- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Computer Management.
2. In the console tree, click **Groups**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Groups

3. Right-click the group in which you want to identify members, and click **Properties**.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

#### Using a command line

1. Open Command Prompt.
2. To list members of the Power Users group, type:

   **net localgroup"***PowerUsersGroupName***"**

   You must include the quotation marks.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- For more information about the **net localgroup** command, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a local group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a local group**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Computer Management.
2. In the console tree, click **Groups**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Groups

3. Right-click the group you want to delete, and then click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The following default groups cannot be deleted:
  - Administrators
  - Backup Operators
  - Guests
  - Network Configuration Operators
  - Performance Log Users
  - Performance Monitor Users
  - Power Users
  - Print Operators
  - Remote Desktop Users
  - Replicator

    - Users

- A deleted group cannot be recovered.

- Deleting a local group removes only the group; it does not delete the user accounts, computer accounts, or group accounts that were members of that group.

- If you delete a group and then create another group with the same group name, you must set new permissions for the new group; it will not inherit the permissions that were assigned to the old group.

#### Using a command line

1. Open Command Prompt.

2. To delete a group, type:

   **net localgroup***GroupName***/delete**

### Notes

- To perform this procedure, you must be a member of the Power Users group, or the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- The following default groups cannot be deleted:

    - Administrators

    - Backup Operators

    - Guests

    - Network Configuration Operators

    - Performance Log Users

    - Performance Monitor Users

    - Power Users

    - Print Operators

    - Remote Desktop Users

    - Replicator

    - Users

- A deleted group cannot be recovered.

- Deleting a local group removes only the group; it does not delete the user accounts, computer accounts, or group

accounts that were members of that group.

- If you delete a group and then create another group with the same group name, you must set new permissions for the new group; it will not inherit the permissions that were granted to the old group.

- For more information about the **net localgroup** command, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow members of the Anonymous Logon group to be members of the Everyone group on a local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow members of the Anonymous Logon group to be members of the Everyone group on a local computer**

1. Open Local Security Settings.
2. In the console tree, double-click **Local Policies**, and then click **Security Options**.
3. In the details pane, right-click **Network access: Let Everyone permissions apply to anonymous users**, and then click **Properties**.
4. On the **Local Security Settings** tab, click **Enabled**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Settings, click **Start**, point to **All Programs**, point to **Administrative Tools**, and then click **Local Security Policy**.
- By default, the inclusion of the Everyone security group in the anonymous user access token is disabled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start programs as an administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Start programs as an administrator**

- Run a program with administrative credentials
- Create a shortcut using the runas command

# Run a program with administrative credentials

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run a program with administrative credentials**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. In Windows Explorer, or on the **Start** menu, right-click the program executable file (or icon) that you want to open, and then click **Run as**.
2. Click **The following user**.
3. In **User name** and **Password**, type the administrator account name and password.

## Notes

- The use of Run as is not limited to administrator accounts.
- You can use Run as to start a program in the context of an administrator account. The administrator context is only used for that specific program and is only available until that program is closed.
- You can also use Run as to start two separate instances of an administrative application, such as Active Directory Domains and Trusts. Each instance can be directed at a different domain or forest to more efficiently perform interdomain or interforest administration tasks.
- You can open most Control Panel items using Run as by holding down the SHIFT key, and then right-clicking the item.
- Some programs do not support Run as.
- If you try to start a program, such as Microsoft Management Console (MMC) or a Control Panel item, from a network location using Run as, it could fail if the credentials used to connect to the shared resource are different from the credentials used to start the program. The credentials used to run the program might not be able to gain access to the same shared resource. For more information about troubleshooting the **runas** command, see Related Topics.
- If Run as fails, the Secondary Logon service may not be running. For more information about how to start a service, see Related Topics.

**Using a command line**

1. Open Command Prompt.
2. To run a program, type:

   **runas/user:***UserName* **"***ProgramNamePathToProgramFile***"**

| Value | Description |
|---|---|

| | |
|---|---|
| *UserName* | Specifies the user credentials to use when running the specified program. You can use the format *user*@*domain* or *domain**user*. |
| " *ProgramName PathToProgramFile* " | Specifies the program name and path to the program file name that you want to open with the specified user credentials.<br><br>For example, to open Active Directory Users and Computers, use the following format:<br><br>**"mmc %windir%\system32\dsa.msc"**<br><br>To open a specific file using Notepad, use the following format:<br><br>**"notepad c:\myfile.txt"** |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- The use of the **runas** command is not limited to administrator accounts.
- You can use the **runas** command to start a program in the context of an administrator account. The administrator context is only used for that specific program and is only available until that program is closed.
- You can also use the **runas** command to start two separate instances of an administrative application, such as Active Directory Domains and Trusts. Each instance can be directed at a different domain or forest to more efficiently perform interdomain or interforest administration tasks.
- Some programs do not support the **runas** command.
- If you try to start a program, such as Microsoft Management Console (MMC) or a Control Panel item, from a network location using the runas command, it could fail if the credentials used to connect to the shared resource are different from the credentials used to start the program. The credentials used to run the program might not be able to gain access to the same shared resource. For more information about troubleshooting the **runas** command, see Related Topics.
- If the **runas** command fails, the Secondary Logon service may not be running. For more information about how to start a service, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a shortcut using the runas command

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a shortcut using the runas command**

1. Right-click the desktop, point to **New**, and then click **Shortcut**.
2. In **Type the location of the item**, type **runas** and the command parameters you want to use. In the following table, see examples for creating shortcuts.
3. Click **Next**, type a name for the shortcut, and then click **Finish**.

**Examples**

| To create a shortcut to | Type |
|---|---|
| A command prompt with administrative credentials | **runas /user:** *ComputerName* **\administrator cmd** |
| Computer Management with administrative credentials | **runas /user:** *ComputerName* **\administrator "mmc %windir%\system32\compmgmt.msc"** |
| Active Directory Users and Computers with domain administrative credentials | **runas /user:** *DomainName* **\administrator "mmc %windir%\system32\dsa.msc"** |
| Active Directory Users and Computers in another forest. | **runas /netonly /user:** *DomainName* **** *UserName* **"mmc %windir%\system32\dsa.msc"** |

**Notes**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Use this procedure if you want to perform administrative tasks when you are logged on as a member of another group. The use of the **runas** command is not limited to administrator accounts.
- Microsoft Management Consoles (MMC) will not display the credentials under which it is running. Be aware of this when you are using the **runas** command.
- Some programs do not support the **runas** command.
- If you try to start a program, such as Microsoft Management Console (MMC) or a Control Panel item, from a network location using the **runas** command, it could fail if the credentials used to connect to the shared resource are different from the credentials used to start the program. The credentials used to run the program might not be able to gain access to the same shared resource. For more information about troubleshooting the **runas** command, see Related Topics.
- If the **runas** command fails, the Secondary Logon service may not be running. For more information about how to start a service, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Local Users and Groups overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local Users and Groups overview**

Local Users and Groups is located in Computer Management, a collection of administrative tools that you can use to manage a single local or remote computer. You can use Local Users and Groups to secure and manage user accounts and groups stored locally on your computer. A local user or group account can be assigned permissions and rights on a particular computer and that computer only. Local Users and Groups is available on the following client and server operating systems:

- Client computers running Microsoft® Windows® 2000 Professional or Windows XP Professional
- Member servers running a product in the Microsoft Windows 2000 Server family or the Windows Server 2003 family
- Stand-alone servers running a product in the Microsoft Windows 2000 Server family or the Windows Server 2003 family

Using Local Users and Groups you can limit the ability of users and groups to perform certain actions by assigning them rights and permissions. A right authorizes a user to perform certain actions on a computer, such as backing up files and folders or shutting down a computer. A permission is a rule associated with an object (usually a file, folder, or printer), and it regulates which users can have access to the object and in what manner.

You cannot use Local Users and Groups to view local user and group accounts once a member server has been promoted to a domain controller. However, you can use Local Users and Groups on a domain controller to target remote computers (that are not domain controllers) on the network. Use Active Directory Users and Computers to manage users and groups in Active Directory.

For more information, see:

- Local user accounts
- Default local groups
- Default security settings for groups
- Active Directory Users and Computers (Windows Server 2003)

# Local user accounts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local user accounts**

The Users folder located in the Local Users and Groups Microsoft Management Console (MMC) displays the default user accounts as well as the user accounts you create. These default user accounts are created automatically when you install a stand-alone server or member server running Windows Server 2003. The following table describes each default user account on servers running Windows Server 2003.

| Default user account | Description |
|---|---|
| Administrator account | The Administrator account has full control of the server and can assign user rights and access control permissions to users as necessary. This account must be used only for tasks that require administrative credentials. It is highly recommended that you set up this account to use a strong password. For more information, see Strong passwords. For additional security considerations for accounts with administrative credentials, see Local Users and Groups Best practices.<br><br>The Administrator account is a member of the Administrators group on the server. The Administrator account can never be deleted or removed from the Administrators group, but it can be renamed or disabled. Because the Administrator account is known to exist on many versions of Windows, renaming or disabling this account will make it more difficult for malicious users to try and gain access to it. For more information about how to rename or disable a user account, see Rename a local user account and Disable or activate a local user account.<br><br>The Administrator account is the account you use when you first set up the server. You use this account before you create an account for yourself.<br><br>**Important**<br><br>• Even when the Administrator account has been disabled, it can still be used to gain access to a computer using Safe Mode. |
| Guest account | The Guest account is used by people who do not have an actual account on the computer. A user whose account is disabled, but not deleted, can also use the Guest account. The Guest account does not require a password. The Guest account is disabled by default, but you can enable it.<br><br>You can set rights and permissions for the Guest account just like any user account. By default, the Guest account is a member of the default Guests group, which allows a user to log on to a server. Additional rights, as well as any permissions, must be granted to the Guests group by a member of the Administrators group. The Guest account is disabled by default, and it is recommended that it stay disabled. |
| HelpAssistant account (installed with a Remote Assistance session) | The primary account used to establish a Remote Assistance session. This account is created automatically when you request a Remote Assistance session and has limited access to the computer. The HelpAssistant account is managed by the Remote Desktop Help Session Manager service and will be automatically deleted if no Remote Assistance requests are pending. For more information about Remote Assistance, see Administering Remote Assistance. |

For more information about creating and managing local user accounts, see Manage Local Users.

# Default local groups

Updated: May 24, 2012

Applies To: Windows 7, Windows 8, Windows Server 2000, Windows Server 2003, Windows Server 2003 R2, Windows Server 2008, Windows Server 2008 R2, Windows Server 2012, Windows Vista, Windows XP

**Default local groups**

The Groups folder located in the Local Users and Groups Microsoft Management Console (MMC) displays the default local groups as well as the local groups that you create. The default local groups are automatically created when you install a stand-alone server or a member server running Windows Server 2003. Belonging to a local group gives a user the rights and abilities to perform various tasks on the local computer. For more information about domain-based groups, see Default groups.

You can add local user accounts, domain user accounts, computer accounts, and group accounts to local groups. However, you cannot add local user accounts and local group accounts to domain group accounts. For more information about adding members to local groups, see Add a member to a local group.

**Note**

- To learn what group you need to be a member of to perform a particular procedure, many procedural topics under **How To** in Help and Support Center provide a note that identifies this information.

The following table provides descriptions of the default groups located in the Groups folder and lists the assigned user rights for each group. These rights are assigned within the local security policy. For complete descriptions of the user rights listed in the table, see User Rights Assignment. For information about editing these rights, see Assign user rights for your local computer.

| Group | Description | Default user rights |
|---|---|---|
| Administrators | Members of this group have full control of the server and can assign user rights and access control permissions to users as necessary. The Administrator account is also a default member. When this server is joined to a domain, the Domain Admins group is automatically added to this group. Because this group has full control of the server, add users with caution. For more information, see Default local groups and Default groups. | Access this computer from the network; Adjust memory quotas for a process; Allow log on locally; Allow log on through Terminal Services; Back up files and directories; Bypass traverse checking; Change the system time; Create a pagefile; Debug programs; Force shutdown from a remote system; Increase scheduling priority; Load and unload device drivers; Manage auditing and security log; Modify firmware environment variables; Perform volume maintenance tasks; Profile single process; Profile system performance; Remove computer from docking station; Restore files and directories; Shut down the system; Take ownership of files or other objects. |
| Backup Operators | Members of this group can back up and restore files on the server, regardless of any permissions that protect those files. This is because the right to perform a backup takes precedence over all file permissions. They cannot change security settings. | Access this computer from the network; Allow log on locally; Back up files and directories; Bypass traverse checking; Restore files and directories; Shut down the system. |
| DHCP Administrators (installed with the DHCP Server service) | Members of this group have administrative access to the Dynamic Host Configuration Protocol (DHCP) Server service. This group provides a way to assign limited administrative access to the DHCP server only, while not providing full access to the server. Members of this group can administer DHCP on a server using the DHCP console or the Netsh command, but are not able to perform other administrative actions on the server. | No default user rights. |

| | | |
|---|---|---|
| DHCP Users (installed with the DHCP Server service) | Members of this group have read-only access to the DHCP Server service. This allows members to view information and properties stored at a specified DHCP server. This information is useful to support staff when they need to obtain DHCP status reports. | No default user rights. |
| Guests | In a computer joined to the domain, members of this group have a temporary profile created at log on, and when the member logs off, the profile is deleted. Profiles in workgroup environments are not deleted. The Guest account (which is disabled by default) is also a default member of this group.<br><br>Members of this group will have a temporary profile created at log on, and when the member logs off, the profile will be deleted. The Guest account (which is disabled by default) is also a default member of this group. | No default user rights. |
| HelpServicesGroup | This group allows administrators to set rights common to all support applications. By default, the only group member is the account associated with Microsoft support applications, such as Remote Assistance. Do not add users to this group. | No default user rights. |
| Network Configuration Operators | Members of this group can make changes to TCP/IP settings and renew and release TCP/IP addresses. This group has no default members. | No default user rights. |
| Performance Monitor Users | Members of this group can monitor performance counters on the server locally and from remote clients without being a member of the Administrators or Performance Log Users groups. | No default user rights. |
| Performance Log Users | Members of this group can manage performance counters, logs and alerts on the server locally and from remote clients without being a member of the Administrators group. | No default user rights. |
| Power Users | Members of this group can create user accounts and then modify and delete the accounts they have created. They can create local groups and then add or remove users from the local groups they have created. They can also add or remove users from the Power Users, Users, and Guests groups. Members can create shared resources and administer the shared resources they have created. They cannot take ownership of files, back up or restore directories, load or unload device drivers, or manage security and auditing logs. | Access this computer from the network; Allow log on locally; Bypass traverse checking; Change the system time; Profile single process; Remove computer from docking station; Shut down the system. |
| Print Operators | Members of this group can manage printers and print queues. | No default user rights. |

| | | |
|---|---|---|
| Remote Desktop Users | Members of this group can remotely log on to a server.<br><br>For more information, see Enabling users to connect remotely to the server. | Allow log on through Terminal Services. |
| Replicator | The Replicator group supports replication functions. The only member of the Replicator group should be a domain user account used to log on the Replicator services of a domain controller. Do not add user accounts of actual users to this group. | No default user rights. |
| Terminal Server Users | This group contains any users who are currently logged on to the system using Terminal Server. Any program that a user can run with Windows NT 4.0 will run for a member of the Terminal Server User group. The default permissions assigned to this group enable its members to run most earlier programs. | No default user rights |
| Users | Members of this group can perform common tasks, such as running applications, using local and network printers, and locking the server. Users cannot share directories or create local printers. By default, the Domain Users, Authenticated Users, and Interactive groups are members of this group. Therefore, any user account created in the domain becomes a member of this group. | Access this computer from the network; Allow log on locally; Bypass traverse checking. |
| WINS Users (installed with WINS service) | Members of this group are permitted read-only access to Windows Internet Name Service (WINS). This allows members to view information and properties stored at a specified WINS server. This information is useful to support staff when they need to obtain WINS status reports. | No default user rights. |

For more information about the most common default groups, see Default security settings for groups.

# Administering Local Users and Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Local Users and Groups**
This section covers:

- Managing files for local user accounts
- Managing local groups from the command line
- Why you should not run your computer as an administrator

# Managing files for local user accounts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing files for local user accounts**
Administrators can use home folders and My Documents to collect user files in one location. User files located in one place simplifies the backup process and makes access control management easier to maintain.

Home folders can be a local folder or a folder located on a shared resource and can be assigned to a single user or many users. When a home folder is assigned to a user, it becomes the user's default folder for the **Open** and **Save As** dialog boxes, for command prompt sessions, and for all programs without a defined working folder.

The My Documents folder is an alternative for home folders, but it does not replace them. When a user tries to save or open a file, most programs determine whether to use the home folder or My Documents in one of two ways:

- Some programs first look in the home folder for files that match the type of file that is to be opened or saved (for example, *.doc or *.txt). If a file with that extension is found, the program opens the home folder and ignores My Documents. If a file of that type is not found, the program opens My Documents.

- In other programs, the home folder is ignored, regardless of whether the home folder contains any files.

For more information about how to assign home folders, see Assign a home folder to a local user account.

When upgrading servers from Windows NT 4.0 or earlier, programs that have stored documents in the home folder will continue to open and save documents in the home folder. However, if a program is installed after you have upgraded, the program uses My Documents to open and save files.

# Managing local groups from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing local groups from the command line**

The following command-line tool can be used to manage local groups.

| Name | Description |
| --- | --- |
| Net localgroup | This command adds, displays, or modifies local groups. |

Additional command-line tools are available in the Support tools folder of the product compact disc and from the Resource Kits.

For information about other command-line tools, see Command-line reference A-Z.

# Why you should not run your computer as an administrator

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Why you should not run your computer as an administrator**

Running your computer as a member of the Administrators group makes the system vulnerable to Trojan horses and other security risks. The simple act of visiting an Internet site or opening an e-mail attachment can be damaging to the system. An unfamiliar Internet site or e-mail attachment may have Trojan horse code that can be downloaded to the system and executed.

If you are logged on as an administrator of a local computer, a Trojan horse could reformat your hard drive, delete your files, and create a new user account with administrative access. If you are logged on as a member of the Domain Admins group, Enterprise Admins group, or Schema Admins group in Active Directory, a trojan horse could create a new domain user account with administrative access and put schema, configuration, or domain data at risk.

On a local computer, it is recommended that you add your domain user account *only* to the Users group (and not to the Administrators group) to perform routine tasks, including running programs and visiting Internet sites. When it becomes necessary to perform administrative tasks on the local computer or in Active Directory, use Run as to start a program using administrative credentials.

Run as allows you to accomplish administrative tasks without exposing your computer or data stored in Active Directory to unnecessary risk. For more information, see Using Run as. For more information about how to use Run as, see Run a program with administrative credentials.

If you need to perform administrative tasks, such as upgrading the operating system or configuring system parameters, then log off and log back on as an administrator.

# Troubleshooting Local Users and Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Received the "The local policy of this system does not permit you to logon interactively" error message, or unable to log on locally.
- Runas command failed.
- Cannot log on to a network computer running Windows 95 or Windows 98.
- Cannot access the Computer Management extension snap-ins on a remote computer.

**Received the "The local policy of this system does not permit you to logon interactively" error message, or unable to log on locally.**
**Cause:** The ability to log on locally to a stand-alone server or member server running Windows Server 2003 is controlled by local security policy.

**Solution:** Add the user account to the Users local group or use the local security policy to assign the particular user or group the right to Allow log on locally.

**See also:** Allow log on locally;Assign user rights for your local computer; Local Security Policy overview

**Runas command failed.**
**Cause:** The Secondary Logon service is not running.

**Solution:** Start the Secondary Logon service.

**See also:** Start, stop, pause, resume, or restart a service

**Cause:** The Secondary Logon service is running; however, you do not have permissions on the shared resource that is running the Secondary Logon service.

**Solution:** Verify that your local user account in Computer Management has the permissions needed to access the shared resource on which the Secondary Logon service is installed. To view permissions in Computer Management, in Control Panel, double-click **Administrative Tools**, and then double-click **Computer Management**.

**See also:** Runas

**Cause:** The Secondary Logon service is running; however, you cannot start or install a program from a shared resource using the **runas** command.

**Solution:** Using the **runas** command, map a network drive to the shared resource using administrative credentials from your local computer, and then start the program again. To do this, open a command prompt by typing the following command in the **Run** dialog box:

**runas /user:administrator cmd**

When prompted, type the administrative password and when the command prompt appears, type:

**net use z: ** *Server* **** *Share* **/user:** *DomainName* **** *UserName* *

This will connect you to the shared resource while still under the security context of the local administrator account.

**See also:** Runas

**Cannot log on to a network computer running Windows 95 or Windows 98.**
**Cause:** Your password is longer than 14 characters.

**Solution:** Create a new user account or change your password to the 14 character maximum for Windows 95 and Windows 98.

**See also:** Reset the password for a local user account

**Cannot access the Computer Management extension snap-ins on a remote computer.**
**Cause:** The Remote Registry service is not running on the remote computer.

**Solution:** Ensure that the Remote Registry service is started on the remote computer. You need appropriate permissions on the remote computer to start the service.

**See also:** Start, stop, pause, resume, or restart a service

**Note**

- You might also receive this error message if the remote computer is running Windows 95. Computer Management does not support remote access to computers that are running Windows 95.

# The Registry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The registry**
The Microsoft® Windows Server 2003 family registry is a database that contains system configuration information for the Windows Server 2003 family operating system.

- For tips about using the registry and Registry Editor, see Registry best practices.
- For help with specific tasks, see Registry How To....
- For general background information, see Registry concepts.

# Registry best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

In the Windows Server 2003 family, system configuration information is centrally located in the registry. While this simplifies the administration of a computer or network, one incorrect edit to the registry can disable the operating system. The following list provides some best practices for using the registry and Registry Editor safely:

- **Before making changes to the registry, make a backup copy.**

  You can back up the registry by using a program such as Backup. After you make changes to the registry, update your Automated System Recovery (ASR) disk. For troubleshooting purposes, keep a list of the changes you make to the registry. For more information, see the "Windows Server 2003 family Registry Reference" at the Microsoft Windows Resource Kits Web site.

- **Do not replace the** Windows Server 2003 **family registry with the registry of another version of the Windows or** Windows NT **operating systems.**

- **Edit the registry carefully.**

  Incorrectly editing the registry may severely damage your system.

- **Limit the number of people who have access to the registry.**

  For example, because members of the Administrators group have full access to the registry, add only users who need such access to the Administrators group. Alternately, you can use Registry Editor to set permissions for specific keys and subtrees, or simply remove Registry Editor from the computers of users whom you do not want to alter the registry.

- **Never leave Registry Editor running unattended.**

- **Do not run Registry Editor as Administrator, except when necessary.**

  A malicious user who has access to Registry Editor running as Administrator can cause severe damage to the operating system and software. Only run Registry Editor as Administrator if you need to see or change keys that you cannot otherwise access.

- **Use Run as to run Registry Editor as Administrator or a different user.**

  To maintain registry security when making changes to a key that requires administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the Regedit icon, clicking Run as, and choosing an account in the local Administrators group. The Regedit icon does not appear by default from the Start menu. To access the icon, open the Windows or WINNT folder on your computer.

- **Do not access HKEY_CURRENT_USER or HKEY_CLASSES_ROOT using services that impersonate more than one user.**

  HKEY_CURRENT_USER and HKEY_CLASSES_ROOT are aliases for other keys in the registry. For example, HKEY_CURRENT_USER is an alias for the key in HKEY_USERS for the user who is currently logged in. If a service accesses one of these keys while running as one user, and again while running as another user, the operating system might still have the alias data cached from the first user. If this happens, an error will result because the second user will not have access rights for keys belonging to the first user.

# Registry How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Open Registry Editor
- Change Keys and Values
- Import or Export Registry Keys
- Load or Unload Registry Hives
- Maintain Registry Security
- Print all or part of the registry

# Open Registry Editor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open Registry Editor**

- Click **Start**, click **Run**, type **regedit**, and then click **OK**.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. Whenever possible, use tools and programs other than Registry Editor to edit the registry.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- Some previous versions of Windows had two versions of Registry Editor: regedit.exe and regedt32.exe. The version of Registry Editor that ships with the Windows Server 2003 family replaces both versions from previous operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change Keys and Values

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change keys and values**

- Find a string, value, or key
- Add a registry key to Favorites
- Add a registry key
- Add a value to a registry key entry
- Change a value
- Delete a registry key or value
- Rename a registry key or value
- Connect to a registry over the network
- Disconnect from a network registry
- Copy a registry key name
- Restore the registry

# Find a string, value, or key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find a string, value, or key**

1. Open Registry Editor.
2. On the **Edit** menu, click **Find**.
3. In **Find what**, type the string, value, or key you want to find.
4. Select the **Keys**, **Values**, **Data**, and **Match whole string only** check boxes to match the type of search you want, and then click **Find Next**.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- You can speed up the search by looking through only one type of information; for example, if you know that you are looking for a entry, you can clear the **Keys** and **Data** check boxes, so that you will not search through those objects.
- To repeat the search, press F3.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a registry key to Favorites

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a registry key to Favorites**

1. Open Registry Editor.
2. Select the registry key you want to add to **Favorites**.
3. On the **Favorites** menu, click **Add to Favorites**.
4. In the **Add to Favorites** dialog box, accept the default registry key name or type a new one.

   The registry key is added to the **Favorites** list. You can then return to this list by simply selecting it from the **Favorites** menu.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- You can create a list of favorite/frequently visited registry keys.
- To remove a registry key from the **Favorites** list, on the **Favorites** menu, click **Remove Favorite**, and you can select one or more registry keys to remove from the **Favorites** list.
- Renaming a favorite does not rename the corresponding registry key.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a registry key**

1. Open Registry Editor.
2. In the registry tree (on the left), click the registry key under which you would like to add a new key.
3. On the **Edit** menu, point to **New**, and then click **Key**.
4. Type a name for the new key, and then press ENTER.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- If you make a mistake that results in your computer not starting properly, you can restore the registry. For instructions, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a value to a registry key entry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a value to a registry key entry**

1. Open Registry Editor.
2. Click the key or entry where you want to add the new value.
3. On the **Edit** menu, point to **New**, and then click the type of value you want to add: **String Value**, **Binary Value**, **DWORD Value**, **Multi-String Value**, or **Expandable String Value**.
4. Type a name for the new value, and then press ENTER.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- If you make a mistake that results in your computer not starting properly, you can restore the registry. For instructions on how to restore the registry, see Related Topics.
- When you add a value, the value name and data type are saved with a default value. For instructions on how to modify the default value, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a value

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a value**

1. Open Registry Editor.
2. Select the entry you want to change.
3. On the **Edit** menu, click **Modify**.
4. In **Value data**, type the new data for the value, and then click **OK**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. # Delete a registry key or value

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a registry key or value**

1. Open Registry Editor.
2. Click the key or entry you want to delete.
3. On the **Edit** menu, click **Delete**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- You can delete keys and values from your registry. However, you cannot delete a predefined key (such as HKEY_CURRENT_USER) or change the name of a predefined key.
- If you make a mistake that results in your computer not starting properly, you can restore the registry. For instructions, see Related Topics.

**Information about functional differences**

# Rename a registry key or value

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename a registry key or value**

1. Open Registry Editor.
2. Click the key or entry you want to rename.
3. On the **Edit** menu, click **Rename**.
4. Type the new name, and then press ENTER.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- If you make a mistake that results in your computer not starting properly, you can restore the registry. For information, see Related Topics.
- You cannot rename the root keys or the default value of a key.

# Connect to a registry over the network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to a registry over a network**

1. Open Registry Editor.
2. On the **File** menu, click **Connect Network Registry**.
3. In the **Select Computer** dialog box, type the name of the computer to whose registry you want to connect.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must be logged on as an administrator or a member of the Administrators group on both your computer and on the remote computer before you can make any changes to the remote computer's registry. Network policy settings may also prevent you from completing this procedure.
- If you make a mistake that results in your computer not starting properly, you can restore the registry. For instructions on how to restore the registry, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restore the registry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restore the registry**

1. Click **Options**, and then click **Print** to print these instructions. (If you are using the Help and Support Center, click **Print** above the topic area.) They will not be available after you shut down your computer in step 3.

2. Open Registry Editor.

3. Click **Start**, and then click **Shut Down**.

4. In the list, click **Restart**, and then click **OK**.

5. When you see the message **Please select the operating system to start**, press F8.

6. Use the arrow keys to highlight **Last Known Good Configuration**, and then press ENTER.

   NUM LOCK must be off before the arrow keys on the numeric keypad will function.

7. Use the arrow keys to highlight an operating system, and then press ENTER.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.

- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.

- Choosing **Last Known Good Configuration** provides a way to recover from problems such as a newly added driver that may be incorrect for your hardware. It does not solve problems caused by corrupted or missing drivers or files.

- When you choose **Last Known Good Configuration**, Windows restores information in registry key HKLM\System\CurrentControlSet only. Any changes you have made in other registry keys remain.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import or Export Registry Keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Import or export registry keys**

- Export all or part of the registry to a text file
- Import some or all of the registry
- Export a registry key to a hive file
- Import a registry key from a hive file

# Export all or part of the registry to a text file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export all or part of the registry to a text file**

1. Open Registry Editor.
2. On the **File** menu, click **Export**.
3. In **File name**, enter a name for the registry file.
4. Under **Export range**, do one of the following:
   - To back up the entire registry, click **All**.
   - To back up only a particular branch of the registry tree, click **Selected branch** and enter the name of the branch you want to export.
5. Click **Save**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- You can use a text editor like Notepad to work with the registry files you create by exporting.
- You can save registry files in the Windows format, in the format used in Windows 95, Windows 98, and Windows NT 4.0, as binary hive files, or as text files. Registry files are saved with .reg extensions, and text files are saved with .txt extensions.
- In Windows Explorer, double-clicking a file with the .reg extension imports the file into the computer's registry.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Import some or all of the registry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import some or all of the registry**

1. Open Registry Editor.
2. On the **File** menu, click **Import Registry File**.
3. Find the file you want to import, click the file to select it, then click **Open**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Note

- In Windows Explorer, double-clicking a file with the .reg extension imports the file into the computer's registry.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export a registry key to a hive file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export a registry key to a hive file**

1. Open Registry Editor.
2. Select the key that you want to save as a file.
3. On the **File** menu, click **Export**.
4. In the **Export Registry File** dialog box, in **Save in**, click the drive, folder, or network computer and folder where you want to save the hive.
5. In **File name**, enter a name for the hive.
6. In **Save as type**, click **Registry Hive Files**.
7. Click **Save**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- Registry Editor provides a number of commands that are designed primarily for the maintenance of your system. For example, **Load Hive** and **Unload Hive** allow a part of your system to be temporarily downloaded onto another computer for maintenance. Before a hive can be loaded or restored, it must be saved as a key, either to a floppy disk or to your hard disk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Unload a hive from the registry

# Import a registry key from a hive file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To import a registry key from a hive file**

1. Open Registry Editor.
2. Select the keys in which you want to restore the hive.
3. On the **File** menu, click **Import**.
4. In **Look in**, select the drive, folder, or network computer and folder in which the hive is located.
5. In **Files of type**, click **Registry Hive Files**.
6. Select the correct file name for the hive.
7. Click **Open**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- A restored hive overwrites an existing registry key and becomes a permanent part of your configuration. For example, to perform maintenance on part of your system, you can use **Export** to save a hive to a disk. When you are ready, you can then use **Import** on the **File** menu to restore the saved key to your system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Load or Unload Registry Hives

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Load or unload registry hives**

- Load a hive into the registry
- Unload a hive from the registry

# Load a hive into the registry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To load a hive into the registry**

1. Open Registry Editor.
2. In the registry tree (on the left), click either the HKEY_USERS or HKEY_LOCAL_MACHINE keys.
3. On the **File** menu, click **Load Hive**.
4. In **Look in**, click the drive, folder, or network computer and folder that contains the hive you want to load.
5. Click **Open**.
6. In **Key Name**, type the name that you want to assign to the hive, and then click **OK**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.
- **Load Hive** and **Unload Hive** affect only the HKEY_USERS and HKEY_LOCAL_MACHINE keys and are active only when these predefined keys are selected. When you load a hive into the registry, the hive becomes a subkey of one of these keys.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To unload a hive from the registry**

1. Open Registry Editor.
2. Select a hive that you have previously loaded onto your system.
3. On the **File** menu, click **Unload Hive**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. # Maintain Registry Security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maintain registry security**

- Assign permissions to a registry key
- Assign special access to a registry key
- Add users or groups to the Permissions list
- Remove a user or group from the Permissions list
- Grant full control of a registry key
- Audit activity on a registry key
- Add users or groups to the Audit list
- Remove a user or group from the Audit list
- Take ownership of a registry key

# Assign permissions to a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign permissions to a registry key**

1. Open Registry Editor.
2. Click the key to which you want to assign permissions.
3. On the **Edit** menu, click **Permissions**.
4. Assign an access level to the selected key as follows:
   - To grant the user permission to read the key contents, but not save any changes made to the file, under Permissions for *name*, for **Read**, select the **Allow** check box.
   - To grant the user permission to open, edit, and take ownership of the selected key, under Permissions for *name*, for **Full Control**, select the **Allow** check box.
   - To grant the user special permission in the selected key, click **Advanced**.
5. If you are assigning permissions to a subkey and you want the inheritable permissions assigned to the parent key to apply to the subkey also, click **Advanced** and select the **Inherit from parents the permission entries that apply to child objects. Include these with entries explicitly defined here** check box.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- If you own a registry key, you can specify the users and groups that can open that key. To determine who can open your registry keys, you need to assign permissions to them. You can add or remove users or groups from those authorized to access your registry keys at any time.
- The **Special Permissions** check boxes indicate whether custom permissions have been set for this key, but you cannot set special permissions by clicking these check boxes. Click **Advanced** to set special permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Assign special access to a registry key

# Assign special access to a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign special access to a registry key**

1. Open Registry Editor.
2. Click the key to which you want to assign special access.
3. On the **Edit** menu, click **Permissions**.
4. Click **Advanced**, and then double-click the user or group to whom you want to assign special access.
5. Under **Permissions**, select the **Allow** or **Deny** check box for each permission you want to allow or deny.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- Assigning special access is useful for situations in which you need to assign permissions that are not defined by either Read or Full Control.
- If you are assigning permissions to a subkey and you want the inheritable permissions assigned to the parent key to apply to the subkey also, select the **Inherit from parents the permission entries that apply to child objects. Include these with entries explicitly defined here** check box.
- If you are assigning permissions to a parent key and want any existing permissions of its subkeys replaced with the parent key's inheritable permissions, select the **Replace permission entries on all child objects with entries shown here that apply to child objects** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add users or groups to the Permissions list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add users or groups to the Permissions list**

1. Open Registry Editor.
2. Click the key whose Permissions list you want to change.
3. On the **Edit** menu, click **Permissions**, and then click **Add**.
4. In the **Select Users, Computers, or Groups** dialog box, click **Locations**, and then click the computer or domain of the users and groups you want to view.
5. Type the name or names of the users or groups you would like to add, separating each name with a semicolon. Click **Examples** to see some examples of the syntax you can use to enter names. Click **Check Names** to validate names with the directory. When you are finished entering names, click **OK**.
6. In the **Permissions** dialog box, under **Permissions** for *name*, assign a type of access to the selected user or group as follows:
   - To grant the user permission to read the key contents but not to save any changes made to it, select the **Allow** check box for **Read**.
   - To grant the user permission to open, edit, and take ownership of the selected key, select the **Allow** check box for **Full Control**.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- If the check boxes under **Permissions** are shaded, the key has inherited permissions from the parent object key.
- To allow permissions assigned to a parent key to apply to its subkeys also, click **Advanced**, and select the **Inherit from parent the permission entries that apply to child objects. Include these with entries explicitly defined here** check box.
- In the **Select Users, Computers, or Groups** dialog box, if you type the name, rather than selecting it, click **Check Names** before clicking **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a user or group from the Permissions list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a user or group from the Permissions list**

1. Open Registry Editor.
2. Click the key whose Permissions list you want to change.
3. On the **Edit** menu, click **Permissions**.
4. Under **Group or user names:** , Click the name of the user or group that you want to remove from the Permissions list.
5. Click **Remove**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. # Grant full control of a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To grant full control of a registry key**

1. Open Registry Editor.
2. Click the key to which you want to grant full control.
3. On the **Edit** menu, click **Permissions**.
4. Under **Group or user names**, click the user to whom you want to grant full control of your registry key.
5. Under **Permissions for** *name*, where *name* represents the name of the user to whom you are granting full control of the key, select the **Allow** check box for **Full Control**.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- You can permit another user to take ownership of a registry key only if you are the current owner of the key.
- To permit a user to to take ownership of a registry key, you must first assign the user Full Control of the key.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Audit activity on a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To audit activity on a registry key**

1. Open Registry Editor.
2. Click the key you want to audit.
3. On the **Edit** menu, click **Permissions**.
4. Click **Advanced**, and then click the **Auditing** tab.
5. Double-click the name of a group or user.
6. Under **Access**, select or clear the **Successful** and **Failed** check boxes for the activities that you want to audit or to stop auditing:

| Select | To audit |
|---|---|
| **Query Value** | Any attempts to read a entry from a registry key |
| **Set Value** | Any attempts to set entries in a registry key |
| **Create Subkey** | Any attempts to create subkeys on a selected registry key |
| **Enumerate Subkeys** | Any attempts to identify the subkeys of a registry key |
| **Notify** | Any notification events from a key in the registry |
| **CreateLink** | Any attempts to create a symbolic link in a particular key |
| **Delete** | Any attempts to delete a registry object |
| **Write DAC** | Any attempts to write a discretionary access control list on the key |
| **Write Owner** | Any attempts to change the owner of the selected key |
| **Read Control** | Any attempts to open the discretionary access control list on a key |

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

**Notes**

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- If your computer is connected to a network, network policy settings might prevent you from completing this procedure.

- You must first add users and groups before specifying the events to audit.
- Auditing activity can slow the computer down significantly. Consider auditing only failures, and not successes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Take ownership of a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To take ownership of a registry key**

1. Open Registry Editor.
2. Click the key you want to take ownership of.
3. On the **Edit** menu, click **Permissions**.
4. Click **Advanced**, and then click the **Owner** tab.
5. Under **Change owner to**, click the new owner, and then click **OK**.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- You can take ownership of a registry key if you are logged on as an administrator or if you have been specifically assigned the permission to take ownership of the registry key by the current owner.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Print all or part of the registry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print all or part of the registry**

1. Open Registry Editor.
2. Click the computer or top-level key of the registry area you want to print.
3. On the **File** menu, click **Print**.
4. You can print the entire registry by clicking **All** or only part of the registry by clicking **Selected Branch** and typing a particular branch in the text box, and then click **OK**.

## Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

## Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- The average registry can take hundreds of pages to print. Consider printing only those branches you need.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Registry overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Registry overview**

In the Microsoft® Windows Server 2003 family, system configuration information is stored centrally in a hierarchical database called the registry. The registry replaces many of the .ini, .sys, and .com configuration files used in Windows for MS-DOS® and Microsoft LAN Manager.

For more information about managing the registry, see "Windows Server 2003 Family Registry Reference" at the Microsoft Windows Resource Kits Web site. For information about Windows Server 2003 support, see Support resources.

# Registry structure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Registry structure**

The registry is organized in a hierarchical structure of subtrees and their keys, subkeys, and entries.

The contents of the registry for one computer may vary widely from that of another, depending on the devices, services, and programs installed on each computer.

Keys can have subkeys and subkeys can, in turn, have subkeys. While most information in the registry is stored on disk and is considered permanent, some information, stored in *volatile keys*, is overwritten each time the operating system starts.

**Registry subtrees**

Windows Server 2003 family operating systems have two registry subtrees: **HKEY_LOCAL_MACHINE** and **HKEY_USERS**. However, to make the information in the registry easier to find, the Registry Editor utilities display five subtrees, three of which are aliases of other parts of the registry. These five subtrees are listed and described in the following table.

| Root key name | Description |
|---|---|
| **HKEY_LOCAL_MACHINE** | Contains information about the local computer system, including hardware and operating system data such as bus type, system memory, device drivers, and startup control data. |
| **HKEY_CLASSES_ROOT** | Contains information used by various OLE technologies and file-class association data. A particular key or value exists in **HKEY_CLASSES_ROOT** if a corresponding key or value exists in either **HKEY_LOCAL_MACHINE\SOFTWARE\Classes** or **HKEY_CURRENT_USER\SOFTWARE\Classes**. If a key or value exists in both places, the **HKEY_CURRENT_USER** version is the one that appears in **HKEY_CLASSES_ROOT**. |
| **HKEY_CURRENT_USER** | Contains the user profile for the user who is currently logged on interactively (as opposed to remotely), including environment variables, desktop settings, network connections, printers, and program preferences. This subtree is an alias of the **HKEY_USERS** subtree and points to **HKEY_USERS***security ID of current user*. |
| **HKEY_USERS** | Contains information about actively loaded user profiles and the default profile. This includes information that also appears in **HKEY_CURRENT_USER**. Users who are accessing a server remotely do not have profiles under this key on the server; their profiles are loaded into the registry of their own computers. |
| **HKEY_CURRENT_CONFIG** | Contains information about the hardware profile used by the local computer system at startup. This information is used to configure settings such as the device drivers to load and the display resolution to use. This subtree is part of the **HKEY_LOCAL_MACHINE** subtree and points to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Hardware Profiles\Current**. |

Each root key name begins with **HKEY_** to indicate to software developers that this is a *handle* that a program can use. A handle is a value used to identify a resource so that a program can access it.

**Note**

- The behavior of **HKEY_CLASSES_ROOT** in Windows 2000 and Windows Server 2003 family operating systems is different from that of the same key in previous versions of Windows. In Windows 2000 and Windows Server 2003 family operating systems, a feature called per-user class registration provides a view of **HKEY_CLASSES_ROOT** that contains both user-specific class registrations and computer-specific class registration. With this feature, different users can have different sets of class registrations (including those for file associations, COM components, and MIME types). Previously, all users shared registrations, so that one user could alter registrations for other users. Per-user class registration isolates each user's registrations and allows the administrator to increase security on **HKEY_LOCAL_MACHINE\Software\Classes**.

**Registry hives and files**

The term hive describes a body of keys, subkeys, and values that is rooted at the top of the registry hierarchy. A hive is backed

by a single file and a .log file that are in the *systemroot*\System32\Config or the *systemdrive*\Documents and Settings*username* folders. The string *systemroot* is a placeholder for the directory name that contains the Windows Server 2003 family system files; the string *systemdrive* is a placeholder for the partition that contains the Windows Server 2003 family system files. For example, if the Windows Server 2003 family system files for a user named Annie are in a directory called Windows in the C: partition, the hive files are stored in the C:\Windows\System32\Config and C:\Documents and Settings\Annie folders. Hives may also be called registry files or registry log files.

By default, most hive files (**DEFAULT**, **SAM**, **SECURITY**, **SOFTWARE**, and **SYSTEM**) are stored in the *systemroot*\System32\Config folder. In the Windows Server 2003 family of operating systems, the location of user profile information for each user of a computer, including the Ntuser.dat and Ntuser.dat.log, may depend on whether the installation of the operating system was a fresh installation or whether it was installed as an upgrade from Windows NT or Windows 2000. In fresh installations, the Ntuser.dat and Ntuser.dat.log files are stored in the *systemdrive*\Documents and Settings*username* folder. In installations that are upgrades from Windows NT or Windows 2000, the Ntuser.dat and Ntuser.dat.log files are stored in the *systemroot*\Profiles*username* folder.

Each hive in the Windows Server 2003 family registry is associated with a set of standard files. The following table shows the standard hives and files for a computer running an operating system in the Windows Server 2003 family.

| Registry hive | File names |
|---|---|
| **HKEY_LOCAL_MACHINE\SAM** | Sam and Sam.log |
| **HKEY_LOCAL_MACHINE\SECURITY** | Security and Security.log |
| **HKEY_LOCAL_MACHINE\SOFTWARE** | Software and Software.log |
| **HKEY_LOCAL_MACHINE\SYSTEM** | System and System.log |
| **HKEY_CURRENT_CONFIG** | System and System.log |
| **HKEY_CURRENT_USER** | Ntuser.dat and Ntuser.dat.log |
| **HKEY_USERS\.DEFAULT** | Default and Default.log |

**Entries in the registry keys**

Each registry key or subkey can contain data called entries. Some entries store information that is specific to each user, while others store information that applies to all users of a computer. An entry has three parts: the name of the value, the data type of the value, and the value itself. The three parts of entries always appear in the following order.

```
        Name                Data type            Value
DependOnService:  REG_MULTI_SZ:  Tcpip Nbtsys Streams
```

Data types describe the format of the data. Data types from 0 through 0x7FFFFFFF are reserved for definition by the system. Programs are encouraged to use these data types, but data types from 0x80000000 through 0xFFFFFFFF are also reserved for use by programs.

The following table lists the data types currently defined and used by the system.

| Data type | Description |
|---|---|
| **REG_BINARY** | Raw binary data. Most hardware component information is stored as binary data and is displayed in Registry Editor in hexadecimal format. |
| **REG_DWORD** | Data represented by a number that is 4 bytes long. Many parameters for device drivers and services are this type and are displayed in Registry Editor in binary, hexadecimal, or decimal format. |
| **REG_EXPAND_SZ** | A variable-length data string. This data type includes variables that are resolved when a program or service uses the data. |
| **REG_MULTI_SZ** | A multiple string. Values that contain lists or multiple values in a form that people can read are usually this type. Entries are separated by spaces, commas, or other marks. |
| **REG_SZ** | A fixed-length text string. |

| | |
|---|---|
| **REG_FULL_RESOURCE_DESCRIPTOR** | A series of nested arrays designed to store a resource list for a hardware component or driver. |
| | |

For more information about managing the registry, see "Windows Server 2003 Family Registry Reference" at the Microsoft Windows Resource Kits Web site.

# Securing the registry

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Securing the registry**

The Registry contains sensitive data about the computer and its applications and files. A malicious user can use the registry to cause severe damage to the computer. It is important that you maintain a high level of registry security.

The registry is given a high level of security by default. Administrators are given full access to the entire registry, while other users generally have full access to the keys related to their own user accounts (which include HKEY_CURRENT_USER) and read-only access to the keys related to the computer and its software. Users have no access to the keys related to other users' accounts. Users with the appropriate permissions for a given key can make changes to the permissions for that key and for any keys it contains.

For help securing the registry, see Maintain Registry Security. For help using permissions, see Access Control.

# Windows Management Instrumentation Command-line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation Command-line**
Windows Management Instrumentation command-line (WMIC) provides you with a simple command-line interface to Windows Management Instrumentation (WMI), so you can take advantage of WMI to manage computers running the Windows Server 2003 family of operating systems. WMIC interoperates with existing shells and utility commands, and can be easily extended by scripts or other administration-oriented applications.

- For tips about using WMIC, see WMIC Best practices.
- For help with specific tasks, see WMIC How To....
- For general background information , see WMIC Concepts.
- For problem-solving instructions, see Troubleshooting WMIC.

# WMIC Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Use the WHERE () clause for specific instances to be returned for an alias.**

- The WHERE() clause must include the WHERE clause for a valid WQL query. The parentheses are only required for complex criteria. See the WMI SDK for WQL syntax. The WHERE() clause must immediately follows the alias name. For example: `process where (processID>300) list brief`

- When the WHERE clause is WHERE NAME='<value>', it is sufficient to give only the value. For example: `SERVICE CLIPSRV`

  Instead of:

  ```
  SERVICE WHERE NAME='CLIPSRV'
  ```

**Use /OUTPUT, /APPEND, and /RECORD commands to redirect output.**

- Commands that output in HTML format (such as CLASS) typically have their output directed to a file. You can then view that file for results of the command. You can redirect the output can by using the /OUTPUT, /APPEND, and /RECORD commands.

**Enclose values in quotation marks if the values contain special characters such as dashes, slashes, or spaces.**

**Use these methods of query for large domains or databases**

- ALIAS

  ```
  WMIC ALIAS PROCESS LIST BRIEF
  ```

- USERACCOUNT

  ```
  WMIC USERACCOUNT WHERE "Name='PutUserNameHere' and Domain='PutDomainNameHere'"
  ```

- FSDIR

  ```
  WMIC FSDIR WHERE Name='c:\\WINDOWS'
  ```

- DATAFILE

  ```
  WMIC DATAFILE WHERE Name="c:\\boot.ini"
  WMIC DATAFILE WHERE "PATH='\\windows\\' and Extension='exe' and FileSize>'108032'"
  GET LastAccessed, LastModified, Name, FileSize
  ```

- NTEVENT

  ```
  WMIC NTEVENT WHERE "LogFile='system' and Type>'0'" GET Message, TimeGenerated
  WMIC NTEVENT WHERE "LogFile='system' and Type>'0'" GET Message, TimeGenerated
  /FORMAT:htable >c:\MySystemEvents.htm
  ```

- Querying:

Use quotes "" to separate WHERE expressions instead of parentheses () :

```
WMIC NTEVENT WHERE "LogFile='system' and Type>'4'"
```

[ Compare to:

```
WMIC NTEVENT WHERE (LogFile='system' and TYPE>4)
```

In this case, Command Shell will misinterpret

```
">4)"
```

and will try to redirect output to file named

```
"4)"
```

]

For information about validation of users in WMI, see Managing WMI Security.

For information about WMIC security, authentication, and authorization, see Security with WMIC.

For more information, see Windows Management Instrumentation Command-line.

# WMIC How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Run WMIC in interactive mode
- Run WMIC in non-interactive mode
- Create a format in WMIC
- Edit a format in WMIC

# Run WMIC in interactive mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run WMIC in interactive mode**

1. Click **Start**, **Run**.
2. Type:

   **WMIC**, and then press ENTER.
3. Type the alias, command, or global switch you want WMIC to perform.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- When you finish using WMIC in interactive mode, you can use the **Exit** or **Quit** command to exit WMIC.
- For more information about the WMIC commands, type **/?** at the command prompt.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Run WMIC in non-interactive mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run WMIC in non-interactive mode**

1. Open Command prompt.
2. At the command prompt, type:

   **WMIC**

   and the command, aliases, or global switches, you want WMIC to perform.
3. Press ENTER.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the command prompt window, click Start, point to All Programs, point to Accessories, and then click Command Prompt.
- In non-interactive mode, WMIC returns you to the command prompt after executing the command.
- For more information about the WMIC commands, type **WMIC /?** at the command prompt.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create translation table in WMIC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a translation table in WMIC**

1. Locate the Managed Object Format (MOF) file, **CliEgAliases.mof**, located in the %WINDIR%\system32\wbem directory.
2. Open the MOF file in Notepad.
3. Create a new translation table as an instance of **MSFT_CliTranslateTable**.
4. Define the **Name** property of the translation table being created.
5. Define the **FromValue** and **ToValue** properties of Instance of **MSFT_CliTranslateTableEntry**.
6. Save the file, using UNICODE encoding.
7. From the command prompt, type:

```
Mofcomp CliEgAliases.mof
```

### Note

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a format in WMIC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a format in WMIC**

1. Create an XSLT-formatted file using the XSL language (for example, *MyNewFormat.xsl*).
2. Copy the file into the **%WINDIR%\system32\wbem** directory.
3. Locate the **xsl-mappings.xml** file in the **%WINDIR%\system32\wbem** directory.
4. Add an entry in the **xsl-mappings.xml** file which will map the format to Keyword:

```
<XSLFORMAT KEYWORD="MyNewKeyword">MyNewFormat.xsl</XSLFORMAT>
```

### Note

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit a format in WMIC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a format in WMIC**

1. Locate an existing XSLT format (an .xsl file) in the **%WINDIR%\system32\wbem** directory.
2. Make the required changes and save.
3. Locate the **xsl-mappings.xml** file in the **%WINDIR%\system32\wbem** directory.
4. Modify the related entry in the xsl-mappings.xml file:

```
<XSLFORMAT KEYWORD="MyModifiedKeyword">MyModifiedFormat.xsl</XSLFORMAT>
```

### Note

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Windows Management Instrumentation overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation overview**
Windows Management Instrumentation (WMI) is the Microsoft implementation of Web-Based Enterprise Management Initiative (WBEM), an industry initiative to establish standards for accessing and sharing management information over an enterprise network. WMI provides integrated support for the Common Information Model (CIM)--the data model that describes the objects that exist in a management environment.

