamedGPOs.wsf | Prints all GPOs in the specified domain that have duplicate names. |
| List GPOs without Apply permission | FindGPOsWithNoSecurityFiltering.wsf | Prints all GPOs in the specified domain that do not apply to anyone because **Apply** permission is not set on the GPO. |
| Listing GPOs Orphaned in SYSVOL | FindOrphanedGPOsInSYSVOL.wsf | Finds and prints all GPOs in SYSVOL with no corresponding component in Active Directory. |
| List domains, organizational units, and sites with external GPO links | FindSOMsWithExternalGPOLinks.wsf | Prints all domains, organizational units, and sites in the specified domain that link to a GPO in a different domain. |
| List unlinked GPOs in a domain | FindUnlinkedGPOs.wsf | Prints all GPOs in the specified domain that have no links. Links outside the domain, including site links, are not checked. |
| Get reports for all GPOs | GetReportsForAllGPOs.wsf | Takes a domain name, and gets reports for all GPOs in that domain. |
| Get reports for GPO | GetReportsForGPO.wsf | Generates XML and HTML reports for a given GPO. |
| List all GPOs in a domain | ListAllGPOs.wsf | Prints all GPOs in the specified domain. |
| Print the scope of management policy tree | ListSOMPolicyTree.wsf | Prints a list of all organizational units in the specified domain with the list of GPOs that are linked to the domain and each organizational unit. |
| List GPO backups in a given file system location | QueryBackupLocation.wsf | Prints information about all backed up GPOs at the file system location specified by the user. |

# Deployment considerations for Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deployment Considerations for Group Policy**
This topic describes deployment issues related to managing Group Policy in enterprise environments. This includes interoperability issues such as handling a mix of client operating system versions, a mix of domain versions, as well as new features included with Windows Server 2003.

To view an item, click the appropriate link:

- Applying Group Policy on different client operating systems
- Using Administrative template files in mixed environments
- Administering a mix of Windows 2000 and Windows Server 2003 domains
- Upgrading Windows 2000 domains to Windows Server 2003 domains and interaction with Group Policy Modeling
- Using Group Policy features across forests
- Group Policy for sites
- Using Group Policy and Internet Explorer enhanced security configuration

**Applying Group Policy on different client operating systems**
Group Policy can apply to client computers running any of the following operating systems or later:

- Any version of Windows 2000.
- Any version of Windows XP Professional.
- Any version of Windows Server 2003.

Except for Local Group Policy objects (LGPOs), Group Policy requires Active Directory. In order for computer configuration settings to apply, the computer account must be in an Active Directory domain. In order for user configuration settings to apply, the user account must be in an Active Directory domain.

Group Policy is not applied to computers running any of the following operating systems:

- Windows 95
- Windows 98
- Windows Millennium
- Windows NT

**Using Administrative template files in mixed environments**
Administrative templates, (or .adm files), enable administrators to control registry settings using Group Policy. Windows comes with a predefined set of Administrative template files, which are implemented as text files (with an .adm extension), that define the registry settings that can be configured in a Group Policy object (GPO). These .adm files are stored in two locations by default: inside GPOs and in the %windir%\inf folder on the local computer.

As new versions of Windows are released, new policy settings are added. In addition to supporting these new settings, each successive version of Windows supports all registry policy settings that were available in earlier versions of Windows. For

example, the Windows Server 2003 family supports all registry policy settings available in Windows 2000 and Windows XP.

It is important to understand that .adm files are not the actual settings that are deployed to client operating systems. The adm file is simply a template file that provides the friendly name for the setting and an explanation. This template file is used to populate the user interface. The settings that are deployed to clients are contained in the registry.pol file inside the GPO. On Windows XP and Windows Server 2003, each registry setting contains a "Supported on" tag that indicates which operating system versions support that policy setting. If a setting is specified and deployed to a client operating system that does not support that setting, the settings are ignored.

Because all successive iterations of .adm files include settings from earlier versions, and because there is no harm if a new setting is applied inadvertently to a computer running an earlier operating system that does not support that setting, it is recommended to always create and edit GPOs from a computer that has the latest .adm files available. Note that the behavior for handling .adm files in GPMC and the Group Policy Object Editor differs.

**Handling .adm files in Group Policy Object Editor**

- The Group Policy Object Editor uses .adm files to display available policy settings in the Administrative Templates section of a GPO.
- By default it attempts to read .adm files from the GPO (from the Sysvol on the domain controller). Alternatively, the .adm file can be read from the local workstation computer. This behavior can be controlled by a policy setting.
- By default, if the version of the .adm file found on the local computer is newer (based on the time stamp of the file) than the version on the Sysvol, the local version is copied to the Sysvol and is then used to display the settings. This behavior can be controlled by a policy setting.
- If the GPO contains registry settings for which there is no corresponding .adm file, these settings cannot be seen in the Group Policy Object Editor. However, the policy settings are still active and will be applied to users or computers targeted by the GPO.

**Handling .adm files in GPMC**

- GPMC uses .adm files to display the friendly names of policy settings when generating HTML reports for GPOs, Group Policy Modeling, and Group Policy Results.
- By default, GPMC uses the local .adm file, regardless of time stamp. If the file is not found, then GPMC will look in the GPO's folder on Sysvol.
- The user can specify an alternate path for where to find .adm files. If specified, this takes precedence over the previous locations.
- GPMC never copies the .adm file to the Sysvol.

**Administering a mix of Windows 2000 and Windows Server 2003 domains**

GPMC exposes features that are available in the underlying operating system. Because new features have been added to Group Policy since Windows 2000, certain features will only be available in GPMC depending on the operating system that has been deployed on the domain controllers. This section describes these dependencies. In general, there are three key issues that determine whether a feature is available in GPMC:

- Whether the forest supports the Windows Server 2003 schema for Active Directory. Certain features are only available once the schema is upgraded. This is the first step that must be taken before any Windows Server 2003 domain controller can be deployed in an existing Windows 2000 forest. The schema is a forest-wide configuration and is upgraded by running **ADPrep /ForestPrep**. ADPrep is a utility included on the Windows Server 2003 CD. Note that it is possible to have the Windows Server 2003 schema in a forest with all Windows 2000 domain controllers.
- Whether there is at least one domain controller in the forest that is running Windows Server 2003. Group Policy Modeling must be performed on a domain controller running Windows Server 2003.
- Whether a domain contains the Windows Server 2003 domain configuration. This is implemented once **ADPrep**

**/DomainPrep** is run in that domain. This is the first step that must be taken before any Windows Server 2003 domain controller can be deployed in an existing Windows 2000 domain.

Note that there is no dependency from the Group Policy perspective on whether a domain is in native mode or mixed mode.

**Delegation of Group Policy Results and Group Policy Modeling**
In order to delegate either Group Policy Modeling or Group Policy Results, the Active Directory schema in the forest must be the Windows Server 2003 schema. Note that you can use Group Policy Results even without this schema, but only users with local administrative privileges on the target computer can remotely access Group Policy Results data. Thus, if the forest does not have the Windows Server 2003 schema, the delegation pages in GPMC for organizational units and domains will not show these permissions.

**Group Policy Modeling**
Group Policy Modeling is a simulation that is performed by a service that can only run on a domain controller running Windows Server 2003 or later. As long as there is at least one domain controller running Windows Server 2003 in the forest, you can use Group Policy Modeling. GPMC will only show the Group Policy Modeling node in the user interface if the Windows Server 2003 schema is present.

**WMI filtering**
WMI filters are only available in domains that have the Windows Server 2003 configuration. Although none of the domain controllers need to be running Windows Server 2003, you must have run **ADPrep /DomainPrep** in this domain. Also note that WMI filters are only evaluated by clients running Windows XP, Windows Server 2003, or later. WMI filters associated with a Group Policy object will be ignored by Windows 2000 clients and the GPO will always be applied on Windows 2000. For more information, see WMI filtering using GPMC.

If **ADPrep /DomainPrep** has not been run in a given domain, the **WMI Filters** node will not be present, and the GPO scope tab will not have a WMI filters section.