WMI includes an object repository, which is the database of object definitions, and the WMI Object Manager, which handles the collection and manipulation of objects in the repository and gathers information from WMI providers. WMI providers act as intermediaries between WMI and components of the operating system, applications, and other systems. For example, the registry provider draws information from the registry, while the SNMP provider provides data and events from SNMP devices. Providers provide information about their components and might provide methods to manipulate the components, properties that can be set or events that can alert you to changes in the components.

WMI can be used by computer management tools, such as Microsoft Systems Management Server, to help you manage your computers. WMI is also used by other Microsoft technologies and tools, such as Microsoft Health Monitor and Microsoft Operations Manager, and by other vendors of computer management systems. You can use WMI with programming or scripting systems (such as Windows Script Host) to retrieve configuration details about most aspects of your computer systems, including server applications, or to affect changes to your systems. For more details, see the WMI SDK.

Several management tools are WMI-enabled, including System Properties, System Information, and the Dependencies component of Services. Brief descriptions of these components follow:

- System Properties lets you view and change system properties on a local or remote computer. You can restart a remote computer to apply settings changes or to detect new hardware, view the computer name and domain information for other computers on your network, or change the settings for the virtual memory paging file on a computer that might run programs requiring a lot of memory. For more information about System Properties, see System Properties.

- System Information collects and displays configuration information about your system. This is is especially useful when a support technician troubleshoots your system. For more information, see System Information.

- Services helps you manage the services on your computer. Services dependencies identify the services on which the current service depends on and the services that depend on it. For more information about Services, see Services Concepts.

For technical information about developing the WMI system, see the Windows Management Instrumentation documentation at the Microsoft Platform Software Development Kit (SDK) Web site.

For information about using the WMI Tester to view and modify WMI objects, see Windows Management Instrumentation Tester overview.

For information about using the command-line interface to WMI, see Windows Management Instrumentation Command-line.

For information about using the WMI Control to configure WMI settings and security on a remote or local computer, see WMI Control Overview.

# Windows Management Instrumentation Command-line overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation Command-line overview**
The Window Management Instrumentation command-line (WMIC) provides you with a simple command-line interface to Windows Management Instrumentation (WMI), so you can take advantage of WMI to manage computers running Microsoft Windows. WMIC interoperates with existing shells and utility commands, and can be easily extended by scripts or other administration-oriented applications.

WMI Providers enable you to use WMI to manage a wide variety of hardware components, operating system subsystems, and application systems. WMIC can be used with all the schemas implemented by those WMI Providers.

WMIC can be used to remotely manage any computer with WMI that is a Windows domain member. WMIC does not have to be available on the remotely managed computer in order for WMIC to manage it.

You can use WMIC to accomplish tasks in the following typical scenarios:

- Local management of a computer--you are at the computer and use the WMIC command to manage it.
- Remote management of a computer--you are at one computer and use WMIC to manage another computer.
- Remote management of multiple computers--you are at on one computer and use WMIC to manage multiple computers with a single command.
- Remote management of a computer (using a remote session)--you use a remote session technology (such as Telnet or Terminal Services) to connect to a remote computer and manage it with WMIC.
- Automated management using administrative scripting--you use WMIC to write a simple management script (batch file) to automate the management of a computer (local, remote, or multiple computers--serially or simultaneously).

**Notes**

- For general background information on WMI, see Windows Management Instrumentation overview.
- For information about how WMI validates users, see Managing WMI security.

# WMIC architecture

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding WMIC architecture**

This topic discusses the relationship of WMIC to WMI, to other computers, and to scripting languages. It also discusses the relationship between aliases, formats, translation tables, and other WMIC elements.

WMIC has an engine to parse, interpret, and execute alias operations called from the command line. The engine is an executable file, called WMIC.exe, which is run on the computer that the user is connected to. Any extension to the WMI command-line interpreter must be done through the addition of alias file definitions or registrations.

Aliases, or friendly names, are defined in Management Object Format (MOF), a language for defining classes and instances in the CIM, and are related to classes in WMI schema.

The WMIC.exe engine receives a command from its stdin interface. The command is parsed by the tool and if it involves an alias, the alias definition is obtained from the current WMI operational namespace (by default, root\cli). The tool interprets the original command with the alias command and current environmental settings, such as the current target namespace. The command is executed as a series of WMI API calls against the target namespace. Any namespace might be used as a target if the namespace is consistent with the alias being processed.

The information returned for the API calls is retrieved in an XML format. The retrieved data is modified by the XSL style sheet, which is associated with the alias. It is applied to the data primarily for presentation formatting. The resulting text is presented back to the user using the stdout interface. The target system and management system need not be on the same computer. However, the original computer must have sufficient credentials to access the target computer.

The style sheet applied to the output defaults is the standard FULL style sheet if no other is specified.

For more information about using WMIC, see Using Windows Management Instrumentation Command-line.

For information about WMI security, see Managing WMI security.

For information about WMIC security, see Security with WMIC.

For more information, see Windows Management Instrumentation Command-line.

# Security with WMIC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**General information about the security model**
Only users in the local Administrators group can start WMIC. The WMI security access model is enforced on any call from WMIC to WMI. The operating system enforces operating system-level security for any operations executed through WMI. For example, you cannot access files through WMI that you cannot access from Windows Explorer.

WMIC is a client for WMI, so all security checks are performed within WMI components. Before connecting to a remote computer, the component uses **PING** functionality to verify validity of the input (remote computer status).

When WMIC is used in a Telnet, Terminal Services, or similar session, all commands are carried out in the context of the user issuing the command.

WMIC allows extension of Aliases and XSLs. Security is addressed by NTFS which enforces administrator-only credential requirements for accessing WMIC's files.

Except for method parameters, WMIC allows input data only through the **/NODE** switch. A list of computer nodes can be provided as a text file using the **@FileList** option. The file and its location should be secured by the Administrator, and the input file should preferably be read from the WBEM directory.

**User permissions**
No special user permissions are required to run WMIC. Implicitly, to be able to use WMIC, a user needs to have full write access to both the WMIC namespaces and a registry key (HKLM\Software\Microsoft\WBEM).

**Authentication and authorization**
Authentication and authorization are provided by the system when these resources are opened. They are stored in a secured location and the Discretionary Access Control List (DACL) is used to verify that client has access to them. They are wholly dependent on Distributed Component Object Model (DCOM) security as well as Windows Management (WINMGMT) for remote access in providing it with user name, password, and requested levels. The **/AUTHLEVEL** switch is used for securing WMIC network traffic. In the Windows Server 2003 family operating systems, the default level is set to **PKTPRIVACY** providing packet privacy encryption level. You can modify the authentication level using the **/AUTHLEVEL** switch.

**Example**:

```
WMIC /AUTHLEVEL:Pktprivacy /NODE:"testcomputer.microsoft.com" BIOS
```

**Configuration data**
The configuration information is stored in the registry and in the WMI repository. The registry configuration holds timestamps and validity of Managed Object Format(MOF)-compiled status for schemas. At the start of each session of WMIC, this is evaluated and WMIC will update the WMI repository when schemas are not valid or were updated by a user.

**Miscellaneous**
WMIC is a powerful command-line tool that allows you to quickly do any task for which you have permissions. If you are not familiar with the WMI environment, you can use the **/INTERACTIVE** switch to set a warning for delete operations. For example:

```
WMI /INTERACTIVE:ON
```

For information about how WMI validates users, see Managing WMI security.

For more information, see Windows Management Instrumentation Command-line.

# Using Windows Management Instrumentation Command-line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows Management Instrumentation Command-line**

This section covers:

- WMIC aliases
- WMIC verbs
- WMIC switches
- WMIC commands
- Security with WMIC
- Creating and Customizing WMIC Components

# Running Windows Management Instrumentation Command-line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Running Windows Management Instrumentation Command-line**
When you run Windows Management Instrumentation Command-line (WMIC) for the first time, it compiles Alias definitions, or Managed Object Format (MOF) files. Whenever MOF files are changed, WMIC recompiles the files and updates the repository.

You can choose to use WMIC in interactive mode or non-interactive mode. The following gives you some information about the characteristics and functions of the two modes:

**Interactive mode**
WMIC in interactive mode returns you to the WMIC command prompt after executing a command. **Root\cli** is the default WMIC role, and is there when you starts WMIC in interactive mode. The **Exit** or **Quit** command is used to exit WMIC.

Interactive mode is useful if you are entering a series of WMIC commands.

To start WMIC in interactive mode see Run WMIC in interactive mode.

The following examples include aliases, commands, and global switches that you can enter at the WMIC prompt when in interactive WMIC mode:

- **CONTEXT** - lists all environment variables (Global switches).
- **OS** - displays data about operating system in a default TABLE format.
- **OS list full** - displays **OS** alias data in **LIST** format.
- **/?** - lists descriptions of available environment variables and alias.
    - **OS /?** - lists options available for operating systems.
    - **OS list /?** - specifies formats for "list" operations.
    - **OS list full /?** - lists switches available.
    - **OS list full /format /?** - lists keywords for available formats.
    - **OS call /?** - lists methods (verbs) available.
    - **OS get /?** - lists properties available.

**Non-Interactive mode**
WMIC in non-interactive mode exits WMIC after performing the command you entered. You are returned to the WMIC command prompt when the command is completed. WMIC aliases, global switches, or commands can also be used in non-interactive mode.

Non-interactive mode is useful if you use WMIC for a batch procedure, or if you only need to execute one WMIC command.

To start WMIC in non-interactive mode see Run WMIC in non-interactive mode.

The following examples show how you can run commands in non-interactive mode:

- <PROMPT>`wmic os get /format:hform>MyOS.htm`

The output is directed to a html file, and you are returned to the command prompt where you started.

- <PROMPT>`wmic /?`

  The Help is listed, and you are returned to the command prompt where you started

For more information, see Windows Management Instrumentation Command-line.

# Using WMIC help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using WMIC help**
WMIC includes on-line Help at the command line. At any level, you can type **/?** for additional details. By itself, **/?** gives you the global switches and the aliases available in the current role. When used after an alias, **/?** gives you the verbs and switches available for that alias. Following a verb, **/?** gives you the details for that verb.

For example:

For a list of alias and syntax, at the command prompt, type `wmic` to start the WMIC shell and then type:

```
/?
```

To display options available for the Process alias, from within the WMIC shell type:

```
process /?
```

**/?:FULL** gives all available details. This can be especially useful for the GET and CALL verbs.

**Notes**

- You can also use a hyphen (**-?**) instead of a forward slash (**/?**).
- For the PATH and CLASS command, progressive help is available for a singular NODE only (on both local and remote computers).

For more information, see Windows Management Instrumentation Command-line.

# WMIC aliases

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMIC aliases**
Aliases are intermediary facilitators that help you access the WMI infrastructure when you are running WMIC. Aliases are friendly names used to capture the features of a WMI class that are relevant to some specific task such as disk or network administration.

Aliases can be used to provide:

- Clearer names for WMI classes, properties, and method.
- Useful output formats of arranged properties.

  The output formats can include specific property values or can be formatted in a manner appropriate to some specific presentation strategy or function. For example, an alias might have a "BRIEF" format that will list only property values essential for the identification of the objects visible through the alias. Management data is retrieved in XML format and processed by built-in or custom XSL output formats. For more information, see Creating and editing formats in WMIC.

WMIC provides aliases for the most commonly used classes of management information. You can add aliases for other classes. Thus, aliases in WMIC may be of the following types:

- Default aliases in the root\cli namespace.
  - For a list of aliases included with WMIC, type `/?` at the WMIC command prompt.
  - For more information about a specific alias, type: `alias_name /?`
  - For more information about alias schema, type: `Alias alias_name list brief`
- Aliases added by you in the root\cli namespace.
- Aliases defined by you in other namespaces. If you define aliases in other namespaces, you must use the **/ROLE** switch to specify the namespace when using it with WMIC. For more information, see Creating and editing aliases.

For information about WMI security, see Managing WMI security.

For information about WMIC security, see Security with WMIC.

For more information, see Windows Management Instrumentation Command-line.

# WMIC verbs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMIC Verbs**

Most aliases support the following verbs. Aliases might also support other verbs. To use verbs in WMIC, enter the alias name followed by the verb. For more information about **<alias> /?**, see "Aliases" in Help. If an alias does not support a verb, you receive the message "provider is not capable of the attempted operation."

| Verb | Action | Parameters or Verb-specific switches | Example |
|---|---|---|---|
| ASSOC | Returns the result of the query: `Associators of {<wmi object>}` Where <wmi object> is the path of objects returned by the **PATH** or **CLASS** commands. The results are instances associated with the object. When ASSOC is used with an alias, the classes associated with the class underlying the alias are returned. By default, the output for class is in TABLE format. See the following table of switches for /ASSOC. | Optionally, an output file format, such as LIST, MOF, or other. | OS ASSOC |
| CALL | Executes methods. | Method and parameter list if appropriate. Parameter lists are comma delimited. Use **SERVICE CALL /?** to get a list of available methods and their parameters for the current alias. | SERVICE WHERE CAPTION='TELNET' CALL STARTSERVICE |
| CREATE | Creates a new instance and sets the property values for the new instance. This cannot be used to create a new class. | Properties equated to values, delimited with commas. Use **CREATE /?** for a list of property names for the alias. | ENVIRONMENT CREATE Name="WMIC_test",VariableValue="WMIC_test_value",UserName="*SYSTEM*" |
| DELETE | Deletes the current instance or set of instances. This can be used to delete a class. | /INTERACTIVE (prompt to confirm) or /NOINTERACTIVE (do not prompt to confirm). | PROCESS WHERE NAME="CALC.EXE" DELETE |

| | | | |
|---|---|---|---|
| GET | Get specific properties. | Property name or switch. See the table of switches for /GET below. Also use **GET /?** for a list of property names and switches for the alias. | PROCESS GET NAME |
| LIST | Show data. LIST is the default verb. | See the following tables of adverbs and switches for LIST. | PROCESS LIST BRIEF |
| SET | Property set operations. | Properties equated to values, delimited with commas. Use **SET /?** for a list of property names for the alias. | ENVIRONMENT WHERE Name="WMIC_test" SET VariableValue="WMIC_test_value1" |

The **List** verb has the following adverbs. To use adverbs in WMIC, enter the alias name followed by a verb and adverb. For more information about **<alias> /?**, see "Aliases" in Help.

| **Adverb** | **Results** |
|---|---|
| BRIEF | A core set of the properties. |
| FULL | The full set of properties. This is the default set of LIST properties. |
| INSTANCE | The instance paths only. |
| STATUS | The status and related properties of the object. |
| SYSTEM | System properties. |
| Alias-specific or user format | Alias-specific or user defined formats might be defined by providing distinct lists of properties and a format to be used in displaying them. |
| WRITEABLE | The writeable properties of the objects. |

The **List** verb has the following switches. To use verb-specific switches in WMIC, enter the alias name followed by a switch (verbs and adverbs might also be used). For more information about **<alias> /?**, see "Aliases" in Help.

| **Switch** | **Effect** |
|---|---|
| /TRANSLATE: <translation table> | Translate the output using the translation table named by the command. BasicXml and NoComma are translation tables included with WMIC. |
| /EVERY:<interval> | Repeat the command every X seconds; X is determined by the interval. |
| /FORMAT:<format specifier> | Specify a keyword or XSL file name to format the data, as explained in the following note. |

The **Get** verb has the following switches.

| **Switch** | **Effect** |
|---|---|
| /VALUE | The output is formatted with each value listed on a separate line and with the name of the property. |
| /ALL | The output is formatted as a table. The default output format is /ALL. |

| | |
|---|---|
| /TRANSLATE: <translation table> | Translate the output using the translation table named by the command. BasicXml and NoComma are translation tables included with WMIC. |
| /EVERY:<interval> | Return values every X seconds, X is the interval. |
| /FORMAT:<format specifier> | Specify a keyword or an XSL file name to format the data, as explained in the following note. |

The **Assoc** verb has the following switches.

| Switch | Effect |
|---|---|
| /RESULTCLASS: <classname> | The returned endpoints associated with the source object must belong to or be derived from the specified class. |
| /RESULTROLE: <rolename> | The returned endpoints must play a particular role in their association with the source object. |
| /ASSOCCLASS: <assocclass> | The returned endpoints must be associated with the source through the specified class or one of its derived classes. |

**Notes**

- For both the LIST and GET verbs, the format specifier is used to designate either the name of an XSL file or the standard formats TABLE or LIST. **/FORMAT:TABLE** is equivalent to **/ALL**, which is the default output format.

- MOF-formatted output can be captured to a file (using the **/RECORD** switch) and the file can be compiled using Mofcomp.exe on another computer to import it into WMI on the other system. However, make sure that computer-specific properties are edited as appropriate for the other computer.

- The order of the /FORMAT and /TRANSLATE switches is important. If /TRANSLATE follows /FORMAT, the output is formatted and then translated. If /FORMAT follows /TRANSLATE, the output is translated and then formatted.

**Examples**

The following examples demonstrate the effective use of the verbs and their adverbs and switches.

- PROCESS GET NAME /FORMAT:XML.XSL /TRANSLATE:BASICXML

  The process names are output in XML format. Without the **/TRANSLATE** switch, the characters around the values are displayed as their HTML equivalents.

- PROCESS WHERE Handle="0" ASSOC

  The instances associated with a specific object (unlike the classes associated with an alias) are returned.

For information about WMI security, see Managing WMI security.

For information about WMIC security, authentication, and authorization, see Security with WMIC.

For more information, see Windows Management Instrumentation Command-line.

# WMIC switches

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMIC switches**

Global switches are used to set defaults for the WMIC environment. You can view the current value of the conditions that the global switches set by entering the **CONTEXT** command.

| Switch | Condition | Possible values | Default |
|---|---|---|---|
| /NAMESPACE | The namespace that the aliases typically use | Any namespace | root\cimv2 |
| /ROLE | The namespace that WMIC typically looks in for aliases and other WMIC information. When the role changes, the WMIC interactive command prompt changes to match the role. WMIC only has one role by default (\\root\cli), so you only have switch roles if you have a management product that has defined other roles, or if other roles have been created at your organization. | Any namespace that contains aliases. | root\cli |
| /NODE | Computer names, comma delimited. All commands are synchronously executed against all computers listed in this value. File names must be prefixed with '@'. Computer names within a file must be comma-delimited, or put on separate lines, or both. | Any computer name, a list of computer names, or a file with computer names in it. | Local computer name |
| /IMPLEVEL | Impersonation level | Anonymous, Identify, Impersonate, Delegate | Impersonate |
| /AUTHLEVEL | Authentication level | Default, None, Connect, Call, Pkt, Pktintegrity, Pktprivacy | Pktprivacy |
| /LOCALE | Locale | MS_409 (English), MS_411 (Japanese), MS_40B (Finnish), and so on. | The default language on the computer when WMIC is installed. |
| /PRIVILEGES | Enable all privileges. | ENABLE or DISABLE | Enabled |
| /TRACE | The success or failure of all functions used to execute WMIC commands is displayed. | ON or OFF | Off |
| /RECORD | Records all output to an XML file. Output is also displayed at the command prompt. | File name | Not set and no default file name exists. |
| /INTERACTIVE | Typically, delete commands are confirmed. | ON or OFF | OFF in NON-INTERACTIVE mode; ON in INTERACTIVE mode |

| | | | |
|---|---|---|---|
| /FAILFAST | Whether or not the **/NODE** computers are checked before trying to execute the WMIC commands against them. When FAILFAST is ON, WMIC pings the computers in the **/NODE** switch before sending WMIC commands to them. If they do not respond to the ping, the WMIC commands are not executed for them. | ON or OFF | OFF |
| /USER | A user name to be used by WMIC when accessing the /NODE computers or computers specified in aliases. You are prompted for the password. A user name cannot be used with a local computer. | Any user name. | Not set |
| /PASSWORD | A password to be used by WMIC when accessing the /NODE computers (possibly including the local computer). The password is visible at the command line. | Any password | Not set |
| /OUTPUT | Specifies a mode for output redirection. All output is directed to the destination given only. Output does not appear at the command line. The destination is cleared before the output begins. | STDOUT, CLIPBOARD, or a file name. STDOUT is the command line. Clipboard is the Windows clipboard. The output can then be pasted to any program that accepts data in the format produced. For more details, see the following note. | STDOUT |
| /APPEND | Specifies a mode for output redirection. All output is directed to the destination given only. Output does not appear at the command line. The destination is not cleared before the output begins. The new output is appended to the current contents of the destination. | STDOUT, CLIPBOARD, or a file name. STDOUT is the command line. Clipboard is the Windows clipboard. The output can then be pasted to any program that accepts data in the format produced. See the following note for more details. | STDOUT |
| /AGGREGATE | Used with the **LIST** and **GET/EVERY** switch. If AGGREGATE is ON, **LIST** and **GET** display their results when all computers in the NODE property have either responded or timed out. If AGGREGATE is OFF, **LIST** and **GET** display their results as soon as they are received. | ON or OFF | ON |
| /AUTHORITY | Specifies the authority type for the connection. | Needed if the value assigned to the IMPLEVEL switch is Delegate (for example, /IMPELEVEL:Delegate). It contains the authority definition string: "kerberos:*TargetDomainName**TargetComputerName*". For this setting to succeed, computers need to have trust for delegation enabled on the Domain Controller. | Not set |

| **Switch** | **Example** |
|---|---|
| /NAMESPACE | /NAMESPACE:\\root or /NAMESPACE:SMS |
| /ROLE | /ROLE:\\root |
| /NODE | /NODE:"*TESTSERVER1*","*TESTSERVER2*",@"*C:\COMPUTERLIST.TXT*" |
| /IMPLEVEL | /IMPLEVEL:Impersonate |

| | |
|---|---|
| /AUTHLEVEL | /AUTHLEVEL:default |
| /LOCALE | /LOCALE:MS_411 |
| /PRIVILEGES | /PRIVILEGES:ENABLE |
| /TRACE | /TRACE:ON |
| /RECORD | /RECORD:output.xml |
| /INTERACTIVE | /INTERACTIVE:ON |
| /FAILFAST | /FAILFAST:ON |
| /USER | /USER:JSMITH or /USER:"" (to reset the user name and password to nothing). |
| /PASSWORD | /PASSWORD:PASSWORD |
| /OUTPUT | /OUTPUT:CLIPBOARD |
| /APPEND | /APPEND:CLIPBOARD |
| /AGGREGATE | /AGGREGATE:OFF |
| /AUTHORITY | /AUTHORITY:"kerberos:*TargetDomainName**TargetComputerName*" |

**Notes**

- To browse for possible ROLE and NAMESPACE namespaces, use the command `WMIC PATH __NAMESPACE`. To see available namespaces in other namespaces, use the **/NAMESPACE** switch to change a target namespace. For example, use `/NAMESPACE:\\root` to change the ROOT namespace.

- The **GET**, **LIST**, and **ASSOC** verbs have WMIC verbs.

- The **/APPEND** and **/OUTPUT** switches can contradict each other (indicating that the results should be sent to different places). When they do contradict each other, **/OUTPUT** predominates in all cases except where **/APPEND** is directing the results to a file. In that case, the results go to both the **/OUTPUT** and **/APPEND** destinations.

- Switches can be used on the same line as commands. For example, you can use `/NODE:"SERVER1" SERVICE` to get a list of all services on SERVER1. The **/NODE** switch works as described above, and all subsequent commands are also applied to SERVER1. However, if **/OUTPUT** and **/APPEND** are used on the same line as a command, the results redirection specified by **/OUTPUT** and **/APPEND** only apply to that command. The results of subsequent commands are directed to the previous value of the OUTPUT and APPEND switches.

- To reset a switch, set its value to "". For example: `/NODE:""` sets NODE back to the current computer name.

For more information, see Windows Management Instrumentation Command-line.

# WMIC commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMIC commands**

The following commands are available at all times:

| Command | Purpose |
|---|---|
| CLASS | Escape from the default alias mode of WMIC to access classes in the WMI schema directly. |
| PATH | Escape from the default alias mode of WMIC to access instances in the WMI schema directly. |
| CONTEXT | Display the current values of all global switches. |
| QUIT | Exit from WMIC. |
| EXIT | Exit from WMIC. |

For more information about the global switches displayed by CONTEXT, see WMIC switches.

For information about how WMI validates users, see Managing WMI security.

For information about WMIC security, authentication, and authorization, see Security with WMIC.

# Creating and Customizing WMIC Components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating and customizing WMIC components**
This section covers:

- Alias namespaces and classes.
- Creating and editing aliases.
- Creating and editing formats in WMIC.
- Creating and editing translation tables.

# Alias namespaces and classes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Alias namespaces and classes**

Examples of WMI alias classes are listed in the following table:

| Alias class | Description |
|---|---|
| MSFT_CliTranslateTable | Verb-specific switches. WMIC includes translation tables called BasicXml and NoComma. |
| MSFT_CliTranslateTableEntry | Used in the translation table. |
| MSFT_CliSeeAlso | The MSFT_CliSeeAlso association provides a relationship between an alias and any aliases with some kind of functional relationship to the alias. You can extend the alias schema to allow aliases to be categorized and navigated in various ways. Use the **SeeAlso** verb of the **Alias** alias to see this information. |
| MSFT_CliAlias | MSFT_CliAlias class is the principal class in the alias schema. Instances of this class are aliases. |

An **MSFT_CliAlias** instance has the following properties:

| Property | Description |
|---|---|
| FriendlyName | The name of the alias. It must be unique. |
| Description | A description of the alias. This is the descriptive text when **/?** is entered at the WMIC command line. |
| Formats | A list, each of which has a name and a list of properties (objects of the class MSFT_CliProperty) to be displayed for that format. All formats are objects of the class MSFT_CliFormat. |
| Verbs | Verbs: A list, each of which are the various behaviors available through this alias. The behaviors come in two forms:<br>• Standard verbs, which are directly supported by the utility.<br>• User-defined verbs, which must map to some method defined for the target of the alias.<br>All verbs are objects of the class MSFT_CliVerb. |
| Qualifiers | A list, similar to WMI qualifiers. All qualifiers are objects of the class MSFT_Qualifier. |
| Target | A list, similar to WMI qualifiers. All qualifiers are objects of the class MSFT_Qualifier. |
| PWhere clause | Optional WHERE clause that limits the Target. It have substitution values which are the parameters of the alias. The substitution values are marked with **#**. If multiple parameters are needed, they are matched with the # markers in sequence. |
| Connection | Details on which computers to connect to, the security details to be used, and so on. If a connection is not specified, the computers to be accessed is the value of **/NODE**, and the namespace is the value of **/NAMESPACE**. If a user name and password are not provided, then the value of **/USER** and **/PASSWORD**, if available, is used (otherwise the current account is used). Connection is an object of the class MSFT_CliConnection. |
| View an alias schema | Use a metaalias Alias to view an alias schema; example: `ALIAS OS` |

**MSFT_CliAlias** properties contain the following classes to define objects that are used in the properties:

| Class | Used in | Description |
|---|---|---|
| MSFT_CliFormat | aliases | The MSFT_CliFormat class defines a named format that determines the set of properties to be displayed by the utility on a **LIST** command. Each MSFT_CliFormat instance has a name, a list of properties and a Format property that contains the name of a style sheet (XSL file) that must be used to format the property display. |
| MSFT_CliProperty | formats | Each MSFT_CliFormat instance contains a list of MSFT_CliProperty instances. Instances of the MSFT_CliProperty class define the set of properties to be displayed for a given format. Each MSFT_CliProperty instance has a derivation that might be either a constant, the name of a property or a WMI command line **GET** command. Each MSFT_CliProperty also has a localized description.<br><br>Formats are related to a specific XSL by the NAME property of the format object. FULL, BRIEF, and INSTANCE correspond to particular XSLs, and the NAME can specify the name of a custom XSL file. |
| MSFT_CliVerb | aliases | Instances of the MSFT_CliVerb class represent verbs defined for the alias. Verbs are either standard verbs (**GET**, **LIST**, **CALL** and **SET** ) or user defined. Standard verbs have descriptions and usages but no parameters. |
| MSFT_CliParam | verbs | |
| MSFT_CliQualifier | aliases and verbs | WMIC qualifiers serve the same purpose as WMI qualifiers. |
| MSFT_CliConnection | aliases | Instances of this class provides connection details. |

**Notes**

- When viewing the role namespaces using WMI browsing tools (such as CIM Studio), only the MSFT_CliAlias and MSFT_CliTranslateTable classes have instances. Their properties might include objects of the other classes, but the other classes will not have instances of their own.

- For this reason, when creating aliases (see Creating and editing aliases), you create instances primarily in the MSFT_CliAlias class. You create instances of the other classes as properties of the MSFT_CliAlias class or as properties of its properties.

For more information, see Windows Management Instrumentation Command-line.

# Creating and editing aliases

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating and editing aliases**

You can use the WMI tools to create aliases as Managed Object Format (MOF) files. You can use WMI Common Information Model (CIM) Studio to generate a MOF file for a selected class. This file should be edited to create an instance of MSFT_CliAlias. The MOF files can then be used to register the alias. Aliases are registered with WMI by compiling the MOF form of the alias.

When viewing the role namespaces using WMI browsing tools (such as WMI CIM Studio), only the MSFT_CliAlias and MSFT_CliTranslateTable classes have instances. Their properties might include objects of the other classes, but the other classes do not have instances of their own. For this reason, when creating aliases, you primarily create instances in the MSFT_CliAlias class. You create instances of the other classes as properties of the MSFT_CliAlias class or as properties of its properties.

Localization is supported by using localized text arrays defined in the schema. Localization of aliases descriptions is done through the MFL file (CliEgAliases.mfl).

**Adding roles** to any WMI namespace can be done, for example, by copying WMIC's CliEgAliases.mof file, and then changing the namespace reference to the namespace that is to be used as a role. The new file can then be compiled with MOFCOMP.exe. Aliases can then be added as described above.

Any WMI namespace can serve as a role; but without the additional steps above, such a role would not have WMIC's interactive help or the base classes required for aliases.

For more information, see Windows Management Instrumentation Command-line.

# Creating and editing formats in WMIC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating and editing formats in WMIC**

Windows Management Instrumentation Command-line (WMIC) uses two types of formats to display properties: **LIST** format and **OUTPUT** format.

**LIST** formats allow displaying and recording of the properties of an alias in a specific way, such as:

| List Format | Properties |
|---|---|
| `Process list brief` | displays a short list of properties. |
| `Process list full` | displays a full list of properties (this is similar to `process get /all`). |
| `Process list memory` | lists properties related to a process memory. |

To see what LIST formats are available for an alias, type:

```
<alias name> list /?.
```

For example:

```
os list /?
```

Each LIST format has a default output format name specified as part of alias definition. For example, FULL is usually associated with TABLE, while BRIEF, with LIST (value list).

As an optional step, add the LIST formats group to the alias class. This makes the formats discoverable and easier to use. You can also specify the default stylesheet to be used for the format output.

**OUTPUT** formats are provided by WMIC using the `/FORMAT` switch to display and record output in a desired way. WMIC uses Extensible Style sheet Language (XSL) to transform and format the Extensible Markup Language (XML) output. The provided formats are stored in the WBEM directory as XSL files. Formats are used with **GET**, or **LIST**. Specific formats can be specified using **GET /FORMAT:**, **LIST /FORMAT:**, **GET /ALL**, or **GET /VALUE**.

Use an XSL editor. You might want to first capture some XML data to use for experimenting while using the XSL editor.

**Custom formats** may be created to display WMIC queries. If you create custom formats, you should also define them in the **Formats** property of the **MSFT_CliAlias** class. Each format must have a name that is unique within the alias.

**Other Output formats** are included in WMIC. These formats can be set as defaults or as specified using keywords:

| Keywords | Output Formats |
|---|---|
| mof.xsl | Converts XML data to Managed Object Format (MOF) format. If aliases or other WMI objects are defined in XML format, this XSL can be used to convert them to MOFs so that they can be MOFCOMPed. - /FORMAT:MOF format. |
| texttable.xsl | /ALL or /FORMAT:TABLE. |
| texttable.xsl | /VALUE format—one line per value. |

For more information on mapping, see **XSL-MAPPINGS.XML** in **%windir%\system32\wbem**.

**Additional XSL files** that are included in WMI and can be useful when you use WMIC are:

| XSL Files | |
|---|---|
| xml.xsl | Similar to rawxml.xsl, except that the output is in HTML format. |
| hform.xsl | Html output—the data is displayed in a vertical table (one row per property or instance name). The table can be very long. |

| | |
|---|---|
| htable.xsl | Html output—the data is displayed in a horizontal HTML table (one row per instance). The table can be very wide. you can specify the column that the data is typically sorted by. Enclose this file name in quotation marks. The column and its datatype are specified by using the following syntax: `/FORMAT:"htable.xsl":"datatype=<datatype>":"sortby=<property>"`. For example, `PROCESS GET /FORMAT:"htable.xsl":"datatype=number":"sortby=ProcessId"`. |
| rawxml.xsl | To output XML data in XML format. All WMIC data is extracted in XML format, so this format gives you data the way that WMIC sees it. This can be useful for creating your own XSL files. Outputting data in XML format is also useful if you want to provide the data to systems that accept XML data. |
| csv.xsl | Comma-delimited—the data is displayed with commas between each value. This format is suitable for importing the data into Microsoft Excel or a similar program. |

**Caution**

- When editing default views, be sure to save your changes to a format outside WMI. If you update WMI or the operating system, the new version of WMIC might return the aliases or output formats to the defaults, overwriting your changes.

For step-by-step procedures on how to create and edit formats, see Create a format in WMIC and Edit a format in WMIC.

For more information, see Windows Management Instrumentation Command-line.

# Creating and editing translation tables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating and editing translation tables**

Like formats, translation tables allow you to change the output of WMIC commands to suit your needs. Translation tables are not as flexible or powerful as formats, but they are much simpler to create and edit.

Translation tables are used when you specify **/TRANSLATE** on the **LIST** or **GET** verbs. WMIC includes translation tables called BasicXML and NoComma. BasicXML converts the HTML symbols for greater-than and less-than characters into the actual characters.

Translation tables are defined in the MSFT_CliTranslateTable WMI class.

For more information, see Windows Management Instrumentation Command-line.

# Troubleshooting WMIC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Parameter not valid
- Value map does not contain the input value for this property
- RPC error on the unsuccessful connection to a computer or node
- Query fails or is slow
- Output is not properly aligned in rows and columns
- Localized version of WMIC is not available (in some Multilingual User Interface (MUI) or Language Interface Packs
- XSL files on Windows XP Professional are not supporting arrays
- Input parameter is of OBJECT type

**Parameter not valid**
**Cause:** A parameter name is misspelled or does not apply to the object in question. A required parameter might also be missing, which can include key values or writeable values.

**Solution:** You must specify the name, user name, and variable value when you create an environment variable.

**Value map does not contain the input value for this property**
**Cause:** Could be that the needed parameter is not used in the query.

**Solution:** You can interpret the value for an input parameter by referring to the schema information, the method's description qualifier in the corresponding Managed Object Format (MOF) file, or to the MSDN description of the method.

Some schema information can be retrieved using WMIC, for example:

- `wmic:root\cli>alias OS list full /format:table`
- `wmic:root\cli>process call /?:full`

**RPC error on the unsuccessful connection to a computer or node.**
**Cause:** The computer or node has a firewall set to block incoming calls.

**Solution:**

- Ping computer's IP for the availability of the computer.
- Disable firewall on computer.

**Cause:** The computer has UNIX, Linux, Windows 95, Windows 98, Windows Millennium Edition, or Windows NT 4 operating system that has no network-enabled WMI or WBEM support.

**Solution:**

- Enable WMI or WBEM support in the operating system.

- Deploy operating systems with network-enabled WMI or WBEM support.

**Query fails or is slow**
**Cause:** The query does not have enough parameters.

**Solution:** Narrow down query using **Named** parameters or **WHERE** clause. For example:

- `wmic:root\cli>Alias OS list brief`
- `wmic:root\cli>nteventlog application get /format:list`
- `wmic:root\cli>UserAccount where "Domain='DomainName' and Name='UserName'" get /all`

**Output is not properly aligned in rows and columns.**
**Cause:** Display space is too small.

**Solution:**

- Increase Screen Buffer Size for Command (CMD) window.
- Use WordPad.exe instead of Notepad to open large text files.
- Use more criteria on query to display only necessary information.
- Use a custom XSL file to display custom formatting.

**Localized version of WMIC is not available (in some Multilingual User Interface (MUI) or Language Interface Packs)**
**Cause:** Installed localized version of operating system.

**Solution:** Use the /LOCALE:ms_409 switch to set up English Locale as the default.

**XSL files on Windows XP Professional are not supporting arrays**
**Cause:** Operating system does not support XSL file arrays.

**Solution:** Use XSL from the Windows Server 2003 family to query other computers, including Windows XP Professional

**Input parameter is of OBJECT type**
**Cause:** Support is not fully implemented yet for input parameters which are of the OBJECT type. The default value (an empty string: "") is the only value currently supported.

**Solution:** Use the following command to set sharing of the c:\test directory for three users:

```
WMIC SHARE CALL Create "","test","3","TestShareName","","c:\test",0
```

# Windows Management Instrumentation Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation Control**

- For help on using WMI Control, see Windows Management Instrumentation Control How To....
- To understand more about WMI Control, see Windows Management Instrumentation Control Concepts.

# Windows Management Instrumentation Control How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Turn WMI error logging on or off
- Backup or restore the WMI repository
- Change the WMI scripting settings
- Authorize WMI users and set permissions
- Modify permissions or delete authorized users

# Turn WMI error logging on or off

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To turn WMI error logging on or off**

1. Open WMI Control.
2. In the console tree, right-click **WMI Control**, and then click **Properties**.
3. Click the **Logging** tab.
4. To turn logging off, click **Disabled** under **Logging level**.
5. To turn logging on click either **Errors only** or **Verbose** under **Logging Level**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the WMI Control console, click **Start**, click **Run**, type **wmimgmt.msc**, and then click **OK**.
- **Errors only** reports errors that occur within WMI. **Verbose** reports all actions and errors.
- Verbose logging can negatively impact system performance, so select **Verbose** only when you need more extensive information about the events leading to errors.
- Log files are maintained for the WMI core and framework, as well as for each WMI-enabled provider.
- You can set the maximum size for log files under **Maximum size**. When a log file has reached the maximum size, it is renamed with the .lo_ extension, and a new log file is created with the .log extension. When that file reaches the defined maximum size, the first file is deleted and the process is repeated.
- You can set logging levels on a remote computer or a local computer. To access a remote computer, right-click **WMI Control**, click **Connect to another computer**, click **Another computer**, and then type the name of the computer to which you want to connect. If you are using WMI Control from the Computer Management console, right-click the **Computer Management** node to connect to the other computer.
- It is recommended that you include log files when reporting issues associated with WMI services.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Backup or restore the WMI repository

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To backup or restore the WMI repository**

1. Open WMI Control.
2. In the console tree, right-click **WMI Control**, and then click **Properties**.
3. Click the **Backup/Restore** tab.
4. Click the **Back Up Now** button or **Restore Now** button.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the WMI Control console, click **Start**, click **Run**, type **wmimgmt.msc**, and then click **OK**.
- When you click the **Back Up Now** button to back up the repository manually, you can back up to a specified file name, and later restore from that saved file. This can be useful if you want to save a specific configuration of classes.
- You can backup or restore a remote computer or a local computer. To access a remote computer, right-click **WMI Control**, click **Connect to another computer**, click **Another computer**, and then type the name of the computer to which you want to connect. If you are using WMI Control from the Computer Management console, right-click the **Computer Management** node to connect to the other computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the WMI scripting settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the WMI scripting settings**

1. Open WMI Control.
2. In the console tree, right-click **WMI Control**, and then click **Properties**.
3. Click the **Advanced** tab.
4. Under **Default namespace for scripting**, click **Change**.
5. In the **Browser for Namespace** dialog box, select a different default namespace as a target for your scripts.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the WMI Control console, click **Start**, click **Run**, type **wmimgmt.msc**, and then click **OK**.
- Set the default targeted namespace to one you use most often in your WMI scripts. If no namespace is identified within a script, the default is used.
- If the computer you are manage runs Microsoft Windows NT 4.0, you can define whether WMI scripts can be run from within Active Server Pages (ASP). If you enable the option, your ASP connects to Windows Management services using the process level identity of Internet Information Services, which might compromise security.
- You can change the scripting namespace on a remote computer or a local computer. To access a remote computer, right-click **WMI Control**, click **Connect to another computer**, click **Another computer**, and then type the name of the computer to which you want to connect. If you are using WMI Control from the Computer Management console, right-click the **Computer Management** node to connect to the other computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Authorize WMI users and set permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To authorize WMI users and set permissions**

1. Open WMI Control.
2. In the console tree, right-click **WMI Control**, and then click **Properties**.
3. Click the **Security** tab.
4. Select the namespace for which you want to give a user or group access, and then click **Security**.
5. In the **Security** dialog box, click **Add**.
6. In the **Select Users, Computers, or Groups** dialog box, enter the name of the object (user or group) that you want to add. Click the **Check Names** button to verify your entry and then click **OK**. You might have to change the location or use the **Advanced** button to query for objects. See the dialog box help for more details.
7. In the **Security** dialog box, under **Permissions**, select the permissions to allow or deny the new user or group.

| Level | Description |
|---|---|
| Execute Methods | Allows methods exported from the WMI classes or instances to be run. |
| Full Write | Allows full read, write, and delete access to all WMI objects, classes, and instances. |
| Partial Write | Allows write access to static WMI objects. |
| Provider Write | Allows write access to objects that are provided by providers. |
| Enable Account | Allows read access to WMI objects. |
| Remote Enable | Allows remote access to the namespace. |
| Read Security | Allows read-only access to WMI security information. |
| Edit Security | Allows read and write access to WMI security information. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the WMI Control console, click **Start**, click **Run**, type **wmimgmt.msc**, and then click **OK**.
- You can set permissions on a remote computer or a local computer. To access a remote computer, right-click **WMI Control**, click **Connect to another computer**, click **Another computer**, and then type the name of the computer to which you want to connect. If you are using WMI Control from the Computer Management console, right-click the **Computer Management** node to connect to the other computer.
- On computers running Windows 95, Windows 98, or Windows ME, all users have full control locally. Security settings are only relevant for remote connection to a computer running Windows 95, Windows 98, or Windows ME.
- You can delete a user's or group's authorization to access WMI services by selecting that user or group and clicking

**Remove**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Permissions for files and folders

# Modify permissions or delete authorized users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify permissions or delete authorized users**

1. Open WMI Control.
2. In the console tree, right-click **WMI Control**, and then click **Properties**.
3. Click the **Security** tab.
4. Select the namespace for which you want to change a user's or group's permissions or delete a user or group, and then click **Security**.
5. In the **Security** dialog box, under **Name**, select the user or group you want to remove or whose permissions you want to modify.
6. Perform one of the following steps:
   - To remove the user or group, click **Remove**.
   - To change security settings, under **Permissions**, modify the permissions which are allowed or denied to the user or group by clearing or selecting the appropriate check boxes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the WMI Control console, click **Start**, click **Run**, type **wmimgmt.msc**, and then click **OK**.
- WMI security is verified only when a user logs on to Windows Management services. Thus, any changes made to a user's permissions while the user is connected do not take effect until the next time the user logs on to WMI. For example, if a user's access is revoked, the changes do not take effect until the user logs off Windows Management services and attempts to log on again.
- You can modify user or group permissions on a remote computer or a local computer. To access a remote computer, right-click **WMI Control**, click **Connect to another computer**, click **Another computer**, and then type the name of the computer to which you want to connect. If you use WMI Control from the Computer Management console, right-click the **Computer Management** node to connect to the other computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# WMI Control Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMI Control overview**
Windows Management Instrumentation (WMI) Control is a tool that enables you to configure WMI settings on a remote computer or local computer. Using the WMI Control, you can manage the following tasks remotely.

**Authorize users or groups and set permission levels**
You can enable an individual user, group, or namespace to access network objects and perform WMI tasks and services. For example, you can enable a group to manage WMI's Common Information Model (CIM) objects on their local computers.

**Configure error logging**
You can turn error logging on or off and, if turned on, set it to report errors only (the default) or all actions (verbose). Error logging can help you troubleshoot WMI problems. You can also define a maximum size for log files and their folder location.

**Back up the repository**
You can configure the WMI Control to back up your repository on a regular schedule, or you can do it manually at any time. The repository is the database of objects that you can access through WMI. You can also restore a previous version of the repository.

**Change the default namespace for scripting**
You can change the default namespace that is targeted in WMI scripts.

For more information, see WMI Overview

For information about using the command-line interface to WMI, see Windows Management Instrumentation Command-line.

# WMI Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**WMI Overview**

Windows Management Instrumentation (WMI) is the Microsoft implementation of WBEM, an industry initiative to establish standards for accessing and sharing management information over an enterprise network. WMI is WBEM-compliant and provides integrated support for the Common Information Model (CIM), the data model that describes the objects that exist in a management environment.

WMI includes a CIM-compliant object repository, which is the database of object definitions, and the CIM Object Manager, which handles the collection and manipulation of objects in the repository and gathers information from WMI providers. WMI providers act as intermediaries between WMI and components of the operating system, applications, and other systems. For example, the registry provider draws information from the registry, while the SNMP provider provides data and events from SNMP devices. Providers provide information about their components, and might provide methods to manipulate the components, properties that can be set, or events that can alert you to changes in the components.

WMI can be used by computer management tools, such as Microsoft Systems Management Server, to help you manage your computers. WMI is also used by other Microsoft technologies and tools, such as Microsoft Health Monitor and Microsoft Operations Manager, and by other vendors of computer management systems. You can use WMI with programming or scripting systems (such as Windows Script Host) to retrieve configuration details about most aspects of your computer systems, including server applications, or to affect changes to your systems. For more information see the WMI SDK.

Several management tools are WMI-enabled, including System Properties, System Information, and the Dependencies component of Services. Brief descriptions of these components follow:

- System Properties lets you view and change system properties on a local or remote computer. You can restart a remote computer to apply settings changes or to detect new hardware, view the computer name and domain information for other computers on your network, or change the settings for the virtual memory paging file on a computer that might run programs requiring a lot of memory. For more information about System Properties, see System Properties.

- System Information collects and displays configuration information about your system. This is is especially useful when a support technician is troubleshooting your system. For more information, see System Information.

- Services helps you manage the services on your computer. Services dependencies identify the services on which the current service depends and the services that depend on it. For more information about Services, see Services Concepts.

For technical information about developing the WMI system, see the Windows Management Instrumentation documentation at the Microsoft Platform Software Development Kit (SDK) Web site

For information about using the WMI Tester to view and modify CIM objects, see Windows Management Instrumentation Tester overview.

For information about using the command-line interface to WMI, see Windows Management Instrumentation Command-line.

For information about using the WMI Control to configure WMI settings and security on a remote or local computer, see WMI Control Overview.

# Managing WMI security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing WMI security**

Windows Management Instrumentation (WMI) supports a limited form of security that validates each user before the user is allowed to connect to WMI, on either the local computer or a remote computer. This security is layered on top of the operating system security. WMI does not override or circumvent security provided by the operating system.

By default, all members of the Administrators group have full control of the WMI services on the managed computer. All others have read/write/execute permissions on their local computer only.

Permissions can be changed by adding a user to the Administrators group on the managed computer or by authorizing users or groups in WMI and setting their permission level. Access is based on WMI namespaces.

On computers running Microsoft Windows 95, Windows 98, or Windows Millennium Edition (ME), all users have full control locally. However, permissions can be set for users managing a Windows 95, Windows 98, or Windows ME computer remotely.

Security is checked only when a user connects to the Windows Management service. Thus, any changes made to a user's permissions while the user is connected do not take effect until the next time the user starts a WMI service. For example, if a user's access is revoked, the changes do not take effect until the user exits from WMI and attempts to connect to the service again.

For more information, see Modify permissions or delete authorized users.

# Windows Management Instrumentation Tester

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation Tester**
Using Windows Management Instrumentation (WMI) Tester, also called WBEMTest, you can view and change Common Information Model (CIM) classes, instances, and methods. You can also use WBEMTest to troubleshoot Windows Management Instrumentation (WMI) and programs that depends on WMI.

- For help with specific tasks, see Windows Management Instrumentation Tester How to....
- For general background information, see Windows Management Instrumentation Tester Concepts.

# Windows Management Instrumentation Tester How to...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Display WMI tester dialog box
- Connect to WMI
- Enumerate Classes
- Create a class
- Delete a class
- Open an instance
- Delete an instance
- Execute a notification query
- Execute a notification query

# Display WMI tester dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display WMI tester dialog box**

1. Click **Start**, click **Run**, and then type **wbemtest.exe**.

## Notes

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect to WMI

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to WMI**

1. Click **Start**, click **Run**, and then type **wbemtest.exe**.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.

## Notes

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.
- The online help procedures use the **root\cimv2** namespace. To step through the procedures, you must be connected to this namespace instead of the default namespace.
- When you start WBEMTest, the **Windows Management Instrumentation Tester** dialog box appears. Before you can use WBEMTest functions, you must log on to WMI.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enumerate Classes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To enumerate classes

1. Open the **Windows Management Instrumentation Tester** dialog box.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.
5. Click **Enum Classes**.
6. In the **Superclass Info** dialog box, type the name of the superclass to enumerate the child classes of a specific class.

   - Select **Immediate only** option if you want to see only the immediate subclasses of the superclass you specify.
   - Select **Recursive** option if you want to see all the classes of the superclass, subclasses of the superclass, and all the subclasses of those subclasses.

7. To see all the top level classes for the current namespace, leave the **Superclass Info** dialog box empty and select **Immediate only** option.
8. To see all the classes in a namespace, subclasses of the superclass, and all the subclasses of those subclasses, leave the **Superclass Info** dialog box empty and select **Recursive** option.

### Notes

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.
- To open the **Windows Management Instrumentation Tester** dialog box, click **Start**, click **Run**, and then type **WBEMTest.exe**.
- You can display the child classes of a superclass by clicking **Enum Classes** in the **Windows Management Instrumentation Tester** dialog box.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a class

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a class**

1. Open the **Windows Management Instrumentation Tester** dialog box.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.
5. Click the **Create Class** button.

   - If you are creating a new base class, leave the **Optional Superclass** dialog box empty.
   - If you are specifying an existing class definition, the new class is based on the current namespace.
   - For example, if you specify **Win32_LogicalDisk** as the superclass, the new child class inherits the properties of the **Win32_LogicalDisk** class.

6. Click **Continue**.
7. In the **Object Editor** dialog box, select the **__Class** property.
8. Select **Edit Property**.
9. In the **Property Editor** dialog box, click **Not Null** and then type the name for the new class in the text box.
10. Click **Save Property**.
11. In the **Object Editor** dialog box, define the properties, qualifiers, and methods for the new class.
12. Click **Save Object** to create the new class.