**Upgrading Windows 2000 domains to Windows Server 2003 domains and interaction with Group Policy Modeling**
Group Policy Modeling is a new feature of Windows Server 2003 that simulates the resultant set of policy for a given configuration. The simulation is performed by a service that runs on Windows Server 2003 domain controllers. In order to perform the simulation in cross-domain scenarios, the service must have read access to all GPOs in the forest.

In a Windows Server 2003 domain (whether it is upgraded from Windows 2000 or installed as new), the Enterprise Domain Controllers group is automatically given read access to all newly created GPOs. This ensures that the service can read all GPOs in the forest.

However, if the domain was upgraded from Windows 2000, any existing GPOs that were created before the upgrade do not have read access for the Enterprise Domain Controllers group. When you click a GPO, GPMC detects this situation and notifies the user that Enterprise Domain Controllers do not have read access to all GPOs in this domain. To solve this problem, you can use one of the sample scripts provided with GPMC, **GrantPermissionOnAllGPOs.wsf**. This script can update the permissions for all GPOs in the domain. To use this script:

- Ensure that the person running this script is either a Domain Admin or has permissions to modify security on all GPOs in the domain.
- Open a command prompt and navigate to the **%programfiles%\gpmc\scripts** folder by typing:

  ```
  CD /D %programfiles%\gpmc\scripts
  ```

- Type the following:

  ```
  Cscript GrantPermissionOnAllGPOs.wsf "Enterprise Domain Controllers"
  /Permission:Read /Domain:value
  ```

The value of domain parameter is the DNS name of the domain.

**Using Group Policy features across forests**
The Windows Server 2003 family introduces a new feature called Forest Trust that enables you to authenticate and authorize access to resources from separate, networked forests. With trusts established between forests, you can manage Group Policy throughout your enterprise, which provides greater flexibility especially in large organizations. For more information on forest trusts, see Forests in Group Policy Management Console.

This section describes Group Policy behavior in an environment with forest trust enabled:

- It is not possible to link a GPO to a domain in another forest.

- With Forest trust, it is possible that a user in forest B could log onto a computer in forest A. In this case, when the computer starts up, it will process policy for the computer configuration from Forest A, as usual. When a user from Forest B logs on, where they receive their policy settings from depends on the value of the **Allow Cross-Forest User Policy and Roaming Profiles** policy setting.

    - When this setting is **Not Configured**, no user-based policy settings are applied from the user's forest. Instead, loopback Group Policy processing will be applied, using the Group Policy objects scoped to the computer. Users will receive a local profile instead of their roaming profile.

    - When this setting is **Enabled**, the behavior is exactly the same as Windows 2000 Server, User policy is applied from the user's forest and a roaming user profile is allowed from the trusted forest.

    - When this setting is **Disabled**, the behavior is the same as **Not Configured**.

  This setting is available on Windows Server 2003 located at: **Computer Configuration\Administrative Templates\System\Group Policy\Allow Cross-Forest User Policy and Roaming Profiles.**

- It is possible to deploy Group Policy settings to users and computers in the same forest, but have those settings reference servers in other trusted forests. For example, the shares that host software distribution points, redirected folders, logon scripts, and roaming user profiles could be in another trusted forest.

- Group Policy Modeling requires that both the user and the computer be in the same forest. If you want to simulate a user from Forest A logging on to a computer in Forest B, you must perform two separate Group Policy Modeling simulations: one for the user configuration and the other for the computer configuration.

- Delegation across forests is supported for managing Group Policy. For example, you can delegate to someone in Forest B the ability to perform Group Policy Modeling simulations on objects in Forest A.

**Group Policy for sites**

GPOs that are linked to Active Directory site objects affect all computers in the site. Therefore, any Group Policy object that is linked to a site is applied to all computers in that site, without regard to which domain (in the forest) contains the computers.

This means that computers in multiple domains within a forest can potentially receive the same Group Policy object when you use site-linked GPOs. It also means that a given client computer could receive GPOs from multiple domains in the forest. Note that the GPO exists as a stored entity only in a single domain and it must be read from that domain when the affected clients read their site-linked Group Policy.

If multiple domains are set up across wide area network (WAN) boundaries, the site configuration should take this into account. If it does not, the computers in another domain access a site-linked GPO across a WAN link. This increases the processing time for Group Policy.

In general, it is recommended that you link GPOs to domains and organizational units rather than sites.

**Using Group Policy and Internet Explorer enhanced security configuration**

Windows Server 2003 includes a new default security configuration for Internet Explorer, called Internet Explorer Enhanced Security Configuration (ESC). ESC impacts the Security Zones and Privacy settings within the Internet Explorer Maintenance settings of a GPO. The Security Zones and Privacy settings can either be ESC enabled or not.

- When you edit settings for Security Zones and Privacy settings in a GPO from a computer where ESC is enabled, that GPO will contain ESC-enabled settings. When you look at the HTML report for that GPO, the Security Zones and Privacy header will be appended with the text **(Enhanced Security Configuration enabled)**.

- When you edit settings for Security Zones and Privacy settings in a GPO from a computer where ESC is not enabled , that GPO will contain ESC disabled settings. ESC is not enabled on any computer running Windows 2000 or Windows XP, nor on computers running Windows Server 2003 where ESC has been explicitly disabled.

ESC settings deployed through Group Policy will only be processed on and applied by computers where ESC is enabled. ESC settings will be ignored on computers where ESC is not enabled (all computers running Windows 2000 and Windows XP, and Windows Server 2003 computers where ESC has been explicitly disabled). The converse is also true: A GPO that contains non-ESC settings will only be processed on and applied by computers where ESC is not enabled.

# Group Policy Management Console icons reference

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy Management Console icons reference**
Group Policy Management Console (GPMC) provides context-specific icons to dynamically represent the state of console objects. There are different icons for Group Policy objects (GPOs), links, WMI filters, sites, forests, and other objects and containers.

**General usage of icons**
Some icons exist in only one version. For example, the icon for GPMC always looks the same:

Other icons have variations in appearance. The variations indicate the state of the object. For example, when the icon for a domain or organizational unit is shown with a blue circle and exclamation point superimposed, such as:

and ,

this means that inheritance is blocked on that domain or organizational unit.

**Glossary of icons**
The following is a list of icons used in GPMC.

GPO icons

GPO link icons

Icons showing whether inheritance is blocked

WMI filtering icons

Resultant Set of Policy icons

Other GPMC icons

**GPO icons**

| Icon | Description |
|---|---|
| | GPO is either fully enabled or half enabled. Either all settings are enabled, or either user configuration or computer configuration settings are enabled. |
| | GPO that is completely disabled. Both user configuration and computer configuration settings are both disabled. |

**GPO link icons**

| Icon | Description |
|---|---|
| | Enabled, non-enforced GPO link. |
| | Enabled, enforced GPO link. |
| | Enabled link to inaccessible GPO. The GPO exists but is not readable, perhaps because you do not have Read access to it. |
| | Enabled link to nonexistent GPO. Either the GPO has been deleted but the link somehow remains, or the GPO was created on another domain controller and it has not yet replicated to the domain controller that GPMC is using. |
| | Unenforced link to completely disabled GPO. |
| | Enforced link to completely disabled GPO. |
| | Disabled link to enabled or half-enabled GPO. |
| | Enforced and disabled link to enabled or half-enabled GPO. |
| | Disabled link to inaccessible GPO. The GPO exists but is not readable, perhaps because you do not have Read access to it. |

| | |
|---|---|
| | Disabled link to nonexistent GPO. Either the GPO has been deleted but the link somehow remains, or the GPO was created on another domain controller, and it has not yet replicated to the domain controller that GPMC is using. |
| | Disabled link to completely disabled GPO. |
| | Enforced and disabled link to completely disabled GPO. |

**Icons showing whether inheritance is blocked**

| Icon | Description |
|---|---|
| | Domain with inheritance allowed. |
| | Domain with inheritance blocked. |
| | Organizational unit with inheritance allowed. |
| | Organizational unit with inheritance blocked. |

**WMI filtering icons**

| Icon | Description |
|---|---|
| | WMI filters container. |
| | WMI filter. |

**Resultant Set of Policy icons**

| Icon | Description |
|---|---|
| | Group Policy Modeling container. |
| | Group Policy Modeling query. |
| | Group Policy Results container. |
| | Group Policy Results query. |

**Other GPMC icons**

| Icon | Description |
|---|---|
| | Forest. |
| | Domains container. |
| | Security principal that could not be resolved. |

# GPMC Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

This section contains links to more information about Group Policy and related technologies.