**Notes**

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.
- To open the **Windows Management Instrumentation Tester** dialog box, click **Start**, click **Run**, and then type

**WBEMTest.exe**.

- To use the **Win32_LogicalDisk** example above, you must be logged in to the **root\cimv2** namespace.
- You can create a new class definition in the current namespace by clicking **Create Class** in the **Windows Management Instrumentation Tester** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a class

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a class**

You can delete a class in the current namespace with **Delete Class** on the **Windows Management Instrumentation Tester** dialog box.

1. Open the **Windows Management Instrumentation Tester** dialog box.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.
5. Click **Delete Class**.
6. In the **Get Class Name** dialog box, type the name of the class you want to delete, and then click **OK**.

   A dialog box is displayed to warn you that the class might have derived classes or instances. This dialog box is displayed even if there are no derived classes or instances.

7. If you are sure you want to delete the class, click **Yes** to delete the class.

## Notes

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.
- To open the **Windows Management Instrumentation Tester** dialog box, click **Start**, click **Run**, and then type **WBEMTest.exe**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

**Concepts**

Get Class Name dialog box

Create a class

# Delete an instance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete an instance**

1. Open the **Windows Management Instrumentation Tester** dialog box.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.
5. Click **Delete Instance**.

   The **Get Object Path** dialog box appears.

6. Type the relative object path for the instance you want to delete.

   **Example?**

   - To delete an instance of MyClass where the key property is F122, type:

     **MyClass.KeyProperty="F122"**

## Notes

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.
- To open the **Windows Management Instrumentation Tester** dialog box, click **Start**, click **Run**, and then type **WBEMTest.exe**.
- You cannot delete dynamic instances of static classes unless the provider supports this capability. For example, if you attempt to delete an instance of **Win32_Process**, a "Provider Not Capable" message appears because the provider does not support the deletion of dynamic instances.
- You can delete an instance of a class by clicking **Delete Instance** in the **Windows Management Instrumentation Tester** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Get Object Path dialog box

# Execute a notification query

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To execute a notification query**

1. Open the **Windows Management Instrumentation Tester** dialog box.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.
5. Click **Notification Query**.
6. In the **Enter Query** box, type an event notification query.

   **Example?**

   - An event query that notifies you when a log event occurs:

     SELECT * FROM __instancecreationevent WHERE TargetInstance ISA 'Win32_NTLogEvent' AND (TargetInstance.LogFile="Application" OR TargetInstance.LogFile="System")

7. Click **Apply**.

   - The text **Operation in Progress** appear in the lower-right corner of the **Query Result** dialog box, indicating that WMI is processing your query. Because event notification queries are never complete, the **Operation in Progress** status message is displayed on the **Query Result** dialog box until you stop the query.
   - For event notification queries that are running semisynchronously, you must specify batch count and time-out values. These values determine how events are extracted from the enumerator.
   - If your event notification query is running asynchronously, events are displayed in the **Query Result** dialog box as the events are received.
   - If you want to view an event notification, double-click the event in the **Query Result** dialog box. The **Instance Of** dialog box appears.
   - To stop the query, click **Close** .

**Notes**

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.

- To open the **Windows Management Instrumentation Tester** dialog box, click **Start**, click **Run**, and then type **WBEMTest.exe**.

- If you want your event notification query to run asynchronously, select the **Execute asynchronously** check box on the **Windows Management Instrumentation Tester** dialog box.

- You can query for event notifications with **Notification Query** on the **Windows Management Instrumentation Tester** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Query dialog box
Query Result dialog box

# Open an instance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open an instance**

1. Open the **Windows Management Instrumentation Tester** dialog box.
2. In the **Windows Management Instrumentation (WMI) Tester** dialog box, click **Connect**.
3. In the **Namespace** box, type the path to the namespace that you want to connect to.

   **Example?**

   - To connect to the namespace where the Win32 provider classes reside, type:

     **root\cimv2**

4. Click **Connect**.
5. Click **Open Instance**.
6. In the **Get Object Path** dialog box, type the relative object path for the instance you want to retrieve. And, then click **OK** to use the **Object Editor** dialog box to view or edit the class instance you have opened.

   **Example?**

   - To open an instance of the **Win32_LogicalDisk** class, type:

     **Win32_LogicalDisk.DeviceID="C:"**

## Notes

- Performing this task on the local computer does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- Performing this task on a remote computer requires that you are a member of the Administrators group on the remote computer, or that you have been delegated the appropriate authority.
- To open the **Windows Management Instrumentation Tester** dialog box, click **Start**, click **Run**, and then type **WBEMTest.exe**.
- You can open an instance of a class with **Open Instance** on the **Windows Management Instrumentation Tester** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Windows Management Instrumentation Tester Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Windows Management Instrumentation Tester overview
- Using WBEMTest user interface

# Windows Management Instrumentation Tester overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Management Instrumentation Tester overview**
Windows Management Instrumentation (WMI) Tester, also called WBEMTest, is a general-purpose tool for viewing and modifying WMI classes, instances, and methods during the development of Windows Management Instrumentation (WMI) providers and WMI applications. You can also use WBEMTest to troubleshoot WMI and programs that depend on WMI.

Use WBEMTest to perform the following tasks:

- Create, enumerate, and delete WMI classes and instances.
- Execute methods.
- Run queries.
- Display the Managed Object Format (MOF) code for classes and instances.

Because WBEMTest acts as an interface to the COM API for WMI, you can also use WBEMTest to check queries, classes, and instances when developing WMI providers and WMI client applications.

The executable file for WBEMTest, Wbemtest.exe, is installed in the WBEM directory of your Windows system directory. On Windows XP systems, this is the %WINDIR%\system32\Wbem folder.

For information about using the command-line interface to WMI, see Windows Management Instrumentation Command-line.

For information about using the WMI Control to configure WMI settings and security on a remote or local computer, see WMI Control Overview.

For information about WMI security, see Managing WMI security.

# Using WBEMTest user interface

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using WBEMTest user interface**
Two dialog boxes make up the primary interface to Windows Management Instrumentation (WMI) Tester, also called WBEMTest, functions.

- The **Windows Management Instrumentation Tester** dialog box provides access to all WBEMTest functions. For information on how to display this dialog box, see Display WMI tester dialog box.
- The **Connect** dialog box enables you to log on to WMI and connect to a namespace.

For more information about other WBEMTest dialog boxes, see:

- Connect dialog box
- Object Editor dialog box
    - Object Editor - Qualifier, Property, and Method functions
    - Object Editor dialog box - other functions
- Get Object Path dialog box
- Get Class Name dialog box
- Superclass Info dialog box
- Query dialog box
- Query Result dialog box
- Class Info dialog box
- Execute Method dialog box
- Property Editor dialog box
- Qualifier Editor dialog box
- Method Editor dialog box
- Query Result dialog box for refresher
- Get Object For Refresher dialog box
- MOF dialog box

For information about WMI security, see Managing WMI security.

# Connect dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connect dialog box**

Before you can use the functions of WBEMTest, you must log on to WMI. Click **Connect** on the **Windows Management Instrumentation Tester** dialog box to log on to WMI. The **Connect** dialog box appears.

Typically, you can accept the default settings displayed in the **Connect** dialog box, described as follows.

- The **Namespace** boxes displays the default namespace for your computer. You can specify a different namespace on your computer or on another computer. For example, for access to the classes of the Win32 provider, you can specify **root\cimv2**. To access the cimv2 namespace on a remote computer named **myserver**, you can specify **\\myserver\root\cimv2**. To access remote computers, you must grant permission to read or write from the remote computer using the WMI Control application, Wbemcntl.exe.

- The **Connection:** boxes specify properties of the connection to WMI. The **Using:** box specifies that **IWbemLocator** is used for obtaining the initial namespace pointer to Windows Management on a particular host computer. The **Returning:** box specifies that a **IWbemServices** pointer is used for accessing Windows Management information. The **Completion** box specifies that processing is synchronous.

- The **Credentials** boxes enable you to specify a user name, password, and authority. You can log on to WMI using credentials different from those of the user who is currently logged on. If you leave these boxes blank, WMI uses the settings of the current Windows logged on user.

- The **Locale** box enables you to specify a different locale by entering a localization code. To use the current locale, leave this box blank. Otherwise, it it must contain the location from which you want information. For Microsoft locale identifiers, the format of the string is "MS_xxx", where *xxx* is a string in hexadecimal form that indicates the Locale Identifier (LCID). For example, American English would appear as "MS_409".

- The **How to interpret empty password** option buttons control what happens if you leave the password box blank. WMI processes a blank password differently from no password at all. The default value for this box is NULL and causes WBEMTest to use the current Windows logged on user password to connect to WMI. To log on to WMI using an empty password, select the **Blank** option button.

- The **Impersonation level** option buttons enable you to set the Distributed COM (DCOM) impersonation level that WBEMTest typically uses. In most cases, you can use the default value, **Impersonate**,for this option button. However, some providers might require specific impersonation settings. Consult the documentation for the provider you are using if you are not sure which value to use. Additionally, the impersonation level that you specify must be applicable to the operating system you use. For example, if you specify an impersonation level of **Delegate** and WBEMTest is not running on a computer that uses the Windows XP Home Edition or Windows XP Professional operating system, this setting is ignored.

  For more information about impersonation, see Impersonation Level Enumeration.

- The **Authentication level** option buttons enable you to specify the Distributed COM (DCOM) authentication level you want to use. These authentication levels control how information is authenticated by DCOM. Typically, you can use **Packet**, the default value for this option button.

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Object Editor dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Object Editor dialog box**
The **Object Editor** dialog box appears when you double-click a class or instance from the **Query Result** dialog box. The **Object Editor** dialog box also appears when you click **Open Class** or **Enum Class** on the **Windows Management Instrumentation Tester** dialog box.

You can use the **Object Editor** dialog box to:

- Edit the qualifiers, properties, and methods for the selected class or instance.
- View the MOF code that creates the class or instance.
- View instances of the class, the derived classes, and the superclass of the class, if you are editing a class definition.
- Refresh the view of the object after you make changes.

For example, when you click **Open Class** in the **Windows Management Instrumentation Tester** dialog box, and then type **Win32_LogicalDisk** in the **Get Class Name** dialog box, the **Object Editor for Win32_LogicalDisk** dialog box appears.

If you double-click any item in a list box, the appropriate editor opens for that object. For example, if you double-click the **reset** method in the methods list box, the method editor for the **reset** method appears.

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Object Editor - Qualifier, Property, and Method functions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Object Editor - Qualifier, Property, and Method functions**

In the **Object editor**, you can do the following:

- Open the **Qualifier Editor** dialog box by clicking **Add Qualifier**. You can use this feature to add qualifiers that apply to the class or instance as a whole as opposed to a specific property of the class or instance. Type in the values for the new qualifier and click **Save Qualifier** to create the new qualifier.
- Open the **Qualifier Editor** dialog box for the qualifier that is selected, by clicking **Edit Qualifier**. You can use this to change the value or flavors assigned to a qualifier.
- Delete the currently selected qualifier, by clicking **Delete Qualifier**.
- Not display system properties in the **Object Editor** dialog box, by clicking **Hide System Properties**.
- Define new properties and assign values to classes or instances, by clicking **Add Property**. When you click **Add Property**, the **Property Editor** dialog box appears.
- Change the definition for the currently selected property, by clicking **Edit Property**.
- Delete the currently selected property, by clicking **Delete Property**.
- Define the methods for a class or instance, by clicking **Add Method**. When you click **Add Method**, the **Method Editor** dialog box appears.
- Edit the methods for a class or instance, by clicking **Edit method**. When you click **Edit Method**, the **Method Editor** dialog box appears.
- Delete the currently selected method, by clicking **Delete Method**.

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Object Editor dialog box - other functions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Object Editor dialog box - other functions**

In the **Object Editor** dialog box, you can do the following:

- Close the **Object Editor** dialog box, by clicking **Close**.
- Save the changes to the current class or instance, by clicking **Save Object**.
- Open the **MOF** dialog box, which contains the managed object format (MOF) code that you can use to construct the current object, by clicking **Show MOF**. It is important to remember that the MOF code shown in this dialog box might not be identical to the actual MOF code that created the class or instance. The original MOF file might have comments and different formatting from text shown, for more information. see Managed Object Format
- Run a schema query that shows the class from which the current class or instance is derived, by clicking **Superclass**.
- Run a schema query that shows the child classes of the current class or instance, by clicking **Derived**.
- Show instances of the current class, by clicking **Instances**.
- Control how the class are updated, by using the **Update type** option. The following tables describe the two groups of option buttons that control the update process.

| Update Type | Meaning |
|---|---|
| **Create only** | Used for creation only. The save operation fails if the class or instance already exists. |
| **Update only** | Causes this call to update. |
| **Either** | Causes the class or instance to be created if it does not exist, or overwritten if it exists already. |

| Update Type | Meaning |
|---|---|
| **Compatible** | Allows a class to be updated are no derived classes and instances for that class exist. It also allows updates in all cases if qualifiers are changed, such as the description qualifier. This is the default value for this option and is used for compatibility with previous versions of WMI. If the class has instances, the update fails. |
| **Safe** | Allows updates of classes even when there are child classes, providing the change does not cause any conflicts with child classes. An example of an update to this value is adding to the base class a new property that was not previously mentioned in any of the child classes. If the class has instances, the update fails. |
| **Force** | Forces updates of classes when conflicting child classes exist. For example, this value forces an update if a class qualifier was defined in a child class, and the base class tries to add the same qualifier in conflict with the existing one. In force mode, this conflict is resolved by deleting the conflicting qualifier in the child class. If the class has instances, the update fails. |

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Get Object Path dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Get Object Path dialog box**

Use the **Get Object Path** dialog box to specify the name of a class or the relative path to a class instance.

Object paths have the format: [Class].[KeyProperty] = Value

For example, an instance of a class called Myclass that has a key property called Keyproperty with a value of "A" the object path is: MyClass.KeyProperty="A".

For more information, see WMI Object Path Requirements.

# Get Class Name dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Get Class Name dialog box**

Use the **Get Class Name** dialog box to specify class names for the WBEMTest Open Class function.

# Superclass Info dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Superclass Info dialog box**

The **Enum Classes** function uses the **Superclass Info** dialog box. If you select the **Recursive** option button, WBEMTest also enumerates all subclasses of the class you specify, instead of only the immediate subclasses of that class.

# Query dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Query dialog box**
Use the **Query** dialog box to compose a query, and then execute it. To display the **Query** dialog box, click **Query** on the **Windows Management Instrumentation Tester** dialog box.

In the **Enter Query** text box, type the WBEMTest query .

In the **Query Type** list box, you can select a query language. Currently, only Windows Management Instrumentation (WMI) Query Language (WQL) is supported.

You can use the **Retrieve class prototype** check box to indicate that you do not want instances from this query, and then to the class that the instances might belong to if returned.

For more information, see Querying WMI.

# Query Result dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Query Result dialog box**

The **Query Result** dialog box is displayed when you perform a function that enumerates classes or instances. This dialog box also appears for event notification queries to display events. For asynchronous event notification queries, this dialog box displays the events as received. New events are delivered when you run a semisynchronous event notification query.

If the query results are instances, the relative path for the instances is displayed. You can double-click any of the objects in the **Query Result** dialog box to display the **Object Editor** dialog box for that object.

For more information, see Object Editor dialog box.

# Class Info dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Class Info dialog box**

Use the **Class Info** dialog box to specify the name of the class for which you want to see instances. This dialog box appears when you click **Enum Instances** on the **Windows Management Instrumentation Tester** dialog box. If you select **Immediate Only**, the default value, only instances of the class you specify are displayed. If you select **Recursive**, instances of the subclasses of the class you specify are displayed.

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Execute Method dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Execute Method dialog box**

In the **Execute Method** dialog box, you can do the following:

- Edit the object path, by clicking **Edit Object Path** and set the object path to refer to a specific instance if necessary.
- Show the current object path in the **ObjectPath** text box.
- Close this dialog box without executing the method, by clicking **Dismiss**.
- Display the methods available for this class in the **Method** drop-down list .
- Set the various parameters the method might require, by clicking **Edit In Parameters**.
- Reset all the input parameters to the default settings, by clicking **Clear In Parameters**.
- View the output parameters for the method, by clicking **Edit Out Parameters**. The output parameters contain data returned from a method.

**Notes**

- To display the **Execute Method** dialog box, click **Execute Method** on the **Windows Management Instrumentation Tester** dialog box.
- You can use the **Execute Method** dialog box to run a method of a class or class instance.

# Property Editor dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Property Editor dialog box**

Use the Property Editor dialog box to create or edit properties of classes. In some cases, for example, when you edit an existing class, you might not be able to set all the fields on this dialog box.

For more information, see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Qualifier Editor dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Qualifier Editor dialog box**

You can define the name, data type, option, and value of a qualifier in the **Qualifier Editor** dialog box.

You can assign five common qualifier options to your qualifier by selecting the check boxes in the option section. The following options are available:

- Propagates to instances
- Propagates to derived classes
- Allows overrides
- Propagated
- Amended

For more information, see WMI-Specific Qualifiers.

# Method Editor dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Method Editor dialog box**

In the **Method Editor** dialog box, you can do the following:

- Enable the **Edit Input Arguments** button by clicking the **Enable Input Args** option button.

  To open the **Object Editor** dialog box for an instance of the __Parameters class, click the **Edit Input Arguments** button. You can use the object editor to edit or define new input parameters for a method.

- Enable the **Edit Output Arguments** button by clicking the **Enable Output Args** option button.

  To display the **Object Editor** dialog box for an instance of the __Parameters class, click the **Edit Output Arguments** button. You can use the object editor to edit or define new output parameters for a method.

- Add, delete, and edit the qualifiers for this method in the **Qualifiers** section.

- Save new methods and update existing methods by clicking **Save Method**.

**Notes**

- To display the **Method Editor** dialog box, in the **Windows Management Instrumentation Tester** dialog box, click the appropriate **IWbemServices** class button. In the next dialog box, select a Method, and then click the appropriate **Method** button.

- You can use the **Method Editor** dialog box to add methods to classes and class instances, and to edit methods.

# Query Result dialog box for refresher

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Query Result dialog box for refresher**

In the **Query Result** dialog box for refresher, you can do any of the following:

- Display the **Get Object For Refresher** dialog box where you can add objects or enumerators to a refresher, by clicking **Add**. Type the name of a class that supports refreshers in the **Object Path** text box to add a refresher to the query.
- Delete objects or enumerators from a refresher by clicking **Delete**.
- Populate the instances with data, clicking **Refresh**.

**Notes**

- To display the **Query Result** dialog box for refresher, on the **Windows Management Instrumentation Tester** dialog box, click **Create Refresher**.
- The refreshers you create are empty until you click **Refresh**. Click **Refresh** as often as necessary to update the data in your refreshers.

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site

# Get Object For Refresher dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Get Object For Refresher dialog box**
In the **Get Object For Refresher** dialog box, you can do the following:

- Refresh an object, by typing the relative path to an instance and then clicking **Add Object**.
- Refresh an enumerator, by typing the class name of your refresher and then clicking **Add Enum**.

**Notes**

- To display the **Get Object For Refresher** dialog box, click **Add** in the **Query Result - REFRESHER** dialog box.
- To specify the object path to an instance you are adding to your refresher or to specify the Class name of the enumerator you want to add to your refresher, use the **Get Object For Refresher** dialog box.

For more information on WBEMTest, see COM API for WMI. Also see the Windows Management Instrumentation documentation at the Microsoft Platform SDK Web site.

# MOF dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MOF dialog box**

The **MOF** dialog box appears when you click **Show MOF** on the **Object Editor** dialog box. You can use the **MOF** dialog box to display Managed Object Format (MOF) code when editing a class or class instance in the **Object Editor** dialog box.

For information, see Object Editor dialog box.

# Microsoft Management Console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Management Console**
Microsoft Management Console (MMC) hosts administrative tools that you can use to administer networks, computers, services, and other system components.

- For help with specific tasks, see MMC How To....
- For MMC background information, see MMC Concepts.
- For information about accessibility features, see Accessibility for MMC.
- For problem-solving instructions, see Troubleshooting MMC.
- For Help information for Windows Server 2003 family of operating systems, see Access Windows Help.
- For security suggestions, see MMC Best Practices and Runas.

# MMC Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Log on as a normal user**

- When you log on with administrative rights, you open the systems over which you have control to attack. For more information, see Why you should not run your computer as an administrator.
- Use the **Runas** command to open specific tools when you need to use them. For more information, see Runas.
- For tools that you use frequently, create shortcuts that use the **Runas** command.These shortcuts will help you work efficiently without compromising security. For more information, see Create a shortcut using the runas command.
- ***When you complete your task, close the tool***. This will eliminate an opportunity for possible security breach of system or computer access by someone using your administrative credentials.

**Follow the security guidelines for the tools that you use.**

- Check the Help that accompanies each tool for security guidelines.

For more security information, see Best practices for security, Security overview, and Local Users and Groups Best practices.

# MMC How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Access Windows Help
- Open MMC and saved console files
- Author an MMC console file
- Modify a saved MMC console file
- Work with MMC and saved console files
- Set policy for MMC and snap-ins

# Access Windows Help

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To access Windows Help**

1. Click **Start**, then click **Help and Support** to access the **Help and Support Center**.

## Notes

- Once Help and Support are open, you can navigate to all Help topics.
- Also see Viewing classic Help in Related Topics. Classic Help is Help in the format that shipped with Windows 2000. It is the same content that appears in **Help and Support Center** with the only difference in the format.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Open MMC and saved console files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Open MMC and saved console files**

- Open MMC
- Open a saved MMC console for local and remote computers
- Create a desktop shortcut to open MMC

# Open MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open MMC**

- Do one of the following:
  - Click **Start**, click **Run**, type **mmc**, and then click **OK**.
  - At the command prompt, type **mmc**, and then press ENTER.

The complete command-line syntax for MMC is:

mmc*path******filename.msc* [/a] [/64] [/32]

*path* **** *filename.msc*

This command starts MMC and opens a saved console. You need to specify the complete path and file name for the saved console file. If you do not specify a console file, MMC opens a new console.

You can use environment variables to create command lines or shortcuts that do not depend on the explicit location of console files. For instance, if the path to a console file is in the system folder (for example, **mmc***c:\windows\system32\console_name.msc*), you can use the expandable data string %systemroot% to specify the location (**mmc***%systemroot%\system32\console_name.msc*). This may be useful if you are delegating tasks to people in your organization who are working on different computers.

**/a**

This switch opens a saved console in author mode and is used to make changes to saved consoles. When consoles are opened with this option, they are opened in author mode, regardless of their default mode. This does not permanently change the default mode setting for files. When you omit this option, MMC opens console files according to their default mode settings.

**/64**

Opens the 64-bit version of MMC (MMC64). Use this option only if you are running a Microsoft 64-bit operating system. For more information, see Running 32-bit and 64-bit snap-ins in Windows Server 2003 and Windows XP Professional operating systems.

**/32**

Opens the 32-bit version of MMC (MMC32). When running a Microsoft 64-bit operating system, you can run 32-bit snap-ins by opening MMC with this command-line option. For more information, see Running 32-bit and 64-bit snap-ins in Windows Server 2003 and Windows XP Professional operating systems.

**Notes**

- After you open MMC or a console file in author mode, you can open any existing console by clicking **Open** on the **File** menu.
- You can use the command line to create shortcuts for opening MMC and saved consoles. A command-line command is used in the **Run** command on the **Start** menu, in any command-prompt window, in shortcuts, or in any batch file or program that calls the command.
- 32-bit is the default.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Open a saved MMC console for local and remote computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open a saved MMC console for local and remote computers**
There are several ways to open a saved MMC console:

- Open the folder where your console is located, and then click the console.
- Click **Start**, click **Run**, type the name of the console file, and then click **OK**.
- You can also open console files by using Run as. With this feature, you can log on to your computer with user rights to perform routine tasks, but open console files to perform administrative tasks with Administrator rights as necessary. You can use this feature by typing **runas** at the command prompt or by right-clicking an .msc file, and then clicking **Run as**.
- If you are using Windows XP Professional or Windows XP Home Edition, click **Start**, click **Control Panel**, click**Administrative Tools**, and then click the console you want to open.
- If you are using Windows 2000, click **Start**, click **Settings**, click **Control Panel**, click**Administrative Tools**, and then click the console you want to open.

### Note

- By default, consoles are saved in the following folder: %systemdrive%\Documents and Settings*username*\Start Menu\programs\Administrative Tools.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a desktop shortcut to open MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a desktop shortcut to open MMC**

1. Right-click an open area on the desktop, point to **New**, and then click **Shortcut**.

2. Follow the instructions on the screen. A shortcut will appear on the desktop.

## Notes

- You can drag a shortcut that you create on the desktop to other folders in the operating system, such as the folder where you keep your .msc files or the folder for the **Start** menu.

- You can also create a shortcut to MMC in folders by using Windows Explorer. To do so, click the folder in which you want the shortcut, and on the **File** menu, point to **New**, click **Shortcut**, and then follow the instructions on the screen.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a snap-in to a new MMC console for a local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a snap-in to a new MMC console for a local computer**

1. Open MMC.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, double-click the item you want to add, and, if prompted, do one of the following:
   - Click **Local computer: (the computer this console is running on)**, and then click **Finish**.
   - If a wizard appears, follow the instructions.
4. To add another item to the console, repeat step 3.

**Notes**

- To open MMC, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- If you add a snap-in to a console, and the snap-in becomes damaged, try adding another instance of the same snap-in to the console. Configure it as needed, and then remove the first instance of the snap-in.
- If a console is saved to the per-user Administrative Tools folder (located at *systemdrive*\Documents and Settings*user*\Start Menu\Programs\Administrative Tools), it becomes available in the Administrative Tools folder on the **Programs** menu for that user.
- You can only access snap-ins published in Active Directory.
- A remote computer is entirely snap-in specific.
- If a snap-in does not appear in the list, you must first install the program, device, or service administered by the snap-in. You can access snap-ins not locally installed from the **Add/Remove Snap-in** dialog box in the Active Directory directory service. You must be using one of the following operating systems for this process to work:
  - Is running Windows 98 with Windows Installer installed;

    –or–
  - Is running Windows NT 4.0 with Windows Installer installed;

    or
  - Is running Windows Millennium Edition;

    –and–
  - Is part of a Windows domain.
  - For more information, see Help.

- To make an item other than the console root subordinate to an item in the console tree, click the appropriate item in **Snap-ins added to** before you click **Add** in step 2.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a published snap-in to a new MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a published snap-in to a new MMC console**

1. Open MMC.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click the published snap-in you want to add, and then click **Add**.
4. If a wizard for Windows Installer appears, follow the instructions, and then do one of the following:
   - Click **Local computer: (the computer this console is running on)**, and then click **Finish**.
   - If a wizard for the snap-in appears, follow the instructions.
5. To add another item to the console, repeat step 3.

## Notes

- To open MMC, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- For snap-ins available from the Active Directory directory service, **Not Installed** displays in the **Vendor** column.
- You can only access extension snap-ins published in Active Directory if the computer you are using is running Windows 98 with Windows Installer, Windows NT 4.0 with Windows Installer, or Windows Millinnium Edition. In addition, the computer must be part of a Windows domain. For more information about publishing applications and Windows Installer, see Help.
- If a console is saved to the per-user Administrative Tools folder (located at *systemroot*\Documents and Settings*User*\Start Menu\Programs\Administrative Tools), it is then available in the Administrative Tools folder on the **Programs** menu for that user.
- To make an item subordinate to an item in the console tree other than the console root, click the appropriate item in **Snap-ins added to** before you click **Add** in step 2.
- For more information on Windows Installer, go to MSDN Online Downloads.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add an extension snap-in to an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add an extension snap-in to an MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc path***filename***.msc/a**, and then click **OK**.

2. On the **File** menu, click **Add/Remove Snap-in**, and then click the item that you want to extend.

3. On the **Extensions** tab, in **Available extensions**, select the check box next to the extension you want to add, and then click **OK**.

## Notes

- To add every extension available for a given item, on the **Extensions** tab, select the **Add all extensions** check box. To add only certain extensions, clear this check box.
- You can also use this procedure to remove extensions from a console by clearing the check box for an extension that was previously selected.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a published extension snap-in to an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a published extension snap-in to an MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. On the **File** menu, click **Add/Remove Snap-in** .
3. On the **Extensions** tab, in **Snap-ins that can be extended**, click the snap-in that you want to extend.
4. In **Available extensions**, select the check box next to the published extension you want to add, and then click **Download**.
5. If one or more wizards appear, follow the instructions on your screen, and then click **OK**.

### Important

- If you select the **Add all extensions** check box on the **Extensions** tab, only extension snap-ins that are locally installed and registered are added to the console. You must specifically download extension snap-ins from the directory service to make them available in a console. Thus, to add all published extensions for a given item, do not select the **Add all extensions** check box, but instead select the check box next to each published extension.

### Notes

- For extension snap-ins that are available from the Active Directory directory service, the snap-in names are followed by the phrase **(not installed)**.
- You can only access extension snap-ins published in Active Directory if the computer you are using is running Windows 98 with Windows Installer, Windows NT 4.0 with Windows Installer, or Windows Millennium Edition. In addition, the computer must be part of a Windows domain. For more information about publishing applications and Windows Installer, see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a taskpad view in a saved MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a taskpad view in a saved MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc path***filename***.msc/a**, and then click **OK**.

2. In the console tree, click a snap-in item.
3. On the Action menu, click **New Taskpad View**.
4. Follow the instructions in the New Taskpad View wizard.
5. If you want to create tasks immediately after you create the taskpad view, select the **Start New Task wizard** check box in the final screen of the wizard.

**Note**

- You can also create a taskpad view in a new console, but you must first add a snap-in to the console.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create tasks for a taskpad view in a saved MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. In the console tree, click an item associated with the taskpad view; and, on the **Action** menu, click **Edit Taskpad View**.
3. On the **Tasks** tab, click **New**.
4. Follow the instructions in the New Task wizard.

## Notes

- If you are creating a new taskpad view and want to add a task, you can start the New Task wizard by selecting the **Start New Task wizard** check box in the final screen of the New Taskpad View wizard.
- On the **Shortcut Menu Command** page of the New Task wizard, in **Command source**, if you selected **Tree item** task and cannot view all items in the console tree, you must expand the console tree manually before starting the New Task wizard.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit a taskpad view in a saved MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a taskpad view in a saved MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. In the console tree, click an item associated with the taskpad view. On the **Action** menu, click **Edit Taskpad View**.

3. On the **General** tab, do the following:

   - To change the name for the taskpad view, in **Name**, type a new name. The name appears in the upper left corner of the taskpad view and on the tab on the bottom edge of the taskpad view.
   - To change the description for a taskpad view, in **Description**, type a new description. The description appears under the name in the taskpad view.
   - To change the list format, or to configure the taskpad view to contain tasks only, under **Style for the details pane,** click a new list format, or click **No list**.
   - To remove the **Standard** tab from view, check **Hide Standard tab**.
   - To configure task descriptions, under **Style for task descriptions**, click **Text** or **InfoTip**. Text descriptions are displayed to the right of a task. InfoTip descriptions are displayed as pop-up windows when a user points to tasks with the mouse.
   - To change the size of the list, in **List size**, click a new size for the width (Vertical list) or height (Horizontal list) of the list.

4. Click **Options**, and then do one of the following:

   - To associate the taskpad view that shows only the currently selected item in the console tree, click **Selected tree item**.
   - To associate the taskpad view that shows all items in the console tree of the same type as the currently selected item, click **All tree items that are the same type as the selected tree item**.

   **Note**

   - If you click this option and want the taskpad view to appear by default, select the **Change default display to this taskpad view for these tree items** check box, instead of the view on the **Standard** tab.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit tasks in a taskpad view in a saved MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit tasks in a taskpad view in a saved MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. In the console tree, click an item associated with the taskpad view, and on the **Action** menu, click **Edit Taskpad View**.

3. On the **Tasks** tab, under **Display these tasks**, click a task, and then do any of the following:

   - To move the selected task up the display list in the taskpad view, click **Move Up**.
   - To move the selected task down the display list in the taskpad view, click **Move Down**.
   - To delete the task from the display list in the taskpad view, click **Remove**.

4. On the **Tasks** tab, under **Display these tasks**, click **Modify**, and then do any of the following:

   - To change the name of a task, on the **General** tab, in **Task name**, type a new name.
   - To change the description for a task, on the **General** tab, in **Description**, type a new description. Depending on how you configured the taskpad view, the result appears either to the right of the task or on the screen when a user points to the task with the mouse.
   - To change the icon for the task, on the **Task Icon** tab, click a new icon, and then click **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add an item to the Favorites list in an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add an item to the Favorites list in an MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. In the console tree, click the item that you want to add to the Favorites list.
3. In the details pane, click either the **Standard** tab or the tab for the taskpad view you want to add.
4. On the **Favorites** menu, click **Add to Favorites**.
5. In **Create in**, do one of the following:

   - To add an item to an existing folder, click the folder in which you want the item to reside, and then click **OK**.
   - To add an item to a new folder, click the folder you want as the parent, and then click **New Folder**. In **Folder name**, type a name, click **OK**, and then click **OK** again.

**Note**

- The **Standard** tab and tabs for taskpad views are only available in the details pane of a console if you click an item in the console tree that is configured to have a taskpad view. Otherwise, no tabs are visible in the details pane.

# Install a program managed by an MMC snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a program managed by an MMC snap-in**

1. Click **Start**.
2. Click **Control Panel**.
3. Click **Add or Remove programs**.
4. Follow the instructions on the screen.

If you are using Windows 2000, do the following:

1. Click **Start**.
2. Click **Settings**.
3. Click **Control Panel**.
4. Click **Add or Remove programs**.
5. Follow instructions on the screen.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set MMC console options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set MMC console options**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. On the **File** menu, click **Options**.
3. To change the title for the console, type a new title in the box.
4. To change the icon for the console, click **Change Icon**. In **File Name**, type the path to a file containing icons.
5. Under **Current icon** click an icon, and then click **OK**.
6. To change the default mode for the console, in **Console mode**, click the mode that you want the console to open in.
7. If the default console mode for the console is one of the user modes, do the following:

   - To prevent users from editing the console, select the **Do not save changes to this console** check box.
   - To enable users to access the **Customize View** dialog box, select the **Allow the user to customize views** check box.

## Notes

- If you change the title of a console, the title bar does not display the path of items clicked in the console tree. However, if you do not change the title, or if you delete the title, the paths are displayed.
- Many files contain icons that can be used for custom consoles. For example, you can find more icons in Shell32.dll, located in the *%systemroot%*\System32 folder.
- To stop receiving the message **Save console settings to** *console name***?**, which appears each time you close a console opened in author mode, set the default mode for the console to one of the user modes and then clear the **Do not save changes to this console** check box. Any changes to the console are saved by default.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save an MMC console file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save an MMC console file**

- In an MMC console opened in author mode, on the **File** menu, click **Save**.

## Notes

- To open a saved console in author mode, right-click the .msc file and then click **Author** or click **Start**, then click **Run**, and type **mmc path**_filename_**.msc /a**.

- If the console is not opened in author mode, the **Save** option on the **File** menu is not available. In this case, saving is determined by whether the Do not save changes to this console check box was selected when the console was configured. This check box is available by clicking **Options** on the **File** menu. If this check box was not selected, changes to the console are automatically saved when you close MMC. If it was selected, changes to the console are discarded when you close MMC.

- If a console is saved to the per-user Administrative Tools folder (located at %systemdrive%\Documents and Settings\user\Start Menu\Programs\Administrative Tools), it is then available in the Administrative Tools folder on the **Programs** menu for that user.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify a saved MMC console file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modify a saved MMC console file**

- Rename an item on the console tree of an MMC console
- Remove a snap-in or other item from an MMC console
- Make a new console window from an MMC console
- Make a new console window from part of an MMC console tree
- Open a saved MMC console for local and remote computers

# Rename an item on the console tree of an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename an item on the console tree of an MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. In the console tree, click the item that you want to rename.

3. On the **Action** menu, click **Rename**, and then type the new name.

### Note

- Not all items in the console tree can be renamed. If the **Rename** command does not appear on the **Action** menu, you cannot rename the item.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a new console window from an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a new console window from an MMC console**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. On the **Window** menu, click **New Window**.

### Note

- The new console window is rooted at the console root of the saved console.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a new console window from part of an MMC console tree

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a new console window from part of an MMC console tree**

1. Open a saved console in author mode by doing one of the following:

   - Right-click the .msc file, and then click **Author**.
   - Click **Start**, click **Run**, type **mmc** *path**filename.msc* **/a**, and then click **OK**.

2. In the console tree, click the item that you want to become the console root of the new console.

3. On the **Action** menu, click **New Window from Here**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- View the associated snap-in and item for a property page

# Viewing extensions to snap-ins

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view extensions to snap-ins**

1. Click **Start**, go to **Additional Programs** or **All Programs**, go to **Administrative Tools**, and then click the console file name.
2. In the **Add/Remove Snap-in** dialog box, go to **Snap-ins added to:** and select the snap-in you want to use.
3. Click the **Extensions** tab.
4. Extensions will be displayed in the **Available extensions** box.
5. Extensions from other snap-ins can be displayed from selections in the **Snap-ins that can be extended:** item list.

## Notes

- You must be in author mode to view the **Add/Remove snap-ins** menu.
- By default, user added snap-ins are saved in Administrative Tools (**%SystemDrive%/Documents and Settings/%UserName%/Start/Programs/Administrative Tools**). They may be saved elsewhere at the user's discretion.
- To open the console file in author mode, right-click the console file name and select **Author**.
- In the opened MMC console, click **File**. From the drop-down menu, select **Add/Remove Snap-in**.
- The **Add/Remove snap-in** menu is not available in any of the user modules.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Using disk cleanup tab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To use the disk cleanup tab

1. Open MMC.
2. Click **File** on the menu bar.
3. Click **Options** on the drop-down menu. The **Options** dialog box opens, displaying two tabs.
4. Click the **Disk Cleanup** tab.
5. To delete the console files, click **Delete Files**.
6. Close the dialog box by clicking **OK**.
7. To cancel, click **Cancel** at the bottom of the dialog box.

### Notes

- To open MMC, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- The text on the **Disk Cleanup** tab states that changes to the view of a console file are saved in your profile. The amount of disk space used on the computer for these console changes is indicated on the **Disk Cleanup** tab.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Hide or display features of a saved MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To hide or display features of a saved MMC console**

1. Open a saved console.
2. On the **View** menu, click **Customize**.
3. Under **MMC**, do the following:
   - To display or hide the console tree, select or clear the **Console tree** check box.
   - To display or hide the **Action** and **View** menus, select or clear the **Standard menus (Action and View)** check box.
   - To display or hide the console toolbar, select or clear the **Standard toolbar** check box.
   - To display or hide the status bar at the bottom of the console window, select or clear the **Status bar** check box.
   - To display or hide the description bar along the top of the details pane, select or clear **Description bar**.
   - To display or hide the tabs along the bottom of the details pane, select or clear the **Taskpad navigation tabs** check box.

### Important

- If you clear the **Standard menus (Action and View)** check box and close the **Customize View** dialog box, you cannot access commands on the **Action** and **View** menus, including the **Customize** command. In this situation, to access the **Customize View** dialog box, click the system menu (the icon in the upper-left corner of the console), and then click **Customize View**.

### Notes

- To open a saved console in author mode, right-click the .msc file and then click **Author**.
- Click **Start**, click **Run**, and then type **mmc** *path**filename.msc* **/a**.
- As you select or clear check boxes, view the console to confirm that the changes you make are what you expected.
- If you hide the **Console tree**, the **Favorites** menu, if applicable, will still be visible on the menu bar.
- Displaying or hiding the tabs along the bottom of the details pane can also be done from any pre-existing taskpad view. Select **Action** from the menu, click **Edit taskpad view**, select or deselect the **Hide Standard tab** check box, and then click **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Hide or display menus and toolbars for snap-ins

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To hide or display menus and toolbars for snap-ins**

1. Open a saved console.
2. On the **View** menu, click **Customize**.
3. Under **Snap-in**, do one or more of the following:
   - To display or hide menus specific to snap-ins, select or clear the **Menus** check box.
   - To display or hide toolbars specific to snap-ins, select or clear the **Toolbars** check box.

## Notes

- To open a saved console in author mode, right-click the .msc file and then click **Author**. Click **Start**, then click **Run**, and type **mmc** *path**filename.msc* **/a**.
- When you select or clear the **Menus** and **Toolbars** check boxes, the menus and toolbars are displayed or hidden for all snap-ins in the console, not just the currently selected snap-in. If toggling the check boxes does not change the view, the currently selected snap-in does not have custom menus or toolbars.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reorder columns in an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reorder columns in an MMC console**

1. In an open MMC console, click an item in the console tree that displays columns in the details pane.
2. On the **View** menu, click **Add/Remove Columns**.
3. In the **Add/Remove Columns** dialog box, under **Displayed columns**, click a column name, and then click **Move Up** or **Move Down** to change the position of the column.

## Notes

- You can also reorder columns in the details pane by using a mouse to drag a column heading to the left or right of its original position. As you drag a column, highlighting between the column headings indicates the new position of the column.
- You can resize columns by using the mouse to drag column headings.
- This feature is not enabled for all items. If you do not see the **Add/Remove Columns** option on the **View** menu, you cannot use this feature for the selected item.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Hide or display columns in an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To hide or display columns in an MMC console**

1. In an open MMC console, click an item in the console tree that displays columns in the details pane.
2. On the **View** menu, click **Add/Remove Columns**.
3. In the **Add/Remove Columns** dialog box, do the following:
   - To hide a column, in **Displayed columns**, click the column you want to hide, and then click **Remove**.
   - To display a column, in **Available columns**, click the column you want to display, and then click **Add**.

## Notes

- You might not be able to hide some columns in the details pane.
- The hide or display columns feature is not enabled for all items. If you do not see the **Choose Columns** option on the **View** menu, you cannot use this feature for the selected item.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Filter rows in an MMC console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To filter rows in an MMC console**

1. In an open MMC console, click an item in the console tree that displays columns in the details pane.

2. On the **View** menu, click **Filter**. Modify the options on the **Filter** tab of the **Application Properties** dialog box as desired.

   Filters appear below the column headings in the details pane.

### Note

- This feature is not enabled for all items. If you do not see the **Filter** option on the **View** menu, you cannot use this feature for the selected item.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export columns in an MMC console to a text file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export columns in an MMC console to a text file**

1. In an open MMC console, click an item in the console tree that displays columns in the details pane.
2. On the **Action** menu, click **Export List**.
3. In the **Export List** dialog box, enter the following information:
   - In **Save in**, click a location to save the file.
   - In **File name**, type a name for the file.
   - In **Save as type**, click a file format in the list.
   - To export only certain rows, select the **Save Only Selected Rows** check box.
4. Click **Save**.

## Notes

- To export only certain rows in the details pane, select the rows.
- If you want to export the entire contents of the details pane, skip the preceding step.
- Some snap-ins do not provide the ability to select more than one row in the details pane. For these snap-ins, you can export all the rows in the details pane, but not selected rows only.
- Unicode file formats are not available in **Save as type** for operating systems earlier than Windows NT 4.0.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the associated snap-in and item for a property page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the associated snap-in and item for a property page**

1. In the console tree or details pane of an open MMC console, right-click the item for which you want to view properties and then click **Properties**.

2. In the properties dialog box, do the following:

    - To view which snap-in provided a particular property page in the dialog box, hold down the CTRL key and point to the label of one of the tabs.

    - To view the location in the console tree for the item associated with the properties dialog box, hold down the CTRL key and point to the title bar of the properties dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set policy for MMC and snap-ins

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set policy for MMC and snap-ins**

- Restrict access to author mode in MMC
- Restrict access to author mode in MMC for a domain
- Restrict access to a permitted list of snap-ins
- Restrict access to a permitted list of snap-ins for a domain
- Permit or restrict access to a snap-in
- Permit or restrict access to a snap-in for a domain

# Restrict access to author mode in MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restrict access to author mode in MMC**

1. Open MMC.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, click **Group Policy Object Editor**, and then click **Add**.
4. In the **Select Group Policy** wizard, do one of the following:
   - To edit the local Group Policy Object, leave the **Group Policy Object** box set to **Local Computer**, and then click **Finish**.
   - To specify a different Group Policy Object, click **Browse**, select the object, click **OK**, and then click **Finish**.
5. Click **Finish**, click **Close**, and then click **OK**.

   The Group Policy Object Editor snap-in opens the specified Group Policy Object Editor.
6. In the console tree, click **Microsoft Management Console**.

   **Where?**

   - *PolicyName* Policy/User Configuration/Administrative Templates/Windows Components/Microsoft Management Console
7. In the details pane, double-click **Restrict the user from entering author mode**.
8. On the **Setting** tab, do one of the following:
   - To allow the user to use author mode in MMC, click **Not Configured** or **Disabled**.
   - To restrict the user from using author mode in MMC, click **Enabled**.

**Notes**

- To open MMC, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- Once **Restrict the user from entering author mode** has been enabled, any attempt to reaccess the console results in an error message indicating blocked access to the console in author mode. Users with administrator credentials can regain access to author mode by clicking **Start/Run/gpedit.msc** which opens the Group Policy Object Editor for local computer policy. Next, click **User Configuration/Administrative Templates/Windows Components/Microsoft Management Console.** Then double-click **Restrict the user from entering author mode** in the details pane. Unclick the radio button **Enabled** so that either **Not Configured or Disabled** has been selected.
- This feature applies only in a network where Group Policy Object Editor has been configured; a system administrator must enable Group Policy Object Editor. Not available in Windows XP Home Edition.

- For more information, click the **Explain** tab in the **Restrict the user from entering author mode properties** dialog box, and see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restrict access to author mode in MMC for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restrict access to author mode in MMC for a domain**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the organizational unit for which you want to configure policy, and then click **Properties**.
3. On the **Group Policy** tab, click **Edit** on the property page.
4. In the console tree, click **Microsoft Management Console**.

   **Where?**

   - *PolicyName* Policy/User Configuration/Administrative Templates/Windows Components/Microsoft Management Console

5. In the details pane, double-click **Restrict the user from entering author mode**.
6. On the **Policy** tab, do one of the following:

   - To allow the user to use author mode in MMC, click **Not Configured** or **Disabled**.
   - To restrict the user from using author mode in MMC, click **Enabled**.

## Notes

- To open Active Directory Users and Computers, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
- Active Directory applies only in a network where Group Policy Object Editor has been configured. You must be a domain Administrator, or have equivalent rights, and use a computer configured as a domain controller to configure Group Policy Object Editor for a domain.
- For more information, click the **Explain** tab in the **Restrict the user from entering author mode properties** dialog box, and see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restrict access to a permitted list of snap-ins

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restrict access to a permitted list of snap-ins**

1. Open MMC.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, click **Group Policy Object Editor**, and then click **Add**.
4. In the **Select Group Policy** wizard, do one of the following:
   - To edit the local Group Policy Object, leave the **Group Policy Object** box set to **Local Computer**, and then click **Finish**.
   - To specify a different Group Policy Object, click **Browse**, select the object, click **OK**, and then click **Finish**.
5. Click **Finish**, click **Close**, and then click **OK**.

   The Group Policy Object Editor snap-in provides access to the specified Group Policy object.
6. In the console tree, click **Microsoft Management Console**.

   **Where?**

   - *PolicyName* Policy/User Configuration/Administrative Templates/Windows Components/Microsoft Management Console
7. In the details pane, double-click **Restrict users to the explicitly permitted list of snap-ins**.
8. On the **Policy** tab, do one of the following:
   - To permit the user to access snap-ins that are not explicitly restricted, click **Not Configured** or **Disabled**.
   - To restrict the user from accessing any snap-in that is not explicitly permitted, click **Enabled**.

**Notes**

- To open MMC, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- This feature is not available in Windows XP Home Edition.
- This feature applies only in a network where Group Policy object has been configured; a system administrator must enable Group Policy object.
- If you enable this policy, only permitted snap-ins appear in the list of available snap-ins in the **Add Standalone Snap-in** dialog box in MMC.
- For more information, click the **Explain** tab in the **Restrict users to the explicitly permitted list of snap-ins**

**properties** dialog box, and see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Setting Group Policy in MMC
Permit or restrict access to a snap-in
Group Policy (pre-GPMC)

# Restrict access to a permitted list of snap-ins for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restrict access to a permitted list of snap-ins for a domain**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the organizational unit for which you want to configure policy, and then click **Properties**.
3. On the **Group Policy** tab, click **Edit**.

   The Group Policy Object Editor appears.
4. In the console tree, click **Microsoft Management Console**.

   **Where?**

   - *PolicyName* Policy/User Configuration/Administrative Templates/Windows Components/Microsoft Management Console
5. In the details pane, double-click **Restrict users to the explicitly permitted list of snap-ins**.
6. On the **Policy** tab, do one of the following:

   - To permit the user to access snap-ins that are not explicitly restricted, click **Not Configured** or **Disabled**.
   - To restrict the user from accessing any snap-in that is not explicitly permitted, click **Enabled**.

## Notes

- To open Active Directory Users and Computers, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
- Active Directory applies only in a network where Group Policy Object Editor has been configured. You must be a domain Administrator, or have administrative credentials, and use a computer configured as a domain controller to configure Group Policy Object Editor for a domain.
- If you enable this policy, only permitted snap-ins appear in the list of available snap-ins in the **Add Standalone Snap-in** dialog box in MMC.
- For more information, click the **Explain** tab in the **Restrict users to the explicitly permitted list of snap-ins properties** dialog box, and see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Group Policy (pre-GPMC)

# Permit or restrict access to a snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To permit or restrict access to a snap-in**

1. Open MMC.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Under **Snap-in**, click **Group Policy Object Editor**, and then click **Add**.
4. In the **Select Group Policy** wizard, do one of the following:
   - To edit the local Group Policy Object, leave the **Group Policy Object** box set to **Local Computer**, and then click **Finish**.
   - To specify a different Group Policy Object, click **Browse**, select the object, click **OK**, and then click **Finish**.
5. Click **Finish**, click **Close**, and then click **OK**.
6. In the console tree, click **Restricted/Permitted snap-ins**.

   **Where?**

   - *PolicyName* Policy/User Configuration/Administrative Templates/Microsoft Management Console/Restricted/Permitted snap-ins
7. In the details pane, double-click the snap-in that you want to permit or restrict, and then do one of the following:
   - To enable the user to access this snap-in (unless the user is restricted by the **Restrict users to the explicitly permitted list of snap-ins** policy), click **Not Configured**.
   - To permit the user to access this snap-in, click **Enabled**.
   - To restrict the user from accessing this snap-in, click **Disabled**.

## Notes

- To open MMC, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- This feature applies only in a network where Group Policy object has been configured; a system administrator must enable Group Policy object.
- For more information, click the **Explain** tab in the *snap-in* **Properties** dialog box, and see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Permit or restrict access to a snap-in for a domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To permit or restrict access to a snap-in for a domain**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the organizational unit for which you want to configure policy, and then click **properties**.
3. On the **Group Policy** tab, click **Edit**.

   The Group Policy Object Editor appears.
4. In the console tree, click **Restricted/Permitted snap-ins**.

   **Where?**

   - *PolicyName* Policy/User Configuration/Administrative Templates/Windows Components/Microsoft Management Console/Restricted/Permitted snap-ins
5. In the details pane, double-click the snap-in that you want to permit or restrict, and then do one of the following:

   - To enable the user to access this snap-in (unless the user is restricted by the **Restrict users to the explicitly permitted list of snap-ins** policy), click **Not Configured**.
   - To permit the user to access this snap-in, click **Enabled**.
   - To restrict the user from accessing this snap-in, click **Disabled**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, point to **programs**, point to **Administrative Tools**, and then click **Active Directory Users and Computers**.
- Active Directory is not available in Windows XP Professional or Windows XP Home Edition.
- This feature applies only in a network where Group Policy Object Editor has been configured. You must be a domain Administrator, or have administrative credentials, and use a computer configured as a domain controller to configure Group Policy Object Editor for a domain.
- When you restrict or explicitly permit access to a snap-in, the snap-in is added to a list of restricted or permitted snap-ins. The restricted list takes precedence over the permitted list, so that if the same snap-in exists on both lists, access to the snap-in is restricted.
- For more information, click the **Explain** tab in the *snap-in* **properties** dialog box, and see Help.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# MMC overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC overview**

You can use Microsoft Management Console (MMC) to create, save, and open administrative tools (called MMC consoles) that manage the hardware, software, and network components of your Windows system. MMC can be run on the various Windows 9x and Windows NT operating systems, as well as Windows XP Home Edition, Windows XP Professional, and the Windows Server 2003 family of operating systems.