- Microsoft.com Group Policy Home Page. Provides an entry point for Group Policy documentation on the Web. Includes links to documentation, knowledge base articles, support information, and newsgroups.

- Windows Server 2003 Deployment Kit, Designing a Managed Environment Book. Describes the technologies in Windows Server 2003 associated with deployment of a managed environment. Has significant coverage of Group Policy and related IntelliMirror technologies. Includes planning, designing and implementation guidance.

- Troubleshooting Windows Server 2003 Group Policy White paper. Provides a structured guide to troubleshooting Group Policy operations. Covers Group Policy processing itself, dependent technologies and relevant troubleshooting tools.

- Group Policy Administration using the Group Policy Management Console White paper. Provides technical details of functionality in GPMC.

- Migrating GPOs Across Domains with GPMC. Explains how to migrate GPOs from one domain to another using GPMC.

- Windows Server 2003 Group Policy Infrastructure White paper. Describes a range of topics related to Group Policy at both the server and the client level. Includes detailed Group Policy processing as well as many best practices useful to the Group Policy administrator.

- **Group Policy Management Console Software Development Kit (SDK).** Provides information about how to use the COM interfaces of Group Policy Management, which support scripting many of the operations supported by Group Policy Management Console.

  **Note**

  - This is available when you install GPMC. See "gpmc.chm" in the **%programfiles%\gpmc\scripts** directory. The SDK is only available in English.

# Resultant Set of Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resultant Set of Policy**
You can use Resultant Set of Policy (RSoP) to simulate and test policy settings that are applied to computers or users using Group Policy.

- For help with specific tasks, see Resultant Set of Policy How To....
- For general background information, see RSoP Concepts.
- For problem-solving instructions, see Troubleshooting RSoP.

# Resultant Set of Policy How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Run RSoP
- Use the RSoP Snap-in
- View Policy Settings with RSoP
- Delegate control of RSoP

# Run RSoP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Run RSoP**

- Run an RSoP query on a computer account
- Run an RSoP query on a user account
- Run an RSoP query on a domain
- Run an RSoP query on an organizational unit
- Run an RSoP query on a site
- Run an RSoP query on a local computer

# Run an RSoP query on a computer account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run an RSoP query on a computer account**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the computer account on which you want to run RSoP.

**Where?**

- Active Directory Users and Computers*domain node*\Computers*computer account*

1. Point to **All Tasks**, and then click **Resultant Set of Policy (Logging)** or **Resultant Set of Policy (Planning)**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- You can also run an RSoP query by adding the RSoP snap-in to a Microsoft Management Console (MMC). For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Run an RSoP query on a local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run an RSoP query on a local computer**

1. Open Microsoft Management Console.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. On the **Standalone** tab, click **Add**.
4. In the **Available Standalone Snap-in** box, click **Resultant Set of Policy**, and then click **Add**.
5. In Microsoft Management Console, right click **Resultant Set of Policy**, and then click **Generate RSoP Data**.
6. In the Resultant Set of Policy Wizard, click **Next**.
7. On the **Mode Selection** page, click **Logging mode**, and then click **Next**.
8. On the **Computer Selection** page, click **This computer**, and then click **Next** to continue the Resultant Set of Policy Wizard.

## Notes

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- Logging mode is the only mode that is available for an RSoP query on a local computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use the RSoP Snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use the RSoP snap-in**

The following topics describe how to use the Resultant Set of Policy (RSoP) snap-in.

RSoP does not display policy settings introduced in Windows Vista® with Service Pack 1 and later releases. Therefore, to view all policy settings that apply to computers and users on computers running Windows Vista SP1 and later, use the Group Policy Results (GPresult.exe) command-line tool rather than RSoP. For information about Group Policy results, see GPResult (http://go.microsoft.com/fwlink/?LinkId=140844).

- Open RSoP as an MMC snap-in
- Access RSoP data for an existing computer and user (logging mode)
- Simulate RSoP data for a computer and user (planning mode)
- Save data from an RSoP query
- Change an existing RSoP query
- Refresh an RSoP query

# Open RSoP as an MMC snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To open RSoP as an MMC snap-in

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Microsoft Management Console.
2. On the **File** menu, click **Add/Remove Snap-in**.
3. On the **Standalone** tab, click **Add**.
4. In the **Available Standalone Snap-in** box, click **Resultant Set of Policy**, and then click **Add**.

### Notes

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- You must add a Resultant Set of Policy snap-in to Microsoft Management Console (MMC) for each new RSoP query.

#### Using a command line

1. Open Command Prompt.
2. Do one of the following:

    - To open RSoP as an MMC snap-in and display RSoP logging mode for the currently logged on user and computer, type:

      **rsop.msc**

    - To open RSoP as an MMC snap-in and display RSoP logging mode for the specified namespace and target computer, type:

      **rsop.msc /RsopNamespace:***NameSpace***/RsopTargetComp:***TargetComputer*

      **Note**

This syntax is intended for use with a WMI script.

### Note

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Run RSoP
Access RSoP data for an existing computer and user (logging mode)

# Access RSoP data for an existing computer and user (logging mode)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To access RSoP data for an existing computer and user (logging mode)**

1. Open Microsoft Management Console.
2. Add a Resultant Set of Policy snap-in to a Microsoft Management Console (MMC).
3. In the console tree, right-click **Resultant Set of Policy**, and then click **Generate RSoP Data**.
4. In the Resultant Set of Policy Wizard, click **Next**.
5. On the **Mode Selection** page, click **Logging mode**, and then click **Next**.
6. On the **Computer Selection** page, specify the computer on which you want to run RSoP, and then click **Next**.
7. On the **User Selection** page, specify the user for which you want to collect RSoP data, and then click **Next**.
8. On the **Summary of Selections** page, click **Next**, and then wait for RSoP to finish processing the data.
9. On the **Completing the Resultant Set of Policy Wizard** page, click **Finish**.
10. In the console tree, click the newly created RSoP query to view the data.

**Notes**

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- To open RSoP as a Microsoft Management Console (MMC) snap-in, see Related Topics.
- The Resultant Set of Policy MMC snap-in runs the Resultant Set of Policy Wizard to generate Resultant Set of Policy (RSoP) data. On the last page of the Resultant Set of Policy Wizard, there is a **Gather extended error information** check box, which is selected by default. When this check box is selected, the Resultant Set of Policy MMC snap-in enumerates all of the events in the application event log of the target computer. This option is useful when you are using Logging mode because it allows you to collect error information on the client computers, where errors are more likely to occur. You can also use this option in Planning mode, which targets a domain controller, to collect error information in case the RSoP simulation on the domain controller experiences problems.
- Selecting the **Gather extended error information** check box, slows down the processing speed. It is recommended that you use this option if errors appear in the RSoP snap-in after the first attempt. Errors that appear in Logging mode indicate problems that occurred on the target computer the last time that the application of Group Policy was attempted. In Planning mode, the errors might indicate an issue with incorrect permissions or other configuration issue with the domain controller targeted by the simulation.
- Only users and computers that are currently logged on to the domain are visible.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Simulate RSoP data for a computer and user (planning mode)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To simulate RSoP data for a computer and user (planning mode)**

- 1. Add the Resultant Set of Policy snap-in to a Microsoft Management Console (MMC).
- 2. Start the Resultant Set of Policy Wizard in planning mode, and then click Next.
- 3. On the User and Computer Selection page, specify the user and computer, and then click Next.
- 4. On the Advanced Simulation Options page, specify the simulation options that you want to apply, and then click Next.
- 5. On the User Security Groups page, verify that the information is complete, and then click Next.
- 6. On the Computer Security Groups page, verify that the information is complete, and then click Next.
- 7. On the WMI Filters for Users page, verify the list of WMI filters, and then click Next.
- 8. On the WMI Filters for Computers page, verify the list of WMI filters, and then click Next.
- 9. On the Summary of Selections page, verify the domain controller, and then click Next.
- 10. On the Completing the Resultant Set of Policy Wizard page, click Finish.