MMC does not perform administrative functions, but hosts tools that do. The primary type of tool you can add to a console is called a snap-in. Other items that you can add include ActiveX controls, links to Web pages, folders, taskpad views, and tasks.

There are two ways that you can use MMC: in user mode, working with existing MMC consoles to administer a system, or in author mode, creating new consoles or modifying existing MMC consoles. For more information about the differences between user and author mode, see Console access options.

Keep security in mind at all times. It is good practice for administrators to use an account with restrictive permissions to perform routine, non-administrative tasks, and to use an account with administrative credentials only when performing specific administrative tasks. To accomplish this without logging off and back on, log on with a regular user account, and then use the **Runas** command to run the tools that require the administrative credentials. For detailed information, see Runas.

For detailed information about all security options, see Best practices for security, Security overview, and Local Users and Groups Best practices.

For Help with other aspects of the Windows Server 2003 family of operating systems, click **Start**, then **Help and Support** to access the **Help and Support Center**.

# Understanding MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding MMC**
This section covers:

- MMC consoles
- Group Policy and MMC
- MMC in author mode

# MMC consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC consoles**

A new MMC console consists of a window divided into two panes. The left pane displays the console tree. The console tree shows the items that are available in the console. The right pane contains the details pane. The details pane shows information about, and functions pertaining to, these items. As you click different items in the console tree, the information in the details pane changes. The details pane can display many types of information including Web pages, graphics, charts, tables, and columns.

Each console has its own menus and toolbar, separate from those of the main MMC window, that help a user perform tasks. For more information about the main MMC window, see The MMC window.

The operating system you are using may already have preconfigured and saved console files available on the **Programs** menu or in the Administrative Tools folder in Control Panel.

Consoles which have been created with older versions of MMC (versions 1.1 and 1.2) can be read by MMC version 2.0. However, when files are saved by MMC version 2.0, they are automatically converted and cannot be restored to earlier versions. For further information, see Using files created with earlier versions of MMC with MMC 2.0.

# Group Policy and MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy and MMC**

Only administrators can use Group Policy to restrict or allow access to specific snap-ins or restrict the ability of a user or group to use author mode in MMC. This applies in a network where Group Policy has been configured.

To set policies for users of a particular computer, you must be an administrator for that computer or have equivalent rights. To set policies for an organizational unit in a domain, you must be an administrator for that domain or have equivalent rights. You cannot use MMC to create computer policies; you can *only* create user policies.

For more information about Group Policy, see Help.

For more information about applying Group Policy to MMC, see Setting Group Policy in MMC.

# MMC in author mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC in author mode**

You can use MMC in author mode to create new consoles or modify existing consoles. To create an administrative tool, you add snap-ins and other items to a console. You can create additional console windows that provide views of the various items that make up a console. You can also create taskpad views that contain shortcut links to run menu commands from different locations and tools in the console, as well as run command-line functions. After a console is saved, you can distribute it to users.

This section covers:

- The MMC window
- Snap-ins
- Taskpad views and tasks
- The console tree and console root
- The Favorites list
- Console access options

# The MMC window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The MMC window**

The components of an MMC console are contained in the MMC window. This window has several menus and a toolbar that provide commands to open, create, and save MMC consoles. The menu and toolbar on the MMC window are called the main menu bar and the main toolbar, respectively. In addition, there is a status bar at the bottom of the window and a description bar along the top of the details pane. To view the MMC window, open MMC by clicking **Start**, then **Run**, typing "mmc", and then clicking **OK**.

When you open a new MMC console, a console window appears in the workspace in the MMC window. In the console window, you can assemble and configure a new console and then work with the tools in the console. After you add items to a console, you can hide the main menu bar, main toolbar, description bar, and status bar to prevent users from making changes to the console. For more information, see Hide or display features of a saved MMC console and Hide or display menus and toolbars for snap-ins.

# Snap-ins

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Snap-ins**

A snap-in is the basic component of an MMC console. Snap-ins always reside in a console; they are not run outside of MMC.

When you install a component that has a snap-in associated with it, the snap-in is available to anyone creating a console on that computer (unless restricted by a user policy). For information about user policies, see Group Policy and MMC.

**Stand-alone and extension snap-ins**

MMC supports two types of snap-ins: stand-alone snap-ins and extension snap-ins. You can add a stand-alone snap-in, typically called a snap-in, to a console tree without adding another item first. An extension snap-in, typically called an extension, is always added to a stand-alone or extension snap-in that is already on the console tree. When extensions are enabled for a snap-in, they operate on the objects controlled by the snap-in, such as a computer, printer, modem, or other device.

When you add a snap-in or extension to a console, it might appear as a new item in the console tree, or it might add shortcut menu items, additional toolbars, additional property pages, or wizards to a snap-in already installed in the console.

**Adding snap-ins to a console**

You can add a single snap-in or multiple snap-ins and other items to a console. In addition, you can add multiple instances of a particular snap-in to the same console to administer different computers or to repair a damaged console. Each time you add a new instance of a snap-in to a console, any variables for the snap-in are set at default values until you configure the snap-in. For instance, if you configure a particular snap-in to manage a remote computer and then add a second instance of the snap-in, the second instance will not automatically be configured to manage the remote computer.

Typically, you can only add snap-ins that are installed on the computer you are using to author a console. However, if your computer is part of a domain, you can use MMC to download any snap-ins that are not locally installed, but that are available in the Active Directory directory service. For more information about adding published snap-ins and extensions to a console, see Creating consoles. For more information about distributing software using Active Directory, see Delegating administration.

# Taskpad views and tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Taskpad views and tasks**

Taskpad views are pages to which you can add views of the details pane of a console, as well as shortcuts to functions both inside and outside a given console. You can use these shortcuts to run tasks such as starting wizards, opening property pages, performing menu commands, running command lines, and opening Web pages. You can configure a taskpad view so that it contains all the tasks a given user might need. In addition, you can create multiple taskpad views in a console, so that you can group tasks by function or user.

A taskpad view may make it easier for new users to perform their jobs. For instance, you can add applicable tasks to a taskpad view and then hide the console tree, so that users can begin using tools before they are familiar with the location of particular items in the console tree or operating system.

You might also use taskpad views to make complex tasks easier. For instance, if you must frequently perform a task involving multiple snap-ins and other tools, you can present tasks to open or run the necessary dialog boxes, property pages, command lines, and scripts in a single location.

For more information about creating taskpad views and tasks, see Creating consoles.

# The console tree and console root

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The console tree and console root**

The console tree is a hierarchical structure in the left pane of an MMC console. The console tree shows the items that are available in a console. These items can include folders, snap-ins, controls, Web pages, and other tools.

To view the console tree of a new console, open MMC by clicking **Start**, then **Run**, type "mmc", and then click **OK**.

In a new console, the only item on the console tree is a folder labeled Console Root. You can create the administrative functions of the console by adding items to the console. For instructions about adding items to a console, see Creating consoles.

You do not need to put a console window on the console root. You can locate a console window on any item in the console tree. This hides items in the console tree above the old root and focuses the window on the new console root and any administrative tools under it.

For instructions about changing where a console is rooted, see Make a new console window from part of an MMC console tree.

**Containers on the console tree**

A container is any item on the console tree to which objects are added. Double-click ⊞ to expand a container and view its contents, and the minus sign ⊟ to collapse the container. The default container is a folder, which you can use to group related items in a console tree. However, you can also use MMC to add tools to items other than folders, which then also become containers.

The console root is a container. Its only function is to contain the console tree. Typically, the top item in a snap-in is a folder or another container.

Another type of item that can contain other items is a viewable item. When you click a viewable item, it displays a list, text, or graphic information in the details pane instead of additional items. Web pages are viewable items because they require a browser, which can open only in the details pane. Do not add items to viewable items because user might hide the console tree. If so, they might not know that a viewable item contains other items. Instead, if you have a collection of viewable items, you can add a folder to the console tree and group the viewable items in the folder. Then a user can select from all the items when the console tree is hidden.

For instructions about hiding the console tree, see Hide or display features of a saved MMC console.

One type of item that cannot contain other items is a leaf. When you click a leaf, it lists items in the details pane. These are typically items that are individually contained on the console tree. However, when items number in the hundreds or thousands, a snap-in uses a leaf instead of a container.

**Adding new functionality to a console**

You might find that none of the snap-ins provided by the **Add/Remove Snap-in** command provide the exact capabilities you require. You can try the following possible solutions:

- Check for additional snap-ins or extensions that might have been posted on the Web by Microsoft or other vendors.
- Author your own extension to an existing snap-in, or author a new stand-alone snap-in.

For more information about these options, see MMC Resources.

# The Favorites list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The Favorites list**

The Favorites list is located on the **Favorites** menu. You can use the Favorites list to create shortcuts to items in the console tree. For your convenience, you can add shortcuts to tools that you use often or tools that are several levels down in the console tree. You can also use the Favorites list to make it easier for new users to complete tasks. For instance, you can create a console that has shortcuts in the Favorites list to only the items in the console tree that a given user needs to perform a task. You can then hide the console tree to further simplify the view.

You can also use the Favorites list to organize taskpad views. For example, a complex console might have multiple taskpad views distributed among the multiple items in the console tree. However, you can add all these taskpad views to the Favorites list, which enables users to access them from a single location.

For more information, see Creating consoles.

# Console access options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Console access options**

When building a custom console, you can assign the console one of two access options: author mode or user mode. There are, in turn, three levels of user mode, so that there are four options for default access to a console:

| Mode | Description |
|---|---|
| Author mode | Enables full customization of the MMC console, including the ability to add or remove snap-ins, create new windows, create Favorites and taskpads, and access to all the options of the **Customize View** and **Options** dialog boxes. Users creating a custom console file for themselves or others typically use this mode. The resulting console is usually saved in one of the following user modes. |
| User mode-full access | The same as author mode, except that users cannot add or remove snap-ins, change console options, create Favorites, or create taskpads. |
| User mode-limited access, multiple windows | Provides access only to those parts of the console tree that were visible when the console file was saved. Users can create new windows but cannot close any existing windows. |
| User mode-limited access, single window | Provides access only to those parts of the console tree that were visible when the console file was saved. Users cannot create new windows. |

You can configure these options in the **Options** dialog box in MMC. For instructions about opening this dialog box, see Set MMC console options.

Changes made to consoles in author mode and consoles in user mode are saved differently. If you work with a console in author mode, when you close the console you are prompted to save your changes. However, if you work with a console in user mode and have cleared the **Do not save changes to this console** check box, available by clicking **Options** on the **File** menu, changes will be saved when you close the console.

If any of the following conditions apply, the default mode for a console is ignored and a console is opened in author mode:

For more information about console modes and their command-line syntax for MMC, see Open MMC.

Author mode access for MMC is unnecessary for users who do not need to create or change MMC consoles. A system administrator can configure user profile settings to prevent users from opening MMC in author mode, by disabling the **/a** option or the shortcut menu option. In addition, an administrator can use Group Policy settings to prevent users from opening MMC and saved consoles in author mode. For more information, see Group Policy and MMC.

# Using MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using MMC**

This section covers:

- Runas
- Using files created with earlier versions of MMC with MMC 2.0
- Using MMC consoles
- Using property pages in saved consoles
- Setting Group Policy in MMC
- Using the MMC help system
- Authoring MMC consoles
- Running 32-bit and 64-bit snap-ins in Windows Server 2003 and Windows XP Professional operating systems

# Using the runas command with MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the runas command with MMC**

It is good practice for administrators to use an account with restrictive permissions to perform routine, nonadministrative tasks, and to use an account with broader permissions only when performing specific administrative tasks. To accomplish this without logging off and back on, log on with a regular user account, and then use the **runas** command to run the tools that require the broader permissions.

With the **runas** command, you can run programs (*.exe), saved MMC consoles (*.msc), shortcuts to programs and saved MMC consoles, and Control Panel items. You can run them as an administrator while you are logged on to your computer as a member of another group, such as the Users or Power Users group.

You can use the **runas** command start any program, MMC console, or Control Panel item. As long as you provide the appropriate user account and password information, the user account has the ability to log on to the computer, and the program, MMC console, or Control Panel item is available on the system and to the user account.

With the **runas** command, you can administer a server in another forest (the computer from which you run a tool and the server you administer are in different domains).

If you try to start a program, MMC console, or Control Panel item from a network location using **runas**, it might fail because the credentials used to connect to the network file share are different from the credentials used to start the program. The latter credentials may not be able to gain access to the same network file share.

Some items, such as the Printers folder and desktop items, are opened indirectly and cannot be started with the **runas** command.

If the **runas** command fails, the **Secondary Logon** service might not be running or the user account you are using might not be valid. To check the status of the **Secondary Logon** service, in Computer Management, click **Services and Applications**, and then click **Services**. To test the user account, try logging on to the appropriate domain using the account.

For details about the **runas** command, see Runas.

# Using files created with earlier versions of MMC with MMC 2.0

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using files created with earlier versions of MMC with MMC 2.0**
MMC 2.0 reads consoles created with older versions of MMC.

Methods of saving files created in older versions of MMC include the following:

- If you work in MMC 2.0 authoring mode with a file created in an earlier version of MMC, you can save the file only in MMC 2.0.
- You can work with an MMC 1.2 file in MMC 2.0 in any of the user modes.
- In user modes, MMC 2.0 saves console changes from an earlier version in the new format into the user's profile directory. That converted file has all of the user's changes, such as window resizing. Additionally, the original console (from the earlier version of MMC) remains intact in its original format. However, when converted files are saved, the earlier format cannot be restored.

When you open a console from an earlier MMC version, MMC 2.0 opens it with the selected modified settings. However, if you copy this modified console to another computer, or delete the settings through the MMC menu **File/Options**, you will lose these modifications.

For more information about MMC, see:

- Add a snap-in to a new MMC console for a local computer
- Create a desktop shortcut to open MMC
- Install a program managed by an MMC snap-in
- Open a saved MMC console for local and remote computers

# Using MMC consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using MMC consoles**

You might need to use preconfigured MMC consoles (commonly called "saved consoles") that are part of your operating system or an application and never need to build custom consoles of your own. Typically, preconfigured consoles are available in the Administrative Tools folder in Control Panel or from the **Start** menu. If you save a custom console to a per-user Administrative Tools folder (located at *systemdrive*\Documents and Settings*user*\Start Menu\Programs\Administrative Tools), it is then available in the Administrative Tools folder on the **Programs** menu for that user.

It is likely that any preconfigured consoles that came as part of your operating system are configured to open in one of the three user modes. The default mode is **User mode - limited access, single window**. For more information about default console mode settings, see Console access options.

**Customizing the view for MMC and saved consoles**

You can use the **Customize View** dialog box on the **Customize** command on the **View** menu to hide or display elements for a console. One of the elements that you can hide is the **View** menu itself. If you do this, but then want to reconfigure the view, you can also access the **Customize View** dialog box from the **Customize View** command on the **System** menu. For more information, see Hide or display features of a saved MMC console and Hide or display menus and toolbars for snap-ins.

**Working with columns in saved consoles**

In saved consoles that display columns in the details pane, you can customize how the columns and rows appear. For instance, you can reorder or hide columns. You can also reorder rows alphabetically or chronologically by clicking the column heading. In addition, with certain snap-ins, you can filter columns based on additional attributes. If this feature is enabled, a row of drop-down list boxes that contain options for filtering is displayed beneath the column headings. For more information, see Reorder columns in an MMC console, Hide or display columns in an MMC console, and Filter rows in an MMC console.

You can also export the contents of columns to a text file. For more information, see Export columns in an MMC console to a text file.

If you customize the columns in a console, your settings are saved from session to session.

**Using consoles from older versions of MMC**

Consoles which have been created with older versions of MMC (versions 1.1 and 1.2) can be read by MMC version 2.0. However, saving these files in MMC 2.0 automatically converts them, and the older format cannot be restored. For further information, see Using files created with earlier versions of MMC with MMC 2.0.

# Using property pages in saved consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using property pages in saved consoles**

Much of the work done using consoles is performed from property pages. In fact, certain snap-ins or extensions may be accessed in a console only from a property page. For some tabs, you may be able to determine which snap-in provided a particular property page if you hold down the CTRL key while you point with the mouse to the label of the tab for the property page. Also, if you hold down the CTRL key while you point to the title bar of a particular properties dialog box, you can determine the path in the console tree to the item associated with the property page. For more information, see View the associated snap-in and item for a property page.

The properties dialog boxes for consoles often become hidden behind consoles and other tools. If you cannot find a property page that you were working on, simply reopen the properties dialog box or minimize the other tools on your screen.

# Setting Group Policy in MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting Group Policy in MMC**

This feature applies only in a network where Group Policy has been configured; a system administrator must enable Group Policy. For detailed information, see Group Policy overview.

| Policy | Action | Result |
|---|---|---|
| Enable **Restrict the user from entering author mode**. | Open a console file that is configured to open in author mode. | Users with administrator credentials can access author mode. Restrict access to author mode in MMC.<br><br>An error message appears indicating denied access to console in author mode. |
| Disable or do not configure **Restrict the user from entering author mode**. | Open a console file that is configured to open in author mode. | Use of author mode is unrestricted. |
| Enable **Restrict users to the explicitly permitted list of snap-ins**. | Open a console that contains a snap-in that is not on the permitted list, or a snap-in that is extended by a snap-in that is not on the permitted list. | An error message appears.<br><br>**Note**<br><br>• If you enable this policy, only explicitly permitted snap-ins appear in the list of available snap-ins in the **Add Standalone Snap-in** dialog box in MMC--all other snap-ins are restricted. |
| Disable or do not configure **Restrict users to the explicitly permitted list of snap-ins**. | Open a console that contains a snap-in that is not on the permitted list, or a snap-in that is not extended by a snap-in on the permitted list. | |
| Explicitly permit a snap-in. | Open a console that contains the snap-in, or a snap-in that is extended by the permitted snap-in. | Use of the console that contains the snap-in is unrestricted. |
| Explicitly restrict a snap-in. | Open a console file that contains the snap-in, or contains a snap-in that is extended by the restricted snap-in. | An error message appears. |
| Do not configure the policy to permit or restrict a snap-in. | Open a console file that contains the snap-in, or contains a snap-in that is extended by this snap-in. | Use of the console that contains the snap-in is unrestricted unless the user, group, or organizational unit is restricted to a list of explicitly permitted snap-ins. |

To open MMC or open a console in author mode:

- Type **mmc** at the command prompt.
- Type **mmc***path**filename*.**msc/a** at the command prompt.
- Right-click an .msc file, and then click **Author**.
- Open a console file that is configured to open in author mode.

To open a console file that contains the snap-in, or contains a snap-in that is extended by this snap-in:

- Type **mmc***path******filename*.**msc** at the command prompt.
- Double-click the .msc file.
- Right-click the .msc file, and then click **Open**.

# Using the MMC help system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the MMC help system**

You can access Help for MMC from the **Help** menu on the main toolbar, from the button on the toolbar of a console window, on the system menu of the MMC window or a console window, by right-clicking an item in the console tree or details pane, or by pressing the F1 key.

Help for MMC displays a combined table of contents that includes general Help for MMC and Help specific to each snap-in included in the console. Snap-in Help is provided only for existing Help files that were associated to snap-ins by their authors. If you are authoring a console, you may want to provide additional documentation for tasks associated with the console or provide information specifically related to your network.

# Authoring MMC consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authoring MMC consoles**
This section covers:

- Creating consoles
- Adding items to the console tree
- Adding taskpad views and tasks
- Viewing the console tree in a console window
- Rooting console windows on items in the console tree
- Adding items to the Favorites list
- Adding items to the Favorites list
- Saving consoles
- Using custom consoles

For more information about author mode, see MMC in author mode.

# Creating consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating consoles**

Before you author a console, identify the tasks the console will perform, the components to be administered, and the snap-ins and controls that are needed to perform the tasks. You should also consider whether you need to create a taskpad view and tasks. After you make these decisions, you can open a new console and start adding items to the console tree.

To create or edit a console, open the console in author mode (use the command-line option **/a**). To view the complete command-line syntax, see Open MMC.

# Adding items to the console tree

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding items to the console tree**

You can help users locate the components they need in the console by arranging items hierarchically or in groups on the console tree. To add items to the console tree, use the **Add/Remove Snap-in** command on the **File** menu of the main toolbar of MMC.

In the **Add/Remove Snap-in** dialog box, **Snap-ins added to** determines the item on the console tree under which new items are added. The default value is **Console Root**. Click an item in **Snap-ins added to** to locate an object elsewhere on the console tree.

The **Add Standalone Snap-in** dialog box displays a list of available snap-ins. For computers that are members of a domain, this list includes both locally-installed snap-ins and snap-ins published in the Active Directory directory service. For snap-ins that are available in Active Directory, **Not Installed** appears in the **Vendor** column.

If you have already installed a snap-in, and you want to enable one of its extension snap-ins, use the **Extensions** tab in the **Add/Remove Snap-in** dialog box. On this tab, select any item in the console tree that can be extended and view the extension snap-ins that you can enable or disable. When you enable an extension snap-in, it is automatically inserted in the console tree under the selected item. If there is more than one instance of a snap-in on the console tree, all instances of the snap-in are extended.

After an extension snap-in is enabled, you might notice that it appears in **Snap-ins that can be extended** along with the stand-alone snap-ins. This means that the extension snap-in also has extensions that you can enable.

Like stand-alone snap-ins, an administrator can also publish extension snap-ins in Active Directory. Extension snap-ins available to a user from Active Directory appear in the list of available extension snap-ins with any locally installed extension snap-ins, except that they are followed by the phrase **(not installed)**. You must specifically download extension snap-ins from the directory service to make them available in a console. Thus, to download all extensions for a given item, do not select the **Add all extensions** check box on the **Extensions** tab of the **Add/Remove Snap-in** dialog box. Instead, clear this check box and select the check boxes next to each extension that you want to download.

To add multiple instances of the same snap-in to a console either to manage multiple remote computers from the same console or to repair a damaged console, add a new instance of the snap-in to the console, configure it as needed, and then remove the old instance of the snap-in from the console. You might need to do this if you noticed that a tool is behaving differently from expected, that its configuration is outdated, or that it is timing out because resources have been removed.

For information about adding items to the console tree, see Add a snap-in to a new MMC console for a local computer, Add a published snap-in to a new MMC console, Add an extension snap-in to an MMC console, and Add a published extension snap-in to an MMC console.

# Adding taskpad views and tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding taskpad views and tasks**

Before you add taskpad views and tasks to a console, determine how many taskpad views you need. If you need multiple taskpad views, you also need to determine how the tasks are divided among those views. In addition, you should decide what kind of taskpad view you want to use--one that displays a list and tasks, or one that displays tasks only.

To create a taskpad view for a console, the console must contain at least one snap-in. Use the New Taskpad View wizard to configure the titles, headings, and lists that appear in the taskpad view, and to define whether a taskpad view is associated with a single item or multiple items in the console tree.

After you complete the New Taskpad View wizard, use the New Task wizard to add tasks to the taskpad view. Tasks can include menu commands for the items in the console, as well as commands that are run from a command prompt. Create commands to act on part of the console tree or details pane, or to open another component on your computer. However, if you create a task from a menu command for an item in the console tree, and then you remove that item, the task is disabled.

For information about creating and editing taskpad views and tasks, see Create a taskpad view in a saved MMC console, Create tasks for a taskpad view in saved MMC console, Edit a taskpad view in a saved MMC console, and Edit tasks in a taskpad view in a saved MMC console.

# Viewing the console tree in a console window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing the console tree in a console window**

When the console tree is visible, it appears in the left pane of a console window. Optionally, hide the console tree. For information about hiding the console tree, see Hide or display features of a saved MMC console.

What you view in a console window is determined by where the console window is rooted on the console tree. The initial window in a new console is rooted at Console Root, as are any windows you create with the **New Window** command on the **Window** menu on the main toolbar.

Close console windows to hide the console root or entire portions of the console tree. Then configure the console to prevent users from viewing hidden portions of the tree. However, the entire console tree is always saved when you save a console.

# Rooting console windows on items in the console tree

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Rooting console windows on items in the console tree**

While you can use MMC to make consoles that meet every administrative need for a group, you can also design simple consoles for less experienced users. For instance, after you add items to a console tree, open additional console windows rooted on any item in the console tree. Use this method to create console windows that display specific administrative components of the console tree. Then close windows that show portions of the console tree that users do not need.

Closing a window does not remove any items from the console tree; when you close a window, you remove only that view of the console tree. The entire tree is still saved when you save the console, and you can always view the console root.

For information about changing the console root, see Make a new console window from part of an MMC console tree.

For information about viewing a console root that is hidden, see Make a new console window from an MMC console.

# Adding items to the Favorites list

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding items to the Favorites list**
Use the Favorites list to create shortcuts to items in the console tree and to taskpad views. Then access these items from the **Favorites** menu.

Note: The **Favorites** tab in the Console scope pane has been removed in MMC 2.0 but is present in MMC 1.2.

For more information about creating the Favorites list, see Add an item to the Favorites list in an MMC console and Organize the Favorites list in an MMC console.

**Configuring console options**
Use the **Options** dialog box, available from the **File** menu, to choose an icon for, change the title of, and choose the default mode for a console.

Icons are available from many sources including the Shell32.dll file, located in the *systemroot*\system32 folder.

When changing the title of a console, keep in mind that, by default, as you click items in the console tree, the title bar displays the path to the selected item. But if you change the title of a console, the title bar will not display this path. However, if you delete the title, the default behavior is restored.

When considering which mode to set as the default for a console, remember that if you use one of the user modes, you can open the console at any time by using the **Author** or **Run As** commands--you do not need to use author mode for most management tasks.

For more information about console options, see Set MMC console options and Console access options.

# Configuring console options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring console options**

Use the **Options** dialog box, available from the **File** menu, to choose an icon for, change the title of, and choose the default mode for a console.

Icons are available from many sources including the Shell32.dll file, located in the *systemroot*\system32 folder.

When changing the title of a console, keep in mind that, by default, as you click items in the console tree, the title bar displays the path to the selected item. If you change the title of a console, the title bar will not display this path. However, if you delete the title, the default behavior is restored.

When considering which mode to set as the default for a console, remember that if you use one of the user modes, you can open the console at any time by using the **Author** or **Run As** commands--you do not need to use author mode for most management tasks.

# Saving consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Saving consoles**

Saving an MMC console to a file preserves the list of loaded snap-ins for the console, the arrangement and contents of console windows in the main MMC window, the default mode, and information about permissions. All the configuration settings for the tools and controls are saved with the console and restored when the console file is opened. You can open a console file on different computers or even different networks and restore the saved settings for all the tools.

Console files have an .msc (management saved console) file name extension. The operating system you are using may already have preconfigured console files that are available from the Administrative Tools folder in Control Panel. Many applications also include preconfigured consoles, which are typically available from the **Start** menu. If you create console files and save them in your per-user Administrative Tools folder (located at *%systemdrive%*\Documents and Settings*user*\Start Menu\Programs\Administrative Tools), they are available from the Administrative Tools folder on the **Programs** menu for you only--the console files are not available for other users of the computer. After you save a console, you can distribute it by using a floppy disk, e-mail, or your network.

If you are working with a console in author mode, you can save changes to the console by using the **Save** command on the **File** menu. If you are working with a console in one of the user modes, saving changes to the console is determined by whether the **Do not save changes to this console** check box (available by clicking **Options** on the **File** menu) was selected when the console was configured. If this check box was not selected, changes to the console are automatically saved when you close MMC; if it was selected, changes to the console are discarded when you close MMC. For more information about saving consoles, see Save an MMC console file. For more information about console modes, see Console access options.

# Using custom consoles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using custom consoles**
After you create and save an MMC console, you can use it on your local computer, send it to other users in e-mail, post it on your network or the Web, or copy it to a floppy disk and install it on other computers. You can also use MMC and the Active Directory directory service to publish consoles or assign consoles to users. For more information about distributing software, see Active Directory.

**Requirements to use a console**
To use a console, you must have access to the services and administrative tools included in the console, either installed on the local computer or available on the network. You must also have administrative permissions for the components on the system that is administered by the console.

**Opening a saved console**
If you save a console to the per-user Administrative Tools folder (located at *systemdrive*\Documents and Settings*user*\Start Menu\programs\Administrative Tools), it is then available to that user in the Administrative Tools folder on the **programs** menu.

If you know the name and location of a console file, you can open it as you would any other document:

- By double-clicking the .msc file
- By right-clicking the .msc file, and then clicking **Open**
- From a command prompt

On computers running Windows 2000, Windows XP Professional, or an operating system in the Windows Server 2003 family, you can log on to your computer with user rights and perform routine tasks. However, you must use the **Run As** command to open console files and perform administrative tasks that require Administrator rights. You can use this command by typing **runas** at the command prompt or by right-clicking an .msc file, and then clicking **Run As**.

For more information about opening consoles, see Open a saved MMC console for local and remote computers, and Open MMC.

# Running 32-bit and 64-bit snap-ins in Windows Server 2003 and Windows XP Professional operating systems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Running 32-bit and 64-bit snap-ins in Windows Server 2003 and Windows XP Professional operating systems**

The 64-bit versions of the Microsoft® Windows°Server™°2003 and Microsoft® Windows®°XP Professional operating systems can run both the 32-bit Microsoft Management Console (MMC32) and the 64-bit MMC (MMC64). MMC32 can run only 32-bit snap-ins, and MMC64 can run only 64-bit snap-ins. However, some snap-ins are available in both 32-bit and 64-bit form. A snap-in is considered available in 64-bit form if it defined by an **HKEY_CLASSES_ROOT\CLSID***snap-in clsid***\InprocServer32** key in the registry, where *snap-in clsid* is the registered CLSID for the snap-in.

This topic describes how to determine and control which version of MMC is run in 64-bit versions of Windows operating systems.

**Start-up considerations if /32 or /64 is specified**

MMC can be run from the command line by using a command such as the following that includes a console file name:

**%systemdrive%\Documents and Settings** *username* **\Start Menu\programs\Administrative Tools\myconsole.msc**

On the 64-bit version of a Windows operating system, you can include one of the following command-line parameters:

**/32**
Specifies MMC32.

**/64**
Specifies MMC64. This is the default on the 64-bit version of a Windows operating system.

If both of these command-line parameters are used, the last one on the command line takes effect. MMC64 yields transparently to MMC32 if certain conditions are met, as described in the following section.

**Start-up considerations if a console file is specified**

If the command for running MMC does not contain a **/32** or **/64** parameter, but does contain a console file name, MMC64 examines the console file before determining which version to run. The decision sequence is as follows:

1. If all snap-ins in the console are available in 64-bit form, MMC64 is used.

2. If all snap-ins in the console are available in 32-bit form and some are not available in 64-bit form, MMC32 is used. (MMC64 starts MMC32, and then MMC64 terminates.)

3. If some of the snap-ins are available only in 64-bit form and others are available only in 32-bit form, the version of MMC that can run the majority of the snap-ins is used. The remaining snap-ins are not loaded.

   For example, if a console contains three snap-ins that are available only in 32-bit form and two snap-ins that are available only in 64-bit form, MMC32 is used and only the three 32-bit snap-ins appear when the console is opened. The two snap-ins that are available only in 64-bit form would not be loaded.

4. If some of the snap-ins are available only in 64-bit form and an equal number of snap-ins are available only in 32-bit form, you will be prompted to specify which version of MMC to run. If you choose MMC64, only the 64-bit snap-ins are loaded. If you choose MMC32, only the 32-bit snap-ins are loaded.

**When to specify the path to the console file**

In Windows XP and Windows Server 2003 operating systems, the system files are stored in the %windir%\system32 folder. In the 64-bit versions of these operating systems, the \system32 folder contains 64-bit files, including 64-bit consoles such as eventvwr.msc. If there is also a 32-bit version of the snap-in, it resides in the %windir%\syswow64 folder. In this example, the 32-bit version of Event Viewer would be %windir%\syswow64\eventvwr.msc.

If there is both a 64-bit version of the console in the \system32 folder and a 32-bit version in the \syswow64 folder and you want to explicitly run the 32-bit version, you must bypass the MMC decision-making process by specifying both the path and

the **/32** command-line parameter. For example:

**MMC /32 %windir%\syswow64\eventvwr.msc**

**Note**

- Double-clicking a shortcut to a file in the \syswow64 folder is like double-clicking the file in Windows Explorer: it will run MMC without the **/32** command-line parameter. To open the 32-bit consoles in the \syswow64 folder, click **Start**, click **Run**, and then type the command specifying both the path and the **/32** command-line parameter, instead of using a shortcut.

# MMC command-line options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC command-line options**

Using MMC command-line options, you can open a specific MMC console, open MMC in author mode, or specify that the 32-bit or 64-bit version of MMC is opened.

**Syntax**

**mmc** *path* **** *filename.msc*[**/a**] [**/64**] [**/32**]

**Parameters**

***path* \ *filename.msc***

Starts MMC and opens a saved console. You need to specify the complete path and file name for the saved console file. If you do not specify a console file, MMC opens a new console.

**/a**

Opens a saved console in author mode. Used to make changes to saved consoles.

**/64**

Opens the 64-bit version of MMC (MMC64). Use this option only if you are running a Microsoft 64-bit operating system and want to use a 64-bit snap-in.

**/32**

Opens the 32-bit version of MMC (MMC32). When running a Microsoft 64-bit operating system, you can run 32-bit snap-ins by opening MMC with this command-line option when you have 32-bit only snap-ins.

**Remarks**

- Using the *path******filename.msc* command-line option

  You can use environment variables to create command lines or shortcuts that do not depend on the explicit location of console files. For instance, if the path to a console file is in the system folder (for example, **mmc** *c:\winnt\system32\console_name.msc*), you can use the expandable data string %systemroot% to specify the location (**mmc**%systemroot%\system32\console_name.msc). This may be useful if you are delegating tasks to people in your organization who are working on different computers.

- Using the **/a** command-line option

  When consoles are opened with this option, they are opened in author mode, regardless of their default mode. This does not permanently change the default mode setting for files; when you omit this option, MMC opens console files according to their default mode settings.

- After you open MMC or a console file in author mode, you can open any existing console by clicking **Open** on the **Console** menu.

- You can use the command line to create shortcuts for opening MMC and saved consoles. A command-line command works with the **Run** command on the **Start** menu, in any command-prompt window, in shortcuts, or in any batch file or program that calls the command.

**Formatting Legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |

| | |
|---|---|
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Program output |

# MMC Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

For more information about MMC, see the following resources:

- The Personal Support Center Web site at the Microsoft Web site contains general support information and articles written by support professionals at Microsoft.

- For further information, see Windows Server 2003, Standard Edition Resource Kit at the Microsoft Web site.

# Accessibility for MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessibility for MMC**
In addition to Microsoft Windows accessibility products and services, MMC provides keyboard shortcuts for selecting commands and for navigating in and between console windows:

- Navigation in MMC
- MMC main window keyboard shortcuts
- MMC console window keyboard shortcuts

Snap-ins and other items that are added to an MMC console may also provide accessibility features. For more information, refer to the Help or other documentation for the console item.

# Navigation in MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Navigation in MMC**

You can browse an MMC console tree by expanding and collapsing branches by clicking the plus sign ⊞ and minus sign ⊟ icons, or by double-clicking with the mouse. The following table lists the keystrokes you can use to move in and between console windows.

| Keystroke action | Result |
|---|---|
| TAB or F6 | Moves forward between panes in the active console window. |
| SHIFT+TAB or SHIFT+F6 | Moves backward between panes in the active console window. |
| CTRL+TAB or CTRL+F6 | Moves forward between console windows. |
| CTRL+SHIFT+TAB or CTRL+SHIFT+F6 | Moves backward between console windows. |
| PLUS SIGN (+) on the numeric keypad | Expands the selected item. |
| MINUS SIGN (-) on the numeric keypad | Collapses the selected item. |
| Asterisk (*) on the numeric keypad | Expands the entire console tree below the root item in the active console window. |
| UP ARROW | Moves the selection up one item in a pane. |
| DOWN ARROW | Moves the selection down one item in a pane. |
| PAGE UP | Moves the selection to the top item visible in a pane. |
| PAGE DOWN | Moves the selection to the bottom item visible in a pane. |
| HOME | Moves the selection to the first item in a pane. |
| END | Moves the selection to the last item in a pane. |
| RIGHT ARROW | Expands the selected item. If the selected item does not contain hidden items, behaves like DOWN ARROW. |
| LEFT ARROW | Collapses the selected item. If the selected item doesn't contain exposed items, behaves like UP ARROW. |
| ALT+RIGHT ARROW | Moves the selection to the next item. Performs the same function as the Forward arrow on the toolbar. |
| ALT+LEFT ARROW | Moves the selection to the previous item. Performs the same function as the Back arrow on the toolbar. |

The following table lists the mouse actions you can use to move through an MMC console tree.

| Mouse action | Result |
|---|---|
| Click | Selects an item. |
| Double-click | Displays or hides items contained by the selected item. Displays properties for or opens an item. |

| | |
|---|---|
| Right-click | Displays the **Action** shortcut menu for the selected item. |

**Note**

- If the mouse buttons do not behave as expected, the right and left buttons might be switched. The computer you are using might be configured so that the default actions result from the left and right mouse buttons being reversed.

# MMC main window keyboard shortcuts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC main window keyboard shortcuts**

The following table lists keyboard shortcuts for the menu commands that act on the entire console or the main window of a console.

| Action | Result |
|---|---|
| CTRL+O | Opens a saved console. |
| CTRL+N | Opens a new console. |
| CTRL+S | Saves the open console. |
| CTRL+M | Adds or removes a console item. |
| CTRL+W | Opens a new window. |
| F5 | Refreshes the content of all console windows. |
| ALT+SPACEBAR | Displays the MMC window menu. |
| ALT+F4 | Closes the console. |
| ALT+A | Displays the **Action** menu. |
| ALT+V | Displays the **View** menu. |
| ALT+F | Displays the **File** menu. |
| ALT+O | Displays the **Favorites** menu. |

**Note**

- The CTRL+W keyboard shortcut is available for consoles opened in author mode or user mode—full access. Other CTRL+ shortcuts are only available for consoles opened in author mode.

# MMC console window keyboard shortcuts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**MMC console window keyboard shortcuts**

The following table lists keyboard shortcuts for the menu commands that act on the active console window in a console or on the contents of a console window.

| Action | Result |
|---|---|
| CTRL+P | Prints the current page or active pane, only if the snap-in implements the printing function. |
| ALT+MINUS SIGN | Displays the window menu for the active console window. |
| SHIFT+F10 | Displays the **Action** shortcut menu for the selected item. |
| F1 | Opens the Help topic, if any, for the selected item. |
| F5 | Refreshes the content of all console windows. |
| CTRL+F10 | Maximizes the active console window. |
| CTRL+F5 | Restores the active console window. |
| ALT+ENTER | Displays the properties dialog box, if any, for the selected item. |
| F2 | Renames the selected item. |
| CTRL+F4 | Closes the active console window. When a console has only one console window, this closes the console. |

# Troubleshooting MMC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Help for a snap-in cannot be found.
- A snap-in is not listed in the Add Standalone Snap-in dialog box.
- When using a console, one or more of the following occurs: the console is not behaving as expected, the console is timing out, or error messages are displayed that you have not seen before.

**Help for a snap-in cannot be found.**
**Cause:** The snap-in may not provide a Help file to merge into the MMC Help table of contents. Instead, the snap-in may use a different method to provide Help.

**Solution:** Open a console in author mode that contains the snap-in, click the item in the console tree for which you want Help, and then click the **Help** menu. A separate command for the snap-in Help may be displayed on the **Help** menu above the **Help Topics** command. If you do not see a separate command, view the contents of the toolbars and details pane for a Help button or additional icon. If you do not see a separate command, button, or icon, then no Help is available from MMC for the snap-in.

**A snap-in is not listed in the Add Standalone Snap-in dialog box.**
**Cause**: The corresponding service or software may not be installed on your computer.

**Solution**: You must install the component to view its snap-in.

**See also**: Install a program managed by an MMC snap-in.

**Cause**: If you are using a computer running Windows 2000, Windows XP Professional, or an operating system in the Windows Server 2003 family, an administrator may have set a policy that restricts you from accessing the snap-in.

**Solution**: An administrator can verify whether a policy setting is restricting access to the snap-in, and change the policy if necessary.

**See also**: Setting Group Policy in MMC

**When using a console, one or more of the following occurs: the console is not behaving as expected, the console is timing out, or error messages are displayed that you have not seen before.**
**Cause**: One of the following might be the cause. The console file may have become damaged. Or, because of changes to your network, the configuration of the console may have become outdated.

**Solution**: Determine which snap-in is causing the problem in the console and then refer to the troubleshooting information in the documentation for that snap-in to find out how to repair or reconfigure the snap-in. To determine which snap-in is causing the problem, right-click the item in the console tree or the details pane, and then click **properties**. Hold down the CTRL key and point to the labels of the tabs in the dialog box.

If you cannot directly repair or reconfigure the console, try adding another instance of the snap-in you are using to the console, configure it as needed, and then remove the old version of the snap-in.

**See also**: Add a snap-in to a new MMC console for a local computer, Snap-ins, and View the associated snap-in and item for a property page.

# Remote Administration Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote administration tools**
This section covers:

- Remote Administration
- Using Web Interface for Remote Administration
- Administering Remote Assistance
- Remote Administration using Terminal Services
- Windows Server 2003 Administration Tools Pack Overview
- Emergency Management Services

# Remote Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Administration**
Using tools included with Microsoft® Windows Server 2003 family operating systems CDs, you can remotely manage your system servers running Microsoft® Windows 2000 and Windows Server 2003 family operating systems. You can also remotely manage Windows Server 2003 family operating systems from a computer using Microsoft® Windows® XP Professional.

- For general information, see Remote administration overview.
- For tips about managing your server remotely, see Remote Administration Best practices.
- For other sources of information, see Remote Administration Resources.

# Remote administration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote administration overview**

The following table presents remote management tasks and links to information about the tools. Unless indicated otherwise, these tools are used on Microsoft® Windows Server™ 2003 operating systems and, in some cases, Microsoft® Windows® XP Professional.

| Task | Tools | Comments |
|---|---|---|
| Manage several servers by performing similar tasks. | Microsoft Management Console<br><br>Author an MMC console file<br><br>Work with MMC and saved console files | You can use appropriate saved MMC consoles, if available, or you can create custom MMC consoles for tasks you frequently either delegate or perform. |
| Log onto one computer remotely and manage it as if you were there. | Remote Desktop Connection | In addition to Windows Server 2003 operating systems, this feature can be used with Microsoft® Windows® 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Switch among several computers that you want to log on to remotely. | Remote Desktops snap-in | In addition to Windows Server 2003 operating systems, this feature can be used with Windows 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Administer a server running Windows Server 2003 from any computer on your network. | Remote Desktop for Administration | In addition to Windows Server 2003 operating systems, this feature can be used with Windows 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Manage servers from Windows XP Professional. | Windows Server 2003 Administration Tools Pack Overview<br><br>Remote Desktop Connection | Windows Server 2003 Administration Tools Pack must be installed on Windows XP Professional to permit server management using these tools. The Remote Desktop feature must be enabled on servers to permit use of the Remote Desktop Connection. |
| Manage your Web server using a Web browser on a remote computer. | Using Web Interface for Remote Administration | Use Internet Explorer, version 6 or later, for remote administration using Web Interface. Web Interface is not installed by default for Web servers. |
| Assist in real time an operator on a remote computer running Windows Server 2003 family operating system, Windows XP Professional or Microsoft® Windows® XP Home Edition. | Administering Remote Assistance (www.microsoft.com) | The Remote Assistance connection requires explicit permission from the connected user, and both computers must be running Windows XP Professional or Windows Server 2003 operating systems. |
| Connect to a remote computer when that computer cannot access a network or is not in a functional state because of hardware or software failure. | Telnet | All commands must be entered through the command line. Capabilities are limited, and security is minimal. |

| | | |
|---|---|---|
| Manage disk space on servers by copying files to a library of magnetic tapes or magneto-optical disks. | Remote Storage | Some Windows components require configuration before they can be used and will be displayed in the **Add or Remove Windows Components** in **Add or Remove programs** in **Control Panel**. Remote storage requires installation. |

**Notes**

- Depending on the Group Policy settings on your network, you might not be able to perform some of these tasks.
- Some features require that specific ports be opened on the server in order for the role to be administered remotely. For information about these port requirements, see Service overview and network port requirements for the Windows Server system (http://go.microsoft.com/fwlink/?LinkID=61531) and Windows Firewall Settings (http://go.microsoft.com/fwlink/?LinkID=38651).
- You can use command-line tools to automate many processes and tasks. For more information, see Automating processes and tasks.
- You must physically access each computer to restart, change hardware, and enable the Remote Desktop feature. Once the Remote Desktop feature has been enabled, it will remain enabled.
- For an explanation of the various Remote Desktop terminologies, see Remote Administration using Terminal Services.
- For more information about remote administration, see the following:
    - Common Administrative Tasks
    - New Features
    - Quick Guide for Finding Tools
    - Remote Administration Resources

# Remote Administration Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**To perform many tasks on a single, remote server, use Remote Desktop for Administration.**

- To remotely administer a server running a Windows Server 2003 family operating system, you do not need to install Terminal Server. Instead, use Remote Desktop for Administration. On these operating systems, Remote Desktop for Administration is on by default but is not enabled. After you enable remote connections, Remote Desktop for Administration allows you to administer your server from any computer on your network running Windows Server 2003 family, Windows XP Professional, and Windows 2000. Windows Server 2003 , Web Edition, does not support remote administration.

- You can use Remote Desktop with Windows 2000 Server. You need to install Terminal Services for Remote Administration as described in the Windows 2000 Help.

  For more information, see Enable or disable Remote Desktop and Remote Desktop for Administration.

**To do similar tasks on many servers, use MMC snap-ins.**

- Most of the administration tools provided with Windows Server 2003 family operating systems are Microsoft Management Console (MMC) snap-ins that can be used to administer remote servers as well as your local computer. The advantages of using MMC include the following:

  - You can create a console with the tools you use for the tasks you do most often.

  - You can set the focus for a tool to any of the servers you administer, and switch between servers and tools within a single MMC console.

  For more information, see Microsoft Management Console.

**To manage servers running Windows Server 2003 family operating systems from a computer using Windows XP Professional , use Windows Server 2003 Administration Tools Pack**

- Windows Server 2003 Administration Tools Pack when installed on Windows XP Professional (ordinarily a client operating system) provides many remote management tools for managing your servers.

- Windows Server 2003 Administration Tools Pack comes as adminpak.msi on the Windows Server 2003 family operating system and is easily installed from the server CD onto Windows XP Professional by installing the .msi from the server to the Windows XP Professional operating system.

- The Administration Tools Packs in the Windows Server 2003 family and Windows 2000 are not mutually compatible. You must use the Windows 2000 Administrative Tools to administer Windows 2000, and the Windows Server 2003 Administration Tools Pack to administer the Windows Server 2003 family operating system.

  For more information, see Windows Server 2003 Administration Tools Pack Overview.

# Remote Administration Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**
The following resources provide additional information about remote administration.

**Windows Server 2003 Resource Kit**
The Microsoft Windows Server 2003 Resource Kit contains additional tools that you can use for remote administration.

**Microsoft Platform Software Development Kits (SDK)**
For technical information about Active Directory Scripting Interfaces (ADSI), Microsoft Management Console (MMC), Windows Management Instrumentation (WMI) Software Development Kits (SDK), see the Microsoft Web site.

**TechNet**
TechNet is a service that contains resources for information technology (IT) professionals. This includes access to articles written by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software.

For more information, see Microsoft TechNet.

# Using Web Interface for Remote Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Web Interface for Remote Administration**
You can use Web Interface for Remote Administration to manage your application server by using a Web browser on a remote computer.

**To install Web Interface for Remote Administration of an application server**

1. Open the Windows Components Wizard.
2. In the Windows Components Wizard, select the **Application Server** check box, and then click **Details**.
3. Select the **Internet Information Services (IIS)** check box, click **Details**, select the **World Wide Web Service** check box, click **Details**, and then select the **Remote Administration (HTML)** check box.

### Notes

- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Web Interface for Remote Administration of an application server is installed by default on Windows Server 2003, Web Edition only. It is not installed by default on other Windows Server 2003 operating systems.
- Internet Explorer version 6.0 or later is recommended for Remote Administration.
- Installation of Remote Administration is not supported on a domain controller.

**To open Web Interface for Remote Administration**

1. Click **Start**, and then click **Run**.
2. Type:

   **https://*ComputerName*:8098**

   Where *ComputerName* is the name of the computer on which you want to run Remote Administration.

### Note

- To open Web Interface for Remote Administration Help, open Web Interface for Remote Administration, and then click the **Help** tab.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remote Administration using Terminal Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Administration using Terminal Services**
In Microsoft® Windows Server 2003 family operating systems, Terminal Services technology is the basis for several features that enable you to connect to remote computers and perform administrative tasks.

- Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode) provides remote server management capabilities for Windows Server 2003 family operating systems. Using this feature, you can administer a server from virtually any computer on your network. No license is required for up to two simultaneous remote connections in addition to the server console session. A corresponding desktop version of Remote Desktop for Administration is available on Microsoft® Windows® XP Professional, and is called Remote Desktop.

- The Remote Desktops MMC snap-in allows you to create remote connections to the console session of multiple terminal servers, as well as computers running Windows 2000 or Windows Server 2003 family operating systems.

- Remote Desktop Connection, available on Windows Server 2003 family operating systems as well as on Microsoft® Windows® XP operating systems, enables you to log on to a remote computer and perform administrative tasks, even from a client computer that is running an earlier version of Windows.

This section provides information about using Remote Desktop for Administration and its related tools:

- Remote Desktop for Administration

- Remote Desktops snap-in

- Remote Desktop Connection

# Remote Desktop for Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktop for Administration**
Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode) provides remote access to the desktop of any computer running a Microsoft® Windows Server 2003 family operating system, allowing you to administer your server from virtually any computer on your network.

- To find features that have been moved, see New ways to do familiar Remote Desktop for Administration tasks.
- For tips about using Remote Desktop for Administration, see Remote Desktop for Administration Best practices.
- For help with specific tasks, see Remote Desktop for Administration How To....
- For general background information, see Remote Desktop for Administration Concepts.
- For problem-solving instructions, see Troubleshooting Remote Desktop for Administration.

# New ways to do familiar Remote Desktop for Administration tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**
This table lists common tasks for Remote Desktop for Administration (formerly Terminal Services in Remote Administration mode). The user interface for performing these tasks is different in Windows Server 2003 family operating systems than it was in Microsoft Windows NT 4.0 or Microsoft Windows 2000.