**1. Add the Resultant Set of Policy snap-in to a Microsoft Management Console (MMC).**

- For more information, see Related Topics.

**2. Start the Resultant Set of Policy Wizard in planning mode, and then click Next.**

- In the console tree, right-click **Resultant Set of Policy**, and then click **Generate RSoP Data**.
- In the Resultant Set of Policy Wizard, click **Next**.
- On the **Mode Selection** page, click **Planning mode**, and then click **Next**.

**3. On the User and Computer Selection page, specify the user and computer, and then click Next.**

- On the **User and Computer Selection** page, under **User information** and **Computer information**, specify the name of the user and computer, and then click **Next**.

**4. On the Advanced Simulation Options page, specify the simulation options that you want to apply, and then click Next.**

- If you want to simulate a slow network connection, select the **Slow network connection** check box.
- If you want to simulate loopback processing, select the **Loopback processing** check box. If you select the **Loopback processing** check box, click either **Replace** to simulate only applied Group Policy objects (GPOs) based on the computer, or **Merge** to simulate applied GPOs based on the computer and the user.

**5. On the User Security Groups page, verify that the information is complete, and then click Next.**

- The security groups that are currently assigned appear under **Security groups**.

- To search for an alternate user security group, click **Add**, type the name of the security group, click **Check Names**, click a security group, and then click **OK**.

- To restore security groups to those currently assigned to the user, click **Restore Defaults**.

**6. On the Computer Security Groups page, verify that the information is complete, and then click Next.**

- The security groups that are currently assigned appear under **Security groups**.

- To search for an alternate computer security group, click **Add**, type the name of the security group, click **Check Names**, click a security group, and then click **OK**.

- To restore security groups to those currently assigned to the computer, click **Restore Defaults**.

**7. On the WMI Filters for Users page, verify the list of WMI filters, and then click Next.**

- To automatically evaluate all WMI filters that are associated with any Group Policy object (GPO) as true, click **All linked filters**.

- To specify which WMI filters associated with any GPO that you want to automatically evaluate as true, click **Only these filters**. If the filter you want is not in the list, click **List Filters**.

- To remove a filter from the list, click the filter name, and then click **Remove**. Remove any filters that would be considered a false condition for the designated computer.

**8. On the WMI Filters for Computers page, verify the list of WMI filters, and then click Next.**

- To automatically evaluate all WMI filters that are associated with any Group Policy object (GPO) as true, click **All linked filters**.

- To specify which WMI filters associated with any GPO that you want to automatically evaluate as true, click **Only these filters**. If the filter you want is not in the list, click **List Filters**.

- To remove a filter from the list, click the filter name, and then click **Remove**. Remove any filters that would be considered a false condition for the designated computer.

**9. On the Summary of Selections page, verify the domain controller, and then click Next.**

- The wizard might take several minutes to run the simulation.

**10. On the Completing the Resultant Set of Policy Wizard page, click Finish.**

- In the console tree, click the RSoP query to view the data.

### Notes

- To open RSoP as a Microsoft Management Console (MMC) snap-in, see Related Topics.

- The Resultant Set of Policy MMC snap-in runs the Resultant Set of Policy Wizard to generate Resultant Set of Policy (RSoP) data. On the last page of the Resultant Set of Policy Wizard, there is a **Gather extended error information** check box, which is selected by default. When this check box is selected, the Resultant Set of Policy MMC snap-in enumerates all of the events in the application event log of the target computer. This option is useful when you are using Logging mode because it allows you to collect error information on the client computers, where errors are more likely to occur. You can also use this option in Planning mode, which targets a domain controller, to collect error information in case the RSoP simulation on the domain controller experiences problems.

- Selecting the **Gather extended error information** check box, slows down the processing speed. It is recommended that you use this option if errors appear in the RSoP snap-in after the first attempt. Errors that appear in Logging mode indicate problems that occurred on the target computer the last time that the application of Group Policy was attempted. In Planning mode, the errors might indicate an issue with incorrect permissions or other configuration issue with the domain controller targeted by the simulation.

- If the information is complete after your specify your settings in a particular wizard page and you want to run RSoP immediately, select the **Skip to the final page of this wizard without collecting additional data** check box, and then click **Next**.

- You can use this procedure to generate RSoP data based on containers, computers, and users.

- You must be a domain administrator or you must have delegated RSoP (planning) authority over the organizational unit to run RSoP.

- You must be an enterprise administrator to cross domain boundaries in the same forest.

- If you only have authority over one of the destinations, RSoP returns data for that destination only.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**To view a list of all Group Policy objects associated with an RSoP query**

1. Open an RSoP query.
2. In the console tree, double-click ***user account* on *computer account* - RSoP**.
3. In the console tree, right-click **Computer Configuration** or **User Configuration**, and then click **Properties**.
4. On the **General** tab, select the **Display all GPOs and filtering status** check box.
5. In the details pane, the list of Group Policy objects appears in the **Group Policy Object** column, and the filtering status appears in the **Filtering** column as either **Applied** or **Not Applied (Empty)**.

## Notes

- To open RSoP, see Related Topics.
- The list includes Group Policy objects that are not applied to the object that is queried.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the scope of management associated with an RSoP query

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the scope of management associated with an RSoP query**

1. Open an RSoP query.
2. In the console tree, double-click ***user account* on *computer account* - RSoP**.
3. Right-click **Computer Configuration** or **User Configuration**, and then click **Properties**.
4. On the **General** tab, select the **Display scope of management** check box.
5. In the details pane, the CNAME of each Group Policy object in Active Directory appears in the **Scope of Management** column.

### Note

- To open RSoP, see Related Topics.

# Delegate control of RSoP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate control of RSoP**

1. Open Active Directory Users and Computers.
2. In the **Name** column, right-click the organizational unit that you want to delegate control of Resultant Set of Policy (RSoP), and then click **Delegate Control**.
3. In the Delegation of Control Wizard, click **Next**.
4. On the **Users or Groups** page, click **Add**.
5. In the **Name** box, type the name of the user or group to which you want to delegate control, and then click **OK**.
6. Verify that the user or group that appears in the **Selected users and groups** box is correct, and then click **Next**.
7. On the **Tasks to Delegate** page, click **Delegate the following common tasks**.
8. Select the **Generate Resultant Set of Policy (logging)** check box or the **Generate Resultant Set of Policy (planning)** check box (you can select both), and then click **Next**.
9. Verify the information that appears, and then click **Finish**.
10. Click the folders in the console tree to view the data in the details pane.

**Notes**

- To open Active Directory Users and Computers, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
- Delegated control is inherited by all child containers below the container to which control is delegated.
- You must be an enterprise administrator to delegate RSoP control at the domain and site level.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# RSoP overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RSoP overview**
Resultant Set of Policy (RSoP) is an addition to Group Policy that makes policy implementation and troubleshooting easier. RSoP is a query engine that polls existing policies and planned policies, and then reports the results of those queries. It polls existing policies based on site, domain, domain controller, and organizational unit. RSoP gathers this information from the Common Information Management Object Model (CIMOM) database (otherwise known as CIM-compliant object repository) through Windows Management Instrumentation (WMI).

RSoP provides details about all policy settings that are configured by an Administrator, including Administrative Templates, Folder Redirection, Internet Explorer Maintenance, Security Settings, Scripts, and Group Policy Software Installation.

When policies are applied on multiple levels (for example, site, domain, domain controller, and organizational unit), the results can conflict. RSoP can help you determine a set of applied policies and their precedence (the order in which policies are applied).

RSoP consists of two modes: planning mode and logging mode. With planning mode, you can simulate the effect of policy settings that you want to apply to a computer and user. Logging mode reports the existing policy settings for a computer and user that is currently logged on.

The Resultant Set of Policy Wizard helps you create an RSoP query. You can open the wizard from Microsoft Management Console (MMC), Active Directory Users and Computers, or Active Directory Sites and Services. You must run the wizard at least once to create an RSoP query. When complete, the wizard displays the query results in the RSoP snap-in in MMC. From here, you can save, change, and refresh your queries. You can create many RSoP queries by adding multiple Resultant Set of Policy snap-ins to MMC, one RSoP snap-in per query.