Please choose your upgrade path:

- Windows NT 4.0 to one of the Windows Server 2003 family operating systems
- Windows 2000 to one of the Windows Server 2003 family operating systems

**Windows NT 4.0 to one of the Windows Server 2003 family operating systems**

| If you want to | In Windows NT 4.0 use | In Windows Server 2003 family operating systems do this |
|---|---|---|
| Create a Terminal Services connection | Terminal Server Client | Open Remote Desktop Connection. For more information, see Remote Desktop Connection. |
| Remotely administer your server with Terminal Services | Not available | Use Remote Desktop for Administration. For more information, see Remote Desktop for Administration overview. |
| Create a Terminal Services connection using the World Wide Web | Not available | Use Remote Desktop Web Connection. For more information, see Remote Desktop Web Connection. |

**Windows 2000 to one of the Windows Server 2003 family operating systems**

| If you want to | In Windows 2000 use | In Windows Server 2003 family operating systems do this |
|---|---|---|
| Create a Terminal Services connection | Client Connection Manager and Terminal Services Client | Open Remote Desktop Connection. For more information, see Remote Desktop Connection. |
| Remotely administer your server with Terminal Services | Use Terminal Services in Remote Administration mode, enabled with **Add or Remove Programs** | Remote Desktop for Administration. For more information, see Remote Desktop for Administration overview. |
| Create a Terminal Services connection using the World Wide Web | Terminal Services Advanced Client | Use Remote Desktop Web Connection. For more information, see Remote Desktop Web Connection. |

# Remote Desktop for Administration Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### Best practices

#### Security

- **Add yourself to the Remote Desktop Users group for your computer.**

  When you do this, you do not have to log on as an administrator to access your computer remotely. You should not add yourself to the Administrators group, and you should avoid running your computer while you are logged on as an administrator unless you are doing tasks that are restricted to administrators. For most computer activity, log on as a member of the Users or Power Users group. If you need to perform an administrator-only task, log on as an administrator, perform the task, and then log off. For more information, see Why you should not run your computer as an administrator.

- **Require all members of the Remote Desktop Users group to log on with a strong password.**

  This is especially important if your computer is connected directly to the Internet. For more information, see Strong passwords.

- **Install the latest version of Remote Desktop Connection.**

  If you are using the Windows 2000 32-bit Terminal Services Client, you should upgrade to the Windows Server 2003 Remote Desktop Connection.

  For more information, see Install Remote Desktop Connection (32-bit computers).

- **Review general security considerations.**

  For more information, see Best practices for security.

#### Remote Administration

- **Coordinate Remote Administration Tasks with Other Administrators**

  The Remote Desktop feature of Windows Server 2003 family operating systems is not meant to provide a managed multiuser experience. Using the two remote connections plus the console can implement a collaborative operation, but it is not designed to support general access by multiple simultaneous administrators. In particular, ensure that administrators do not run potentially destructive applications at the same time. For example, two administrators trying to reconfigure the disk subsystem can undermine each other's work, or even worse, destroy data. Use the Terminal Services Manager tool or the Query user command line utility to check for the presence of other administrators.

  To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.

- **Remote Administration Is Not Application Serving**

  Many general office applications require special installation, install scripts, or environment management to perform well in a remote session. Terminal Services provides these when you install Terminal Server, but they are not available for Remote Desktop for Administration. For general desktop and application remote access requirements, use a dedicated server with Terminal Server installed.

  For more information, see Terminal Server.

- **Configure the Remote Desktop Session to Disconnect When Connection is Broken**

  This is the default setting, and is especially important if you perform system updates over unreliable network connections. If a session is interrupted due to a network problem, the session goes into a disconnected state and continues executing the processes that were running before the interruption occurred. If the session is configured to reset when the connection breaks, all processes running in that session will stop, which is similar to stopping an application by using End Task.

- **Configure Disconnect and Reset Timeouts**

  Because it is not possible to have more than two remote sessions, remote administrators might be locked out of a server if two remote sessions (using different user accounts) are in either an active or disconnected state. When configuring disconnect timeouts, it is critical that sessions that are disconnected do not get reset prematurely. For this reason, it may be useful to perform remote administration tasks that should not be accidentally reset using a shared administrator account, such as a local machine account. You can use the account **Properties** tab to configure this account not to reset after it is disconnected.

  **Notes**

  - Group Policy settings may override settings in the user account **Properties** tab.
  - Using a shared administrator account will not allow you to track individual administrators using the computer.

  For more information, see Configuring Remote Desktop for Administration.

- **Avoid Tasks that Require Reboots**

  Some tasks, for example system upgrades and domain controller promotion, require reboots at their completion. These tasks work correctly from within a Remote Desktop session, but you should be aware that something as simple as a floppy disk in the drive or a bad boot sector on the disk could prevent the server from restarting. Therefore, it is advisable not to remotely reboot mission-critical servers unless you have the ability to physically intervene at the server if a problem occurs.

- **Avoid relying on Server Console Messages**

  It is not possible to see server console messages when logging on using Terminal Services unless you are connected to the console session. Therefore, it is good practice to check the Server event logs, rather than relying on a system pop-up.

- **Administrator Collaboration**

  Using the Terminal Services Manager, you can control another Terminal Services session remotely. However, you cannot interact with the console from the Terminal Services Manager.

  For more information, see Remotely control a session.

# Remote Desktop for Administration How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Enable or disable Remote Desktop
- Connect to Remote Desktop for Administration
- Add users to the Remote Desktop Users group
- Share the client setup folder
- Install Remote Desktop Connection (32-bit computers)
- Install Remote Desktop Web Connection
- Connect to another computer using Remote Desktop Web Connection
- Connect to the console session of a server using Remote Desktop for Administration
- Change the icon associated with the shortcut to a connection file

# Enable or disable Remote Desktop

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable Remote Desktop**
**Using Group Policies (best practice)**

1. Open Group Policy.

2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Allows users to connect remotely using Terminal Services** setting.

3. Do one of the following:

   - To enable Remote Desktop, click **Enabled**.

   - To disable Remote Desktop, click **Disabled**.

     If you disable Remote Desktop while users are connected to the target computers, the computers maintain their current connections, but will not accept any new incoming connections.

**Important**

When you enable Remote Desktop on a computer, you enable the capability for other users and groups to log on remotely to the computer. However, you must also decide which users and groups should be able to log on remotely, and then manually add them to the Remote Desktop Users group. For more information, see Enabling users to connect remotely to the server and Add users to the Remote Desktop Users group.

You should thoroughly test any changes you make to group Policy settings before applying them to users or computers. Fore more information about testing policy settings, see Resultant Set of Policy

**Note**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator. Then, you must start Group Policy by using the **Active Directory Users and Computers** snap-in.

- If the **Allows users to connect remotely using Terminal Services** Group Policy setting is set to **Not Configured**, the **Enable Remote Desktop on this computer** setting (on the **Remote** tab of the **System Properties** dialog box) on the target computers takes precedence. Otherwise, the **Allows users to connect remotely using Terminal Services** Group Policy setting takes precedence.

- Be aware of the security implications of remote logons. Users who log on remotely can perform tasks as though they were sitting at the console. For this reason, you should ensure that the server is behind a firewall. For more information, see VPN servers and firewall configuration and Security information for IPSec.

- You should require all users who make remote connections to use a strong password. For more information, see Strong passwords.

- Remote Desktop is disabled by default in Windows Server 2003 operating systems.

**Using System Properties**

1. Open **System** in Control Panel.

2. On the **Remote** tab, select or clear the **Enable Remote Desktop on this computer** check box, and then click **OK**.

### Important

When you enable Remote Desktop on a computer, you enable the capability for other users and groups to log on remotely to the computer. However, you must also decide which users and groups should be able to log on remotely, and then manually add them to the Remote Desktop Users group. For more information, see Enabling users to connect remotely to the server and Add users to the Remote Desktop Users group.

### Note

- You must be logged on as a member of the Administrators group to enable or disable Remote Desktop.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- Any configuration set with Group Policy overrides the configuration set by using **System properties**, as described in this procedure.

- Be aware of the security implications of remote logons. Users who log on remotely can perform tasks as though they were sitting at the console. For this reason, you should ensure that the server is behind a firewall. For more information, see VPN servers and firewall configuration and Security information for IPSec.

- You should require all users who make remote connections to use a strong password. For more information, see Strong passwords.

- Remote Desktop is disabled by default in Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect to Remote Desktop for Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to Remote Desktop for Administration**

- At the server
- At the remote computer

**At the server**

Be sure you have the appropriate permission to use Remote Desktop for Administration. You must be an Administrator, or you must be a member of the Remote Desktop Users group. To learn more about joining the Remote Desktop Users group, see Add users to the Remote Desktop Users group

1. Be sure **Remote Desktop for Administration** is enabled.
2. You must have the network computer name or IP address of the server.
3. You must not turn off the server.
4. Print this page and take these instructions to the remote computer.

### Notes

- To determine your network computer name, open **System** in Control Panel. On the **Computer Name** tab, locate the **Full computer name** item. Your computer name is the part of the text string to the left of the first period.
- To print this page, right-click anywhere on the text, and choose **Print** from the context menu.

**At the remote computer**

- From Windows Server 2003 family operating systems
- From an operating system other than a Windows Server 2003 family operating system

**From Windows Server 2003 family operating systems**

1. Connect to your company network by means of Local Area Network (LAN), modem, or Virtual Private Network (VPN) connection.
2. To open Remote Desktop Connection, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
3. Type in the name or IP address of the server you want to connect to, and then click **Connect.**

**From an operating system other than a Windows Server 2003 family operating system**

1. Log on to your Internet Service Provider (ISP).
2. Install the necessary client software from the Remote Desktop Connection Software Download page.
3. To open Remote Desktop Connection, click **Start**, point to **All programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

4. Type in the name or IP address of the server you want to connect to, and then click **Connect**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add users to the Remote Desktop Users group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add users to the Remote Desktop Users group**

1. Open Computer Management.
2. In the console tree, click the **Local Users and Groups** node.
3. In the details pane, double-click the **Groups** folder.
4. Double-click **Remote Desktop Users**, and then click **Add...**.
5. On the **Select Users** dialog box, click **Locations...** to specify the search location.
6. Click **Object Types...** to specify the types of objects you want to search for.
7. Type the name you want to add in the **Enter the object names to select (examples):** box.
8. Click **Check Names**.
9. When the name is located, click **OK**.

## Notes

- By default, the Remote Desktop Users group is not populated. You must decide which users and groups should have permission to log on remotely, and then manually add them to the group.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Share the client setup folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To share the client setup folder**

1. On your computer that is running one of the Windows Server 2003 family operating systems, open Windows Explorer.
2. Browse to the %Systemroot%\System32\Clients\Tsclient folder, where *systemroot* is the folder containing your Windows installation files (for example, C:\Windows\System32\Clients\Tsclient).
3. Right-click the \Tsclient folder, and then click **Sharing and Security...**.
4. Click **Share this folder.** The share name is displayed as **tsclient.** You can change the user limit by clicking **Allow this number of users** and choosing a number from the scroll box.

## Notes

- To share folders and drives, you must be logged on as a member of the Administrators, Server Operators, or Power Users group.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Install Remote Desktop Connection (32-bit computers)

# Install Remote Desktop Connection (32-bit computers)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Remote Desktop Connection (32-bit computers)**

1. On a computer running one of the Windows Server 2003 family operating systems, share the client setup folder.
2. From the computer running Windows 95, Windows 98, Windows NT 4.0 or Windows 2000, connect to the Local Area Network that contains the computer running one of the Windows Server 2003 family operating systems.
3. Click **Start**, and then click **Run**.
4. In **Open**, type the following:

   ```
   \\computername\Tsclient\Win32\Setup.exe
   ```

   Where *computername* is the network computer name of the computer running one of the Windows Server 2003 family operating systems. Click **OK**.
5. Follow the directions that appear on your screen.

### Notes

- To share folders and drives, you must be logged on as a member of the Administrators, Server Operators, or Power Users group.
- You can also install Remote Desktop Connection directly from the Microsoft Web Site.
- To determine your network computer name, open **System** in Control Panel. On the **Computer Name** tab, locate the **Full computer name** item. Your computer name is the part of the text string to the left of the first period.
- To use Microsoft IntelliMirror to deploy Remote Desktop Connection, share the Msrdpcli.msi file in the \Tsclient\Win32 folder.
- To use Group Policy to deploy Remote Desktop Connection, assign the program on a per-computer basis to a terminal server. For more information, see article Q324750, "HOW TO: Assign Software to a Specific Group By Using a Group Policy in Windows Server 2003" in the Microsoft Knowledge Base.
- When you use the Msrdpcli.msi file to install Remote Desktop Connection on computers that are not running one of the Windows Server 2003 family operating systems, the existing shortcut on the **Communications** menu is updated. In addition, the installation process adds a shortcut for Remote Desktop Connection to the **All Programs** menu. This also applies if you install the .msi file on a computer running a Windows XP operating system, which already has a version of Remote Desktop Connection installed by default.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Remote Desktop Web Connection**

1. Open Add or Remove Programs in Control Panel.
2. Click **Add/Remove Windows Components**.
3. Click **Application Server**, and then click **Details**.
4. Select **Internet Information Services**, and then click **Details**.
5. In the **Subcomponents of Internet Information Services** list, select **World Wide Web Service**, and then click **Details**.
6. In the **Subcomponents of World Wide Web Service** list, click the **Remote Desktop Web Connection** check box. Click **OK**. Click **OK** again, and then click **OK** a third time.
7. In the Windows Components wizard, click **Next**.
8. Verify that the RDP-Tcp connection is checked in the **Connection types:** box, and then click **Next** to begin the installation of the Remote Desktop Web Connection.

## Notes

- You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings may also prevent you from completing this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Connect to another computer using Remote Desktop Web Connection

# Connect to another computer using Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to another computer using Remote Desktop Web Connection**

1. Ensure that Remote Desktop Web Connection is installed and running on the Web server.

2. Ensure that your client computer has an active network connection and that the DNS server service (or other name resolution method) is functioning.

3. On your client computer, start Microsoft Internet Explorer.

4. In the **Address** box, type the Uniform Resource Locator (URL) for the home directory of the Web server hosting Remote Desktop Web Connection.

   The URL is "http://" followed by the Windows Networking name of your server, followed by the path of the directory containing the Remote Desktop Web Connection files (default = /Tsweb/). (Note the forward slash marks.) For example, if your Web server is registered with the DNS server as "Admin1", in the **Address** box you type: **http://admin1/tsweb/**, and then press **ENTER**. The Remote Desktop Web Connection page appears on the screen.

5. In **Server**, type the name or IP address of the remote computer to which you want to connect.

6. Optionally, specify the screen size and logon information for your connection.

7. Optionally, select the **Send logon information for this connection** checkbox and type your user name and domain.

8. Click **Connect**.

## Notes

- Remote Desktop Web Connection requires Internet Explorer 5 or higher.

- You may need to specify the fully qualified domain name of the computer you are connecting to if that computer is not part of your local area network.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect to the console session of a server using Remote Desktop for Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to the console session of a server**

Using the Remote Desktops MMC Snap-in

Using the command line

**Using the Remote Desktops MMC Snap-in**

1. Open Remote Desktops snap-in.
2. If you have not already done so, create the connection to the terminal server or computer to which you want to connect.
3. In the console tree, right-click the connection.
4. In the context menu, click **Connect**.

### Note

- To open Remote Desktops, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Desktops**.

**Using the command line**

1. Open Command Prompt.
2. Type:

   **mstsc /console**.
3. Remote Desktop Connection will start. Type the computer name or IP address of the computer you want to connect to in the **Computer** box.
4. Configure any other desired options, and then click **Connect**.

### Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To view the complete syntax for this command, at a command prompt, type:

  **mstsc /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the icon associated with the shortcut to a connection file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the icon associated with the shortcut to a connection file**

1. Create a connection file (.rdp file), or use an existing .rdp file.
2. Open Windows Explorer and create a shortcut to the .rdp file.
3. Right-click the shortcut, click **Properties,** and then click **Change Icon.**
4. Select an icon in the list on the **Change Icon** dialog box, and then click **OK.**
5. Click **OK** to close the **Shortcut Properties** dialog box.
6. Deploy the .rdp file and the shortcut to the appropriate users.

## Notes

- You might also have to deploy the icon (.ico) file, if it is not available on the users' computers.
- The default connection file, Default.rdp, is stored as a hidden file in **My Documents**. Connection files that you create are also stored in **My Documents**, but they are not hidden.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Remote Desktop for Administration:

- Remote Desktop for Administration overview
- Using Remote Desktop for Administration for remote server administration
- Configuring Remote Desktop for Administration
- Deploying Remote Desktop for Administration

# Remote Desktop for Administration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktop for Administration overview**
Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode) provides remote access to the desktop of computers running any Microsoft® Windows Server 2003 family operating system, allowing you to administer your server from virtually any computer on your network. For detailed information about using Remote Desktop for Administration for remote server administration, see Using Remote Desktop for Administration for remote server administration.

**Important**

- Be aware of the security implications of remote logons. Users who log on remotely can perform tasks as though they were sitting at the console. For this reason, you should ensure that the server is behind a firewall. For more information, see VPN servers and firewall configuration and Security information for IPSec.

- You should require all users who make remote connections to use Strong passwords.

To use Remote Desktop for Administration, you must enable remote connections at the server you plan to connect to. For more information, see Enable or disable Remote Desktop.

To connect to Remote Desktop for Administration from a remote computer, use Remote Desktop Connection. For more information, see Remote Desktop Connection.

**Notes**

- Remote Desktop for Administration is disabled by default in Windows Server 2003 family operating systems.

- By default, the Remote Desktop Users group is not populated. You must decide which users and groups you want to have permission to log on remotely, and then manually add them to the group. For more information, see Add users to the Remote Desktop Users group.

- Remote administration of servers with Remote Desktop for Administration is available on any computer running a Windows Server 2003 family operating system. A simpler version of Remote Desktop is also available on Microsoft Microsoft® Windows® XP Professional. For information on installing and configuring Terminal Server, see Terminal Server.

# Using Remote Desktop for Administration for remote server administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Remote Desktop for Administration for remote server administration**

Remote Desktop for Administration can greatly reduce the overhead associated with remote administration. Enabled by Terminal Services technology, Remote Desktop for Administration is specifically designed for server management. Therefore, it does not install the application-sharing and multiuser capabilities or the process scheduling of the full Terminal Server component (formerly called Terminal Services in Application Server mode). As a result, Remote Desktop for Administration can be used on an already busy server without noticeably affecting CPU performance, which makes it a convenient and efficient service for remote management.

Remote Desktop for Administration does not require you to purchase special licenses for client computers that access the server. It is not necessary to install Terminal Server Licensing when using Remote Desktop for Administration.

Administrators can also fully administer computers running Windows Server 2003 family operating systems from computers running earlier versions of Windows by installing Remote Desktop Connection.

**Notes**

- Remote Desktop for Administration is disabled by default in Windows Server 2003 family operating systems. For more information, see Enable or disable Remote Desktop.
- To connect to Remote Desktop for Administration from a remote computer, use Remote Desktop Connection. For more information, see Remote Desktop Connection.

**How Remote Desktop for Administration works**

You can use Remote Desktop for Administration to manage a network remotely using a configuration similar to the one shown in the following illustration.

Remote Desktop for Administration provides remote access to the server desktop by using the Terminal Services Remote Desktop Protocol (RDP) on port 3389. RDP transmits the user interface to the client session, and also transmits keyboard and mouse clicks from the client to the server. You can create up to two simultaneous remote connections. Each session you log on to is independent of other client sessions as well as the server console session. In essence, you can use Remote Desktop for Administration to log on to the server remotely as though you were logged on locally.

If you need to connect to the server console session remotely (for example, to access applications that direct only their user interface to the console), either use the Remote Desktops snap-in management tool or use Remote Desktop Connection from the command line. When you attempt to connect to the console session, whether remotely or locally, you will be notified if there is already another user connected to the console session. The notification message will be shown after your logon credentials are validated, and will include information about the user who is logged on to the console session, including user name, location of logon (local or remote), and the state of the session (in use, locked, or idle).

**Important**

- Be aware of the security implications of remote logons. Users who log on remotely can perform tasks as though they were sitting at the console. For this reason, you should ensure that the server is behind a firewall. For more information, see VPN servers and firewall configuration and Security information for IPSec.

- You should require all users who make remote connections to use a strong password. For more information, see Strong passwords.

The connection to Remote Desktop for Administration uses TCP/IP, either over an existing network connection or by remote access. A remote access server running one of the Windows Server 2003 family operating systems provides two different types of remote access connectivity:

- Network and Dial-up Connections
- Virtual private networking

The following illustration shows how you can connect to a computer running one of the Windows Server 2003 family operating systems from a remote location using remote access.

For more information, see Remote Access.

**Administering Windows Server 2003 family operating systems remotely**

After you are connected to a computer running a Windows Server 2003 family operating system, you can use Remote Desktop for Administration to remotely administer the server and its local computers. Remote Desktop for Administration gives you access to a variety of administrative tools you can use to configure and manage computers. Through a Terminal Services session, you can access Microsoft Management Console (MMC), Active Directory, Systems Management Server, network configuration tools, and most other administrative tools.

Remote Desktop for Administration is extremely useful because it provides remote access to most configuration settings, including Control Panel, which usually cannot be configured remotely. Also, using Remote Desktop for Administration can be particularly convenient for diagnosing a problem and testing multiple solutions quickly.

You can access the servers from anywhere in the world by using a wide-area network (WAN), a virtual private network (VPN), or a dial-up connection. You can start time-consuming batch administrative jobs (for example, tape backups), disconnect, and later reconnect to the corporate network to check progress.

Server application and operating system upgrades can be completed remotely as well as tasks that are not usually possible unless you are sitting at the console, such as domain controller promotion/demotion and disk defragmentation. Server file system tasks such as copying large files and virus scanning are much more efficient when performed within a Remote Desktop for Administration session, rather than using utilities that are executed from a client computer.

Administrative tasks are quicker and more intuitive than using command line utilities, although it is still possible to open a command shell.

**Note**

- For some third-party applications, pop-up messages cannot be seen from a Terminal Services session. This is because there is a different security context or desktop for the connected session that does not display the application's pop-up messages. The pop-up messages in these instances will go directly to the console. If you need to see these messages, connect to the console session using Remote Desktop Connection from the command line or the Remote Desktops MMC snap-in.

  For more information, see Connect to the console session of a server using Remote Desktop for Administration.

# Configuring Remote Desktop for Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Remote Desktop for Administration**
You can use the Terminal Services administrative tools to configure computers and users for Remote Desktop for Administration connections.

In addition to the standard administrative tools, Windows Server 2003 family operating systems include the following Terminal Services tools, Windows Server 2003 tool extensions, and commands for administering Terminal Services connections, computers, and users. While many of these tools are primarily intended for configuring Terminal Server for multiple users, they can also be used to configure Remote Desktop for Administration connections.

**Terminal Services Group Policies**
Use Terminal Services Group Policies to configure individual computers or groups of computers, or to assign policies for Remote Desktop for Administration users or user groups.

To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Terminal Services Manager**
Use Terminal Services Manager to manage and monitor users, sessions, and processes on any terminal server on the network.

- Display information about servers, sessions, users, and processes.
- Connect to and disconnect from sessions.
- Monitor sessions.
- Reset sessions.
- Send messages to users.
- Log off users.
- Terminate processes.

For more information on Terminal Services Manager, see Terminal Services Manager Overview.

To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Terminal Services Configuration**
During the installation of any Windows Server 2003 family operating system, a connection is configured for the Remote Desktop Connection (RDP) protocol. The connection provides the link clients use to log on to a session on the server for either Remote Desktop for Administration or Terminal Server connections. After installation, you can use Terminal Services Configuration (Tscc.msc) to change the properties of this connection on the local computer or to add new connections.

**Note**

- Many of these settings can also be set with Terminal Services Group Policy or Windows Management Instrumentation (WMI), in which case Terminal Services Configuration settings are overridden.

Use Terminal Services Configuration to:

- Name a connection.
- Specify a connection type.

- Specify a connection transport and transport properties.
- Set the maximum number of sessions allowed.
- Enable or disable logons through the connection.
- Set connection time-outs.
- Set the level of encryption.
- Set whether to disconnect broken connections.
- Enable or disable session remote control.
- Enable or disable automatic logons.
- Specify a program to run automatically when a user logs on.
- Override user profile settings for wallpaper.
- Set permissions on the connection.
- Set client device mapping and connection parameters.

For more information on Terminal Services Configuration, see Terminal Services Configuration Overview.

To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Active Directory Users and Computers and Local Users and Groups extensions**
Terminal Services extends Active Directory Users and Computers and Local Users and Groups to allow you to control Terminal Services features for each user. You can also use Terminal Services Group Policies to control these features, in which case settings you have specified might be overridden.

Use the Terminal Services extension to:

- Set the path to the Terminal Services user profile of each user.
- Enable or disable logons.
- Set time limits on session.
- Set whether to disconnect or reset a broken connection.
- Enable or disable remote control.
- Specify a program to run automatically when a user logs on.
- Automatically connect client drives and printers at logon.

For more information on the Terminal Services extensions, see Terminal Services Configuration Overview.

To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

Open Computer Management.

**System Monitor counters**
Terminal Services extends System Monitor by adding User and Session objects and their counters. You can use these objects and counters to monitor the resources that a user or session consumes. Terminal Services also adds counters to the Process and System objects.

For more information on Terminal Services performance monitoring, see Performance monitoring.

**Task Manager additional fields**
Terminal Services provides two additional fields, **ID** (session ID) and **User**, to Task Manager for monitoring and ending processes for all sessions. For more information, see Task Manager overview.

**Command line**
Use Terminal Services command-line functions to configure Terminal Services from the command prompt.

| Command | Function |
|---|---|
| change logon | Temporarily disables logons to a Terminal server. |
| change port | Changes COM port mappings for MS-DOS program compatibility. |
| change user | Changes the .ini file mapping for the current user. |
| Cprofile | Removes user-specific file associations from a user's profile. |
| dbgtrace | Enables and disables debug tracing. |
| flattemp | Enables or disables flat temporary directories. |
| logoff | Ends a client's session. |
| msg | Sends a message to one or more clients. |
| query process | Displays information about processes. |
| query session | Displays information about Terminal Services sessions. |
| query termserver | Lists Terminal Services servers on the network. |
| query user | Displays information about users logged on to the system. |
| register | Registers a program so that it has special execution characteristics. |
| reset session | Allows you to reset (delete) a session from the Terminal server. |
| shadow | Allows you to monitor or remotely control an active session of another user. |
| tscon | Connects to another existing Terminal Services session. |
| tsdiscon | Disconnects a client from a Terminal Services session. |
| tskill | Terminates a process. |
| tsprof | Copies user configuration and changes profile path. |
| tsshutdn | Shuts down a Terminal Services server. |

For more information on Terminal Services command-line functions, see Terminal Services commands.

**Terminal Services WMI Provider**
With the Terminal Services WMI provider, you can create customized scripts for configuring, managing, and querying terminal servers. For more information, see Configuring Terminal Services with WMI.

# Deploying Remote Desktop for Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying Remote Desktop for Administration**
This section covers:

- Getting the client software
- Enabling users to connect remotely to the server
- Deploying Remote Desktop Web Connection

# Getting the client software

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Getting the client software**

To set up your client computer to connect to Remote Desktop for Administration, you need the following:

- Access to the remote computer (the computer running a Windows Server 2003 family operating system) by means of Local Area Network (LAN), modem, or Virtual Private Network (VPN) connection.

- Remote Desktop Connection or Terminal Services client installed on the client computer. See the following table for instructions on installing the client software for your operating system.

  **Important**

  - You should install the latest version of Remote Desktop Connection. If you are using the Windows 2000 32-bit Terminal Services Client, you should upgrade to the version of Remote Desktop Connection that is provided with all Windows Server 2003 family operating systems.

| Operating System | Client version | How to access |
|---|---|---|
| Windows Server 2003 family operating systems (all versions) | **Remote Desktop Connection** installed by default | **Start/Programs/Accessories/Communications/Remote Desktop Connection** |
| Windows XP (all versions) | **Remote Desktop Connection** installed by default | **Start/Programs/Accessories/Communications/Remote Desktop Connection** |
| Microsoft Windows 2000 Professional | Not installed | See Install Remote Desktop Connection (32-bit computers) |
| Microsoft Windows 2000 Server | Not installed | See Install Remote Desktop Connection (32-bit computers) |
| Microsoft Windows 95 & Microsoft Windows 98 | Not installed | See Install Remote Desktop Connection (32-bit computers) |
| Windows NT 4.0 | Not installed | See Install Remote Desktop Connection (32-bit computers) |
| Microsoft Windows CE | Not installed | Go to the Microsoft Web Site and follow the directions to install the Windows CE client. |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enabling users to connect remotely to the server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling users to connect remotely to the server**
To enable users to connect remotely to a terminal server, you must ensure that:

- Remote Desktop is enabled on the server. For instructions on how to enable Remote Desktop, see Enable or disable Remote Desktop.
- Users have the appropriate rights and permissions to log on remotely to the server.

To perform these two tasks, you must be logged on as a member of the Administrators group.

**Using the Remote Desktop Users group to grant access to a terminal server**
You can easily manage permissions and rights for a terminal server on a per-computer basis, by using the Remote Desktop Users group. The Remote Desktop Users group is one of the built-in users groups available when you install one of the Windows Server 2003 operating systems. Members of this group are able to log on remotely to a terminal server on which Remote Desktop is enabled.

By default, the Remote Desktop Users group is not populated. Therefore, you must decide which users and groups should have access to log on remotely to a terminal server, and then add them to this group. For instructions on how to add users to the Remote Desktop Users group, see Add users to the Remote Desktop Users group.

It is highly recommended that you use the Remote Desktop Users group to grant individuals access to terminal servers, rather than assigning the required permissions manually

**Caution**

If you alter the default permissions on the Remote Desktop Users group or remove this group, members of this group might lose the ability to log on remotely to terminal servers.

**Assigning Permissions Manually**
In some cases, it might be necessary to manage access to a terminal server on a per-connection basis and to manually customize rights and permissions. Keep in mind that if you do not use the Remote Desktop Users group to grant users access to log on to a terminal server, you must assign those users the same rights and permissions manually. The required rights and permissions are as follows:

| Right or permission | Comments |
|---|---|
| Allow log on through Terminal Services | This right determines which users or groups have permission to log on as a Terminal Services client.<br><br>Configure by navigating to **Computer Configuration\Windows Settings\Security Settings\Local Policies\User Rights Assignment**.<br><br>For configuration instructions, see Edit security settings on a Group Policy object. |

| | |
|---|---|
| User Access | • This permission type grants the following special permissions: Query Information, Logon, and Connect. These special permissions allow a user to:<br>• Log on to a session on the terminal server.<br>• Query information about a session.<br>• Send messages to other user sessions.<br>• Connect to another session.<br><br>Configure by using Terminal Services Configuration.<br><br>For configuration instructions, see Change the permissions a user or group has to a connection. |

You can also explicitly deny an individual user access to a terminal server by modifying that user's terminal server profile. Doing this is useful if you have granted a large group access to a terminal server, but want to make individual exceptions as needed. For instructions, see Deny a user permissions to log on to terminal servers.

# Deploying Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying Remote Desktop Web Connection**
This section provides information about deploying Remote Desktop Web Connection. Remote Desktop Web Connection is a Web application consisting of an ActiveX component and sample connection pages. When you deploy Remote Desktop Web Connection on a Web server, you can provide client connectivity to terminal servers and other computers via Internet Explorer and TCP/IP.

This section provides general background information about deploying Remote Desktop Web Connection:

- About Remote Desktop Web Connection.
- Setting up Remote Desktop Web Connection.
- Providing for Client Security
- About the Sample Web Page
- Customizing Remote Desktop Web Connection

# About Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**About Remote Desktop Web Connection**

Remote Desktop Web Connection is a Web application that consists of an ActiveX control, sample web pages, and other files. When deployed on a Web server, Remote Desktop Web Connection allows users to create a Terminal Services connection within Internet Explorer, even if a Terminal Services client program is not installed on the user's computer.

Remote Desktop Web Connection offers the following benefits:

- **Simple, straightforward deployment of a Terminal Services client.** With Remote Desktop Web Connection, deploying a Terminal Services connection can be as easy as sending a URL.
- **Support for roaming users.** Users who are away from their computers can use Remote Desktop Web Connection to gain secure access to their primary workstation or favorite terminal server from any computer running Windows and Microsoft Internet Explorer 5 or later.
- **A lowest common denominator cross-platform system.** Remote Desktop Web Connection may meet the needs of organizations that want identical clients on different platforms.
- **Delivery of extranet applications.** Corporations that want to deploy Terminal Services connections to vendors, suppliers, or customers can use Remote Desktop Web Connection to distribute them easily, inexpensively, and efficiently over the Internet.

**How Remote Desktop Web Connection works**

When a Web user accesses a Web page that contains the embedded Remote Desktop Web Connection ActiveX Client Control, the following sequence of events occurs:

- If necessary, Internet Explorer (IE), version 5 or later, downloads the .cab file pointed to by the CODEBASE parameter of the OBJECT tag. This is necessary in the following circumstances:
    - The computer that accessed the Web page does not have an installation of the full Remote Desktop Connection program or the Terminal Services Advanced Client with Web support.
    - The installed version of the .cab file on the client computer is older than the version on the Web page.
- After downloading, IE decompresses the .cab file and installs the ActiveX Client Control in IE's default location for downloaded controls on the target computer.
- The default connection page appears, asking the user for server, logon, and connection information.
- The Remote Desktop opens in the Web page. Depending on the parameters passed and the settings of the remote computer to which the user is trying to connect, the Windows logon screen appears.

For information on using Remote Desktop Web Connection from the client computer, see Connect to another computer using Remote Desktop Web Connection.

# Setting up Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up Remote Desktop Web Connection**
Remote Desktop Web Connection is an optional World Wide Web Service component of Internet Information Services, which is included in Windows XP Professional and Windows Server 2003 family operating systems. Remote Desktop Web Connection is not installed by default, but must be installed using **Add or Remove programs**.

When you install Remote Desktop Web Connection, the files are copied by default to the **%systemroot%\Web\Tsweb** directory of your web server. The included sample default.htm page can be used as is, or you can modify it to meet the needs of your application.

On the client side, Remote Desktop Web Connection requires that the computer have a TCP/IP connection to the Internet or network, and be running Microsoft Internet Explorer 5 or later.

**Important**

- If you are setting up a Web site for yourself or for some non-Administrator users of a server running one of the Windows Server 2003 family operating systems, you must disable the Internet Explorer Enhanced Security Configuration setting for Internet Explorer. Otherwise, all server users, including Administrators, will be prevented from downloading files or ActiveX controls such as Remote Desktop Web Connection from the Web site. To change this setting, use **Add/Remove Windows Components** in **Add or Remove programs**. For more information, see Internet Explorer Enhanced Security Configuration.

For more information, see:

- Install Remote Desktop Web Connection.
- Connect to another computer using Remote Desktop Web Connection.
- About the Sample Web Page.

For information on customizing Remote Desktop Web Connection, see the Microsoft Platform SDK.

# Providing for Client Security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing for client security**

To allow clients to protect themselves from potentially untrustworthy servers, some properties of the Remote Desktop Web Connection ActiveX component object are restricted to certain Internet Explorer security zones. This means that when a Web user accesses the page from a computer in a less secure zone, these properties are disabled.

Some of these restricted properties are:

**StartProgram**
Specifies a program to start upon connection.

**WorkDir**
Specifies the working directory for the program specified in StartProgram.

**FullScreen**
Specifies whether the connection will be displayed as full screen or windowed mode.

Servers using Remote Desktop Web Connection can display these restricted properties in the following Internet Explorer security zones:

- My Computer
- Local Intranet
- Trusted Sites

Servers using Remote Desktop Web Connection cannot display restricted these properties in the following zones:

- Internet
- Restricted Sites

For more information about Remote Desktop ActiveX Control interfaces, see Remote Desktop Control ActiveX Interface (http://go.microsoft.com/fwlink/?LinkId=102079).

# About the Sample Web Page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**About the Sample Web page**

When you install Remote Desktop Web Connection, a sample Web page, Default.htm, is copied to the installation directory on your computer. This page can be run as is, or it can be modified.

Default.htm is a default logon page that is designed to collect connection information from the user. This page contains a required field for the terminal server or remote computer to which the user wants to connect and optional fields for screen size and user logon information (username and domain). After this data is collected, it is passed to the ActiveX Client Control (Msrdp.ocx) to initiate a remote desktop session. The entire process works as follows:

1. If necessary, IE downloads the .cab file containing the ActiveX component and installs it on the user's computer.
2. The user types in the fully qualified domain name or IP address of the remote computer. Optionally, the user specifies a screen size for the connection. If no screen size is specified, the session opens in Full Screen mode (if the user is in a trusted zone. See Providing for Client Security for more information).
3. Optionally, the user supplies automatic logon information (username, domain) for the remote session.
4. When the user clicks the **Connect** button, Default.htm passes the parameters to the ActiveX Client Control.
5. The remote desktop opens in the browser window (or full screen).

When Default.htm opens for the first time in Internet Explorer, a dialog box appears and asks if the user wants to download the Msrdp.ocx ActiveX component. This happens only under the following conditions:

- The computer that accessed the Web page does not have an installation of the full Terminal Services Client with Web support.
- The installed version of the .cab file on the client computer is older than the version on the Default.htm page.

For security reasons, some options that are available in Remote Desktop Web Connection are restricted to certain Internet Explorer security zones when called by the Remote Desktop Web Connection ActiveX Client Control. See Providing for Client Security for more information.

The screen size specified by the user in this form is the size of the remote desktop upon connection. The remote desktop appears at the specified size in the browser window or, if the session opens in the default full-screen mode, the browser controls and borders disappear and the remote desktop expands to the size of the user's screen. As with the full Remote Desktop Connection program, the user can toggle between full-screen and windowed mode by pressing CTRL+ALT+BREAK.

The size of the remote desktop session is specified in Default.htm. To change the screen size, the user must return to Default.htm (after disconnecting the session) and edit the connection. If no screen size is specified, the remote desktop opens in the browser window in the default full-screen mode. At this resolution, the IE tool bars and window frames disappear, and the remote desktop expands to match the full dimensions of the user's screen. As with the full Remote Desktop Connection client, the user can toggle between full-screen and windowed mode by pressing CTRL+ALT+BREAK.

See Providing for Client Security for information on specifying a program to run upon connection.

# Customizing Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Customizing Remote Desktop Web Connection**

The sample Default.htm page is installed with Remote Desktop Web Connection and can be used as is, or can be customized to fit the needs of your organization. Web authors can embed the Remote Desktop Web Connection ActiveX Control in a Web page with the HTML <OBJECT> tag, and can use the scriptable interfaces, for example, to specify a specific program to run upon connection, to allow seamless logon, and to specify advanced configuration options for the client connection.

If you have enabled a Virtual Channels application in your Terminal Services deployment, you can also make this application available to client computers that access the terminal server by means of the Remote Desktop Web Connection ActiveX component.

For a complete documentation of the full set of Remote Desktop Web Connection ActiveX Control parameters, see the Microsoft Platform SDK.

# Troubleshooting Remote Desktop for Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Client fails to connect with "This initial program cannot be started" message.
- Cannot disconnect active RAS connections with Terminal Services.
- The connection does not automatically log on to the server. I am prompted for my user name and password on connection.
- The Remote Desktop connection is very slow.
- The screen saver on my Remote Desktop is blank.

**Client fails to connect with "This initial program cannot be started" message.**
**Cause:** The client connection might have been configured to start a program upon connection, but the program path and filename are incorrect.

**Solution:** Check the properties for the client connection to ensure that the program path and filename are correct, and that the program exists in this location on the server.

**Cause:** The server administrator might have specified a program to start upon connection, using Group Policy, Terminal Services Configuration, or other Terminal Services administration tools.

**Solution:** Check the server configuration to ensure that the program path and filename specified for this user are correct, and that the program exists in this location on the server.

**Cannot disconnect active RAS connections with Terminal Services.**
**Cause:** When a RAS connection is established in a Terminal Services session, the current ID of the session is added to the port. When disconnecting the RAS connection, the current session ID must match the session ID that was added to the port, or it cannot be disconnected.

**Solution:** A RAS connection can only be disconnected from inside the session in which it was established.

**The connection does not automatically log on to the server. I am prompted for my user name and password on connection.**
**Cause:** Due to encryption enhancements for Windows Server 2003 family operating systems, the Windows NT 4.0 version of Terminal Services Client does not recognize the user name and password in the automatic logon portion of the connection file.

**Solution:** From the Windows NT 4.0 version of Client Connection Manager, right-click the connection and select **Properties**. On the **General** tab, select **Automatic logon**, and then type the user name, password, and domain.

**Solution:** Upgrade the client software to Remote Desktop Connection.

**Cause:** The server administrator has configured the server to deny automatic logon.

**Solution:** Type your user name and password when prompted.

**Cause:** User name and password information has not been added to Remote Desktop Connection.

**Solution:** In Remote Desktop Connection, on the **General** tab, type your user name and password, and then select the **Save my password** checkbox.

**The Remote Desktop connection is very slow.**
**Cause:** A low-bandwidth connection can slow Remote Desktop performance.

**Solution:** On the remote computer, set the background selection to **None.**

**Solution:** Do not run memory-intensive applications, for example, video games, over Remote Desktop.

**The screen saver on my Remote Desktop is blank.**

**Cause:** When a screen saver is activated on Remote Desktop, it is blank. This is true regardless of whether you have previously selected a different screen saver.

**Solution:** Continue to use the blank screen saver.

# Remote Desktops snap-in

Updated: May 9, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktops snap-in**

The Remote Desktops snap-in enables you to manage Remote Desktop connections to terminal servers and computers that are running Windows 2000 Server or Windows Server 2003 operating systems. The following topics provide information about this snap-in:

- For general background information, see Remote Desktops snap-in overview.
- For help with specific tasks, see Remote Desktops snap-in How To....

# Remote Desktops snap-in How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Add the Remote Desktops snap-in
- Create a new connection with the Remote Desktops snap-in
- Connect to a session
- Disconnect from a session
- Change an existing connection
- Delete a connection

# Add the Remote Desktops snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add the Remote Desktops snap-in**

1. Run MMC by doing one of the following:

   - Click **Start**, click **Run**, type `mmc`, and then click **OK.**
   - At a command prompt, type `mmc`, and then press ENTER.

2. On the **Console** menu, click **File,** and then click **Add/Remove Snap-in.**
3. In the dialog box that opens, click **Add.** In the **Available Standalone Snap-ins** list, click **Remote Desktops**.
4. Click **Add,** and then click **Close.**
5. Click **OK** to close the **Add/Remove Snap-in** dialog box.

**Note**

- You can also open the Remote Desktops snap-in from the Administrative Tools folder in Control Panel. To open Remote Desktops, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Desktops**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Enable or disable Remote Desktop

# Create a new connection with the Remote Desktops snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new connection**

1. Open Remote Desktops snap-in.
2. In the console tree, right-click **Remote Desktops**.
3. Click **Add new connection...**.
4. In the **Add New Connection** dialog box, in **Server name or IP address**, type the name or TCP/IP address of the server. Click **Browse** to look for a server.
5. Optionally, in **Connection Name**, type a friendly name for this connection.
6. Uncheck **Connect to console** if you do not want to connect to the console session on the server.

   **Important**

   - A connection to the console session always provides a full desktop session, just as you would see if you were logged on to the server locally. If you want to start a specific program on connection to the server, you must uncheck **Connect to console** ands specify a program path and file name on the **Other** tab.

7. Optionally, In **Logon information**, supply the User name, Password and Domain for automatic logon to the server. Click **OK**.

**Notes**

- To open Remote Desktops, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Remote Desktops**.
- Depending on the configuration of the Terminal server, you might be prompted to supply your password upon connection even if you specify it in the **Add New Connection** dialog box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remote Desktops snap-in overview

Updated: May 9, 2008

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktops snap-in overview**

The Remote Desktops snap-in is a tool that administrators can use to administer multiple computers from a single remote location. By using the Remote Desktops snap-in, you can create Remote Desktop connections to multiple servers (including terminal servers) that are running Windows 2000 Server or Windows Server 2003 operating systems. You can also create connections to computers that are running the Windows XP Professional operating system. A navigable tree display provides easy switching between connections.

The Remote Desktops snap-in is included with Windows Server 2003. It is also included with the Windows Server 2003 Administration Tools Pack (Adminpak.msi). The Administration Tools Pack provides server management tools that enable administrators to remotely manage Windows 2000 Server-based or Windows Server 2003-based servers from a Windows XP-based or Windows Server 2003-based computer. You can download the Windows Server 2003 Service Pack 2 (SP2) version of the Administration Tools Pack from the following Web sites:

- Windows Server 2003 SP2 Administration Tools Pack for x86 editions (http://go.microsoft.com/fwlink/?LinkId=114415)
- Windows Server 2003 SP2 Administration Tools Pack for x64 editions (http://go.microsoft.com/fwlink/?LinkId=114416)

By default, when you connect to a Windows Server 2003-based computer, the Remote Desktops snap-in connects you to the console session of the computer that you specify in the connection. To run a specific program upon connection, create a new connection that specifies the program name, and ensure that the default behavior is not selected. For more information, see Specify a program to start upon connection using Remote Desktops snap-in.

Most of the procedures that you can perform with the Remote Desktops snap-in require that you be logged on as an administrator or as a member of the Administrators group. If your computer is connected to a network, network policy settings may prevent you from completing a given procedure.

# Remote Desktop Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktop Connection**
With Remote Desktop Connection, you can easily connect to a terminal server or to any computer running Remote Desktop. All you need is network access and permissions to connect to the other computer. Optionally, you can specify special settings for your connection and then save the settings for the next time you connect.

For help with specific tasks, see Remote Desktop Connection How To....

For general background information, see Remote Desktop Connection Concepts.

For troubleshooting information, see Troubleshooting Remote Desktop Connection.

**Notes**

- To enable your computer to accept remote connections, your computer must be running Windows NT4 Terminal Server Edition, Windows 2000 Server, Windows XP Professional, or a Windows Server 2003 operating system. Check Help for your operating platform for more information.

- To open **Remote Desktop Connection**, click **Start**, point to **programs** or **All programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

- To view a list of available computers on the domain, click the **Computer** arrow and select **<Browse for more...>**.

# Remote Desktop Connection How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Create a new connection with Remote Desktop Connection
- Reestablish a prior connection
- Save your connection settings to a file
- Open a saved connection
- Connect to the console session of a server using Remote Desktop Connection
- Disconnect without ending a session
- Log off and end the session
- Copy and paste a file from a local computer to a remote computer
- Copy and paste a file from a remote computer to a local computer
- Change Connection Settings

# Create a new connection with Remote Desktop Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new connection**

1. Open **Remote Desktop Connection**.

2. In **Computer**, type a computer name or IP address. The computer can be a terminal server, or it can be a computer running Windows XP Professional or a Windows Server 2003 operating system that has Remote Desktop enabled and for which you have Remote Desktop permissions.

   To connect to the console session of the remote computer, in **Computer**, type:

   ***computername or IP address* /console**

3. Click **Connect**.

   The **Log On to Windows** dialog box appears.

4. In the **Log On to Windows** dialog box, type your user name, password, and domain (if required), and then click **OK**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **programs** or **All programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

- To change your connection settings, (such as screen size, automatic logon information, and performance options), click **Options** before you connect. For more information, see Change Connection Settings.

Reestablish a prior connection

Save your connection settings to a file

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reestablish a prior connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reestablish a prior connection**

1. In the **Remote Desktop Connection** window, click the **Computer** arrow and select the name of the computer to which you want to connect.

2. Click **Connect**.

   The **Log On to Windows** dialog box appears.

3. In the **Log On to Windows** dialog box, type your user name, password, and domain (if required), and then click **OK**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

- To view a list of available computers on the domain, click the **Computer** arrow and select **<Browse for more...>**.

# Save your connection settings to a file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save your connection settings to a file**

1. Open **Remote Desktop Connection**.
2. Click **Options**.
3. Specify the connection settings that you want for this connection, (such as screen size, automatic logon information, and performance options).
4. On the **General** tab, click **Save As**.
5. Enter a file name for the saved connection file, and then click **Save**.

## Notes

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Connections are saved as Remote Desktop protocol (.rdp) files. An .rdp file contains all of the information for a connection to a terminal server, including the **Options** settings that were configured when the file was saved. You can customize any number of .rdp files, including files for connecting to the same server with different settings. For example, you can save a file that connects to *MyServer* in full screen mode and another file that connects to the same computer in 800×600 screen size. The default connection file, Default.rdp, is stored as a hidden file in **My Documents.** Connection files that you create are also stored in **My Documents,** but they are not hidden. To edit an .rdp file and change the connections settings it contains, right-click the file and then click **Edit**.
- For more information about specifying connection settings, see Change Connection Settings.

# Open a saved connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open a saved connection**

1. In Windows Explorer, open the **My Documents** folder.
2. Double-click the .rdp file for the connection you want to open.

**Note**

- A Remote Desktop protocol (.rdp) file contains all of the information for a connection to a remote computer, including the **Options** settings that were configured when the file was saved. You can customize any number of .rdp files, including files for connecting to the same server with different settings. For example, you can save a file that connects to *MyServer* in full screen mode and another file that connects to the same computer in 800×600 screen size. The default connection file, Default.rdp, is stored as a hidden file in **My Documents.** Connection files that you create are also stored in **My Documents,** but they are not hidden. To edit an .rdp file and change the connections settings it contains, right-click the file and then click **Edit**.

# Connect to the console session of a server using Remote Desktop Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to the console session of a server**

1. Open Command prompt.

2. Type:

   **mstsc/v:***server***/console**

| Value | Description |
|---|---|
| Server | The DNS name or IP address of the server to which you want to connect |

**Notes**

- To open command prompt, Click **Start**, point to **programs** or **All programs**, point to **Accessories**, and then click **Command prompt**.

- You can also connect to the console session of a server by specifying "/console" when you type a server name or IP address in the **Computer** field on the **General** tab on the Remote Desktop Connection **Options** dialog box.

- Each computer has only one console session. When you connect to the console session remotely, other users may be unable to log on to the computer locally.

- Some client option settings are not applied when a connection is made to the console session of a remote computer running Windows XP. For example, if the client has specified a program to start upon connection to a remote computer, that program does not start if the connection is made to the console session of the remote computer. Instead, the default desktop appears. If the connection is made to a session other than the console session, the specified program starts as expected. The console session is the only session available for Remote Desktop on Windows XP Professional, so the default desktop always appears when a connection is made, even if the client has specified a different program.

- To view the complete syntax for this command, at a command prompt, type:

  **mstsc /?**

# Disconnect without ending a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect without ending a session**

1. In the Remote Desktop Connection window, click **Start**, and then click **Shut Down**.

   The **Shut Down Windows** dialog box appears.

2. Click **Disconnect**, and then click **OK**.

## Notes

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- You can also disconnect from a session by closing the Remote Desktop Connection window.
- Remote Desktop Connection automatically reconnects to this session the next time you connect to this computer (if the remote computer is configured to allow reconnection of disconnected sessions).

# Log off and end the session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To log off and end the session**

1. In the **Remote Desktop Connection** window, click **Start**, and then click **Shut Down**.

   The **Shut Down Windows** dialog box appears.

2. Click **Log Off <*username*>**, and then click **OK**.

**Note**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

# Copy and paste a file from a local computer to a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy and paste a file from a local computer to a remote computer**

1. Use Remote Desktop Connection to establish a connection to a remote computer.

2. Click **Start** on the task bar of the remote computer, and then click **My Computer**, or double-click the **My Computer** icon on the desktop of the remote computer.

   When Windows Explorer opens on the remote computer, it displays the drives on the remote computer. If you have chosen to make your local drives available in a session, Windows Explorer on the remote computer also displays the drives on your local computer. The following example shows how the drives on your local computer are named when they appear in Windows Explorer on the remote computer.

   ```
   <driveletter> on <computername>
   ```

   *tsclient* is the name that Remote Desktop Connection assigns to your local computer.