**RSoP and the CIMOM database**
RSoP uses the CIMOM database through WMI. When a computer logs on to a network, information such as the computer hardware, Group Policy Software Installation settings, Internet Explorer Maintenance settings, Scripts, Folder Redirection settings, and Security Settings, is written to the CIMOM database. When you start RSoP in logging mode, RSoP reports policy settings that have been applied from information provided in the CIMOM database.

**RSoP, Active Directory, and policy precedence**
Unlike the CIMOM database, Active Directory® directory services stores objects regardless of the state of a computer or user. Group Policy uses Group Policy objects (GPOs) in Active Directory to store policy settings. With Group Policy, administrators can:

- Deploy registry keys (Administrative Templates)
- Deploy software (Group Policy Software Installation)
- Deploy security: Safer, IPSec (Security Settings)
- Deploy scripts: logon, logoff, startup, shutdown (Scripts)
- Configure the browser (Internet Explorer Maintenance)

After you define a policy setting for an object, it is applied the next time that object logs on. When an object logs on to a network, the policy settings are applied in the following order:

- Local policy
- Site-level policy
- Domain-level policy
- Domain controller policy (if the domain controller is left in the domain controller container)

- Organizational unit policy

When a Group Policy object overwrites the settings of a different GPO that was applied previously, the new GPO has precedence over the GPO that it has overwritten. When a Group Policy object has a **no overwrite** attribute, it has precedence over all of the policies that are applied subsequently. RSoP can simulate and test the application of policy settings and precedence to Group Policy objects in Active Directory.

**RSoP and Group Policy Software Installation**
A significant part of Group Policy are the software settings extensions, which monitor Group Policy Software Installation. In an RSoP report, RSoP displays which applications are available for any given user or computer, as well as any software setting changes that are advertised or applied. By identifying all of the software that is available for a given user, as well as updates and configuration changes, RSoP makes deployment scenario planning and implementation easier.

**RSoP and security issues**
RSoP provides the following features that you can use to determine which comprehensive security policy meets your needs:

- Provides security templates for creating and assigning security settings for one or more computers. A security template is a file representation of a security setting configuration. It can be applied to a local computer or it can be imported to a Group Policy object in Active Directory. When you import a security template to a Group Policy object, Group Policy processes the security template and makes the corresponding changes to the members of that Group Policy object, which can be users or computers. RSoP verifies those changes. By polling the system and displaying the resultant policy, RSoP indicates a misapplied or overwritten policy setting and the policy setting's precedence, which enables you to fix a security breach.

- RSoP reports the scope of a Group Policy object according to security group membership. RSoP does this through Group Policy filtering.

- Processes and displays the resulting policy for any computer or user. Through individual security settings, Administrators can define a security policy in Active Directory that contains specific security settings for nearly all security areas. Security settings in a local Group Policy object can also establish a security policy on a local computer. When there are conflicts, security settings that are defined in Active Directory always override any security settings that are defined locally.

# Using RSoP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using RSoP**

RSoP provides the following tools that you can use to obtain the information necessary to best configure Group Policy for your organization:

- **The RSoP snap-in--**You can use the RSoP snap-in to create detailed reports about applied policy settings. The RSoP snap-in has two modes: logging mode and planning mode. Logging mode displays policy settings that are applied to computers or users that have logged on. For more information, see RSoP logging mode. Planning mode simulates policy settings that will be applied to a computer or user, or you can use planning mode to check assigned policy settings for a computer that is not currently available or a user that is not currently logged on. For more information, see RSoP planning mode. For information about the RSoP snap-in, see Use the RSoP Snap-in.

- **Advanced System Information - Policy--**In Help and Support Center, you can use **Advanced System Information - Policy** to view an HTML report of Group Policy results. Similar to RSoP logging mode, this tool provides a detailed assessment of policy settings applied to the computer and user that are currently logged on. You can print this report. For more information, see View an RSoP report in HTML.

- **Gpresult--**You can use the **gpresult** command at the command line to get similar detailed information provided by RSoP logging mode. You can export query results to a text file. For more information, see Gpresult.

# Using the RSoP Snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the RSoP snap-in**

This section covers:

- RSoP logging mode
- RSoP planning mode
- RSoP planning mode options
- Viewing RSoP query results

# RSoP logging mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RSoP logging mode**
Resultant Set of Policy (RSoP) logging mode helps administrators review existing policy settings that have been applied to computers and users.

Logging mode is most helpful in the following situations:

- You want to discover which policy settings are applied to a computer or user.
- You want to discover failed or overwritten policy settings.
- You want to see how security groups affect policy settings.

For more information, see Access RSoP data for an existing computer and user (logging mode) and View individual policy settings with RSoP.

To run RSoP logging mode on a remote computer, you must be logged on as a member of the Domain Admins security group, Enterprise Admins security group, or be delegated **Generate Resultant Set of Policy (logging)** rights. For more information about security groups, see Default groups. For more information about delegating control of RSoP, see Delegate control of RSoP. Any local user account can run a single RSoP logging mode query when logged onto a local computer.

# RSoP planning mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RSoP planning mode**
Resultant Set of Policy (RSoP) planning mode helps administrators plan for growth and reorganization. With RSoP planning mode, you can poll existing Group Policy objects (GPOs) for all of the policy settings that can be applied. Then, you can use the results to construct a "What if?" scenario to predict the effect of changes in policy settings.

Planning mode is most helpful in the following situations:

- You want to simulate the affect of specific policy settings on a computer or user, domain, organizational unit, or site.
- The user is in Active Directory only (for example, a new account).
- You want to test policy precedence in the following situations:
    - The user and the computer are in different security groups.
    - The user and the computer are in different organizational units.
    - The user or the computer is moving to a new location.
- You want to create a slow network simulation.
- You want to create a loopback simulation.

After you decide that a change is necessary, you can run a series of RSoP planning simulations to see what will happen to a user or a group of users if they are moved to another location or security group, or even to another computer. This includes what policy settings will be applied and which files will be loaded automatically after you implement the change. For more information, see RSoP planning mode options.

To run RSoP planning mode on a remote computer, you must be logged on as a member of the Domain Admins security group, Enterprise Admins security group, or be delegated **Generate Resultant Set of Policy (planning)** rights. For more information about security groups, see Default groups. For more information about delegating control of RSoP, see Delegate control of RSoP.

# RSoP planning mode options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RSoP planning mode options**
Resultant Set of Policy (RSoP) provides several planning mode options. You can configure the Resultant Set of Policy Wizard to run each option separately or in conjunction with other options. For more information about running RSoP in planning mode, see RSoP planning mode and Simulate RSoP data for a computer and user (planning mode).

**Slow network connection**
This option simulates a slow network connection in the reporting of Group Policy settings. If the rate at which data is transferred (that is, from the domain controller that provides a policy update to the computers in this group) is slower than the rate that is specified by this policy, the system considers the connection to be slow. The system's response to a slow network connection varies among policy settings. During slow connections, some policy settings might not be applied. RSoP simulates a slow network connection and displays the expected results.

**Loopback processing**
Loopback processing simulates the application of alternate user policy settings when a user logs on to a computer that is affected by the alternate user policy settings. The loopback processing simulation directs the system to apply the set of Group Policy objects (GPOs) for the computer to any user who logs on to a computer that is affected by the alternate user policy settings. It is intended for special-use computers, such as those in public places, laboratories, and classrooms, where you must modify the user policy based on the computer that is being used.

By default, the user's Group Policy objects determine which user policy settings apply. When you apply loopback processing, you need to select one of the following options:

- **Replace--**Indicates that the user policies that are defined in the computer's Group Policy objects replace the user policies that are normally applied to the user.

- **Merge--**Indicates that the user policies that are defined in the computer's Group Policy objects and the user policy settings that are normally applied to the user are combined. If the policy settings conflict, the user policy settings in the computer's Group Policy objects take precedence over the user's existing policy settings.

When you run the query, the computer's Group Policy objects determine which set of Group Policy objects applies.

**Site name**
This option specifies which site and physical location of the subnet that RSoP will use. A site is required. A domain controller, is not required. Use a site to test policy settings that are based on startup or logon being on a subnet other than the one on which the query is currently being run. Use a domain controller to test policy for computers and users that could be operating in location other than the one in which the query is being run, such as a field office.