3. Right-click the file residing on your local computer that you want to transfer to the remote computer, and then click **Copy.**

4. Navigate in the same Windows Explorer window to the location on the remote computer where you want to paste the file.

5. Right-click the folder icon and then click **Paste.**

**Note**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

# Change Connection Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change connection settings**

- Provide information for automatic logon
- Reconnect if connection is dropped
- Change the screen size for connections
- Change the color settings for connections
- Improve the performance of connections
- Display the connection bar in full-screen mode
- Specify a program to start upon connection Remote Desktop Connection
- Configure connections to play audio
- Make your local disk drives available in a session
- Make your local printer available in a session
- Make your local serial port available in a session
- Make a smart card available in a session
- Configure Windows shortcut keys in a session
- Configure bitmap caching

# Provide information for automatic logon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To provide information for automatic logon**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **General** tab, under **Logon settings**, in the **User name** box, verify that your user name is correct.
3. If required, in the **Domain** box, type the domain to automatically log on to.
4. Optionally, clear the **Save my password** check box, and then enter your password in the **Password** box.
5. Click **Connect**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Depending on the policies of your network or the configuration of the terminal server to which you want to connect, you might be prompted to supply your password upon connection, even if you supply it for automatic logon.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Reconnect if connection is dropped

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reconnect if connection is dropped**

1. Open **Remote Desktop Connection**.
2. Click **Options**
3. On the **Experience** tab, select the **Reconnect if connection is dropped** check box.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- To change your connection settings, (such as screen size, automatic logon information, and performance options), click **Options** before you connect.

# Change the screen size for connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the screen size for connections**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **Display** tab, under **Remote desktop size**, drag the slider to choose the size of your remote desktop. Drag the slider all the way to the right for full screen.
3. Click **Connect**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Change the color settings for connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the color settings for connections**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **Display** tab, in the **Colors** list, click the color resolution you want.
3. Click **Connect**.

## Notes

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Depending on the policies of your network or the configuration of the terminal server to which you want to connect, the maximum color resolution for your remote connection might be limited. If the color resolution you select is higher than the allowable setting, Remote Desktop Connection creates the connection at the maximum allowable color resolution.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Improve the performance of connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To improve the performance of connections**

1. In the **Remote Desktop Connection** dialog box, click **Options**, and then click the **Experience** tab.

2. In the **Performance** box, choose the speed of your connection.

   To improve the performance of the connection, you can allow certain characteristics of the remote Windows session to appear if they are enabled on the remote computer. The characteristics that can be changed depend on the speed of your connection.

   If you choose **Custom**, you can check any combination of boxes. Your choices are saved in a connection (.rdp) file.

## Notes

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

- The default connection speed is **Modem (56 Kbps).** This speed offers very good performance for most networks. Use the faster speed settings to enable richer graphical features, such as desktop wallpaper or menu sliding and fading. To select a combination of individual effects, use the **Custom** setting.

- Depending on the speed of your connection, you can specify the following characteristics:

  - Desktop background

  - Show window contents while dragging

  - Menu fading and sliding

  - Themes

  - Bitmap caching

# Display the connection bar in full-screen mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display the connection bar in full-screen mode**

1. In the **Remote Desktop Connection** window, click **Options.**
2. On the **Display** tab, check the **Display the connection bar when in full screen mode** box.
3. Click **Connect.**

## Notes

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- For the first five seconds of a remote connection, the connection bar is displayed so you can verify that you are connected to the correct remote computer. This occurs even though you have chosen not to display the connection bar.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp. To create connections with different or connection-specific options, see Save your connection settings to a file.

# Specify a program to start upon connection Remote Desktop Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a program to start upon connection**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **programs** tab, under **Start a program**, click **Start the following program on connection**.
3. In the **program path and file name** box, type the path and file name of the program that you want to run after the connection is created.
4. Optionally, in the **Start in the following folder:** box, type the path to the working directory of the program.
5. Click **Connect**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **programs** or **All programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- This option works only if you are connecting to a terminal server.
- When the connection is made, only the specified program runs on the remote computer.
- Some client option settings are not applied when a connection is made to the console session of a remote computer running Windows XP. For example, if the client has specified a program to start upon connection to a remote computer, that program does not start if the connection is made to the console session of the remote computer. Instead, the default desktop appears. If the connection is made to a session other than the console session, the specified program starts as expected. The console session is the only session available for Remote Desktop on Windows XP Professional, so the default desktop always appears when a connection is made, even if the client has specified a different program.
- There are two ways to end a session.
    - To end the session and close the program, use the program's **Exit** command.
    - To disconnect the session and leave the program running on the remote computer, close the Remote Desktop Connection window.
- To specify a path, type the drive letter followed by a colon (:) and a backslash (\), type the names of the folders and subfolders that contain the file, separating each name with a backslash, and then type the name of the file or folder you want to open.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Configure connections to play audio

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure connections to play audio**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **Local Resources** tab, in the **Remote computer sound** list, click the option you want.
   - To run sound files in your Remote Desktop session and hear them on your local computer, choose **Bring to this computer**.
   - To run sound files in your Remote Desktop session and play them only on the remote computer, choose **Leave at remote computer**.
   - To disable all sound in Remote Desktop sessions, choose **Do not play**.
3. Click **Connect**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Depending on the policies of your network, audio redirection might be disabled for some or all remote connections. Additionally, audio redirection does not work when you connect to a server running Windows 2000 or earlier.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Make your local disk drives available in a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make your local disk drives available in a session**

1. In the **Remote Desktop Connection** window, click **Options.**
2. On the **Local Resources** tab, Under **Local devices**, click **Disk drives.**
3. Click **Connect.**

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Mapping local drives is not available on computers running Windows 2000 or earlier versions of Windows.
- Depending on the policies of your network, local drive mapping might be disabled for some or all remote connections.
- You might see a Remote Desktop Connection Security Warning, which asks whether you want to connect your local disk drives, local ports, or smart card to the remote computer. To enable one or more of these connections, check the appropriate check boxes. If you choose not to enable these connections, a Remote Desktop Connection is still established, but these resources are not available to the remote computer.
- When you click **Connect**, the information you enter in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make your local serial port available in a session**

1. In the **Remote Desktop Connection** window, click **Options.**
2. On the **Local Resources** tab, under **Local devices**, click **Serial ports.**
3. Click **Connect.**

## Notes

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Depending on the policies of your network, local serial port mapping might be disabled for some or all remote connections.
- You might see a Remote Desktop Connection Security Warning, which asks whether you want to connect your local disk drives, local ports, or smart card to the remote computer. To enable one or more of these connections, check the appropriate check boxes. If you choose not to enable these connections, a Remote Desktop Connection is still established, but these resources are not available to the remote computer.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Make a smart card available in a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a smart card available in a session**

1. In the **Remote Desktop Connection** window, click **Options.**
2. On the **Local Resources** tab, Under **Local devices**, click **Smart card.**

   **Note**

   - The option to enable smart card redirection is not displayed unless a smart card is present and the service is enabled.

3. Click **Connect.**

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection.**
- Depending on the policies of your network, smart card redirection might be disabled for some or all remote connections.
- You might see a Remote Desktop Connection Security Warning, which asks whether you want to connect your local disk drives, local ports, or smart card to the remote computer. To enable one or more of these connections, check the appropriate check boxes. If you choose not to enable these connections, a Remote Desktop Connection is still established, but these resources are not available to the remote computer.
- When you click **Connect**, the information you enter in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Configure Windows shortcut keys in a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Windows shortcut keys in a session**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **Local Resources** tab, under **Keyboard**, click the **Apply Windows key combinations** list, and then click the option you want. This option affects the behavior of Windows shortcut key combinations (such as **ALT+TAB**) when you are connected to a remote computer.
   - To configure your connection so that Windows shortcut keys always apply to your local desktop, choose **On the local computer**.
   - To configure your connection so that all Windows shortcut keys apply to the desktop of the remote computer, choose **On the remote computer**.
   - To configure your connection so that Windows shortcut keys apply to the remote computer only when the connection is in full screen mode, choose **In full screen mode only**.
3. Click **Connect**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- When you click **Connect**, the information you have entered in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.
- This procedure does not apply if you are using Remote Desktop Connection on a computer running Windows 95, Windows 98, or Windows Millennium Edition.
- CTRL+ALT+DEL always goes to the local desktop. If you need to send CTRL+ALT+DEL to the remote computer, you must use CTRL+ALT+END.
- To toggle between full screen and non-full screen mode during a Terminal Services session, use CTRL+ALT+BREAK.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure bitmap caching

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure bitmap caching**

1. In the **Remote Desktop Connection** window, click **Options**.
2. On the **Experience** tab, verify that the **Bitmap caching** check box is selected. Or, to disable bitmap caching, clear the **Bitmap caching** check box.
3. Click **Connect**.

**Notes**

- To open **Remote Desktop Connection**, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- Bitmap caching can speed up your connection by storing frequently used images on your local hard disk. By default, bitmap caching is enabled for Remote Desktop connections. It is recommended that you use bitmap caching unless instructed otherwise by your network administrator.
- When you click **Connect**, the information you enter in **Options** becomes the default setting for all Remote Desktop connections and is saved in a file called Default.rdp.

# Remote Desktop Connection Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

- Cutting and pasting to and from remote sessions
- Making local resources available to a terminal server
- Using a smart card to log on to a terminal server
- Accessing local files and folders in a remote session
- Printing to your local printer from a remote session
- Using Terminal Services shortcut keys

# Cutting and pasting to and from remote sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cutting and pasting to and from remote sessions**
Many Remote Desktop and Terminal Server connections provide clipboard sharing, allowing you to cut and paste from programs running in your Remote Desktop session to programs running on your local computer.

When you cut or copy information from a program, it is moved to the Clipboard and remains there until you clear the Clipboard or until you cut or copy another piece of information. The Clipboard window in ClipBook Viewer (Clipbrd.exe) shows the contents of the Clipboard. You can paste the information from the Clipboard into any document as often as you like. However, the information is only stored on the Clipboard temporarily.

The shared clipboard synchronizes its contents with the local clipboard. You can copy and paste text or graphics from a document within the Remote Desktop Connection window, and paste it into a document on your local computer. For information about copying, pasting, and using local files and folders in a Remote Desktop session, see Accessing local files and folders in a remote session.

**Note**

- Depending on the policies of your network and the version of Windows that is running on the remote computer, clipboard sharing might not work in some instances.

# Making local resources available to a terminal server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Making local resources available to a terminal server**

Depending on the Group Policy settings on the network, you can choose whether to allow a terminal server to have access to the disk drives, serial ports, printers, or smart card on your local computer. This is called resource redirection. Unless Group Policy settings prohibit resource redirection, you can redirect local resources to the terminal server by checking the appropriate checkbox in the Local devices section on the Local Resources tab in Remote Desktop Connection.

Making these resources available to a terminal server means that they can be used by that terminal server for the duration of the session. For example, suppose you choose to make your local disk drive available to the terminal server. While this allows you to easily copy files to or from the terminal server, it also means that the terminal server has access to the contents of your local disk drive. If there are times when this would not be appropriate, you can uncheck the appropriate checkbox to keep your local disk drive, or any other local resource, from being redirected to the terminal server.

By default, resource redirection for disk drives, serial ports, and smart cards is turned off. To turn on resource redirection, see Make your local serial port available in a session, Make your local disk drives available in a session, and Make a smart card available in a session.

# Using a smart card to log on to a terminal server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using a smart card to log on to a terminal server**

Smart cards are the most secure way to log on to a computer that is connected to a network. Because smart cards are tamper-resistant, they offer much stronger security than password-based logons can provide.

Many people choose passwords they can remember easily, which makes password-based logons weak and open to attack. If an unauthorized individual obtains your password, that individual can use your identity to connect to a network. However, to log on to a network by using your smart card, an unauthorized individual would have to obtain both the smart card and your personal identification number (PIN), which is far less likely.

Using a smart card to log on to a terminal server verifies your identity to the terminal server and allows you to access the programs you need to do your work. You can also make the smart card available to the terminal server for the duration of the session, in the same way that you can make your local disk drives available to the terminal server. However, the terminal server cannot access any private information stored on the smart card without your consent.

For information on making a smart card available to a terminal server, see Make a smart card available in a session. The option to enable smart card redirection is not displayed unless a smart card is present and the service is enabled.

# Accessing local files and folders in a remote session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Accessing local files and folders in a remote session**

You can configure Remote Desktop Connection to make your local drives available when you connect to a remote computer.

Within a Remote Desktop Connection session, your local drives appear in Windows Explorer with the following designation:

```
<driveletter> on <computername>
```

To access local drives from a command line or a run line in a remote session, type:

```
\\tsclient\<driveletter>
```

where *driveletter* is the drive letter (without a colon) of the local drive.

**Notes**

- Depending on your network policies, automatic drive mapping might be disabled for some or all computers on your network. To ensure that Remote Desktop Connection is configured to map local drives, see Make your local disk drives available in a session.

- Automatic drive mapping is not available when you are connecting to a terminal server running Windows 2000 or earlier.

# Printing to your local printer from a remote session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing to your local printer from a remote session**
Printer redirection routes printing jobs from the terminal server or Remote Desktop computer to a printer attached to your local computer (also called the "client computer"). There are two ways to provide access to local printers: automatic and manual printer redirection. Use manual redirection when your local printer requires a driver that is not available on the version of Windows that is running on the remote computer.

**Automatic printer redirection**
Printer redirection is automatic when the local printer uses a driver that is installed on the server. When you log on to a session on a terminal server, or to a computer running Windows Professional or Server and Remote Desktop, any printers that are installed on the client (local) computer, as well as network printers, are automatically detected and a local queue is created on the server. The client computer printer settings for the default printer and some properties (such as printing on both sides of the page) are used by the server.

When you disconnect or end the session, the printer queue is deleted, and any incomplete or pending print jobs are lost. Information about the client's local printers and settings are saved on the client computer. On subsequent logons, the printer queue is created using the information stored on the client computer.

If a printer driver is not found on the server, an event is logged and the client printer is not created. To make the printer available, the driver must be manually installed on the server.

**Manual printer redirection**
Printers attached to LPT and COM ports on the client (local) computer can be manually redirected, although manual redirection of printers connected through USB ports is not supported.

To manually redirect a client printer, contact your administrator and provide the name of your computer (or IP address for a Windows-based Terminal). The client must be connected to the remote computer during manual redirection.

After the initial manual redirection, printers are automatically redirected during subsequent logons.

### Notes

- Redirected printers are available for use with applications running on the server. Redirected printers appear in the Printers and Faxes folder in Control Panel. For more information on redirecting a local printer, see Make your local printer available in a session.

- When you disconnect or log off from a session, the printer queue is deleted, and incomplete or pending print jobs are lost.

# Using Terminal Services shortcut keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Terminal Services shortcut keys**

If you choose not to apply Windows key combinations to your Terminal Services sessions, you can use these shortcut keys to perform many of the same functions. For more information about applying Windows key combinations, see Configure Windows shortcut keys in a session.

| Shortcut key | Description |
|---|---|
| ALT+PAGE UP | Switches between programs from left to right. |
| ALT+PAGE DOWN | Switches between programs from right to left. |
| ALT+INSERT | Cycles through the programs in the order they were started. |
| ALT+HOME | Displays the **Start** menu. |
| CTRL+ALT+BREAK | Switches the client between a window and full screen. |
| CTRL+ALT+END | Brings up the **Windows Security** dialog box. |
| ALT+DELETE | Displays the **Windows** menu. |
| CTRL+ALT+Minus (-) symbol on the numeric keypad | Places a shadow copy of the active window within the client, on the Terminal server clipboard, which provides the same functionality as pressing PrintScrn on a local computer. |
| CTRL+ALT+Plus (+) symbol on the numeric keypad | Places a shadow copy of the entire client window area on the Terminal server clipboard, which provides the same functionality as pressing ALT+PrintScrn on a local computer. |

**Notes**

- On an NEC98, these shortcut keys are different in two cases:
  - CTRL+ALT+BREAK is replaced by CTRL+GRPH+VF2.
  - CTRL+ALT+END is replaced by CTRL+GRPH+VF1.
- CTRL+ALT+BREAK and CTRL+ALT+END are available in all Remote Desktop Connection sessions, even if you choose to apply Windows key combinations on the remote computer.

# Troubleshooting Remote Desktop Connection

- Troubleshooting Specific Remote Desktop Problems

# Troubleshooting General Remote Desktop Error Messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting General Error Messages**
Which message are you getting?

- Because of an error in data encryption, this session will end. Please try connecting to the remote computer again.
- The remote connection has timed out. Please try connecting to the remote computer again.
- The remote session was disconnected because the total logon time limit was reached. This limit is set by the server administrator or by network policies.
- The specified computer name contains invalid characters. Please verify the name and try again.
- The specified remote computer could not be found. Verify that you have typed the correct computer name or IP address, and then try connecting again.
- The remote session to the remote computer was ended by means of an administration tool. Your administrator might have ended your connection.
- The remote session was disconnected because your session was logged off at the remote computer. Your administrator or another user might have ended your session.
- The remote session was disconnected because another user has connected to the session.
- The remote session was disconnected because the total logon time limit was reached. This limit is set by the server administrator or by network policies.
- The local computer is low on memory. Close some programs, and then connect to the remote computer again.
- The connection was ended because of a network error. Please try connecting to the remote computer again.
- The client could not connect. You cannot connect to the console from a console session of the same computer.
- The client could not connect to the remote computer. Remote connections might not be enabled or the computer might be too busy to accept new connections. It is also possible that network problems are preventing your connection. Please try your connection again later. If the problem continues to occur, contact your administrator.
- Error: Out of memory. The remote session will be disconnected. Close some programs on the local computer, and then try connecting to the remote computer again.
- An internal state error has occurred. The remote session will be disconnected. Your local computer might be low on memory. Close some programs, and then try connecting to the remote computer again.
- Because of a protocol error, this session will be disconnected. Please try connecting to the remote computer again.
- Because of a protocol error (error_code), the remote session will be disconnected. Please try connecting to the remote computer again.
- Because of a security error, the client could not connect to the remote computer. Verify that you are logged on to the network, and then try connecting again.

- The remote session was disconnected because the remote computer is low on memory.
- Because of an unknown error, the remote session will be disconnected. The local computer might be low on memory. Close some programs, and then try connecting to the remote computer again.
- An unrecoverable error occurred while the client was attempting to connect. Close some programs, and then try connecting to the remote computer again.
- An error occurred when the client attempted to connect to the remote computer. Check your system memory and then try the connection again.
- Unable to allocate window resources. The remote session will be disconnected. Close some programs on the local computer, and then try connecting to the remote computer again.

**Because of an error in data encryption, this session will end. Please try connecting to the remote computer again.**
**Cause:** Data encryption provides security for data traveling over network connections. A data encryption error can end a session for security reasons.

**Solution:** Try connecting to the remote computer again. Encryption policies can vary between systems and domains. If you continue to see this error message, contact the server administrator.

**The remote connection has timed out. Please try connecting to the remote computer again.**
**Cause:** The terminal server disconnected your session because you did not send a response within the time limit set for responses.

**Solution:** Try connecting to the terminal server again. If you receive this error message, try to reconnect at a later time. If you continue to receive this error message, contact the server administrator.

**Cause:** A slow network connection, caused by excessive network traffic, has delayed your response to the terminal server.

**Solution:** Try connecting to the terminal server again. If you receive this error message, try to reconnect at a later time. If you continue to receive this error message, contact the server administrator.

**The remote session was disconnected because the total logon time limit was reached. This limit is set by the server administrator or by network policies.**
**Cause:** Your connection to the terminal server exceeded the time limit.

**Solution:** Try connecting to the terminal server again. If you receive this error message, try to reconnect at a later time. If you continue to receive this error message, contact the server administrator.

**The specified computer name contains invalid characters. Please verify the name and try again.**
**Cause:** The name of the remote computer is incorrect. This might be a typing error.

**Solution:** Try typing the name of the remote computer again. If you receive the same message, contact the server administrator to be sure you are using the correct name for the remote computer.

**The specified remote computer could not be found. Verify that you have typed the correct computer name or IP address, and then try connecting again.**
**Cause:** The name or IP address of the remote computer is incorrect. This might be a typing error.

**Solution:** Try typing the name or IP address of the remote computer again. If you receive the same message, contact the server administrator to be sure you are using the correct name or IP address for the remote computer.

**The remote session to the remote computer was ended by means of an administration tool. Your administrator might have ended your connection.**
**Cause:** The most common cause of this error is that the server administrator needed to perform maintenance tasks on the terminal server. These tasks can be performed only when there are no remote connections to the terminal server.

**Solution:** Try to reconnect at a later time. If you receive the same message, contact the server administrator.

**The remote session was disconnected because your session was logged off at the remote computer. Your administrator or another user might have ended your session.**
**Cause:** The most common cause of this error is that the server administrator needed to perform maintenance tasks on the terminal server. These tasks can be performed only when there are no remote connections to the terminal server.

**Solution:** Try to reconnect at a later time. If you receive the same message, contact the server administrator.

**The remote session was disconnected because another user has connected to the session.**
**Cause:** The most common cause of this error is that the server administrator needed to perform maintenance tasks on the terminal server. These tasks can be performed only when there are no remote connections to the terminal server.

**Solution:** Try to reconnect at a later time. If you receive the same message, contact the server administrator.

**The remote session was disconnected because the total logon time limit was reached. This limit is set by the server administrator or by network policies.**
**Cause:** Your connection to the terminal server exceeded the time limit set.

**Solution:** Try connecting to the remote computer again. If you receive the same message, try to reconnect at a later time. If you still have problems connecting, contact the server administrator.

**The local computer is low on memory. Close some programs, and then connect to the remote computer again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.
- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

**The connection was ended because of a network error. Please try connecting to the remote computer again.**
**Cause:** A network error prevented your computer from communicating with the terminal server.

**Solution:** Try connecting to the remote computer again. If you receive the same message, be sure that your computer is connected to the network. If you are still unable to connect to the remote computer, contact the server administrator.

**The client could not connect. You cannot connect to the console from a console session of the same computer.**
**Cause:** You are logged on to a computer and you are trying to connect to that same computer.

**Solution:** If you are not on the same computer, contact the server administrator.

**The client could not connect to the remote computer. Remote connections might not be enabled or the computer might be too busy to accept new connections. It is also possible that network problems are preventing your connection. Please try your connection again later. If the problem continues to occur, contact your administrator.**
**Cause:** The remote computer might not be set up to accept remote connections.

**Solution:** Try connecting to the remote computer at a later time. If you receive the same message, contact the server administrator.

**Cause:** The remote computer might already have the maximum number of remote connections it is set up to accept.

**Solution:** Try connecting to the remote computer at a later time. If you receive the same message, contact the server administrator.

**Cause:** Network problems might be preventing the connection.

**Solution:** Try connecting to the remote computer at a later time. If you receive the same message, contact the server administrator.

**Error: Out of memory. The remote session will be disconnected. Close some programs on the local computer, and then try connecting to the remote computer again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.
- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

**An internal state error has occurred. The remote session will be disconnected. Your local computer might be low on memory. Close some programs, and then try connecting to the remote computer again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.
- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

**Because of a protocol error, this session will be disconnected. Please try connecting to the remote computer again.**
**Cause:** A protocol specifies the way a computer communicates with other computers. A protocol error prevents your computer from communicating with the terminal server to which you were connected.

**Solution:** Try connecting to the remote computer again. If you receive the same message, contact the server administrator.

**Because of a protocol error (error_code), the remote session will be disconnected. Please try connecting to the remote computer again.**
**Cause:** A protocol specifies the way a computer communicates with other computers. A protocol error prevents your computer from communicating with the terminal server to which you were connected.

**Solution:** Try connecting to the remote computer again. If you receive the same message, contact the server administrator, and provide the error code that was displayed in the message.

**Because of a security error, the client could not connect to the remote computer. Verify that you are logged on to the network, and then try connecting again.**
**Cause:** The most common causes are network errors or slowdowns.

**Solution:** Be sure your computer is connected to the network. Try to reconnect at a later time. If you cannot connect, contact the server administrator.

**The remote session was disconnected because the remote computer is low on memory.**
**Cause:** Memory errors have a variety of causes, but the result is the same. The remote computer does not have enough memory to start and maintain the connection you are attempting to make.

**Solution:** Contact the server administrator.

**Because of an unknown error, the remote session will be disconnected. The local computer might be low on memory. Close some programs, and then try connecting to the remote computer again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.
- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

**An unrecoverable error occurred while the client was attempting to connect. Close some programs, and then try connecting to the remote computer again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.

- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

**An error occurred when the client attempted to connect to the remote computer. Check your system memory and then try the connection again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.
- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

**Unable to allocate window resources. The remote session will be disconnected. Close some programs on the local computer, and then try connecting to the remote computer again.**
**Cause:** Not enough RAM available on your computer. If your computer has too little RAM available, it cannot free enough processing capacity to start new functions, such as applications or connections.

**Solution:** Close all unnecessary programs, and try your connection again.

**Cause:** Not enough disk space available on your hard drive. If the hard drive on your computer is full, there might not be enough space available to allow the swap file to operate correctly. The swap file allows your computer to perform some RAM functions even when there is not enough RAM space available.

**Solution:** Free some space on your hard drive by:

- Emptying your recycle bin.
- Deleting temporary Internet files.
- Moving documents and other data files to a different drive.
- Removing programs that you rarely use.
- Deleting old temporary files from your hard disk. Temporary files have a .tmp file name extension, or names that begin with a tilde (~), and are usually found in the C:\Temp or C:\Windows\Temp folder.
- Emptying your recycle bin after you delete files.

# Troubleshooting Remote Desktop Licensing Error Messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting Licensing Error Messages**
This topic lists licensing error messages that can appear on client computers, and it describes the causes of and solutions for these errors. Although these error messages appear on clients, they are frequently caused by problems with the Windows Server 2003 Terminal Server license server or the terminal server. Therefore, when you troubleshoot Terminal Server Licensing issues, it is useful to first determine whether there are server configuration issues or problems with network connectivity.

**Important**

The solutions in this topic are intended to be implemented by administrators. If you are not an administrator, contact your server administrator for assistance in resolving these error messages. If you are an administrator, to help prevent Terminal Server Licensing issues and to more efficiently diagnose issues, it is highly recommended that you see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627), and Windows Server 2003 Terminal Server Licensing Issues and Requirements for Deployment (http://go.microsoft.com/fwlink/?LinkID=23444).

Which message are you getting?

- The remote session was disconnected because the local computer's client access license could not be upgraded or renewed. Please contact the server administrator.
- The remote computer disconnected the session because of an error in the licensing protocol. Please try connecting to the remote computer again or contact your server administrator.
- The remote session was disconnected because there were network problems during the licensing protocol. Please try connecting to the remote computer again.
- A licensing error occurred while the client was attempting to connect. (Licensing timed out.) Please try connecting to the remote computer again.
- The remote session was disconnected because there are no Terminal Server client access licenses available for this computer. Please contact the server administrator.
- The remote session was disconnected because there are no Terminal Server License Servers available to provide a license. Please contact the server administrator.
- Because of a security error, the client could not connect to the terminal server. After making sure that you are logged on to the network, try connecting to the server again.

**The remote session was disconnected because the local computer's client access license could not be upgraded or renewed. Please contact the server administrator.**
**Cause:** The Terminal Server licensing mode on the terminal server might be set to Per Device, while the license server might be configured to issue only Per User client access licenses (CALs). If this is the case, then the license server issues only temporary licenses that cannot be upgraded. When the temporary licenses are within several days of expiring, "Event ID 26, Source: Application Pop-up" appears in the application event log on the client. The event message indicates the number of days remaining before the temporary license expires. Similarly, "Event ID 1011, Source TermService" appears in the application event log on the terminal server.

**Solution:** Change the Terminal Server licensing mode from Per Device to Per User.

**Important**

Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. This does not remove administrators from End User License Agreement (EULA) requirements to have a valid terminal server CAL for each user. Failure to have a Per User CAL for each user, if Per Device CALs are not being used, is a violation of the EULA.

The following text is from the EULA for Windows Server 2003:

"Two different TS CALs are available to you: 'Device' and 'User.' Each TS Device CAL permits one Device (used by any User) to conduct Windows Sessions on any of your Servers. Each TS User CAL permits one User (using any Device) to conduct Windows Sessions on any of your Servers. You may use a mix of TS Device CALs and TS User CALs simultaneously with the Server Software in your environment. You can have a Terminal Server request Per User licenses or Per Device (default) but not both simultaneously."

**See also:** Configure the Terminal Server Licensing mode

**The remote computer disconnected the session because of an error in the licensing protocol. Please try connecting to the remote computer again or contact your server administrator.**
**Cause:** The terminal server might not be able to locate the license server.

**Solution:** Perform the following steps:

1. Verify that the license server is correctly installed.

2. Verify that the Terminal Server Licensing service is running on the license server.

3. Verify that the client, the terminal server, and the license server can communicate by ensuring that Domain Name System (DNS) is configured correctly on each computer. To do this, run the **ping** command from each computer to each computer using the IP address, FQDN, and the NetBIOS name. If any of the **ping** commands fail, verify the DNS configuration on the network.

4. On the terminal server, set a preferred licensing server to connect to. You can do this by using the registry, a Windows Management Instrumentation (WMI) script, or, in Windows Server 2003 with Service Pack 1, you can use Group Policy settings or Terminal Server Configuration.

**See also:** Install Terminal Server Licensing; Set preferred Terminal Server license servers; Terminal Server license server roles

**Solution:** If the previous solution does not resolve this problem, create a backup of the **MSLicensing** registry key and its subkeys on the client, and then remove the original key and subkeys by doing the following:

1. On the client, navigate to the following registry subkey:
   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**.

2. Click **MSLicensing.**

3. On the **Registry** menu, click **Export Registry File**.

4. In the **File name** box, type **mslicensingbackup**, and then click **Save**.

5. If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.

6. On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing** registry subkey.

7. Close Registry Editor, and then restart the computer.

When the client is restarted, the missing registry key is rebuilt.

To resolve this problem automatically, click the Fix this problem link. Then, click Run in the File Download dialog box.

Fix this problem

| **Note** |
| --- |
| This wizard may be in English only; however, the automatic fix also works for other language versions of Windows. |

| Note |
| --- |
| If you are not on the computer that has the problem, save the automatic fix to a flash drive or to a CD so that you can run it on the computer that has the problem. If you do not want to use the automatic fix, you can do it yourself by performing the steps in the procedure above. |

**Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**See also:** Removing Terminal Server Licenses From an RDP Client (http://go.microsoft.com/fwlink/?LinkId=38560)

**The remote session was disconnected because there were network problems during the licensing protocol. Please try connecting to the remote computer again.**
**Cause:** The terminal server might not be able to locate the license server.

**Solution:** Perform the following steps:

1. Verify that the license server is correctly installed.

2. Verify that the Terminal Server Licensing service is running on the license server.

3. Verify that the client, the terminal server, and the license server can communicate by ensuring that Domain Name System (DNS) is configured correctly on each computer. To do this, run the **ping** command from each computer to each computer using the IP address, FQDN, and the NetBIOS name. If any of the **ping** commands fail, verify the DNS configuration on the network.

4. On the terminal server, set a preferred licensing server to connect to. You can do this by using the registry, a Windows Management Instrumentation (WMI) script, or, in Windows Server 2003 with Service Pack 1, you can use Group Policy settings or Terminal Server Configuration.

**See also:** Install Terminal Server Licensing; Set preferred Terminal Server license servers; Terminal Server license server roles

**Cause:** The license server might be running Windows 2000, and it might be configured to prohibit anonymous connections, except by resources that have been explicitly granted access to the server.

**Solution:** On the Windows 2000 license server, do one of the following:

**Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

- In the registry, navigate to **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Lsa\RestrictAnonymous**, and set the **RestrictAnonymous** registry key to a value of **1** or **0**.

- In Local Security Policies, open the appropriate policy and, in the console tree, navigate to Computer Configuration\Windows Settings\Security Settings\Local Policies\Security Options. Then, enable either **Do not allow enumeration of SAM accounts and shares** (equivalent to a **RestrictAnonymous** value of **1** or **None**) or **Rely on default permissions** (equivalent to a **RestrictAnonymous** value of **0**).

**Notes**

- If the license server is a member of an Active Directory domain and a conflicting security setting is configured for the license server in Group Policy, the Group Policy setting overrides the local security setting. In this case, to ensure that the security setting that you want to apply takes effect, configure the setting in Group Policy.

- In Windows Server 2003, you cannot set **RestrictAnonymous** to a value of **2** to prohibit anonymous connections. If you need to prohibit anonymous users from being granted the same access that is granted to members of the Everyone

group, you must use the new **Everyone Network access: Let Everyone permissions apply to anonymous users** setting in Local Security Policies.

**Solution:** If the previous solution does not resolve this problem, create a backup of the **MSLicensing** registry key and its subkeys on the client, and then remove the original key and subkeys by doing the following:

1. On the client, navigate to the following registry subkey: **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**.
2. Click **MSLicensing.**
3. On the **Registry** menu, click **Export Registry File**.
4. In the **File name** box, type **mslicensingbackup**, and then click **Save**.
5. If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.
6. On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing** registry subkey.
7. Close Registry Editor, and then restart the computer.

When the client is restarted, the missing registry key is rebuilt.

To resolve this problem automatically, click the Fix this problem link. Then, click Run in the File Download dialog box.

Fix this problem

| **Note** |
| --- |
| This wizard may be in English only; however, the automatic fix also works for other language versions of Windows. |

| **Note** |
| --- |
| If you are not on the computer that has the problem, save the automatic fix to a flash drive or to a CD so that you can run it on the computer that has the problem. If you do not want to use the automatic fix, you can do it yourself by performing the steps in the procedure above. |

**Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**See Also:** How To Use the RestrictAnonymous Registry Value in Windows 2000 (http://go.microsoft.com/fwlink/?LinkId=38561)

**A licensing error occurred while the client was attempting to connect. (Licensing timed out.) Please try connecting to the remote computer again.**
**Cause:** If you are using Internet Protocol security (IPsec) to help protect traffic over TCP between clients and terminal servers, then packet fragmentation might occur. As a result, some packets might not reach their destination, and client connections to terminal servers might fail.

**Solution:** Configure IPsec to help protect traffic over UDP rather than over TCP.

**See Also:** Define IPSec Policies

**The remote session was disconnected because there are no Terminal Server client access licenses available for this computer. Please contact the server administrator.**
**Cause:** The license server might not have any remaining Per Device CALs to issue.

**Solution:** Use Terminal Server Licensing to determine the number of CALs remaining on the license server. To open Terminal Server Licensing, click **Start**, **Programs**, **Administrative Tools**, and then point to **Terminal Server Licensing**. If the license server does not have any remaining CALs to issue to clients, purchase and install additional CALs as required.

**See also:** Purchase client access licenses; Install Client Access Licenses; Purchasing and installing client access licenses on a Terminal Server license server

**Cause:** The Terminal Server licensing mode on the terminal server might be set to Per Device, while the license server might have only Per User CALs. If this is the case, the license server issues only temporary licenses that cannot be upgraded. When the temporary licenses are within several days of expiring, "Event ID 26, Source: Application Pop-up" appears in the application event log on the client. The event message indicates the number of days remaining before the temporary license expires. Similarly, "Event ID 1011, Source TermService" appears in the application event log on the terminal server.

**Solution:** Change the Terminal Server Licensing mode from Per Device to Per User.

**Important**

Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. This does not remove administrators from End User License Agreement (EULA) requirements to have a valid terminal server CAL for each user. Failure to have a Per User CAL for each user, if Per Device CALs are not being used, is a violation of the EULA.

The following text is from the EULA for Windows Server 2003:

"Two different TS CALs are available to you: 'Device' and 'User.' Each TS Device CAL permits one Device (used by any User) to conduct Windows Sessions on any of your Servers. Each TS User CAL permits one User (using any Device) to conduct Windows Sessions on any of your Servers. You may use a mix of TS Device CALs and TS User CALs simultaneously with the Server Software in your environment. You can have a Terminal Server request Per User licenses or Per Device (default) but not both simultaneously."

**See also:** Configure the Terminal Server Licensing mode

**Cause:** The terminal server might not be able to locate the license server.

**Solution:** Perform the following steps:

1. Verify that the license server is correctly installed.

2. Verify that the Terminal Server Licensing service is running on the license server.

3. Verify that the client, the terminal server, and the license server can communicate by ensuring that Domain Name System (DNS) is configured correctly on each computer. To do this, run the **ping** command from each computer to each computer using the IP address, FQDN, and the NetBIOS name. If any of the **ping** commands fail, verify the DNS configuration on the network.

4. On the terminal server, set a preferred licensing server to connect to. You can do this by using the registry, a Windows Management Instrumentation (WMI) script, or, in Windows Server 2003 with Service Pack 1, you can use Group Policy settings or Terminal Server Configuration.

**See also:** Install Terminal Server Licensing; Set preferred Terminal Server license servers; Terminal Server license server roles

**Solution:** If the previous solution does not resolve this problem, create a backup of the **MSLicensing** registry key and its subkeys on the client, and then remove the original key and subkeys by doing the following:

1. On the client, navigate to the following registry subkey:
   **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**.

2. Click **MSLicensing.**

3. On the **Registry** menu, click **Export Registry File**.

4. In the **File name** box, type **mslicensingbackup**, and then click **Save**.

If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.

5. On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing** registry subkey.

6. Close Registry Editor, and then restart the computer.

When the client is restarted, the missing registry key is rebuilt.

To resolve this problem automatically, click the Fix this problem link. Then, click Run in the File Download dialog box.

Fix this problem

| **Note** |
| --- |
| This wizard may be in English only; however, the automatic fix also works for other language versions of Windows. |

| **Note** |
| --- |
| If you are not on the computer that has the problem, save the automatic fix to a flash drive or to a CD so that you can run it on the computer that has the problem. If you do not want to use the automatic fix, you can do it yourself by performing the steps in the procedure above. |

**Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**See Also:** How To Use the RestrictAnonymous Registry Value in Windows 2000 (http://go.microsoft.com/fwlink/?LinkId=38561)

**The remote session was disconnected because there are no Terminal Server license servers available to provide a license. Please contact the server administrator.**
**Cause:** The terminal server might not be able to locate the license server.

**Solution:** Perform the following steps:

1. Verify that the license server is correctly installed.

2. Verify that the Terminal Server Licensing service is running on the license server.

3. Verify that the client, the terminal server, and the license server can communicate by ensuring that Domain Name System (DNS) is configured correctly on each computer. To do this, run the **ping** command from each computer to each computer using the IP address, FQDN, and the NetBIOS name. If any of the **ping** commands fail, verify the DNS configuration on the network.

4. On the terminal server, set a preferred licensing server to connect to. You can do this by using the registry, a Windows Management Instrumentation (WMI) script, or, in Windows Server 2003 with Service Pack 1, you can use Group Policy settings or Terminal Server Configuration.

**See also:** Install Terminal Server Licensing; Set preferred Terminal Server license servers; Terminal Server license server roles

**Cause:** The client might have exceeded its Terminal Server Licensing grace period, and a license server has not yet been installed or activated to issue the client a CAL.

**Solution:** Install Terminal Server Licensing, activate the license server, and then install and purchase a sufficient number of CALs to support the clients in your organization.

**See also:** Terminal Server Licensing grace period; Install Terminal Server Licensing; Activate a Terminal Server License Server;

Purchase client access licenses; Install Client Access Licenses; Purchasing and installing client access licenses on a Terminal Server license server; Activating a Terminal Server license server

**Because of a security error, the client could not connect to the terminal server. After making sure that you are logged on to the network, try connecting to the server again.**

**Cause:** If you upgraded a Windows NT domain to Windows 2000 or Windows Server 2003, then the certificate on the terminal server might be corrupt. As a result, Windows 2000 Terminal Services clients might be repeatedly denied access to the terminal server.

**Solution:** On each terminal server and client, perform the following steps:

1. On each terminal server, create a backup of the registry.
2. Navigate to the following registry subkey: **HKLM\SYSTEM\CurrentControlSet\Services\TermServices\Parameters**.
3. On the **Registry** menu, click **Export Registry File**.
4. In the **File name** box, type **exported-parameters**, and then click **Save**.

   If you need to restore this registry subkey in the future, double-click **exported-parameters.reg**.
5. Under the **Parameters** registry subkey, right-click each of the following values:
   - **Certificate**
   - **X509 Certificate**
   - **X509 Certificate ID**
6. Click **Delete**, and then click **Yes** to confirm the deletion.
7. Close Registry Editor, and then restart each terminal server.
8. On the client, create a backup of the **MSLicensing** registry key and its subkeys, and then remove the original key and subkeys by doing the following:
   - Navigate to the following registry subkey: **HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\MSLicensing**.
   - Click **MSLicensing**.
   - On the **Registry** menu, click **Export Registry File**.
   - In the **File name** box, type **mslicensingbackup**, and then click **Save**.
   - If you need to restore this registry key in the future, double-click **mslicensingbackup.reg**.
   - On the **Edit** menu, click **Delete**, and then click **Yes** to confirm the deletion of the **MSLicensing** registry subkey.
   - Close Registry Editor, and then restart the client computer.

**Caution**

Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Solution:** If the client still cannot connect to the terminal server, perform the following variation of this procedure:

1. Deactivate the license server.

2. Reactivate the license server by using the Telephone connection method in the Terminal Server License Server Wizard.

   When you activate Terminal Server Licensing by using the Telephone option, Terminal Server Licensing uses a different certificate.

3. On each terminal server, create a backup of the registry, and then delete the **Certificate**, **X509 Certificate**, and **X509 Certificate ID** registry keys, as described in the preceding procedure.

4. Close Registry Editor, and then restart each terminal server.

5. On the client, create a backup of the **MSLicensing** registry key and its subkeys on the client, and then remove the original key and subkeys as described in the preceding procedure.

6. Close Registry Editor, and then restart the computer.

When the client is restarted, the missing registry key is rebuilt.

**See also:** Deactivate a Terminal Server license server; Reactivate a Terminal Server license server

**Cause:** Windows XP-based clients might be attempting to connect to a Windows 2000-based Terminal Services server in a low-bandwidth network environment, in which client sessions are encrypted. In this case, IP packet fragmentation can cause encrypted frames that are sent by a client to be decrypted incorrectly.

**Solution:** Obtain the latest service pack for Windows 2000.

**Cause:** The Remote Desktop Protocol (RDP) encryption settings on the terminal server computer and the client might not be compatible. For example, the terminal server might be running 128-bit encryption with an encryption level set to **High**. When this occurs, "Event ID 50, Source: TermDD" appears in the system event log on the terminal server.

**Solution:** Change the RDP encryption level on the terminal server to **Medium** or **Low**.

**See also:** Because of a Security Error, the Client Could Not Connect to the Terminal Server (http://support.microsoft.com/default.aspx?scid=kb;en-us;329896); Terminal Services Sessions Are Disconnected Because of a Decryption Error (http://go.microsoft.com/fwlink/?LinkId=38563); Terminal Services Client Cannot Connect to a Server Running 128-bit Encryption (http://go.microsoft.com/fwlink/?LinkId=38559); Configure authentication and encryption on the server

# Troubleshooting Specific Remote Desktop Problems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting Specific problems**
What problem are you having?

- I cannot copy text from an application on the terminal server to another application that is on my local computer.
- I minimized the Remote Desktop Connection dialog box, and then my screen went blank.
- The screen saver on my Remote Desktop is blank.
- I'm supposed to be able to connect to a specific application when I log on to the remote computer, but it doesn't start.
- Remote Desktop Connection is very slow.

**I cannot copy text from an application on the terminal server to another application that is on my local computer.**
**Cause:** It is possible that Remote Desktop Connection was not installed correctly.

**Solution:** Uninstall and then reinstall Remote Desktop Connection. If you need assistance, contact the server administrator.

**I minimized the Remote Desktop Connection dialog box, and then my screen went blank.**
**Cause:** Using a password-protected screen saver can cause this problem. Your applications are still running on the remote computer, but you can no longer use them.

**Solution:** Disconnect Remote Desktop Connection, or ask the server administrator to disconnect you.

**Solution:** Do not minimize the Remote Desktop Connection dialog box if your computer uses a password-protected screen saver.

**Solution:** Do not use a password-protected screen saver on your local computer.

**The screen saver on my Remote Desktop is blank.**
**Cause:** By default, when a screen saver is activated on Remote Desktop, it is blank. This is true regardless of whether you have previously selected a different screen saver.

**Solution:** Continue to use the blank screen saver.

**I'm supposed to be able to connect to a specific application when I log on to the remote computer, but it doesn't start.**
**Solution:** If the remote computer is running Windows XP Professional, the complete contents of the Desktop are always displayed. Start the program you want to use by double-clicking its icon on the Desktop or using the Start menu.

**Cause:** The client connection might have been configured to start a program upon connection, but the program path and file name are incorrect.

**Solution:** Check the properties for the client connection to ensure that the program path and file name are correct. Also, confirm that the program exists in this location on the server.

**Cause:** The server administrator might have specified a different program to start upon connection, using Group Policy, Terminal Services Configuration, or other Terminal Services administration tools.

**Solution:** Contact the server administrator.

**Remote Desktop Connection is very slow.**
**Cause:** A low-bandwidth connection can slow Remote Desktop performance.

**Solution:** On the remote computer, set the background selection to **None.**

**Solution:** Do not run memory-intensive applications over Remote Desktop Connection.

**Solution:** Consider upgrading your modem or purchasing a high-speed service.

# Windows Server 2003 Administration Tools Pack

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003 Administration Tools Pack**
To make the remote management of your servers easier, Microsoft has included Windows Server 2003 Administration Tools Pack on the Microsoft® Windows Server 2003 family CDs Using these CDs, you can install Windows Server 2003 Administration Tools Pack onto computers running the following operating systems.

- Windows Server 2003 family
- Windows XP Professional with Service Pack 1 or later
- Windows XP Professional with QFE Q329357

For tips about administering servers from Windows XP Professional and Windows 2000 Professional, see Windows Server 2003 Administration Tools Pack Best practices.

For information about installing, reinstalling, deploying, and uninstalling Windows Server 2003 Administration Tools Pack, see Windows Server 2003 Administration Tools Pack How to....

For an overview of the tools, see Windows Server 2003 Administration Tools Pack Overview.

For help with specific tasks and links to detailed information about these tools, see Managing remotely with the Windows Server 2003 Administration Tools Pack tools.

For help with common problems, see Troubleshooting Windows Server 2003 Administration Tools Pack.

Windows Server 2003 Administration Tools Pack tools will not work on computers running Microsoft® Windows 2000. For additional information, see Windows 2000 Server online Help.

# Windows Server 2003 Administration Tools Pack Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Check security requirements for each component**

- For a broader security discussion and links to additional security information, see the following.
    - Best practices for security
    - Security overview
    - Local Users and Groups Best practices

**Always install help contents from the Windows Server 2003 operating system**

- The help content on a Windows Server 2003 operating system differs from Windows XP Professional Help. After you install the help content from a Windows Server 2003 operating system onto your computer running Windows XP Professional, you can switch between the different help content as often as you like, but you cannot use both simultaneously. To switch between different help systems, in **Help and Support Center**, click the **Options** menu. Under **Options**, click **Install and share Windows Help**, click **Switch from one operating system's Help content to another**, and then follow the instructions on the screen.

- If you are administering servers running Windows Server 2003 from a computer running Windows XP Professional with Service Pack 1 or Windows XP Professional with hotfix Q329357, you should install the help content from the Windows Server 2003 operating system onto the computer running Windows XP Professional.

  For instructions, see Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional.

**Make sure that the firewall settings on the server you want to administer permit remote administration**

- With Windows Firewall enabled, you might need to make specific configuration settings in order to use or remotely administer technologies that ship with Windows Server 2003. For information about these settings, see Windows Firewall Settings.

**Administering computers running Windows 2000 Server**

- Windows Server 2003 Administration Tools Pack has been designed solely for use on servers running Windows Server 2003, Windows XP Professional with Service Pack 1 or later, and Windows XP Professional with QFE Q329357 installed. Windows Server 2003 Administration Tools Pack will not run on computers running Windows 2000 operating systems. Windows 2000 operating systems can use only the Windows 2000 version of Administrative Tools.
    - Install Windows 2000 Administrative Tools onto a computer running Windows 2000 professional. For additional information, see Windows 2000 Help.
    - Use the Remote Desktop Connection from Windows XP Professional or Windows 2000 professional to the server running Windows 2000 and manage that server from the remote session. For more information, see Remote Desktop Connection.

# Windows Server 2003 Administration Tools Pack How to...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install or reinstall Windows Server 2003 Administration Tools Pack
- Deploy Windows Server 2003 Administration Tools Pack
- Uninstall Windows Server 2003 Administration Tools Pack
- Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional

# Install or reinstall Windows Server 2003 Administration Tools Pack

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install or reinstall Windows Server 2003 Administration Tools Pack**

- Using the Windows interface
- Using a command line

**Using the Windows interface**
**If you are using a Windows Server 2003 family CD:**

1. Put your Windows Server 2003 CD into the CD tray of the computer on which you want to install the Administration Tools Pack.
2. When the Welcome screen appears, click **Perform additional tasks**.
3. Click **Browse this CD**.
4. Open the server cd i386 folder.
5. Right-click adminpak.msi, then click **Install**.

**If you are using a Windows Server 2003 family CD image or net share:**

1. Put your Windows Server 2003 CD into the CD tray of the computer on which you want to install the Administration Tools Pack and open the i386 folder on the Windows Server 2003 operating system image or net share.
2. Right-click adminpak.msi, then click **Install** to begin installation of Windows Server 2003 Administration Tools Pack onto the Windows XP Professional operating system.

**Note**

- If the **Welcome to the Microsoft Server 2003 Family** screen does not appear, click **Start**, then **Run**. Click **Browse** and select the drive holding the server cd. In the **Browse** dialog box, set **Files of type** to **All files**, then open the server cd i386 folder. Right-click adminpak.msi, then click **Install**.

**Using a command line**

1. With the Windows Server 2003 family CD in the CD tray of your computer running Windows XP Professional, open Command Prompt.
2. Type the path to adminpak.msi. For example, if the CD drive is drive E, "E:\i386\adminpak.msi".
3. Press **Enter**, and adminpak.msi will install Windows Server 2003 Administration Tools Pack onto the computer running Windows XP Professional with Service Pack 1 operating system.

   **Note**

   - To open the Command Prompt, click **Start**, then click **Run**, and type cmd.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Administrative Tools, click **Start**, click **Control Panel**, and then double-click **Administrative Tools**.

- Installed Windows Server 2003 Administration Tools Pack MMC snap-ins are listed in **Administrative Tools** on the Windows XP Professional **Start** menu. They are also listed in **Administrative Tools** in **Control Panel**.

- You can reinstall Windows Server 2003 Administration Tools Pack at any time by using any of the installation methods. Reinstallation will overwrite any prior installation.

- Command-line tools are not available on the **Start** menu. Command-line tools can be accessed from the command line.

- After upgrading from Windows 2000 Server, you must install Windows Server 2003 Administration Tools Pack. It is not installed automatically during upgrades.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Windows Server 2003 Administration Tools Pack Overview
Deploy Windows Server 2003 Administration Tools Pack
Uninstall Windows Server 2003 Administration Tools Pack
Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional

# Deploy Windows Server 2003 Administration Tools Pack

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To deploy Windows Server 2003 Administration Tools Pack**

1. If you do not already have a user group for the administrators who will receive adminpak.msi, create one. For more information, see Group Policy in Related Topics.

2. Copy adminpak.msi from the Windows Server 2003 family CD to your software distribution share and publish or assign it as you would any other program. For more information about assigning and publishing software, see Group Policy in Related Topics.