**Alternate security groups**
This option simulates the application of alternate security groups to both computer and user configurations. With this option you can run a query that simulates what happens when a user or computer belongs to alternate security groups and how this affects the application of the Group Policy object. Administrators can use security groups to further refine which computers and users a Group Policy object influences. For any Group Policy object, administrators can filter the Group Policy object's effect on computers or users that are members of specified security groups. You can set this filtering by using the standard access control list (ACL) editor. To use the ACL editor, click the **Security** tab in a Group Policy object's properties dialog box. Administrators can also use the ACL editor to delegate who can modify the Group Policy object.

**WMI filters**
This option enables RSoP to include configured Windows Management Instrumentation (WMI) filters. With a WMI filter, an administrator can specify a WMI-based query to filter the effect of a Group Policy object based on certain information, such as installed hardware and software. You can find WMI filters in the properties dialog box for a Group Policy object. In addition, RSoP also displays existing WMI filters that are currently enabled.

# Viewing RSoP query results

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing RSoP query results**

After you run the Resultant Set of Policy Wizard, you can view the results from the RSoP query for computer configuration and user configuration in the RSoP snap-in. In the RSoP query in Microsoft Management Console (MMC), under Computer Configuration and User Configuration, the query results for Software Settings, Windows Settings, and Extra Registry Settings appear in the MMC details pane.

**Software Settings**

You can view the Resultant Set of Policy (RSoP) results for Software Settings in the details pane, which displays the five default columns described in the following table.

| Column | Description |
|---|---|
| Name | Lists the name of the deployed package |
| Version | Lists the software version of the deployed package |
| Deployment state | Indicates whether the package is assigned or published |
| Source | Specifies the source location of the deployed package |
| Origin | Lists the name of the Group Policy object that deployed the package |

**Windows Settings**

You can view the Resultant Set of Policy (RSoP) results for Windows Settings in the details pane, which contains results for the following:

- **Scripts**--If a policy setting applies scripts, four default columns appear in the details pane, which are described in the following table.

  | Column | Description |
  |---|---|
  | Name | Lists the name of the script |
  | Parameters | Lists any parameters that are assigned to the script |
  | Last Executed | Lists the date that the script was last run |
  | GPO Name | Lists the name of the Group Policy object that assigned the script |

- **Security Settings**--The Security Settings results in Windows Settings appear the same way that they do for Group Policy. However, when you double-click a policy setting, the **Security Policy Settings** tab is not available and there is a new **Precedence** tab. The **Precedence** tab that indicates which Group Policy objects affect this policy setting from newest to oldest.

- **Internet Explorer Maintenance**--The Internet Explorer Maintenance results appear the same way that they do for Group Policy. However, for each policy setting there is an additional **Precedence** tab that indicates which Group Policy objects affect this policy setting in order from newest to oldest.

- **Administrative Templates**--You can view the Resultant Set of Policy (RSoP) results for Administrative Templates in the details pane. The details pane appears the same way that it does for Group Policy, except that only those policy settings that have been changed from the default setting appear and there is an additional column called **GPO Name**, which displays the Group Policy object name.

  To view more information about an Administrative Template setting, in the details pane double-click the setting. A dialog box appears with three tabs. The following table lists and describes these tabs.

| Tab | Description |
| --- | --- |
| Setting | Indicates the state of the policy setting (unavailable) |
| Explain | Describes the policy setting |
| Precedence | Indicates Group Policy object precedence, from newest to oldest |

**Extra Registry Settings**

You can view the Resultant Set of Policy (RSoP) results for Extra Registry Settings in the details pane. Extra Registry Settings is a collection of policy-based registry settings that do not have an Administrative Template associated with them. Because there is no association with an Administrative Template, there is no explanation of the setting except for the registry key and the Group Policy object that set the key. If no Extra Registry Settings are applied, Extra Registry Settings does not appear in the RSoP query results.

### Note

- To view an HTML report of Group Policy policy settings, you can use **Advanced System Information - Policy** in Help and Support Center. You can use this feature to quickly determine which policy settings are currently being applied, without running RSoP logging mode. For more information, see View Group Policy settings in HTML.

# View Group Policy settings in HTML

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**View Group Policy settings in HTML**

In Help and Support Center, the **Advanced System Information - Policy** tool provides an HTML report of Group Policy settings and Resultant Set of Policy (RSoP) as applied to the local computer and currently logged on user. This tool uses the same functions as RSoP logging mode to determine policy settings specified in the system logging provider (CIMOM database through WMI). Although this tool does not provide the level of detail provided by the RSoP snap-in, it can help you quickly determine the policy settings that are currently applied. For more information, see View an RSoP report in HTML.

Use **Advanced System Information - Policy** to view the following:

- Group Policy results for local computer, which includes the following:
    - Computer Information: Computer name, domain, site, and last time Group Policy was applied
    - Applied Group Policy objects
    - Security group membership when Group Policy was applied
    - Startup scripts
    - Shutdown scripts
    - Security settings - Restricted groups
    - Security settings - File system
    - Security settings - Registry
    - Programs Installed (by using Group Policy Software Installation)
    - Programs listed in Add or Remove Programs (determined by last use of current user)
    - Registry settings
- Group Policy results for current user, which includes the following:
    - User Information: User name, domain, and last time Group Policy was applied
    - Applied Group Policy objects
    - Security group membership when Group Policy was applied
    - Internet Explorer automatic browser configuration
    - Internet Explorer proxy server settings
    - Logon scripts
    - Logoff scripts
    - Redirected folders

- Programs installed (by using Software Installation)
- Programs listed in Add or Remove Programs (determined by last use of current user)
- Registry settings

**Note**

- The RSoP snap-in provides more detailed information about applied policy settings. For more information, see Using the RSoP Snap-in.

# Troubleshooting RSoP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The Active Directory query for the specified user, user container, computer, or computer container failed.
- I received the error message "The container path entered is actually a user object. Please select a container which holds user objects instead."
- I received the error message "The container path entered is actually a computer object. Please select a container which holds computer objects instead."
- I received the error message "Failed to generate RSoP data due to the error listed below. (The planning mode provider failed.)"
- I received the error message "The DomainName domain does not contain a domain controller with the RSoP planning mode functionality available."
- I received the error message "The domain controller you have selected does not have the RSoP planning mode functionality available. Please select a different domain controller."
- I received the error message "The selected computer currently does not have RSoP logging enabled. Do you want to continue?"
- I received the error message "The RSoP snap-in was unable to enumerate the users on the selected computer due to the error listed below."
- I received the error message "The selected computer does not support RSoP logging. RSoP logging support is available in operating system releases after Windows 2000."

**The Active Directory query for the specified user, user container, computer, or computer container failed.**
**Cause:** The domain controller that holds this object is unavailable, or the domain controller that holds this object is not responding to requests for information.

**Solution:** Do the following:

- Verify that the domain controller is available.
- Check the network connections, responses, and throughput.

**Cause:** The client does not have access to the Read properties of the object that is queried.

**Solution:** Verify that the client has access to the Read properties of the object that is queried.

**I received the error message "The container path entered is actually a user object. Please select a container which holds user objects instead."**
**Cause:** The indicated path points to a user account instead of to a container.

**Solution:** Verify that the path points to a container object.

**I received the error message "The container path entered is actually a computer object. Please select a container which holds computer objects instead."**
**Cause:** The indicated path points to a computer account instead of to a container.

**Solution:** Verify that the path points to a container object.

**I received the error message "Failed to generate RSoP data due to the error listed below. (The planning mode provider failed.)"**
**Cause:** The planning mode provider failed.

**Solution:** See the event log file for more details.

**I received the error message "The DomainName domain does not contain a domain controller with the RSoP planning mode functionality available."**
**Cause:** This message appears when the client browses for a domain controller. The client polls a Windows 2000 domain controller, but Windows 2000 does not have planning mode functionality. The user is informed that no domain controller is available.

**Solution:** Connect to a different domain, or upgrade the domain to Windows Server 2003, Standard Edition or Windows Server 2003, Enterprise Edition.