## Notes

- You assign an application when you want the targeted user group to have the application assigned to his or her computer for installation. With Windows Server 2003 Administration Tools Pack installed on Windows XP Professional with Service Pack 1 or Windows XP Professional with QFE Q329357, you click each snap-in on the Administrative Tools menu to install only that snap-in and any related snap-ins.

- You publish an application when you want the targeted user group to be able to install the application at users' discretion.

- You must open all internal snap-ins from the **Start** menu before you open that console or the contained snap-ins do not load.

- If you publish Windows Server 2003 Administration Tools Pack in Active Directory, targeted users can use **Add or Remove programs** in **Control Panel** on the remote computer to install it when needed.

- After Windows Server 2003 Administration Tools Pack has been installed to a Windows XP Professional computer, you can access the tools from the **Start** menu. Click **Start**, point to **programs**, and then point to **Administrative Tools**. Click the name of the tool that you want to use.

- Command line tools are not available on the **Start** menu. Command line tools can be accessed from the command line.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Uninstall Windows Server 2003 Administration Tools Pack

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To uninstall Windows Server 2003 Administration Tools Pack**

1. Open Add or Remove Programs in Control Panel.
2. Select **Change or remove programs**.
3. In Windows Server 2003 Administration Tools Pack, click **Remove**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install help content from a Windows Server 2003 operating system onto a computer running Windows XP professional**

1. On the computer running Windows XP Professional, click **Start**, then **Help and Support**.
2. In Help and Support Center, click the **Options** menu.
3. Under **Options**, click **Install and share Windows Help**, click one of the following:
   - **Install Help content from another Windows computer**
   - **Install Help content from a CD or disk image**
4. Follow the instructions on the screen.

## Notes

- The help content on a Windows Server 2003 operating system differs from Windows XP Professional Help. After you install the help content from a Windows Server 2003 operating system onto your Windows XP Professional computer, you can switch between the different help content as often as you like, but you cannot use both simultaneously. To switch between different help systems, in **Help and Support Center**, click the **Options** menu. Under **Options**, click **Install and share Windows Help**, click **Switch from one operating system's Help content to another**, and then follow the instructions on the screen.
- If you are administering computers running Windows Server 2003 operating systems from a computer running Windows XP Professional, you should install the help content from the Windows Server 2003 operating system onto the computer running Windows XP Professional.
- You can only install and share Help content on computers that are running Windows XP Professional or a product in the Windows Server 2003 family. For example, you cannot install Help content from Windows XP or a product in the Windows Server 2003 family on a computer running Windows 2000, or vice versa.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Windows Server 2003 Administration Tools Pack Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Server 2003 Administration Tools Pack Overview**
Microsoft® Windows Server 2003 Administration Tools Pack provides administrators with tools for managing their servers remotely from platforms:

- The Windows Server 2003 family
- Windows XP Professional with Service Pack 1 (SP1)
- Windows XP Professional with QFE Q329357

These tools are packaged as adminpak.msi on the Microsoft® Windows Server 2003 family CDs. These tools support 32-bit and 64-bit server operating systems.

These tools can be classified into four categories.

- System administration
- Network administration
- Storage management
- Directory services administration

Windows Server 2003 Administration Tools Pack also provides Convenience Consoles which combine certain of these tools into packages for managing or delegating frequent tasks.

For Windows Server 2003 Administration Tools Pack to be installed on Windows XP Professional, you must either apply Service Pack 1 to the operating system or install the hotfix included with Knowledge Base Article Q329357. See article Q329357, "Windows Server 2003 adminpak.msi may not run on Windows XP 2600 Machines," in the Microsoft Knowledge Base.

For more information, see Windows Server 2003 Administration Tools Pack Best practices.

You must have administrative permissions on the local computer to install or run Windows Server 2003 Administration Tools Pack. For security reasons, Windows Server 2003 Administration Tools Pack should be removed if the computer running Windows XP Professional is to be used by a non-administrator. In addition, you should be aware of specific security requirements for each tool.

For more information, see:

- Managing remotely with the Windows Server 2003 Administration Tools Pack tools
- Convenience Consoles in Windows Server 2003 Administration Tools Pack

**Finding Windows Server 2003 Administration Tools Packs**
You can find and download Windows Server 2003 Administration Tools Packs on the following Web sites:

- Windows Server 2003 Administration Tools Pack (http://go.microsoft.com/fwlink/?LinkID=91722)

  Allows administrators to remotely manage Windows 2000 Server and Windows Server 2003.

- Windows Server 2003 Service Pack 1 Administration Tools Pack (http://go.microsoft.com/fwlink/?LinkID=54895)

Allows administrators to remotely manage computers running Windows 2000 Server and Windows Server 2003 family operating systems. This site provides the Service Pack 1 version (build 5.2.3790.1830) of the adminpak.msi file.

- Windows Server 2003 R2 Administration Tools Pack (x86) (http://go.microsoft.com/fwlink/?LinkID=73895)

  Allows administrators to remotely manage computers running 32-bit versions of the Windows Server 2003 R2 family of operating systems. The management tools downloadable from this site allow management of features specific to Windows Server 2003 R2.

- Windows Server 2003 R2 Administration Tools Pack (x64) (http://go.microsoft.com/fwlink/?LinkId=110584)

  Allows administrators to remotely manage computers running 64-bit versions of the Windows Server 2003 R2 family of operating systems. The management tools contained in these packages manage features specific to Windows Server 2003 R2.

# Managing remotely with the Windows Server 2003 Administration Tools Pack tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing remotely with the tools**
**System Administration**

| Task | Tool | In a Convenience Console? |
|---|---|---|
| Support on-demand, image-based, operating system installations over a network connection from a RIS server to a client computer to simplify the management of operating systems and applications, and to improve failure recovery. | Remote Installation Services | No |
| Provide application developers a flexible framework for integrating role-based access control into their applications and administrators who use those applications access in a natural, intuitive way: through assigned user roles relating to job function. | Authorization Manager | No |
| Issue certificates to individuals, computers, or organizations that affirm the identity and other attributes of the certificate subject to other entities | Certification Authorities | Public Key Management |
| Track the licenses that have been issued to many terminal servers concurrently. | Terminal Server Licensing | No |
| Manage and monitor users, sessions, and processes on any server running Terminal Services on the network. | Terminal Services Manager | No |
| Manage Web Services directly through standards-based XML Web service for development tools and business applications. | UDDI Services overview | No |

**Network Administration**

| Task | Tool | In a Convenience Console? |
|---|---|---|
| Define features for remote access clients so that customers can connect to your service. | Connection Manager Administration Kit | No |
| Manage centrally IP addresses and other related configuration details used on your network. | DHCP | IP Address Management |
| Manage files distributed across multiple servers to appear to users as if they reside in one place on the network. | Distributed File System (DFS) | No |
| Manage TCP/IP networks, such as the Internet, to locate computers and services through user-friendly names. | DNS | Active Directory Management and IP Address Management |
| Manage exchange with NNTP snap-in. | Choosing components to install<br><br>Microsoft NNTP Service (Requires installing the NNTP service first). | No |

| | | |
|---|---|---|
| Manage telecommunications with the computer to communicate over direct connections to local computers, phone lines, LANs, WANs, and the Internet. | Telephony | No |
| Map NetBIOS names to IP addresses , particularly for NetBIOS name resolution in routed networks that use NetBIOS over TCP/IP. | WINS | IP Address Management |

**Storage Management**

| Task | Tool | In a Convenience Console? |
|---|---|---|
| Manage a group of independent computer systems working together as a single system to ensure that mission-critical applications and resources remain available to clients. | Windows Clustering | No |
| Manage all hosts of a Network Load Balancing cluster from a single computer. | Network Load Balancing Clusters | No |
| Manage server disk volumes and automatically copy infrequently-used files to a tape or disk library. | Remote Storage | No |

**Directory services administration**

| Task | Tool | In a Convenience Console? |
|---|---|---|
| Manage the trust relationships between domains. | Active Directory<br>Manage Domains<br>Manage Trusts<br>Manage Forests | Active Directory Management |
| Manage users, computers, security groups and other objects in the Active Directory. | Active Directory<br>Manage Users, Groups, and Computers<br>Group Policy (pre-GPMC) | Active Directory Management |
| Replicate Active Directory information. | Active Directory<br>Manage Sites | Active Directory Management |
| Manage stored object information in Active Directory schemas from the command line (schmmgmt.msc). | Active Directory<br>Manage the Schema | No |
| Delegate control to select users or groups, organizational units and objects. | Active Directory<br>Delegating administration | No |
| Manage Active Directory information via the command line. | Directory service command-line tools | No |
| Manage the Active Directory database from the command line. | Ntdsutil | No |
| Manage Group Policy from the command line (gpedit.msc) | Group Policy (pre-GPMC) | No |

# Convenience Consoles in Windows Server 2003 Administration Tools Pack

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Convenience Consoles in Windows Server 2003 Administration Tools Pack**

Convenience consoles combine related features into Microsoft Management Consoles (MMC). For example, to administer and troubleshoot an Active Directory deployment, administrators generally need to use Active Directory Users and Computers, Active Directory Domains and Trusts, Active Directory Sites and Services, and DNS. Windows Server 2003 Administration Tools Pack includes a saved console in MMC called **Active Directory Management** that contains these tools.

The Windows Server 2003 family contains three Convenience Consoles:

| Convenience Console | Contents | Snap-ins |
|---|---|---|
| Active Directory Management | Manage Users, Groups, and Computers<br>Manage Domains<br>Manage Sites<br>DNS | ADMgmt.msc |
| Public Key Management | Certification Authorities<br>Certificate Templates<br>Certificates for Current User<br>Certificates for Local Computer | PKMgmt.msc |
| IP Address Management | DHCP<br>DNS<br>WINS | IPAddrMgmt.msc |

Convenience Consoles are displayed in **Administrative Tools** on computers running Windows XP Professional with Windows installed. These consoles contain snap-ins included separately in Windows.

For further information, see Windows Server 2003 Administration Tools Pack.

# Troubleshooting Windows Server 2003 Administration Tools Pack

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Broken links in Help files
- Trouble installing Windows Server 2003 Administration Tools Pack
- Windows Server 2003 Administration Tools Pack will not install on Windows XP Professional

**Broken links in Help files**
**Cause:** When Windows Server 2003 Administration Tools Pack is installed on Windows XP Professional, some Help links will be broken. Server and Windows XP Professional Help systems differ.

**Solution:** Install the Server Help on Windows XP Professional. Switch to the other installed Help if links in one Help system are broken. In most cases, this will resolve the broken link problem

**See:** Install Help content from a Windows Server 2003 server operating system onto a computer running Windows XP Professional

**Trouble installing Windows Server 2003 Administration Tools Pack**
**Cause**: You need local administrator credentials to install Windows Server 2003 Administration Tools Pack.

**Solution:** Use the Runas command. For more information, see Runas.

**Windows Server 2003 Administration Tools Pack will not install on Windows XP professional**
**Cause:** Windows Server 2003 Administration Tools Pack cannot be installed on computers running Windows XP Professional without first applying Service Pack 1 to the operating system or installing the hotfix contained in Q329357.

**Solution**: Install the QFE or apply Windows XP Professional with Service Pack 1.

**See:** Article Q329357, "Windows Server 2003 adminpak.msi may not run on Windows XP 2600 Machines," Microsoft Knowledge Base.

# Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Emergency Management Services**
The Microsoft® Windows Server 2003 family provides native support for server operation and management that can be performed without a local keyboard, mouse, or monitor. Emergency Management Services is one element of an out-of-band management solution that you can use to manage servers remotely when the operating system is not running properly. Emergency Management Services is available with or without a video card.

- For recommendations on setting up and using Emergency Management Services most effectively, see Emergency Management Services Best Practices.
- For help with using Emergency Management Services to solve problems with your system, see Emergency Management Services How To....
- For general background information on Emergency Management Services, see Emergency Management Services Concepts.
- For help solving problems that might occur in Emergency Management Services, see Troubleshooting Emergency Management Services.

# Emergency Management Services Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- Best practices for using in-band tools
- Best practices for selecting and configuring hardware
- Best practices for implementing security measures

# Best practices for using in-band tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for using in-band tools**

**Try using in-band tools before using Emergency Management Services.**

- If your server becomes unstable, try to use in-band tools before using Emergency Management Services to troubleshoot your operating system.

  This is important because Emergency Management Services is designed to be used only when in-band means of accessing and managing the server are unavailable. For example, you would use Emergency Management Services to force your system to reset only if you are unable to reset it using the standard, in-band tools. In addition, be aware that Emergency Management Services is not a complete management solution; your ability to access and manage the server at all times depends upon your hardware configuration.

  For more information, see In-band management.

**Enable and configure in-band tools during Setup.**

- Because in-band tools can be difficult or impossible to configure remotely after Setup has completed, it is important to enable and configure these tools during Setup. Examples of in-band tools include Terminal Services Remote Desktop for Administration and Telnet.

  For more information, see In-band management.

# Best practices for selecting and configuring hardware

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for selecting and configuring hardware**

**Ensure that the BIOS supports console redirection and the SPCR table.**

- If there is no Serial Port Console Redirection (SPCR) setting, the basic input/output system (BIOS) either enables it automatically or does not support it. It is preferable to have a BIOS that supports the SPCR table. If this is not the case, you must enable and configure Emergency Management Services manually. You can do this during Setup or by using the Bootcfg.exe tools in the operating system. Configure Emergency Management Services to use the same settings as the BIOS console redirection. Be sure to make a note of the baud rate and the serial port that you set.

- You might find it necessary to enable console redirection in the BIOS settings. COM 1 is the preferred COM port. Make a note of the baud rate and the COM port that you set. You must use this information to attach a serial cable properly to the correct port. You also must use this information to configure your terminal emulator to the correct baud rate.

- If the SPCR table is supported by the BIOS, it can be enabled automatically when BIOS redirection is enabled. If the BIOS has a setting for SPCR or SPCR table, be sure to configure it.

- Configure your server to reboot automatically if a Stop error occurs. This allows the server to reboot without requiring you to access !Special Administration Console (!SAC) or the power switch to reboot it manually. This provides maximum availability if a Stop error occurs.

  For more information, see Firmware console redirection.

**Choose the highest baud rate that your hardware and Emergency Management Services allows.**

- This gives you the best performance.

- This also prevents a slow text-mode Setup process.

- For the preferred Remote Installation Services (RIS) implementation, use a redirecting BIOS that prompts you to boot from the network and a version of Startrom.com that does not redirect.

  For more information, see Configuring Serial Ports.

**When using Emergency Management Services with a serial port, use a null modem cable with carrier detect.**

**Select service processors that support Emergency Management Services.**

- A service processor can provide additional management functionality that complements that of Emergency Management Services. This gives you a more complete remote-management solution.

- Use an original equipment manufacturer (OEM) service processor that provides, at a minimum, reset and BIOS console redirect capabilities.

- You must select a service processor that supports Emergency Management Services. In addition, you might find it necessary to enable the service processor so that it provides that support.

- It might be necessary to update your firmware to enable it to support Emergency Management Services. Service processors can require their own firmware updates in addition to system firmware updates. With the proper firmware updates, your current service processors might support Emergency Management Services.

For more information, see Service processors.

**Configure your server to reboot automatically if a Stop error occurs.**

- This makes it unnecessary for you to access !SAC or the power switch to reboot the server manually. It also provides maximum availability if a Stop error occurs.

**Select hardware and firmware that supports VT-UTF8.**

- If your hardware and firmware do not use the same terminal type that Emergency Management Services uses, it can be extremely difficult to send the proper command escape sequences. This is because the command escape sequences change according to whether the hardware, firmware, or Emergency Management Services is controlling the port.

- Hardware and firmware that support VT-UTF8 or VT100+ provide the best compatibility. To prevent incompatibility, you must at least select hardware and firmware that support VT100.

- It might be necessary to update your system and service processor firmware to enable VT-UTF8 or VT100+ output.

  For more information, see VT-UTF8, VT100+, and VT100 conventions.

# Best practices for implementing security measures

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for implementing security measures**

**Limit the ability of users to access your out-of-band infrastructure.**

- When used incorrectly or maliciously, Emergency Management Services and out-of-band management hardware can be made to disrupt the use of a server. To prevent this problem, limit physical access to the server. This will also keep unwanted users from accessing Emergency Management Services through a serial port. To provide this level of physical security, be sure to protect sensitive areas such as racks, computer labs, server farms, and data centers by locking them.

- Use a terminal concentrator with security features. If you access your servers out-of-band through a terminal concentrator, choose one that provides security when you connect through the network.

- Select service processors with well-designed security implementations. Service processors can provide improved access mechanisms, such as network interfaces. With these improvements, however, come the added security risks of network access. You must ensure that any service processor you enable provides a secure access mechanism.

- Consider setting up a separate network dedicated exclusively to management traffic, including that of Emergency Management Services. A separate network for management traffic adds an additional layer of security. Only known, secure management workstations should be granted access to this network and its out-of-band server connections. The management network must not allow any connections to the Internet, and it must authenticate only trusted users.

  For more information, see Remotely administered servers, Service processors, and Terminal concentrators.

# Emergency Management Services How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Verify that Emergency Management Services is enabled
- Start the computer
- View the POST status and errors
- View and manage the system while the loader and kernel initialize
- View and manage the system during text-mode Setup
- Determine the cause of a pause or failure during GUI-mode Setup
- Resolve system resource problems using SAC
- Respond to a Stop error message
- Respond if SAC and !SAC become unavailable
- Change channels

# Verify that Emergency Management Services is enabled

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To verify that Emergency Management Services is enabled**
You can use Bootcfg to quickly verify that Emergency Management Services is active in an x86-based or Itanium-based system without connecting devices to the out-of-band port.

- At a command prompt, type:

  **bootcfg/query**

### Note

- You can also check the registry to verify Emergency Management Services installation. For more information on working with the registry, see "Resources" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Enabling Emergency Management Services
Emergency Management Services Resources
Troubleshooting Emergency Management Services

# Start the computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start the computer**

Depending on the remote computer's hardware configuration, you can use one or more of the following approaches to start your computer. For more information, see your hardware manufacturer's documentation.

- Use the interface supplied by a service processor, if one is present, to turn on the remote computer.
- Use the interface supplied by a power switch or uninterruptible power supply (UPS) with remote computer management capabilities, if one is present, to turn on the computer.
- Use wake-on-LAN functionality by sending a network request that "wakes" the remote computer from sleep mode. This feature must be supported by both the system motherboard and firmware. Follow the instructions provided by your computer and network adapter motherboard manufacturers to enable this functionality.
- If none of these approaches is appropriate, you can go to the physical location of the target computer and start it by pressing the power button.

### Note

- For general background information on wake-on-LAN functionality, see "Routing and Remote Access" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Routing and Remote Access

# View the POST status and errors

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the POST status and errors**

Depending on the remote computer's hardware configuration, one or more of the following approaches can help the computer complete the power-on self test (POST).

For all of these options, you must configure the remote computer's firmware or service processor, if one is present, to redirect the POST. You will then be able to view the progress of the POST. For more information, see to your hardware manufacturer's documentation.

- Connect to the remote computer's service processor, if one is present, and restart the computer.
- If a service processor is present, and the out-of-band tools are available, perform diagnostic procedures using the service processor's out-of-band tools.
- Use a power switch or uninterruptible power supply (UPS) with remote computer management capabilities, if one is present, to restart the remote computer.

### Note

- Windows Server 2003 operating systems cannot start if the remote computer stops responding before completing the POST.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View and manage the system while the loader and kernel initialize

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view and manage the system while the loader and kernel initialize**

- Ensure that Emergency Management Services is enabled on the remote computer.
- If the remote computer's operating system fails to initialize, note whether an error message appears. If you do not receive an error message, use the **D** command in either Special Administration Console (SAC) or !Special Administration Console (!SAC) to view the log.
- Restart the remote computer using SAC or !SAC and correct the problem.

## Notes

- You can use both firmware console redirection and Emergency Management Services console redirection to monitor the remote system's startup as if you were at a local console. It is preferred that the remote computer's firmware be able to pass the configuration settings of the out-of-band port to the operating system using the Serial Port Console Redirection (SPCR) table. If your system uses Extensible Firmware Interface (EFI), Windows reads the boot settings from the SPCR table. If your system does not use EFI, Windows reads the boot settings from the boot.ini file.
- For more information, see "Verifying that Emergency Management Services is configured" in Related Topics.
- For more information about how to restart the remote computer, see "Startup options" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View and manage the system during text-mode Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view and manage the system during text-mode Setup**

Depending on the remote computer's hardware configuration, one or more of the following approaches can help you view and manage the system during text-mode Setup. If the remote computer has a serial port console redirection (SPCR) table, Emergency Management Services will automatically display the pertinent information. For more information, see your hardware manufacturer's documentation.

- For x86-based systems, use Remote Installation Services (RIS) to install Windows Server 2003 operating systems.
- If you are not using unattended Setup files, you must choose Express Setup when prompted.
- If Setup fails, note any error messages that appear and attempt to correct any problems you discover.

## Notes

- When you are using GUI-mode Setup, you must perform an unattended Setup. This allows GUI-mode Setup to proceed without prompting you for input. If you do not perform an unattended Setup, GUI-mode Setup will fail.
- You can use RIS-based installations to perform unattended Setups. When you RIS-based installations for this purpose, it is not necessary to use the operating system CD or a floppy disk containing a Winnt.sif file. For more information on RIS and the Winnt.sif file, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Determine the cause of a pause or failure during GUI-mode Setup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To determine the cause of a pause or failure during GUI-mode Setup**

- To determine the reason for a pause or failure during a GUI-mode Setup on a remote computer, use the **ch** command in the Special Administration Console (SAC), or press ESC+TAB. You can use either of these methods to view one of the three setup logging channels.

- If GUI-mode Setup pauses, use the **cmd** command in SAC to open a command-prompt channel. You can then use this command-line environment to navigate the system, and, if necessary, repair the $winnt$.sif file located in the *systemroot*\System32 folder.

## Notes

- When you are using GUI-mode Setup, you must perform an unattended Setup. You can then respond from your local computer when the remote computer prompts you for input during setup. If you do not perform an unattended Setup, GUI-mode Setup will fail.

- If setup fails, but the remote computer is still responding, there might be a problem with the setup files.

- If you examine the setup log channels and are still unable to determine the reason for the pause or failure of GUI-mode Setup, you might need to monitor a local display to determine the cause.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Resolve system resource problems using SAC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To resolve system resource problems using SAC**

- Use the **T** command in Special Administration Console (SAC) to view the processes that are running on the remote computer, the amount of CPU time they have consumed, and the amount of memory they are using. See "Task list headings" in Related Topics for more information on analyzing the output from the **T** command.
- Use the **R** and **L** SAC commands to modify the priority of any processes that might be preventing the use of in-band tools on the remote computer.
- Use the **K** SAC command to end a process that is causing a problem on the remote computer.
- If the problem persists, or if you do not know which process is causing the problem, use the **restart** SAC command to restart the remote computer.

## Notes

- Before you use SAC to resolve a system resource problem, first try using in-band tools. Use SAC only if using in-band tools fails to resolve the problem.
- You might be able to determine which processes are consuming the most resources by comparing two consecutive task lists.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Respond to a Stop error message

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To respond to a Stop error message**

- View the Stop error message information remotely, and use !Special Administration Console (!SAC) to restart the remote computer. Viewing the kernel log with the **D** command can help to determine the cause of the error, especially if the Stop error message appeared during the startup process.

## Notes

- To display !SAC, press ENTER when viewing the Stop screen.
- You can manually generate a Stop error message and force a memory dump file to be created by using the SAC **crashdump** command. To do so, however, you must have crash dump enabled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Respond if SAC and !SAC become unavailable

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To respond if SAC and !SAC become unavailable**

Depending on the remote computer's hardware configuration, one or more of the following approaches can be helpful if Special Administration Console (SAC) and !SAC become unavailable. For more information, see your hardware manufacturer's documentation.

- Perform diagnostic procedures using the service processor's out-of-band tools if a service processor is present, and if the tools are available.
- Restart the remote computer by using the interface supplied by a service processor, if one is present.
- Restart the remote computer by using the interface supplied by a power switch or an uninterruptible power supply (UPS) with remote computer management capabilities, if one is present.
- If none of these approaches is appropriate, start the remote computer by pressing the power button.

**Note**

- If you restart the remote computer using a power switch or UPS, its firmware must be configured to turn on when power is restored.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Emergency Management Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Emergency Management Services overview**

Emergency Management Services is a new feature that is included with the Microsoft® Windows Server 2003 family. You can use this feature to perform remote-management and system recovery tasks when the server is unavailable through the network or other standard remote-administration tools and mechanisms. Emergency Management Services is available for x86-based and Itanium-based systems.

When a server is operating normally, you can manage it remotely by using a variety of administrative tools that are provided in your Windows Server 2003 operating system. Using these tools to access and manage the server is referred to as in-band management. It usually requires a network that is fully available. For more information on this topic, see In-band management.

When the network is unavailable, you can use Emergency Management Services to access and manage the server. You do so through an out-of-band connection. This method does not require operating-system network drivers. In addition, you can use an out-of-band connection to troubleshoot the server when it is not fully initialized and functioning. Typically, you can do this without being physically present at the computer. When the appropriate out-of-band hardware is in place, the server requires physical access only when hardware must be installed or replaced. Emergency Management Services also eliminates the need for a keyboard, mouse, monitor, or video adapter on the remotely administered server. Emergency Management Services is available with or without a video card. For more information about this topic, see Out-of-band management.

With Emergency Management Services, you use a straightforward but powerful terminal text mode instead of a graphical user interface (GUI). As a result, you can use Emergency Management Services with a wide range of communication media (including serial connections) and current out-of-band infrastructure (including terminal concentrators and terminal emulators). It also provides interoperability with other platforms, such as UNIX.

Emergency Management Services features are fully or partially available when the operating system loads, when it is active (setting up and starting up), and when it is in distress (responding improperly or experiencing a Stop error). For a visual overview of these situations, see the System-state diagram.

For additional information on how to integrate Emergency Management Services into your infrastructure, see "Deploying Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# System-state diagram

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System-state diagram**

**System-state diagram conventions**

- The shaded boxes represent situations in which Emergency Management Services features are fully or partially available.
- The dashed lines represent transitions into distress or failure states. The operating system might not be able to recover unless assisted. You can use Emergency Management Services to attempt remote recovery if the system is at least partially functioning.
- The ability to manage the system remotely, which is represented by the non-shaded boxes, varies by system. Consult your system documentation to determine whether your system includes features, such as firmware redirection or a service processor, that can affect your ability to manage the system remotely.
- The solid lines represent normal or expected behavior. In these situations, you would expect the computer to turn on, initialize system firmware, and start the operating system without problems.
- The numbers are a sequential representation of the system states.
- For information about system-recovery procedures that correspond to situations represented in this diagram, see Emergency Management Services How To....

# Understanding Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Emergency Management Services**
This section covers:

- Remotely administered servers
- In-band management
- Out-of-band management
- Emergency Management Services components
- RIS and PXE requirements
- Firmware console redirection
- Emergency Management Services console redirection
- Service processor console redirection

# Remotely administered servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remotely administered servers**
For servers equipped with the proper firmware, Emergency Management Services provides functionality that you can use to administer a server remotely. You can usually do so without a local keyboard, mouse, or display device. Except for hardware maintenance and replacement, all administrative functions that you can accomplish locally should be available remotely. This includes starting your system and performing system-recovery tasks.

Remote administration does present security issues, however. For more information on securing a system that is managed with Emergency Management Services, see Best practices for implementing security measures.

You should be able to perform the following administrative tasks on a remotely administered server:

- Start up a server.
- Change basic input/output system (BIOS) settings.
- View power-on self test (POST) results.
- Install Windows using a standard mechanism such as Remote Installation Services (RIS).
- Select which operating system to start.
- Manage Windows using standard management tools such as Windows Management Instrumentation (WMI), Terminal Services Remote Desktop for Administration, Microsoft Management Console (MMC), Telnet, Windows Script Host, and non-Microsoft tools.
- Manage a Windows Server 2003 operating system when it is unavailable over the network.
- View system Stop errors.
- Reset a server.

To support operations performed without a keyboard, mouse, or display device attached to the system, Windows Server 2003 operating systems are able to boot without most video card support. For Advanced Configuration and Power Interface (ACPI) systems, the Windows Server 2003 family supports operating without a legacy keyboard controller. Universal serial bus (USB) systems running these operating systems can also support optional keyboard and mouse attachments. Consult your hardware documentation to determine whether your system supports this functionality.

Windows Server 2003 operating systems use the out-of-band management port to support Remote Installation Services (RIS). This makes it easier to install and repair servers remotely. For more information about RIS, see RIS and PXE requirements.

Managing a server that is running normally is referred to as in-band management. It typically involves connecting through the network directly to the server. A server that is functioning normally can be administered remotely with tools provided in the Windows Server 2003 family and listed earlier in this topic.

Troubleshooting a server that is not functioning normally often requires out-of-band management because you must access the server without relying on the network. To perform out-of-band management, you must establish a secure connection through a phone line or serial port, or through an additional network connection (possibly on a secondary network). The goal of out-of-band management is always to return the server to a fully functioning state where in-band connection is available.

Although you can use Emergency Management Services to manage the server remotely when the system is not functioning normally, Emergency Management Services must be set up and configured with the appropriate hardware and firmware. This is necessary so you can access the full range of its out-of-band management capabilities. When you have the proper hardware and Emergency Management Services configuration, out-of-band console input/output (I/O) support is provided for all kernel components, the loader, Setup, Recovery Console, and Stop errors.

When the server is functioning properly, support is also provided for a text-mode management console called Special Administration Console (SAC). For more information, see Emergency Management Services components.

For more information about hardware requirements for Emergency Management Services, see Selecting Hardware for Emergency Management Services.

# In-band management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**In-band management**

Windows Server 2003 operating systems provide a variety of in-band tools you can use to manage computers remotely.

Unlike out-of-band connection, in-band connection is available only when the server is initialized and functioning properly. In-band connection relies on operating-system network drivers to establish computer connections.

The most common in-band remote-management hardware device is the network adapter. Analog modems and Integrated Services Digital Network (ISDN) adapters are also classified as network adapters.

You can use remote-access connections to manage servers. The remote-access connection is made through the in-band port that resides on the target server.

You can use the following administrative tools to perform remote-management tasks through an in-band connection:

- Microsoft Management Console (MMC)
- Systems Management Server
- Telnet
- Terminal Services Remote Desktop for Administration
- Windows Management Instrumentation (WMI)
- Remote Command Service (Rcmd.exe and Rcmdsvc.exe). For more information on this tool, see Windows Resource Kit Tools Help.

You can also use appropriate non-Microsoft management tools to perform remote management tasks through an in-band connection.

If you lose the ability to manage your server through an in-band connection, you can manage the server using an out-of-band connection. For more information on this topic, see Out-of-band management.

# Out-of-band management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Out-of-band management**
When you are unable to manage a server over an in-band connection, you can access the server through an alternate but reliable connection called an out-of-band connection. An out-of-band connection does not depend upon operating-system network drivers, and is available even when your server has not loaded or is not functioning properly.

The following list describes situations in which you cannot use in-band management, and where it might therefore be appropriate to use out-of band management:

- The system is turned off. Because Emergency Management Services is unavailable, special hardware or firmware is required to manage systems in this situation.
- The basic input/output system (BIOS) is conducting the power-on self test (POST). Because Emergency Management Services is unavailable, special hardware or firmware is required to manage systems in this situation.
- The server is not functioning properly due to a Stop message event.
- The server is very low on resources, which causes the network driver to be very slow or makes it unable to respond to requests.
- The network stack is malfunctioning or has failed.
- An operating-system component is running (such as the loader or Recovery Console) that does not support in-band communication.
- The server is not yet fully initialized

The serial port is the hardware interface most commonly used by Emergency Management Services. There are several advantages to this. First, the serial port is simple and reliable enough to allow flexibility and availability. Second, the communication standards that govern serial ports are well defined. This makes interoperability with non-Microsoft systems such as UNIX possible. The third advantage is that most x86-based servers have at least one serial port.

For more information about in-band connections and in-band administrative tools that are available in Windows Server 2003 operating systems, see In-band management.

# Emergency Management Services components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Emergency Management Services components**
Emergency Management Services consists of components that are standard features of Windows Server 2003 operating systems, and to which console redirection functionality has been added. Emergency Management Services also includes two remote-management consoles that are unique to it.

**Components that support Emergency Management Services console redirection**
The components that support Emergency Management Services console redirection include Setup loader, text-mode Setup, the Recovery Console, Remote Installation Services (RIS), loader, and Stop error messages. When the operating system is configured to run with Emergency Management Services, these components will redirect their output to the out-of-band management port and to the video card, if one is attached. Emergency Management Services is available, however, with or without a video card. All Emergency Management Services output is accessible using a terminal emulator. For more information about console redirection, see Emergency Management Services console redirection.

There are also Emergency Management Services-specific versions of the Startrom.com file that is used in Remote Installation Services (RIS) installations. For more information about this, see RIS and PXE requirements.

**Remote-management consoles: SAC and!SAC**
The two remote-management consoles designed for Emergency Management Services are Special Administration Console (SAC) and !Special Administration Console (!SAC). You access these consoles through an out-of-band remote management port using terminal software that supports VT-UTF8, VT100+, or VT100.

**Special Administration Console (SAC)**
Special Administration Console (SAC) is the primary Emergency Management Services command-line environment hosted by Windows Server 2003 operating systems. It is separate from the command-line environment and provides different functionality.

Because SAC is available early in the boot process, you can use it to manage the server during normal system operation and initiation of most Windows Server 2003 family components. You can also use it when the system is in Safe Mode and during GUI-mode Setup. When Emergency Management Services is enabled, SAC remains active as long as the kernel is running.

SAC provides a set of commands you can use to perform a number of management tasks that help return your system to a normally functioning state. These tasks include:

- Restarting or shutting down the server.
- Viewing a list of processes that are currently active.
- Ending processes.
- Setting or viewing the Internet Protocol (IP) address of the server.
- Generating a Stop error to create a memory dump file.
- Starting and accessing command prompts.

For more information about using SAC commands, see Special Administration Console (SAC) and SAC commands.

**!Special Administration Console (!SAC)**
!Special Administration Console (!SAC) is an auxiliary Emergency Management Services command-line environment that is hosted by Windows Server 2003 operating systems. It also accepts input and sends output through the out-of-band port. !SAC is a separate entity from both SAC and Windows Server 2003 family command-line environments. After a specific failure point is reached, Emergency Management Services components determine when the shift should be made from SAC to !SAC. !SAC becomes available automatically if SAC fails to load or is not functioning.

!SAC provides a subset of SAC commands you can use to restore system functionality during a failure. Its two primary

functions are:

- To redirect Stop error message text.
- To restart the computer if SAC becomes unavailable.

For more information about using !SAC commands, see !Special Administration Console (!SAC) and !SAC commands.

**Windows command-prompt channels and Emergency Management Services**

The Special Administration Console Helper service (Sacsvr) is a user-mode service you can use to create Windows command-prompt channels when you type **cmd** at the SAC prompt. With the command-prompt channels, you can use in-band tools on a remotely administered server when an in-band connection is not available.

For example, when the network is down, you can still run text-based utilities as you would through Telnet. These tools include command-shell utilities such as **dir**, and text-based console programs such as the boot configuration utility (Bootcfg.exe). You cannot run programs with a graphical user interface (GUI) such as Notepad.exe, however.

Although access to in-band tools through the command-prompt channels provides extensibility and convenience, it does not guarantee that the tools will perform as reliably as they would when run over an in-band connection; the out-of-band functionality and robustness of Emergency Management Services applies only to SAC. In addition, Windows command-prompt channels require system resources, which might cause SAC to be available but the command prompt to be unavailable.

To use a command-prompt channel, you must provide valid logon credentials to a local or domain account, and log on to each command-prompt instance. Press ESC+TAB to switch back and forth between the command prompt channels and SAC. If a command prompt channel becomes unresponsive, you can close it and then open another.

For more information about the SAC commands for managing channels, see Special Administration Console (SAC) and SAC commands.

**Setup log access**

SAC provides access to the setup logs during GUI-mode Setup. You can press ESC+TAB to switch between the setup logs and SAC. When accessing the setup logs from Emergency Management Services, you can see which portions of Setup have completed and whether any errors have occurred. This is a very useful way to check the progress of your setup and to diagnose setup failures.

The three setup log channels are as follows:

**setuplog.txt**
Monitors setup progress.

**setupact.log**
Displays any warnings during setup.

**setuperr.log**
Displays any errors that might occur during setup.

# RIS and PXE requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RIS and PXE requirements**

Remote Installation Services (RIS) supports remote installations of Windows Server 2003 operating systems. This means that you can initiate RIS-based installations remotely on a computer without being physically present at the computer. RIS eliminates the need to use either the operating system CD or a floppy disk containing a Winnt.sif file. For more information, see Enabling Emergency Management Services during a new installation.

- RIS support is available on both x86 and Itanium-based systems.

For remote installations to be possible, the client computers must have a network adapter that is Pre-Boot eXecution Environment (PXE) capable. You can then perform installations using a network connection on systems without CD-ROM drives and on systems that have non-formatted or non-partitioned hard disks.

The firmware should recognize the PXE-capable network adapter as a valid boot device and as part of the boot order selection. In addition, the firmware should provide the option of using the F12 key to initiate a remote boot using a keystroke, thus circumventing the boot order. You can use this ability to change the boot order to implement emergency recovery procedures if necessary.

**Startrom.com**

The Startrom.com file is the first file that an x86-based RIS client downloads to begin the boot process. There are multiple versions of this file. Based on the PXE capabilities of your firmware, you can use Emergency Management Services-specific versions of Startrom.com to make use of console redirection for x86-based RIS clients. The Boot Information Negotiation Layer service (BINLSVC) creates an answer file that allows the rest of Setup to run without user input. Itanium-based RIS clients do not use Startrom.com, however. Instead, you can configure the Extensible Firmware Interface (EFI) to redirect output, and then use the PXE-capable network adapter to boot the computer.

Although you can use the Startrom.com files with systems that are not designed to work with Emergency Management Services, it is better to rely on the firmware to redirect its console output to the out-of-band management port and to use a standard Startrom.com file. This allows Startrom.com to be more flexible in its use of baud rates.

- **Hdlscom1.com and Hdlscom2.com.** For systems that do not support firmware console redirection, these files display the **Press F12 for network boot** prompt, using console redirection to serial port 1 or 2. Users can either press F12 to proceed with the boot process, or they can exit the boot process by not pressing F12. If a user presses the F12 key when prompted, Hdlscom1.com and Hdlscom2.com cause the PXE client to boot into the Client Installation Wizard only when the basic input/output system (BIOS) attempts a network boot. These files are installed by default with RIS.

- **Hdlscom1.n12 and Hdlscom2.n12.** For systems that support firmware console redirection, these files do not display the **Press F12 for network boot** prompt and do not wait for user input. When you use one of these files, the PXE client will always boot into the Client Installation Wizard when the BIOS attempts a network boot.

All Emergency Management Services-specific versions of Startrom.com rely on the BIOS to redirect their output to the out-of-band management port and to the video card, if one is attached. Emergency Management Services is available with or without a video card.

To use a Hdlscom*x*.com or Hdlscom*x*n12 file, you must first rename it to Startrom.com, and then copy it to the BINLSVC server. By default, these files are located in the *ServerName*\reminst\oschooser\i386 folder, where *ServerName* is the name of the RIS server running the BINLSVC.

**Client Installation Wizard**

The Client Installation Wizard automatically directs its entire user interface through the out-of-band port and a local console if one is attached to the computer. The Client Installation Wizard determines which out-of-band port to use by either reading the Serial Port Console Redirection (SPCR) table (if available) or by using the same port as Startrom.com. For more information, see Enabling the SPCR table.

For more information about RIS, see Remote Installation Services.

# Firmware console redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Firmware console redirection**

Firmware can provide redirection before the operating system starts. See the System-state diagram for a visual overview of how firmware and Emergency Management Services console redirection work together.

Types of firmware include both basic input/output system (BIOS) for x86-based computers and Extensible Firmware Interface (EFI) for Itanium-based computers. You can perform the following remote-management tasks using firmware console redirection:

- **View the power-on self-test (POST) status remotely.** Typically, computers with firmware that supports console redirection allow a system to complete the POST without a keyboard, mouse, or display device attached.

- **View and edit firmware settings remotely.** You can use the built-in firmware configuration program to change computer hardware settings.

- **Start a Remote Installation Services (RIS)-based setup.** If the firmware supports Pre-Boot execution Environment (PXE), you can use firmware console redirection to initiate Remote Installation Services (RIS)-based setups. In order to support PXE, the firmware must recognize the network adapter as a boot device. If necessary, the firmware must also allow you to change the settings of the BIOS boot order. For more information, see RIS and PXE requirements.

- **Respond to the prompt remotely when starting your computer. Press any Key to Boot from CD** You can do this by using the operating system CD. Before you begin a CD-based Windows Server 2003 operating system setup, enable firmware console redirection so you can view and respond to this prompt remotely. Your computer's BIOS must support the bootable CD (no emulation mode) format. Check with your computer manufacturer if you do not know whether your BIOS includes this feature. The BIOS specifies the boot order. The CD-ROM should be listed as the first boot device. Emergency Management Services is self-configured during a bootable CD installation by reading the Serial Port Console Redirection (SPCR) table.

**Notes**

- The firmware must be able to release control of the serial port to the operating system when the operating system starts.

- Firmware console redirection is typically available in text mode only.

Without firmware console redirection, you cannot perform out-of-band remote management during the period of time between system restart and the initial load phase of the Windows Server 2003 operating system. When firmware redirection is coupled with Emergency Management Services, however, you can manage and monitor a server remotely as soon as the POST process begins and until the operating system components are initialized. It is recommended that the firmware support the SPCR table. For more information, see Enabling the SPCR table.

# Emergency Management Services console redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Emergency Management Services console redirection**
Windows Server 2003 family components such as the Windows loader (Ntldr) can provide Emergency Management Services console redirection. Console redirection makes video output appear in text format when the output is sent to the out-of-band port and local monitor, if one is attached. The computer continues to receive keyboard input from the out-of-band port and the local keyboard, if attached. While the operating system is booting, the console takes over redirection from the firmware. See the System-state diagram for a visual overview of this process.

**Important**

- Your computer must have firmware console redirection for you to be able to view information from the remotely administered server. For more information, see Firmware console redirection.

Emergency Management Services does not provide console redirection for the following:

- The **Press any key to boot from CD** prompt that appears when you start your system by using the operating system CD.
- The Windows Server 2003 family GUI-mode Setup.
- Disk related error messages caused by problems such as a damaged master boot record (MBR).
- Startrom.com at baud rates greater than 9600 baud.
- For Itanium-based systems, Emergency Management Services relies on the firmware to redirect the operating system boot menu.

With Emergency Management Services console redirection, you can manage a server remotely through an out-of-band connection to do the following:

- Verify the initial load of Windows Server 2003 family components when administrative tools for in-band management are not yet available.
- For x86-based systems, select an operating system to load on multiple boot systems.
- View the progress of the Windows Server 2003 family text-mode Setup.
- For systems without firmware console redirection, respond to the **F12** prompt remotely when using Remote Installation Services (RIS) to initiate a Setup program.
- Respond to Windows Server 2003 family text-mode Setup prompts.
- View Stop error messages remotely when a system problem has occurred.
- Use the Recovery Console to troubleshoot startup problems remotely.
- Start and access command prompts.

# Service processor console redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service processor console redirection**

If your system includes a service processor, enhanced out-of-band management features, including console redirection, might be available to you. When selecting service processor hardware to use with Emergency Management Services, ensure that the hardware supports the following functions:

- Turn the computer on.
- Turn the computer off.
- Reset.
- Console redirection.
- Field-replaceable components (for example, service processors that are installed in sockets rather than soldered permanently in place).

For more information about selecting a service processor to complement Emergency Management Services, see Service processors. If your computer is currently equipped with a service processor, check your system documentation for more information about the out-of-band management features it provides.

# Setting up Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up Emergency Management Services**

This section covers:

- Selecting Hardware for Emergency Management Services
- Configuring Hardware for Emergency Management Services
- Selecting client terminal software for Emergency Management Services
- Enabling Emergency Management Services

# Selecting Hardware for Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Selecting hardware for Emergency Management Services**
Emergency Management Services must be integrated with properly designed hardware in order to manage Windows Server 2003 operating systems completely and successfully.

The three key areas you must address to fully integrate your platform with Emergency Management Services are as follows:

- **Ensure that you have appropriate hardware** for an out-of-band management port. Windows Server 2003 operating systems support a legacy serial port and hardware that uses the Universal Asynchronous Receiver/Transmitter (UART) interface provided by a service processor.

- **The user interface** for the system firmware and out-of-band management service processor should use the same communication medium as Emergency Management Services. If the firmware is using the out-of-band port, the firmware should deliver the medium over to Emergency Management Services cleanly after the power-on self test (POST) process has completed. The firmware should also use the same terminal conventions as Emergency Management Services, using the same keystrokes to represent keys such as F12. These criteria are recommended, not required. For more information, see VT-UTF8, VT100+, and VT100 conventions.

- **The firmware** must be able to pass the configuration settings of the out-of-band port to the operating system using the Serial Port Console Redirection (SPCR) table. The firmware stores configuration settings in the SPCR table, and the operating system reads them if the appropriate settings are in the Boot.ini file or the Extensible Firmware Interface (EFI). For more information, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

For additional information about selecting hardware, see Support resources.

This section covers:

- Serial ports

- Service processors

- Terminal concentrators

# Serial ports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Serial ports**
The most common out-of-band hardware interface is the serial port, also called the COM port. This serial port must be a 16550 Universal Asynchronous Receiver/Transmitter (UART). If your system firmware is compatible with Emergency Management Services, it is recommended that you configure it to use the same serial port settings. Emergency Management Services and the Windows debugger cannot share the same COM port. The system can have only a single out-of-band management port. Windows Server 2003 operating systems do not support a configuration in which one out-of-band port sends outgoing communication and a different out-of-band port (on a second device) receives incoming data.

For more information about serial ports, see:

- Enabling firmware console redirection
- Configuring Serial Ports

For additional information about selecting hardware for Emergency Management Services, see:

- "Emergency Management Services" at the Microsoft Windows Resource Kits Web site
- Support resources

# Service processors

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service processors**

To use Emergency Management Services console redirection, Special Administration Console (SAC), or !Special Administration Console (!SAC), the operating system loader or kernel must be at least partially functioning. Therefore, when severe system problems cause a computer to completely stop responding, you must have a remote-management medium that can function entirely without the operating system. Service processors integrated onto system motherboards and Peripheral Component Interconnect (PCI) adapters provide such a medium.

Service processors can function this way because they operate independently of the processors in a computer. In addition, they use their own custom firmware and can even use a separate power supply to enhance reliability. You can communicate directly with a service processor through an out-of-band connection.

The management tools, features, and client interfaces provided by service processors differ from one manufacturer to another. They can range in complexity from a simple Telnet console to a rich Web-browser environment. You should evaluate the management features and troubleshooting tools provided by a service processor to ensure that they meet the needs of your organization.

Service processors can also provide support through media that are more complex than serial ports, such as Transmission Control Protocol/Internet Protocol (TCP/IP) on Ethernet. Service processors are typically integrated into system motherboards or add-in PCI adapters and function separately from the system's CPU.

Some service processors are also called Application Specific Integrated Circuits (ASICs). Depending on their original equipment manufacturer (OEM), service processors or ASICs can be implemented with many different types of out-of-band connection ports, including serial ports, Universal Serial Buses (USBs), modem connections, and RJ-45 Ethernet ports. The type of out-of-band connection you use determines which additional components are required to allow out-of-band access to your servers.

When selecting service processor hardware for use with Emergency Management Services, verify that the following functions are supported:

- Turn on the computer
- Turn off the computer
- Reset
- Access to Emergency Management Services
- Console redirection
- Field replaceable units (FRUs); for example, a hard disk

**Internal hardware interface requirements**

To provide complementary functionality, Emergency Management Services and service processors or ASICs must be available for remote management. The service processor must provide a pass-through connection between the operating system and the remote management client. With this functionality, you can use both Emergency Management Services and the service processor through a single connection medium.

The service processor must include an appropriate 16550 or 16450 Universal Asynchronous Receiver/Transmitter (UART) in its system input/output (I/O) as an internal hardware interface for Emergency Management Services. This UART hardware must be available to Emergency Management Services at all times, including when the operating system loader is running, when the operating system is fully loaded, and when a Stop error has occurred.

The UART interface must be fully described in the Serial Port Console Redirection (SPCR) table, or, in Itanium-based systems, through the Extensible Firmware Interface (EFI) console device path. For more information, see Enabling the SPCR table.

**User interfaces for service processors**

Original equipment manufacturers (OEMs) can define a range of user interfaces for their service processors. Serial ports and RJ-45 Ethernet interfaces are examples of two such user interfaces. Some interfaces might support more than one communication protocol; for example, Ethernet supports Telnet and Hypertext Transfer Protocol (HTTP), as well as others. Other interfaces use a single communication channel, such as a serial port.

With an interface that uses a serial port as its communication channel, you can use only one out-of-band management tool (Emergency Management Services or the service processor) at a time. Emergency Management Services and the service processor must share the interface reliably. Integration between Emergency Management Services and the service processor is especially important during the operating system's boot process because you are interacting with both Emergency Management Services and the service processor using the same serial interface. In addition, you are relying on both Emergency Management Services and the service processor to follow the same I/O conventions.

After a system restart, the service processor must release control of the serial port to Emergency Management Services. For this to occur, internal UART hardware must be available so that the service processor and Emergency Management Services can communicate with each other. If the service processor and Emergency Management Services both use VT100 conventions, communication will be successful, and the service processor can be invoked and exited. For more information about this, see VT-UTF8, VT100+, and VT100 conventions.

When the user interface is a multiple-channel interface, such as an RJ-45 Ethernet, the requirements for providing access to Emergency Management Services change. Access to Emergency Management Services must be available simultaneously with the out-of-band functionality provided by the service processor. The terminal interface that you use to manage the server should support VT100+ conventions.

**Power switches or uninterruptible power supplies (UPS) with remote computer management capabilities**
A power switch or uninterruptible power supply (UPS) provides control of the power that is supplied to the server. It can also provides basic remote-management capabilities, such as the ability to reset the system or turn it off. A power switch or UPS can also allow the serial communication between a management system and a server to pass through its port. That is, the port on the computer used for management can have a serial connection to an external serial port on the UPS, which can then have a serial connection to the server.

If you use a power switch or a UPS, it must provide unrestricted communication between the management computer and the Windows Server 2003 family out-of-band tools. A power switch or UPS can interrupt the out-of-band tools by using an escape sequence that is sent by the management computer. To use a power switch or UPS, the server must be configured to boot automatically when power is applied.

The following requirements must be met before you use a power switch or UPS with Emergency Management Services:

- The UPS must be able to reset the system.
- The UPS user interface must support the escape sequences and VT100+ conventions.

It might be preferable for the power switch or UPS to provide terminal concentrator functionality. For more information, see Terminal concentrators.

The following resources provide additional information about selecting hardware for Emergency Management Services:

- "Emergency Management Services" at the Microsoft Windows Resource Kits Web site
- Support resources

# Terminal concentrators

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal concentrators**

A terminal concentrator is a hardware device that consolidates serial access to multiple servers into a single networked device. You can use this device to monitor a large number of servers simultaneously from one location.

Terminal concentrators include many serial ports connected to multiple servers using null modem cables. Typically, you access terminal concentrators over the network through the Telnet protocol. Terminal concentrators provide an interface through which you can remotely view data on multiple servers that use serial ports as their out-of-band connection.