**I received the error message "The domain controller you have selected does not have the RSoP planning mode functionality available. Please select a different domain controller."**
**Cause:** This message is generated when the client browses for a domain controller. The client is running in a Windows 2000 domain, but Windows 2000 does not have planning mode functionality. The user is informed that no domain controller is available.

**Solution:** Connect to a different domain controller, or upgrade the domain controller and domain to Windows Server 2003, Standard Edition or Windows Server 2003, Enterprise Edition.

**I received the error message "The selected computer currently does not have RSoP logging enabled. Do you want to continue?"**
**Cause:** The client is trying to poll a computer that does not have the **Turn off Resultant Set of Policy logging** policy setting disabled.

**Solution:** Disable the **Turn off Resultant Set of Policy logging** policy setting.

**I received the error message "The RSoP snap-in was unable to enumerate the users on the selected computer due to the error listed below."**
**Cause:** The RSoP snap-in cannot enumerate a list of users on a specific domain controller, usually because the client user does not have Read permissions for that domain controller.

**Solution:** Try a different domain controller, or obtain Read permissions for the user.

**I received the error message "The selected computer does not support RSoP logging. RSoP logging support is available in operating system releases after Windows 2000."**
**Cause:** The client is trying to poll a computer with Windows 2000, and Windows 2000 does not support RSoP logging mode.

**Solution:** Poll a different computer, or update the operating system to Windows XP Professional or a product in the Windows Server 2003 family.

# Computer Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computer Management**

You can use Computer Management to manage local or remote computers.

- For help with specific tasks, see Computer Management How To....
- For general background information, see Computer Management Concepts.
- For problem-solving instructions, see Troubleshooting Computer Management.

# Computer Management How To...

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Connect to another computer
- Export information from Computer Management

# Connect to another computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to another computer**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management**, and then click **Connect to another computer**.
3. In the **Select Computer** dialog box, type the name of the computer that you want to manage, or click **Browse** to find it, and then click **OK**.

## Notes

- You must have the appropriate user rights or you must have been delegated the appropriate authority on the target computer to connect to that computer.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The name of the computer that you are managing appears in parentheses next to Computer Management in the console tree.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export information from Computer Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export information from Computer Management**

1. Open Computer Management.
2. In the console tree, select the item that you want to export information for.
3. On the **Action** menu, click **Export List**. This opens the **Export List** dialog box.
4. In **Save in**, click or type the file location where you want to save the exported file.
5. In **File name**, type the name of the file.
6. In **Save as type**, click the file type, and then click **Save**.

## Notes

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The name of the computer that you are managing appears in parentheses next to Computer Management in the console tree.
- You can export information to a tab-delimited text (.txt) file, which is the default, or to a comma-delimited (.csv) file.
- This export functionality may not be available for some items in the console tree.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Computer Management Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computer Management overview**
Computer Management is a collection of administrative tools that you can use to manage a single local or remote computer. It combines several administrative utilities into a console tree, and it provides easy access to administrative properties and tools.

You can use Computer Management to:

- Monitor system events, such as logon times and application errors.
- Create and manage shared resources.
- View a list of users who are connected to a local or remote computer.
- Start and stop system services, such as Task Scheduler and Indexing Service.
- Set properties for storage devices.
- View device configurations and add new device drivers.
- Manage applications and services.

Computer Management contains three items: System Tools, Storage, and Services and Applications. For more information, see:

- System Tools overview
- Storage overview
- Services and Applications overview

**Note**

- If you are not a member of the Administrators group, you may not have the administrative credentials required to view or modify some properties or to perform some tasks that Computer Management hosts.

# System Tools overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Tools overview**

System Tools is the first item in the Computer Management console tree. You can use the default tools--Event Viewer, Shared Folders, Local Users and Groups, Performance Logs and Alerts, and Device Manager--to manage system events and performance on the specified computer.

- For more information about Event Viewer, see Event Viewer.
- For more information about Shared Folders, see Shared Folders.
- For more information about Local Users and Groups, see Local Users and Groups.
- For more information about Performance Logs and Alerts, see Performance Logs and Alerts overview.
- For more information about Device Manager, see Device Manager.

# Storage overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Storage overview**
Storage is the second item in the Computer Management console tree. It displays storage devices that are installed on the specified computer. You can use the default tools--Removable Storage, Disk Defragmenter, and Disk Management--to manage the properties of storage devices.

- For more information about Removable Storage, see Removable Storage.
- For more information about Disk Defragmenter, see Disk Defragmenter.
- For more information about Disk Management, see Disk Management.

# Services and Applications overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services and Applications overview**
Services and Applications is the third item in the Computer Management console tree. You can use the default tools--Services, WMI Control, Telephony, and Indexing Service--to help you manage services and applications on the specified computer. For example, you can use Services to view and manage the properties of the Net Logon service.

- For more information about Services, see Services Snap-in.
- For more information about WMI Control, see WMI Overview.
- For more information about Telephony, see Telephony.
- For more information about Indexing Service, see Indexing Service.

**Note**

- The actual set of tools and applications that you see may vary, depending on which services are installed on the specified computer. You may not see the installed services and applications if the specified computer is a remote computer and either of the following conditions is true: you are not a member of the Administrators group on the specified computer or the Remote Registry service is not running on the specified computer.

# Understanding Computer Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Computer Management**
Computer Management has a two-pane view that is similar to Windows Explorer. The console tree is in the left pane, and the details pane is in the right pane. When you select an item in the console tree, information about that item appears in the details pane. This information might include details about the contents, data, or subtools that are available for the selected item. For example, if you click **Sessions** under Shared Folders in System Tools, you can view information about the current user sessions, if any, on the target computer.

The console tree contains three items: System Tools, Storage, and Services and Applications. For more information about these items, see:

- System Tools overview
- Storage overview
- Services and Applications overview

For more information about working with a console tree in Microsoft Management Console (MMC), see Microsoft Management Console.

**Note**

- If you are not a member of the Administrators group, you may not have the administrative credentials required to view or modify some properties or to perform some tasks that Computer Management hosts.

# Troubleshooting Computer Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- I cannot access the tools that are hosted in Computer Management on a remote computer.

**I cannot access the tools that are hosted in Computer Management on a remote computer.**
**Cause:** The Remote Registry service is not running on the remote computer.

**Solution:** Ensure that the Remote Registry service is started on the remote computer. For more information, see Start, stop, pause, resume, or restart a service. To start the service, you need the appropriate administrative credentials on the remote computer.

**See also:** Troubleshooting Performance monitoring for System Monitor and Performance Logs and Alerts

**Note**

- You may also receive this error message if the remote computer is running Windows 95. Computer Management does not support remote access to computers running Windows 95.

# Local Users and Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local Users and Groups**

Use Local Users and Groups to create and manage users and groups that are stored locally on a computer.

- For tips about using Local Users and Groups, see Local Users and Groups Best practices.
- For help with specific tasks, see Local Users and Groups How To....
- For general background information, see Local Users and Groups Concepts.
- For problem-solving instructions, see Troubleshooting Local Users and Groups.

# Local Users and Groups Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **As a security best practice, it is recommended that you do not log on to your computer with administrative credentials.**

  When you are logged on to your computer without administrative credentials, you can use Run as to accomplish administrative tasks.

  For more information, see Using Run as.

- **To further secure your local computer, it is recommended that you implement the following security guidelines:**

  - Limit the number of users in the Administrators group since members of the Administrators group on a local computer have Full Control permissions on that computer.

    For more information, see Why you should not run your computer as an administrator.

  - Rename or disable the Administrator account.

    For more information, see Local user accounts.

  - Leave the Guest account disabled. The Guest account is used by people who do not have an actual account on the computer. The Guest account does not require a password, so it is a security risk. The Guest account is disabled by default, and it is recommended that it stay disabled.

    For more information, see Local user accounts.

  - Some default user rights assigned to specific default local groups may allow members of those groups to gain additional rights on your computer, including administrative rights. Therefore, your organization must equally trust all personnel that are members of the Administrators, Power Users, Print Operators, and Backup Operators groups.

    For more information about these groups, see Default local groups.

  - Review important security considerations about local users and groups.

    For more information, see Default security settings for groups.

- **Use passwords no longer than 14 characters if you are on a network with computers running Windows 95 and Windows 98.**

  You can create a password containing up to 127 characters. However, computers running Windows 95 and Windows 98 support passwords up to only 14 characters. If your password is longer, you may not be able to log on to the network from those computers.

  For more information, see Create a local user account.

# Local Users and Groups How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Manage Local Users
- Manage Local Groups
- Start programs as an administrator

# Manage Local Users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage local users**

- Create a local user account
- Reset the password for a local user account
- Disable or activate a local user account
- Delete a local user account
- Rename a local user account
- Assign a logon script to a local user account
- Assign a home folder to a local user account

# Create a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. On the **Action** menu, click **New User**.
4. Type the appropriate information in the dialog box.
5. Select or clear the check boxes for:

   - **User must change password at next logon**
   - **User cannot change password**
   - **Password never expires**
   - **Account is disabled**

6. Click **Create**, and then click **Close**.

**Notes**

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A user name cannot be identical to any other user or group name on the computer being administered. It can contain up to 20 uppercase or lowercase characters, except for the following:

  " / \ [ ] : ; | = , + * ? < >

  A user name cannot consist solely of periods (.) or spaces.

- In **Password** and **Confirm password**, you can type a password containing up to 127 characters. However, if the network consists of computers running Windows 95 or Windows 98, consider using passwords no longer than 14 characters. If your password is longer, you may not be able to log on to the network from those computers.
- The use of strong passwords and appropriate password policies can help protect your computer from attack. For more

information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reset the password for a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset the password for a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. Right-click the user account for which you want to reset the password, and then click **Set Password**.
4. Read the warning message, and if you want to continue, click **Proceed**.
5. In **New password** and in **Confirm password**, type a new password and then click **OK**.

## Notes

- To perform this procedure, you must be the member of the Power Users group who created the account or a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Strong passwords improve computer and network security. For more information, see Related Topics.
- Resetting a local user account password may result in some data loss for that user. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable or activate a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable or activate a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. Right-click the user account you want to change, and then click **Properties**.
4. Do one of the following:

   - To disable the selected user account, select the **Account is disabled** check box.
   - To activate the selected user account, clear the **Account is disabled** check box.

## Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When a user account is disabled, the user is not permitted to log on. The account appears in the details pane with an X on the icon.
- Before activating a disabled account, ensure that the account was not locked out for security reasons. For more information, see Related Topics.
- When a user account is activated, the user is permitted to log on normally.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. Right-click the user account that you want to delete, and then click **Delete**.

## Notes

- To perform this procedure, you must be the member of the Power Users group who created the account or a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- When you need to delete a user account, it is recommended that you first disable the account. When you are certain that disabling the account has not caused a problem, you can safely delete it.
- A deleted user account cannot be recovered.
- The Administrator and Guest account cannot be deleted.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

Delete a local user account
Disable or activate a local user account

# Rename a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. Right-click the user account you want to rename, and then click **Rename**.
4. Type the new user name, and then press ENTER.

## Notes

- To perform this procedure, you must be the member of the Power Users group who created the account or a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Because it retains its security identifier (SID), a renamed user account retains all its other properties, such as its description, password, group memberships, user profile, account information, and any assigned permissions and user rights.
- A user name cannot be identical to any other user or group name of the computer being administered. It can contain up to 20 uppercase or lowercase characters, except for the following:

  " / \ [ ] : ; | = , + * ? < >

  A user name cannot consist solely of periods (.) or spaces.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Local user accounts
Assign a logon script to a local user account
Assign a home folder to a local user account

# Assign a logon script to a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign a logon script to a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. Right-click the user account you want, and then click **Properties**.
4. On the **Profile** tab, in **Logon script**, type the file name and relative path of the script.

## Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- Logon scripts can contain malicious commands. It is recommended that you be familiar with the contents of the logon script before assigning it to a user.
- Logon scripts that are stored on a local computer apply only to users logging on to that local computer.
- Local logon scripts must be stored in a shared folder, or subfolders of the shared folder, named **Netlogon**. If this folder does not exist by default, you must create it. To specify a logon script that is stored in a subfolder of the Netlogon folder, precede the file name with the relative path to that folder. For example, to assign the Startup.bat logon script stored in *ComputerName*\Netlogon*FolderName* to a local user, in **Logon script**, type: *FolderName*\Startup.bat

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign a home folder to a local user account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign a home folder to a local user account**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

3. Right-click the user account for which you want to specify a home folder, and then click **Properties**.
4. On the **Profile** tab, do one of the following:

   - To specify a local home folder, click **Local path**, and then type the path. For example, c:\users\nicolette
   - To specify a home folder on a shared resource, click **Connect**, click the proper drive letter, and then type the network path. For example, \\airedale\users\nathan

## Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The My Documents folder provides a convenient alternative to home folders, but does not replace them. Each user has a My Documents folder on the boot volume. To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.
- If no home folder is assigned, the system assigns a default local home folder to the user account (on the root directory where the operating system files are installed as the initial version).
- To specify a network path for the home folder, you must first create the shared resource and set permissions that allow the user access.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Local Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage local groups**

- Create a local group
- Add a member to a local group
- Identify members of a local group
- Delete a local group
- Allow members of the Anonymous Logon group to be members of the Everyone group on a local computer

# Create a local group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a local group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management.
2. In the console tree, click **Groups**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Groups

3. On the **Action** menu, click **New Group**.
4. In **Group name**, type a name for the new group.
5. In **Description**, type a description of the new group.
6. To add one or more members to the new group, click **Add**.
7. In the **Select Users, Computers, or Groups** dialog box, do the following:

   - To add a user or group account to this group, under **Enter the object names to select**, type the name of the user account or group account that you want to add, and then click **OK**.
   - To add a computer account to this group, click **Object Types**, select the **Computers** check box, and then click **OK**. Under **Enter the object names to select**, type the name of the computer account that you want to add, and then click **OK**.

8. In the **New Group** dialog box, click **Create**, and then click **Close**.

## Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- A local group name cannot be identical to any other group or user name on the local computer being administered. It can contain up to 256 uppercase or lowercase characters, except for the following:

" / \ [ ] : ; | = , + * ? < >

A group name cannot consist solely of periods (.) or spaces.

#### Using a command line

1. Open Command Prompt.

2. To create a group, type:

   **net localgroup***GroupName***/add**

### Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- A local group name cannot be identical to any other group or user name on the local computer being administered. It can contain up to 256 uppercase or lowercase characters, except for the following:

  " / \ [ ] : ; | = , + * ? < >

  A group name cannot consist solely of periods (.) or spaces.

- For more information about the **net localgroup** command, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a member to a local group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a member to a local group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management.
2. In the console tree, click **Groups**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Groups

3. Right-click the group in which you want to add a member, click **Add to Group**, and then click **Add**.
4. In the **Select Users, Computers, or Groups** dialog box, do the following:

   - To add a user account or group account to this group, under **Enter the object names to select**, type the name of the user account or group account that you want to add to the group, and then click **OK**.
   - To add a computer account to this group, click **Object Types**, select the **Computers** check box, and then click **OK**. Under **Enter the object names to select**, type the name of the computer account that you want to add to the group, and then click **OK**.

## Notes

- To perform this procedure, you must be the member of the Power Users group who created the account or a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To remove a member from a local group, select the user account, computer account, or group account in **Members**, and then click **Remove**.
- All the rights and permissions assigned to a group are assigned to all members of that group. For more information, see Related Topics.
- Limit the number of users in the Administrators group since members of the Administrators group on a local computer have Full Control permissions on that computer.
- If the computer is joined to a domain, you can add user accounts, computer accounts, and group accounts from that domain and from trusted domains to a local group.

**Using a command line**

1. Open Command Prompt.

2. To add a member to the Power Users group, type:

   **net localgroup "***PowerUsersGroupName***""***MemberName***"/add**

   You must include the quotation marks.

## Notes

- To perform this procedure, you must be the member of the Power Users group who created the account or a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- All the rights and permissions assigned to a group are assigned to all members of that group. For more information, see Related Topics.

- Limit the number of users in the Administrators group since members of the Administrators group on a local computer have Full Control permissions on that computer.

- If the computer is joined to a domain, you can add user accounts, computer accounts, and group accounts from that domain and from trusted domains to a local group.