Terminal concentrators can improve your management of servers because they can establish in-band connections to the servers and then perform out-of-band management tasks. In addition, terminal concentrators make it easier to manage servers for the following reasons:

- You can use terminal concentrators to manage multiple servers without needing to be within a serial cable's distance to the computer.
- Several administrators can simultaneously view the output of different servers.
- Using an out-of-band connection, you can use terminal concentrators to monitor servers methodically. You can also manage multiple servers from one location.

Several companies manufacture terminal concentrators; their setup, features, and configuration details vary. When assessing the appropriateness of a particular terminal concentrator, consider the following:

- The number of serial ports available.
- Built-in Telnet security features, such as passwords.
- Remote-access capabilities.
- The number of Ethernet ports available.

Telnet security features are not standard across terminal concentrators. If your device does not include security features, consider using a secondary private management network accessible through a direct-dial remote access connection or a virtual private network (VPN) connection. You can also use a router to secure network traffic going to the terminal concentrator.

For more information, see Checklist: Installing and configuring the router and Checklist: Installing and configuring the remote access server.

Using Telnet over Internet Protocol security (IPSec) can enhance security. See Internet Protocol Security (IPSec) for additional information.

For more information on terminal concentrators, see Configuring terminal concentrators.

For additional information about selecting hardware for Emergency Management Services, see:

- "Emergency Management Services" at the Microsoft Windows Resource Kits Web site
- Support resources

# Configuring Hardware for Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring hardware for Emergency Management Services**
This section covers:

- Configuring Serial Ports
- Configuring terminal concentrators

# Configuring Serial Ports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring serial ports**
This section covers:

- Configuring serial port hardware settings
- Enabling firmware console redirection
- Enabling the SPCR table
- Selecting the terminal definition setting

# Configuring serial port hardware settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring serial port hardware settings**

The serial port, also known as the COM port, is the most common out-of-band hardware interface. For information about selecting serial ports that complement Emergency Management Services, see Serial ports.

Emergency Management Services uses the first serial port (COM 1 at 3F8) by default. If a device already occupies that serial port, you can either move the device to another serial port or use another serial port for Emergency Management Services.

To prepare serial ports for out-of-band communication, you must first verify that motherboard serial ports are enabled. This is important if you have not already attached serial devices to determine whether the ports are working. To conduct this test, follow the manufacturer's instructions on how to access the x86-based basic input/output system (BIOS) or Itanium-based Extensible Firmware Interface (EFI) setup utility. Then navigate to the menu items that pertain to device configuration.

Serial ports allow the configuration of specific hardware resources such as input/output (I/O) addresses and hardware interrupt requests (IRQs). Depending on your system firmware, serial port resources might be user configurable, or they might have **Enabled** or **Disabled** as the only choices available. You should configure the appropriate port so it is enabled and at the default settings for a given COM port.

For more detailed procedures and best practices related to configuring serial ports, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site

# Enabling firmware console redirection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling firmware console redirection**

With firmware console redirection, your system can redirect text output to the out-of-band port.

Typically, you must enable firmware console redirection in the system firmware settings. Consult the original equipment manufacturer (OEM) or the documentation that came with your computer for information about how to change the firmware settings.

It is preferable for a system to indicate its firmware redirection settings through the Serial Port Console Redirection (SPCR) table. For more information about this topic, see Enabling the SPCR table.

For more information about firmware console redirection, see Firmware console redirection.

For more information about possible firmware settings and setup procedures, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# Enabling the SPCR table

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling the SPCR table**

The Serial Port Console Redirection (SPCR) table provides information on how the system firmware and the service processor use the out-of-band management port. For example, if the out-of-band management port is a serial port, the SPCR table contains information such as serial port number, baud rate, terminal type, and other settings used for out-of-band communication. If the out-of-band management port is a non-legacy Universal Asynchronous Receiver/Transmitter (UART) interface on a service processor, the SPCR table provides information about the location and type of UART interface.

The SPCR table ensures that there is a smooth transition between the system firmware and Emergency Management Services.

The SPCR table is usually enabled automatically if you have a service processor that supports Emergency Management Services, or you have enabled firmware console redirection. See your original equipment manufacturer (OEM) documentation to determine whether your computer supports the SPCR table and whether you must adhere to special requirements to enable it.

Windows Server 2003 operating systems attempt to configure Emergency Management Services hardware resource settings to match SPCR table settings without user intervention. If your system does not have an SPCR table, you must configure the Emergency Management Services settings to match the firmware settings, providing the operating system with the Emergency Management Services out-of-band port parameters.

For more information about required or recommended settings, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# Selecting the terminal definition setting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Selecting the terminal definition setting**

Terminal definition standards ensure that communications between the remotely administered server and the computer that manages it are standardized. For background information on these standards, see VT-UTF8, VT100+, and VT100 conventions.

Be sure to select a terminal definition setting for your firmware or service processor that is compatible with the Windows Server 2003 family and client terminal software. The best setting is VT-UTF8. If VT-UTF8 is not available, the next best choices, given in order of preference, are VT100+ and VT100. For a list of required or recommended settings, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# Configuring terminal concentrators

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring terminal concentrators**

A terminal concentrator consolidates access to multiple servers. You can use a terminal concentrator to establish remote out-of-band connections through the Telnet protocol over an in-band network connection. For information about selecting a terminal concentrator to complement Emergency Management Services, see Terminal concentrators.

Telnet security features are not standard across terminal concentrators. If your device does not include security features, consider using a secondary private management network that is accessible through a direct-dial remote access or virtual private network (VPN) connection. You can also use a router to secure network traffic to the terminal concentrator.

For more information, see Checklist: Installing and configuring the router and Checklist: Installing and configuring the remote access server.

You can also use Telnet over Internet Protocol security (IPSec) for increased security. See Internet Protocol Security (IPSec) for additional help.

If you choose not to use a terminal concentrator, you can use null modem cables to connect a single networked computer running a Windows Server 2003 operating system to multiple servers running Emergency Management Services.

For more information on selecting and configuring terminal concentrators, see "Emergency Management Services" in *Windows Server TechCenter* at the Microsoft Web site.

# Selecting client terminal software for Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Selecting client terminal software for Emergency Management Services**
Before you can access Emergency Management Services remotely, you must ensure that you are using compatible client software.

The out-of-band management hardware installed on your server determines which client software you should use. HyperTerminal or other VT-UTF8 terminal emulation software might be an option. For more information, see VT-UTF8, VT100+, and VT100 conventions and the HyperTerminal Help.

If your system has a service processor that requires a specialized client, both the service processor and the client must be capable of displaying Emergency Management Services output. For communication with service processors using RJ-45 Ethernet, Transmission Control Protocol/Internet Protocol (TCP/IP) might be an appropriate choice.

**Viewing non-English output from Emergency Management Services**
Emergency Management Services supports localized output on non-English versions of Windows Server 2003 operating systems. To view non-English characters, you must have an out-of-band management application that supports the VT-UTF8 terminal definition. HyperTerminal supports the VT-UTF8 terminal type.

For some terminals that support the VT-UTF8 terminal type, you must configure the operating system in order to be able to view output from a server that is a non-English language that is different from the language on your local computer.

For example, if the server runs a Chinese version of the Windows Server 2003 operating system, but the computer you use to manage the server runs an English version of the operating system, it might be necessary to configure the local computer's operating system. This is typically done in Regional and Language Options. The procedure can vary, however, according to the terminal application you use. It might also be necessary to install additional fonts.

For step-by-step information on how to view non-English output from Emergency Management Services, see View East Asian languages with the VT-UTF8 terminal emulator in Hyperterminal.

# Enabling Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling Emergency Management Services**

This section covers:

- Enabling Emergency Management Services during a new installation
- Enabling Emergency Management Services during an upgrade (x86-based systems)
- Enabling Emergency Management Services after Setup (x86-based systems)
- Enabling Emergency Management Services after Setup (Itanium-based systems)

# Enabling Emergency Management Services during a new installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling Emergency Management Services during a new installation**

You can initiate an Emergency Management Services embedded installation when you start the computer from the Windows Server 2003 operating system CD if your system supports firmware console redirection and the Serial Port Console Redirection (SPCR) table.

Before you begin a CD-based Windows Server 2003 operating system Setup, enable firmware console redirection. You can then remotely view and respond to the prompt **Press any key to boot from CD-ROM**, which appears when you start the system using the operating system CD.

Emergency Management Services configures itself during a bootable CD installation by reading the SPCR table. If Emergency Management Services is enabled, you are prompted at the end of text-mode Setup to allow Setup to automatically configure your system without user input. You must choose this option; otherwise, the next portion of Setup, known as GUI-mode Setup, completes only if you provide input through a local monitor and keyboard. After Setup is complete, you can reconfigure the setting appropriately.

If your firmware does not support the SPCR table, you must fully automate your setup. If your firmware supports the SPCR table, and you want to disable Emergency Management Services, you can configure Setup using Unattend.txt and Winnt.sif files.

**Unattend.txt and Winnt.sif files**

You must have the Unattend.txt and Winnt.sif files if you want to fully automate the remote installation of a Windows Server 2003 operating system.

A sample Unattend.txt file is provided on the operating system CD. You can either use the default settings or customize your installations by modifying or adding parameters. When you edit the Unattend.txt files, insert the parameters in the **[Data]** section, as shown in the following table:

| [Data] Parameter | Possible values |
|---|---|
| **EMSPort=**{**com1**\|**com2**\|**usebiossettings**} | • **com1** or **com2** (where 1 or 2 specifies serial port 1 or 2). This option is valid for x86-based systems only.<br>• **usebiossettings**<br>This is the default value. This parameter instructs the operating system to detect and use SPCR settings. If you use this parameter and an SPCR table is not present, Emergency Management Services is not enabled. |
| | |
| **EMSBaudRate=** *value* | The default value is 9600 baud, with the values of 19200, 57600, and 115200 possible, depending on the capabilities of the serial port. This must be used with **EMSPort=** or the parameter is ignored. |

You can create a Winnt.sif file by copying an Unattend.txt file to a floppy disk and renaming it to Winnt.sif. Because CD media is read-only, CD-based Windows Server 2003 operating system installations must read custom setup information from the floppy drive. The table later in this topic lists unattended Setup parameters required for Winnt.sif. When editing a Winnt.sif file, insert the parameters listed in both tables into the **[Data]** section.

For remote Setup to complete successfully without a local keyboard or monitor, you must configure your setup scripts so they are completely unattended. For more information about unattended Setups, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

| [Data] Parameter | Possible values |
|---|---|

| | |
|---|---|
| **Autopartition**={**0**\|**1**} | Allows unattended Setup to choose a partition in which to install. The value must be set to **1** for unattended Setups. If you do not set the value, text-mode Setup stops and waits for your input. |
| **MsDosInitiated**={**0**\|**1**} | Informs the Setup Loader that an unattended installation is occurring directly from the CD. The value must be set to **0** for unattended Setups. |
| **UnattendedInstall**={**No**\|**Yes**} | The value must always be set to **Yes** for CD-based unattended installations. |

**Important**

- To use Winnt.sif files, you must set the CD-ROM as the primary boot device and leave the floppy disk containing a Winnt.sif file in the floppy drive.
- Unattended Setups for Windows Server 2003 operating systems do not pause for user input. With console redirection, you can view text-mode Setup remotely for monitoring purposes.

For specific examples and additional information about creating unattended setups, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

**Remote Installation Services (RIS)**

With Remote Installation Services (RIS), you can install a Windows Server 2003 operating system on computers without being physically present at those computers. If the firmware on the target computers supports Pre-Boot eXecution Environment (PXE), console redirection, and the Serial Port Console Redirection (SPCR) table, you can use Emergency Management Services to initiate and complete Setup from remote setup media.

If your firmware does not support the SPCR table, you can configure your Emergency Management Services settings in the RISTNDRD.txt file just as you would configure them in the normal setup scripts, Unattend.txt and Winnt.sif. If your firmware does not support console redirection, you can use special versions of Startrom.com that output to a generic serial port, com1 or com2, at 9600 baud.

For more information about remote installation, see RIS and PXE requirements.

# Enabling Emergency Management Services during an upgrade (x86-based systems)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling Emergency Management Services during an upgrade (x86-based systems)**
During an upgrade, you can enable Setup on an x86-based system by using Winnt32.exe. After inserting the Windows Server 2003 operating system CD into your computer, map a network drive connection to the path containing the installation files. At the command prompt type:

*Drive* **\i386\winnt32.exe**

*Drive* represents the drive letter assigned to the CD-ROM drive or shared folder. Follow this with one or any combination of the command-line parameters listed in the following table:

| [Data] Parameter | Possible values |
|---|---|
| **EMSPort=**{**com1**\|**com2**\|**usebiossettings**} | • **com1** or **com2** (where the numeral 1 or 2 specifies serial port 1 or 2).<br><br>This option is valid for x86-based systems only.<br><br>• **usebiossettings**<br><br>This is the default value. This parameter instructs the operating system to detect and use Serial Port Console Redirection (SPCR) settings. If you use this parameter and an SPCR table is not present, Emergency Management Services is not enabled. |
| **EMSBaudRate=** *value* | The default value is 9600 baud, with other values of 19200, 57600, and 115200 possible, depending on the capabilities of the serial port. This must be used with **EMSPort=** or the parameter is ignored. |

Winnt32.exe copies setup files to your system and then prompts you to confirm a restart. After restarting the system, text-mode Setup begins, followed by GUI-mode Setup. During text-mode Setup, you can view setup messages through Emergency Management Services console redirection. During GUI-mode Setup, you can access Special Administration Console (SAC), but you cannot view Setup prompts.

**Important**

- Winnt32.exe is a GUI-based tool and does not support Emergency Management Services; you cannot start or monitor Winnt32.exe by using the out-of-band port. For this purpose, you must use a GUI-based tool, such as Terminal Services Remote Desktop for Administration.

For more information about using Winnt32.exe to enable Emergency Management Services, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# Enabling Emergency Management Services after Setup (x86-based systems)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling Emergency Management Services after setup (x86-based systems)**
To enable Emergency Management Services after setting up a Windows Server 2003 operating system, you must edit the Boot.ini file to enable Windows loader console redirection and Special Administration Console (SAC). The Boot.ini file controls startup; it is located on the system partition root.

Use Bootcfg (Bootcfg.exe) to edit the Boot.ini file.

To view examples of how to edit the Boot.ini file, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

You can enable Emergency Management Services console redirection in the Recovery Console. You do this by editing the Winnt.sif file, located in the Cmdcons folder on the system partition root. Note that the Winnt.sif for the Recovery Console is separate from the floppy disk Winnt.sif file that is referenced in Enabling Emergency Management Services during a new installation.

For specific information about setting Recovery Console Bootcfg parameters for Emergency Management Services, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# Enabling Emergency Management Services after Setup (Itanium-based systems)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling Emergency Management Services after setup (Itanium-based systems)**

To enable Emergency Management Services on Itanium-based installations of a Windows Server 2003 operating system, you must first enable firmware console redirection.

To do so, follow the instructions in your hardware manufacturer's documentation. Then, edit the Extensible Firmware Interface (EFI) boot manager settings using Bootcfg. The **Bootcfg** command enables Emergency Management Services console redirection and Special Administration Console (SAC).

For more information about using Bootcfg to enable Emergency Management Services, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

# Using Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Emergency Management Services**

This section covers:

- Special Administration Console (SAC) and SAC commands
- !Special Administration Console (!SAC) and !SAC commands
- VT-UTF8, VT100+, and VT100 conventions
- Task list headings

# Special Administration Console (SAC) and SAC commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Special Administration Console (SAC) and SAC commands**
You perform most remote-management and recovery tasks using an out-of-band management port with Special Administration Console (SAC). The server must be at least partially functioning in order to use SAC.

After Emergency Management Services is enabled, SAC is always running unless Emergency Management Services components are prevented from loading properly. If Emergency Management Services components are prevented from loading properly, the server starts !Special Administration Console (!SAC). In addition, a set of SAC commands is available for performing management tasks.

The following prompt appears when SAC is active:

**SAC>**

For more information, see Emergency Management Services components and !Special Administration Console (!SAC) and !SAC commands.

**SAC commands**
The following table lists SAC commands that are available for remote management tasks.

| Command | Description |
|---|---|
| **ch** | Lists all channels. |
| **cmd** | Creates Windows command-prompt channels. To use a command-prompt channel, you must provide valid logon credentials. You must log on to each command-prompt instance. |
| **crashdump** | Manually generates a Stop error message and forces a memory dump file to be created. |
| **D** | Dumps the current kernel log. |
| **F** | Toggles the information output by the t-list command, which shows processes only, or shows processes and threads. |
| **I** | If no parameters are passed, this command lists Internet Protocol (IP) information. You can configure IP parameters to display or set the IP address, subnet mask, and gateway of a given network interface device by providing the network number, IP address, and subnet information. To do so, use the following format: *<network#> <IPaddress> <subnet>* |
| **Id** | Displays identification information about the server. |
| **K***<PID>* | Ends the given process. *PID* is the process identification number you specify. |
| **L***<PID>* | Lowers the priority of a process (and any associated child processes) to the lowest possible level. |
| **lock** | Restricts access to Emergency Management Services command-prompt channels. You must provide valid logon credentials to unlock a channel. |
| **M***<PID> <MB-***allow***>* | Limits the memory usage of a process (and any associated child processes) to a specified number of megabytes. *MB* is the number of megabytes you specify. |
| **P** | Causes t-list command output to pause after displaying one full screen of information. |
| **R***<PID>* | Raises the priority of a process and any associated child processes up by one level. |
| **restart** | Restarts the computer. |

| | |
|---|---|
| **S** | If no parameters are passed, this command displays the current date using the 24-hour clock format. You can set the system time by providing the date and, optionally, the time in this format: *mm***/***dd***/***yyyyhh***:***mm*. |
| **shutdown** | Shuts down the computer. Do not use this command unless you can be physically present at the computer when you are ready to restart it. |
| **T** | Lists the processes and threads that are currently running. |
| **? or help** | Lists the available commands. |

**Channel-management commands**

The following table lists the subset of SAC commands available for managing out-of-band port channels.

| Command | Description |
|---|---|
| **ch** | Lists all channels. |
| **ch -si** <*n*> | Changes to the channel with the number, *n*, which you specify. |
| **ch -sn** <*name*> | Changes to the channel with the *name* you specify. |
| **ch -ci** <*n*> | Closes the channel with the number, *n*, which you specify. |
| **ch -cn** <*name*> | Closes the channel with the *name* you specify. |
| <**Esc**><**Tab**> | Enables you to change channels. |
| <**Esc**><**Tab**>**0** | Returns you to the SAC channel. |
| **ch -?** | Displays the channel-management commands Help. |

# !Special Administration Console (!SAC) and !SAC commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**!Special Administration Console (!SAC) and !SAC commands**
You can use !Special Administration Console (!SAC) to perform remote management tasks if the Windows Server 2003 operating system stops functioning due to a Stop error message.

The main functions of !SAC are as follows:

- Redirect Stop error message explanatory text.
- Restart the system.
- Obtain computer identification information.

When !SAC becomes available, the following prompt appears:

**!SAC>**

!SAC includes a subset of SAC commands, which are listed in the following table:

| Command | Description |
|---|---|
| **restart** | Restarts the server immediately. |
| **D** | Displays all log entries (screen pauses at each page of information). |
| **Id** | Displays computer identification. |
| **Q** | Quits !SAC and resumes normal out-of-band port operation. |
| **? or Help** | Lists available commands. |

For additional information about topics related to !SAC, see Emergency Management Services components and Special Administration Console (SAC) and SAC commands.

# VT-UTF8, VT100+, and VT100 conventions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VT-UTF8, VT100+, and VT100 conventions**

Industry terminal definition conventions provide a smooth way for you to send commands from the remote management console--usually Special Administration Console (SAC)-- to the server. These terminal definition conventions ensure a consistent mechanism for managing systems in all states of operation and failure. Windows Server 2003 operating systems use the commands, which are described later in this topic. The firmware, service processors and client terminal software should also use these commands.

The VT100 Terminal Definition is the standard convention used to configure and conduct emergency management tasks with UNIX-based servers. VT100 does not support all keys on the standard PC 101-key layout, however. The VT-UTF8 convention makes available additional keys that are not provided by VT100 for the PC 101 keyboard. With VT-UTF8, you can also use colors and some standardized escape sequences that are commonly used for management tasks. With VT-UTF8, output sent to the serial port can be localized while UNIX interoperability for English is sustained.

For more information about viewing non-English output from Emergency Management Services, see Selecting client terminal software for Emergency Management Services.

VT100+ is a subset of VT-UTF8 that handles only VT100-compatible characters--that is, American National Standards Institute (ANSI) characters 0 through 127. VT-UTF8 is the preferred terminal type for viewing Emergency Management Services output using a terminal emulator, such as HyperTerminal, and for firmware or service processor output. In either case, if VT-UTF8 is not available, your next best choices are to try VT100+ and then VT100, in that order.

**VT-UTF8 and VT100+ keyboard-to-escape-sequence mappings**

If you plan to use a VT100, VT100+, or VT-UTF8 terminal emulator to communicate with Emergency Management Services or some other management console, the key mappings provided later in this topic should occur automatically when you press the associated key.

For example, to send an **F2** keystroke to a remotely administered server from a terminal using the VT100+ or VT-UTF8 terminal definition, press **F2**. If you use VT100 emulation software or a terminal emulator that does not support all the key mappings or management escape sequences, however, you can type the escape sequences directly into the terminal. For example, to send an **F2** from a VT100 terminal, type **<ESC>**, and then type **2**.

The following table defines these VT100+ and VT-UTF8 key mappings.

| VT100+ key | Escape sequence sent |
|---|---|
| **HOME** | <ESC> h |
| **END** | <ESC> k |
| **INSERT** | <ESC> + |
| **DELETE** | <ESC> - |
| **PAGE UP** | <ESC> ? |
| **PAGE DOWN** | <ESC> / |
| **ALT** | <ESC>^A |
| **CTRL** | <ESC>^C |
| **F1** | <ESC> 1 |
| **F2** | <ESC> 2 |
| **F3** | <ESC> 3 |
| **F4** | <ESC> 4 |

| | |
|---|---|
| **F5** | <ESC> 5 |
| **F6** | <ESC> 6 |
| **F7** | <ESC> 7 |
| **F8** | <ESC> 8 |
| **F9** | <ESC> 9 |
| **F10** | <ESC> 0 |
| **F11** | <ESC> ! |
| **F12** | <ESC> @ |

**Note**

- PC function keys are not equivalent to the VT100 terminal function keys.

The following table lists VT-UTF8 escape sequences used to send special commands:

| Action | Escape sequence |
|---|---|
| **Start firmware setup utility** | ^F |
| **Reset**<br><br>The computer will reset without shutting down Windows. This command requires either service processor support, or a power switch or uninterruptible power supply (UPS) with remote computer management capabilities. | <ESC>R<ESC>r<ESC>R |
| **Invoke service processor**<br><br>The service processor monitors the serial traffic for this escape sequence. When it detects the sequence, the service processor assumes control of the out-of-band port and immediately sends an acknowledgement sequence (defined later in this table). You cannot use Emergency Management Services until you exit the service processor. This command requires service processor support. | <ESC>( |
| **Invoke power switch or UPS**<br><br>The power switch or UPS monitors the serial traffic for this escape sequence. When it detects the sequence, the power switch assumes control of the out-of-band port and immediately sends an acknowledgement sequence (defined later in this table). You cannot use Emergency Management Services until you exit the power switch. This command requires a power switch or UPS with remote computer management capabilities. | <ESC>) |
| **Power switch, UPS, or service processor acknowledgement**<br><br>After taking control of the out-of-band port, the power switch, UPS, or service processor sends this escape sequence. This indicates that the power switch, UPS, or service processor has assumed control of the port and is ready for interaction. This command requires either service processor support, or a power switch or UPS with remote computer management capabilities. | <ESC>* |
| **Exit power switch, UPS, or service processor; display a user interface (UI)**<br><br>The power switch, UPS, or service processor releases control of the out-of-band port. Before it does so, it might display a user interface message. For example, it might display a warning message such as: "Do you want to save setting and exit? [y/n]." This command requires either service processor support, or a power switch or UPS with remote computer management capabilities. | Q |

| | |
|---|---|
| **Exit power switch, UPS, or service processor; do not display a UI**<br><br>The power switch, UPS, or service processor releases control of the out-of-band port without displaying a user interface (UI). | <ESC>Q |

For more information, see Selecting the terminal definition setting.

# Task list headings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Task list headings**

The following table describes the output from the Special Administration Console (SAC) **T** command, which lists the processes and threads currently running.

| Task list heading | Description |
|---|---|
| User Time | The amount of user-mode time charged to a process since the last time the computer was restarted. |
| Kernel Time | The amount of kernel-mode time charged to a process since the last time the computer was restarted. |
| ws | Working set, or the amount of physical memory assigned to a process by the operating system. |
| Faults | The page faults that have occurred since the last time the computer was restarted. A page fault is an interrupt that occurs when software attempts to read from or write to a virtual memory location that is marked *not present*. |
| Commit | The amount of memory that a process is using. |
| Pri | The default thread priority. |
| Hnd | The number of handles charged to a process. |
| Thd | The thread count. |
| Pid | The process identifier (PID) or numerical identifier that uniquely distinguishes a process while it runs. |
| Name | The name of the process. |

For more information on using the **T** command, see Resolve system resource problems using SAC.

# Emergency Management Services Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

For information on how to integrate Emergency Management Services into your existing environment, see "Deploying Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

For more detailed information on how to select and configure hardware and enable Emergency Management Services, see "Emergency Management Services" at the Microsoft Windows Resource Kits Web site.

For information about compatible hardware, product support services, and tools, see Support resources.

# Troubleshooting Emergency Management Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting Emergency Management Services**

**Important**

- You can use the approaches provided in this topic to troubleshoot Emergency Management Services components, not to troubleshoot your system. For information about using Emergency Management Services to troubleshoot your system, see Emergency Management Services How To....

What problem are you having?

- The out-of-band port is briefly unavailable; no status information appears.
- Status information appears, but Emergency Management Services does not respond to terminal input.
- The kernel debugger disables !Special Administration Console (!SAC). Garbled characters might appear.

**The out-of-band port is briefly unavailable; no status information appears.**

**Cause:** The Windows Server 2003 family components that provide Emergency Management Services load and unload as part of the startup process, which causes components to become briefly disabled. This is called a "black-out period."

**Solution:** If Special Administration Console (SAC) or !Special Administration Console (!SAC) do not respond, wait for operating system components to initialize before restarting or stopping the system using whatever means are available, such as a service processor or uninterruptible power supply (UPS). If a service processor is present, consult your documentation to determine other diagnostic tools that it provides.

**See also:** Using Emergency Management Services.

**Status information appears, but Emergency Management Services does not respond to terminal input.**

**Cause:** The Windows Server 2003 family components that provide Emergency Management Services load and unload as part of the startup process, which causes components to provide limited functionality. This is called a "gray-out period."

**Solution:** Gray-out periods might become interactive if the component provides !Special Administration Console (!SAC) functionality. If !SAC does not respond, however, wait for operating system components to initialize before restarting or stopping the system using other means, such as a service processor or uninterruptible power supply (UPS). If a service processor is present, consult your documentation to determine other diagnostic tools that it provides.

**See also:** !Special Administration Console (!SAC) and !SAC commands.

**The kernel debugger disables !Special Administration Console (!SAC). Garbled characters might appear.**

**Cause:** The kernel debugger and !SAC cannot use the same serial port simultaneously. In addition, when a kernel debugger is running, !SAC becomes unavailable because the debugger takes control of the system if a Stop error occurs.

**Solution:** Use different serial ports for the kernel debugger and !SAC. It is important to specify the correct COMx parameters in the Boot.ini file. You should also disable kernel debuggers on servers during normal operations.

# Monitoring and Status Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring and status tools**
This section covers:

- Task Manager overview
- Using Network Diagnostics
- System Information
- System Properties
- Services Snap-in
- Event Viewer
- Network Monitor
- Monitoring Performance
- Shutdown Event Tracker
- SNMP
- Device Manager
- Windows Management Instrumentation Control

# Task Manager overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Task Manager overview**
Task Manager provides information about programs and processes running on your computer. It also displays the most commonly used performance measures for processes.

You can use Task Manager to monitor key indicators of your computer's performance. You can see the status of the programs that are running and end programs that have stopped responding. You can also assess the activity of running processes using as many as fifteen parameters, and see graphs and data on CPU and memory usage.

In addition, if you are connected to a network, you can view network status and see how your network is functioning.

If you have more than one user connected to your computer, you can see who is connected, what they are working on, and you can send them a message.

**Programs that are running**
The **Applications** tab shows the status of the programs running on your computer.

On this tab, you can end, switch to, or start a program.

**Processes that are running**
The Processes tab shows information about the processes running on your computer.

For example, you can display information on CPU and memory usage, page faults, handle count, and a number of other parameters.

**Performance measures**
The **Performance** tab displays a dynamic overview of your computer's performance, including:

- Graphs for CPU and memory usage.
- Totals for the number of handles, threads, and processes running on your computer.
- Totals, in kilobytes, for physical, kernel, and commit memory.

**Viewing Network performance**
The **Networking** tab displays a graphical representation of network performance. It provides a simple, qualitative indicator that shows the status of the network(s) that are running on your computer. The Networking tab is displayed only if a network card is present.

On this tab, you can view the quality and availability of your network connection, whether you are connected to one or more than one network.

**Monitoring Sessions**
The **Users** tab displays users who can access this computer, and session status and names. **Client Name** specifies the name of the client computer using the session, if applicable. **Session** provides a name for you to use to perform such tasks as sending another user a message or connecting to another user’s session.

The **Users** tab is displayed only if the computer you are working on has Fast User Switching enabled, and is a member of a workgroup or is a standalone computer. The **Users** tab is unavailable on computers that are members of a network domain.

# Using Network Diagnostics

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Network Diagnostics**

With Network Diagnostics, you can display information about your network environment quickly and easily. This tool provides information about your computer, operating system, network, and network adapters. Using Network Diagnostics, you can perform standard tests for network connectivity, such as running the ping command to test the network path to a server or trying to connect to a server. Network Diagnostics reports both successful and unsuccessful attempts to reach network resources.

To open Network Diagnostics, click **Start**, click **Help and Support**, click **Tools**, click **Help and Support Center Tools**, and then click **Network Diagnostics**.

**Note**

- Network tests are run only on your computer to ensure the privacy and integrity of your data. No information is sent to Microsoft.

# System Information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Information**
System Information collects and displays information about the configuration of your system. You can view information for a local computer or for a computer to which you are connected.

- For help with specific tasks, see System Information How To....
- For general background information, see System Information Concepts.

# System Information How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Find system data
- View system history
- Export system data to a text file
- Print system data

# Find system data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find system data**

1. Open System Information.
2. In the **Find what** box at the bottom of the **System Information** window, type the word or words that correspond to the system information for which you are searching.
3. Select the appropriate search option:
   - To search only a portion of the categories in the console tree, select the **Search selected category only** check box. This starts the search at the top of the currently selected category and searches all of its subcategories. To start the search at the root, clear this check box.
   - To search only the categories in the console tree, ignoring any matches in the details pane, select the **Search category names only** check box. To search both the console tree and the details pane, clear this check box.
   - To search all categories in both panes, clear both check boxes.
4. Click **Find**.
5. To search for the item again, click **Find Next**.

## Notes

- To access System Information on a remote computer, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open System Information, click **Start**, and then click **Help and Support**. Under **Support Tasks**, click **Tools**, and then click **Help and Support Center Tools**. Click **Advanced System Information**, and then click **View detailed system information (Msinfo32.exe)**.
- If the **Find** options do not appear at the bottom of the System Information window, on the **Edit** menu, click **Hide Find** to clear the check mark and restore the options.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# System Information Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about System Information:

- System Information overview
- Managing System Information from the command line
- Understanding System Information

# System Information overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Information overview**

System Information collects and displays system configuration information for local and remote computers. This includes information about hardware configurations, computer components, and software, including signed drivers and unsigned drivers. You can use System Information to quickly find the information that you need to resolve a system problem.

System Information saves data files in a native (.nfo) format. By default, system data is automatically saved in an .nfo file format that is compatible with the current version of System Information. You can also save data as a Version 5.0/6.0 System Information (.nfo) file, which is compatible with older versions of System Information.

You can use System Information to view system history. System history is collected when changes are made to certain system devices and settings. This system history data is compared periodically to the previous system settings, and if there are any changes, those changes are saved in the System History view. Only the most recent changes are compared against previous settings; therefore, it is possible to make multiple changes to a certain device or driver and have only one of the changes appear in the System History view. For more information, see View system history.

You can also open .cab files and .xml files in System Information. When you open .cab files, you can view the contents of those files by using the **Tools** menu.

# Managing System Information from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing System Information from the command line**
In addition to the System Information support tool in Help and Support Center, you can use the **msinfo32** command to view information about a computer that you are managing. With this command, you can:

- Use System Information from a batch file.
- Create .nfo files or .txt files that contain information from specified categories.
- Open System Information, displaying only specified categories.
- Save a System Information file without opening the System Information tool.
- Start System Information for a remote computer. (You must have the appropriate permissions.)
- Create a shortcut that opens System Information in a commonly used configuration.

For more information about the **msinfo32** command, see Msinfo32. For information about other command-line utilities, see Command-line reference A-Z. For information about manageability, see Management Strategies and Tools.

# Understanding System Information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding System Information**
System Information is a support tool that you can use to quickly locate information about your computer and its operating system. The category tree in the left pane contains items in a folder view that is similar to Windows Explorer. The details pane on the right side of the window displays information about the items that you select in the category tree.

This section covers:

- System Summary
- Hardware Resources
- Components
- Software Environment
- Internet Settings

# System Summary

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Summary**
System Summary is the first category in the System Information category tree. The details pane displays general information about your computer and its operating system. You can view information about the operating system name, version, manufacturer, and directory location. You can verify the version of the BIOS or EFI, the processor type, and memory information.

You can use System Summary to:

- Check the BIOS or EFI version and date.
- Determine the directory in which the operating system is installed.
- Verify that new memory is installed correctly by checking Total Physical Memory and Available Physical Memory.
- Check the Page File Space value if the computer is having memory problems. Page File Space is the physical space on the hard disk that the operating system uses to increase the apparent size of RAM.
- Check your activation status. This information appears only if you have not activated the product. For more information, see Windows Product Activation.

For more information about updating your system BIOS or EFI, or about installing new memory, refer to your hardware manufacturer's documentation.

# Hardware Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware Resources**
The Hardware Resources category in System Information displays information about resource assignments and possible sharing conflicts among DMA, Forced Hardware, I/O, IRQs, and Memory resources.

For more information about these items, see the following:

- Conflicts/Sharing
- DMA
- Forced Hardware
- I/O
- IRQs
- Memory

# Conflicts/Sharing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Conflicts/Sharing**

Conflicts/Sharing is located in the Hardware Resources category in System Information. It displays devices that share the same resources, such as direct memory access (DMA), IRQs, and memory.

In general, shared resources are not problematic, but investigating potential conflicts can help resolve issues. If you are having a problem with a device, check Conflicts/Sharing to verify that there are no sharing conflicts. Locate the device in the **Device** column in the details pane, and then verify which resource the device uses in the **Resource** column. Devices that share the same resource have duplicate entries in the **Resource** column. For example, you may have two adapters that share the same IRQ channel, such as IRQ 5. If the problem device shares a resource with another device, there may be a conflict. You can use Device Manager to troubleshoot the problem. For more information about Device Manager, see Device Manager.

For more information about Hardware Resources, see Hardware Resources.

# DMA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DMA**

DMA is located in the Hardware Resources category in System Information. It displays information about your system's direct memory access (DMA). DMA transfers data between system memory and hardware devices without passing it through the CPU. The **Resource** column in the details pane displays the DMA channel that is being used by the device, which is listed in the **Device** column. The **Status** column displays the status of the device.

If the **Status** column indicates an error, such as Error, Degraded, Unknown, Pred Fail, Starting, Stopping, or Service, you can try the following troubleshooting solutions:

- Use Device Manager to locate and troubleshoot the problem. For more information about Device Manager, see Device Manager.
- Contact the device manufacturer to obtain an updated device driver.
- Reconfigure the settings in the system BIOS or EFI.

For more information about Hardware Resources, see Hardware Resources.

# Forced Hardware

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Forced Hardware**

Forced Hardware is located in the Hardware Resources category in System Information. The **Device** column in the details pane identifies the type of device. The **PNP Device ID** column lists the device ID.

Forced hardware is any device that you have to configure manually or that has user-specified resources, as opposed to system-specified resources. The category Forced Hardware also applies to devices that are not Plug and Play compatible, such as legacy Industry Standard Architecture (ISA) devices.

If there is a conflict with a manually configured hardware device, use Device Manager to locate and troubleshoot the problem. For more information about Device Manager, see Device Manager.

For more information about Hardware Resources, see Hardware Resources.

# I/O

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**I/O**

I/O is located in the Hardware Resources category in System Information. I/O is the communication channel among hardware devices in your computer. The **Resource** column in the details pane displays the resource that is used by an I/O device, which appears in the **Device** column. The **Status** column displays the status of the device.

If there is a sharing conflict with a device that uses an I/O channel, locate the device in Conflicts/Sharing or in I/O, and then use Device Manager to locate and troubleshoot the problem. For more information about Device Manager, see Device Manager.

For more information about Hardware Resources, see Hardware Resources.

# IRQs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IRQs**

IRQs is located in the Hardware Resources category in System Information. It displays information about interrupt request (IRQ) channels on your system. The **Resource** column and the **Device** column indicate which devices are assigned to each channel, and the **Status** column displays the status of the device. The operating system allows you to use only certain IRQs. Other IRQs are reserved for a standard set of devices.

If there is a sharing conflict with an IRQ, such as a mouse not responding, use Device Manager to locate and troubleshoot the problem. For more information about Device Manager, see Device Manager.

For more information about Hardware Resources, see Hardware Resources.

# Memory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Memory**
Memory is located in the Hardware Resources category in System Information. The **Resource** column in the details pane displays the memory address of the device that is listed in the **Device** column.

Memory address ranges are used for communication between devices and the operating system. Each device requires its own range of memory. If you are experiencing problems, and two devices are configured to use the same memory address range, you can try the following troubleshooting solutions:

- Use Device Manager to locate and troubleshoot the problem. For more information about Device Manager, see Device Manager.
- Contact the device manufacturer to obtain an updated device driver.
- Adjust the memory address ranges for COM ports in the system BIOS or EFI. Contact your hardware manufacturer for more information.

For more information about Hardware Resources, see Hardware Resources.

# Components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Components**
The Components category in System Information contains information about the various components and devices on your system. Most of the subcategories contain an **Item** column, which identifies the component, and a **Value** column, which provides additional information about the component, such as drive location or version number.

For more information about these items, see the following:

- Multimedia
- CD-ROM
- Sound Device
- Display
- Infrared
- Input
- Modem
- Network
- Ports
- Storage
- Printing component
- Problem Devices
- USB

# Multimedia

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Multimedia**

Multimedia is located in the Components category in System Information. It contains two subcategories: Audio Codecs and Video Codecs. These subcategories contain information about audio and video codecs.

If you experience problems when playing back multimedia files, or if there are errors in multimedia applications, such as Windows Media Player, you can check this Multimedia category to verify their settings.

For more information about Components, see Components.

# CD-ROM

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**CD-ROM**

CD-ROM is located in the Components category in System Information. It contains information about the CD-ROM drive, including the drive letter assigned to it and its description, manufacturer, and status.

If you are experiencing problems when you play a CD, try cleaning the CD. If cleaning the CD does not fix the problem, you can use Device Manager to troubleshoot the problem. For more information about Device Manager, see Device Manager.

Occasionally, the drive letter that is assigned to the CD-ROM device is reassigned. You can use Disk Manager to verify the drive letter assignments. For more information about disk management, see Disk Management.

For more information about Components, see Components.

# Sound Device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Sound Device**

Sound Device is located in the Components category in System Information. It contains information about the sound devices on your system, including the name, manufacturer, and status of the sound device and driver details.

When you are troubleshooting problems with a sound device, verify that the hardware is properly connected and that the sound control is set correctly. You can also use Device Manager to verify that the sound device driver is signed. For more information about Device Manager, see Device Manager.

For more information about Components, see Components.

# Display

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Display**

Display is located in the Components category in System Information. It lists information about the display devices on your system. You can use this information to determine the manufacturer of a device and then contact the manufacturer for device updates. You can also verify the display resolution, which helps troubleshoot display problems.

To ensure that your hardware meets the minimum compatibility requirements, see Hardware compatibility information in the Windows Catalog (search page) at the Microsoft Web Site. You can also use Device Manager to verify that your system is using signed drivers. For more information about Device Manager, see Device Manager.

For more information about Components, see Components.

# Infrared

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Infrared**

Infrared is located in the Components category in System Information. It contains information about infrared (IR) devices and ports on your system. These devices might not exist on all computers.

For more information about Components, see Components.

# Input

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Input**

Input is located in the Components category in System Information. It contains two subcategories: Keyboard and Pointing Device. These subcategories contain information about your keyboard, pointing device (mouse), and other input devices.

You can troubleshoot keyboard problems by double-clicking **Keyboard** in Control Panel. You can troubleshoot pointing device problems by double-clicking **Mouse** in Control Panel.

For more information about Components, see Components.

**Important**

- If you are troubleshooting an input device that is not a universal serial bus (USB) device, you must shut down the computer before you unplug or reconfigure the device. Refer to your hardware manufacturer's documentation for more information.

# Modem

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Modem**

Modem is located in the Components category in System Information. It displays information about any telephone modems that are installed on your system.

For more information about modems, see Installing and configuring Modems. For more information about Components, see Components.

# Network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network**

Network is located in the Components category in System Information. It contains three subcategories: Adapter, Protocol, and WinSock. These subcategories display information about the network adapters, protocols, and WinSock settings on your system. You can use this information to verify network configurations.

You can also use the Network Diagnostics tool to access information about your network settings. For more information about this tool, see Windows interface administrative tool reference A-Z: Network Diagnostics.

For more information about Components, see Components.

# Ports

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ports**

Ports is located in the Components category in System Information. It contains two subcategories: Serial and Parallel. For both serial ports and parallel ports, the details pane displays information such as name, status, I/O port (the communication channel among hardware devices that are installed on your computer), IRQ channel, and driver.

For more information about Components, see Components.

# Storage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Storage**

Storage is located in the Components category in System Information. It contains four subcategories: Drives, Disks, SCSI, and IDE. Storage displays information about the drives, disks, SCSI controllers, and IDE controllers on your system.

Drives displays information for all the drives on your system, including information about the drive letter, file system, size, free space, volume name, and volume serial number. Disks displays information about your disk drive, including the manufacturer, model, size, number of partitions, and partition size. SCSI and IDE display information about each of the device controllers, including the name, manufacturer, status, IRQ channel, and driver.

For more information about Components, see Components.

# Printing component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Printing**

Printing is located in the Components category in System Information. It displays information about printers that are installed on your system. The **Name** column in the details pane displays the name of the printer. The **Port Name** column displays the port to which the printer is attached. The **Server Name** column displays the name of the print server, if the printer is on a network.

If you have a printer problem, such as a lost printer connection, use Printers and Faxes to locate and troubleshoot the problem. For more information about Printers and Faxes, see Printing. For more information about the print jobs that are currently printing on your system, see Print Jobs.

For more information about Components, see Components.

# Problem Devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Problem Devices**

Problem Devices is located in the Components category in System Information. It displays information, including the device ID and the error code, about devices that may have a problem. For more information about Components, see Components.

You can use Device Manager to locate and troubleshoot any device problems. For more information about Device Manager, see Device Manager.

The following table contains a list of error codes that may appear in the Problem Devices category, as well as descriptions of the errors. Only error codes that are valid for Windows 2000 and the Windows Server 2003 family of operating systems are included. For more information about troubleshooting these errors, see Article Q245386, "Windows 2000 Configuration Manager Error Code Meanings and Troubleshooting," in the Microsoft Knowledge Base.

| Error Code | Description |
|---|---|
| Code 1 | This device is not configured correctly. |
| Code 2 | Windows cannot load the driver for this device. |
| Code 3 | The driver for this device might be corrupted, or your system may be running low on memory or other resources. |
| Code 4 | This device is not working properly. One of its drivers or your registry might be corrupted. |
| Code 5 | The driver for this device needs a resource that Windows cannot manage. |
| Code 6 | The boot configuration for this device conflicts with other devices. Cannot filter. |
| Code 7 | Cannot filter. |
| Code 8 | The driver loader for the device is missing. |
| Code 9 | This device is not working properly because the controlling firmware is reporting the resources for the device incorrectly. |
| Code 10 | This device cannot start. |
| Code 11 | This device failed. |
| Code 12 | This device cannot find enough free resources that it can use. |
| Code 13 | Windows cannot verify this device's resources. |
| Code 14 | This device cannot work properly until you restart your computer. |
| Code 15 | This device is not working properly because there is probably a renumeration problem. |
| Code 16 | Windows cannot identify all the resources this device uses. |
| Code 17 | This device is asking for an unknown resource type. |
| Code 18 | Reinstall the drivers for this device. |
| Code 19 | Your registry might be corrupted. |
| Code 21 | Windows is removing this device. |
| Code 22 | This device is disabled. |

| | |
|---|---|
| Code 24 | This device is not present, is not working properly, or does not have all its drivers installed. |
| Code 25 | Windows is still setting up this device. (Same text as Code 26.) |
| Code 26 | Windows is still setting up this device. (Same text as Code 25.) |
| Code 27 | This device does not have valid log configuration. |
| Code 28 | The drivers for this device are not installed. |
| Code 29 | This device is disabled because the firmware of the device did not give it the required resources. |
| Code 31 | This device is not working properly because Windows cannot load the drivers required for this device. |
| Code 32 | A driver for this device was not required and has been disabled. |
| Code 33 | Windows cannot determine which resources are required for this device. |
| Code 34 | Windows cannot determine the settings for this device. |
| Code 35 | Your computer's system firmware does not include enough information to properly configure and use this device. |
| Code 36 | This device is requesting a PCI interrupt but is configured for an ISA interrupt (or vice versa). |

# USB

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**USB**

USB is located in the Components category in System Information. It displays information about universal serial bus (USB) devices and controllers on your computer. The **Device** column in the details pane lists each USB device, and the **PNP Device ID** column lists the ID for the device.

If there is a problem with a USB device, first try unplugging and plugging in the device. If that does not fix the problem, you can use Device Manager to locate and troubleshoot the problem. For more information about Device Manager, see Device Manager.

For more information about Components, see Components.

# Software Environment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Software Environment**

The Software Environment category in System Information contains information about your system configuration, including details about system drivers, environment variables, and current print jobs. In Software Environment, you can view information about the following items:

- System Drivers
- Signed Drivers
- Environment Variables
- Print Jobs
- Network Connections System Information
- Running Tasks
- Loaded Modules
- Services
- Program Groups
- Startup Programs
- OLE Registration
- Windows Error Reporting

# System Drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Drivers**

System Drivers is located in the Software Environment category in System Information. It displays information about the system drivers that are installed on your system, including their name, description, type, state, status, and other information. For example, you can check the **State** column in the details pane to see which drivers are running and which are stopped.

For more information about Software Environment, see Software Environment.

# Signed Drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Signed Drivers**
Signed Drivers is located in the Software Environment category in System Information. It displays information about the signed drivers that are installed on your system, including their device name, device class, driver version, manufacturer, device ID, and other information. Signed drivers are drivers that have been certified by Microsoft.

To confirm that your hardware is designed for the Windows Server 2003 family of operating systems, see the compatibility information in Support resources. In addition, you can use Device Manager to verify that your system is using signed drivers. For more information about Device Manager, see Device Manager.

For more information about Software Environment, see Software Environment.

For more information about driver signing, see the following:

- Driver signing for Windows
- Designed for Microsoft Windows logo
- To set file signature verification options

# Environment Variables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Environment Variables**

Environment Variables is located in the Software Environment category in System Information. It displays information about your computer environment, including the number of processors, the operating system path, and the location of temporary folders.

For more information about Software Environment, see Software Environment.

# Print Jobs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Print Jobs**

Print Jobs is located in the Software Environment category in System Information. It contains information about the current print jobs on your system, including document name, size, owner, time submitted, pages printed, and other information. Only documents that are currently printing appear here. For more information about the printers that are installed on your system, see Printing component.

For more information about Software Environment, see Software Environment.

# Network Connections System Information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network Connections**

Network Connections is located in the Software Environment category in System Information. It displays information, including local name, remote name, type, status, and user name, about mapped drives, network connections, and other shared resources to which your computer is connected. For more information about Network Connections, see Network Connections.

For more information about Software Environment, see Software Environment.

# Running Tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Running Tasks**

Running Tasks is located in the Software Environment category in System Information. It displays information about processes that are currently running on your system, including the name, path, ID, and version of each process and the priority that the system assigns to each process.

If there is a problem with a running task, such as a program not responding, use Task Manager to locate and troubleshoot the problem. You can use Task Manager to close a task, if necessary.

For more information about Software Environment, see Software Environment.

# Loaded Modules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Loaded Modules**

Loaded Modules is located in the Software Environment category in System Information. It displays information about programs that are running on your system, including their associated DLLs. You can use Loaded Modules to verify the version of a DLL on your system. You can also check the DLL's size, file date, and path.

For more information about Software Environment, see Software Environment.

# Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services**

Services is located in the Software Environment category in System Information. It displays information about the services that are running on your system, including their display name; short name; state; start mode (auto, manual, or disabled); service type; and path.

You can use the Services snap-in to manage the services on your system. For more information about the Services snap-in, see Services Snap-in.

For more information about Software Environment, see Software Environment.

# Program Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Program Groups**

Program Groups is located in the Software Environment category in System Information. It displays information about groups of programs on your system, including the group name, system path and name, and user name that is assigned to the group. These programs appear on the **Start** menu.

You can manage program groups with **Taskbar and Start Menu** in Control Panel.

For more information about Software Environment, see Software Environment.

# Startup Programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Startup Programs**

Startup Programs is located in the Software Environment category in System Information. It displays information, including the user name and location, about programs that start automatically on your system, even if they are hidden.

You can manage program groups with **Taskbar and Start Menu** in Control Panel.

For more information about Software Environment, see Software Environment.

# OLE Registration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**OLE Registration**

OLE Registration is located in the Software Environment category in System Information. It contains information, including the object and local server, about components that are registered as OLE programs.

For more information about Software Environment, see Software Environment.

# Windows Error Reporting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Error Reporting**
Windows Error Reporting is located in the Software Environment category in System Information. It contains information, including the time, type, and details, about faults that are generated in the Event Log, which you can see by using Event Viewer. For more information about diagnostic tools such as Event Viewer, see Monitoring and Status Tools.

For more information about Software Environment, see Software Environment.

For more information about error reporting, see the following topics:

- System and program error reporting overview
- Exclude programs from error reporting
- Enable error reporting
- Send an error report to Microsoft
- Disable error reporting

# Internet Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Settings**

The Internet Settings category in System Information contains information about Internet settings on the computer. The information in this category is provided by the browser, and it includes information about the browser version, network connections, and cache summary, as well as certificate settings and security settings.

For more information about Internet settings and connections, see Network Connections.

# System Properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Properties**

Using System Properties, you can view and change system properties on a local or remote computer.

- For help with specific tasks, see System Properties How To....
- For general background information, see System Properties Concepts.

# System Properties How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- View system properties
- Set Performance Options
- Add or change environment variables
- Set Startup and Recovery Options

# View system properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view system properties**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then click **Properties**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- The **General** tab shows which version of Windows is installed, the name of the person registered to use this copy of Windows, the type of processor, and the total physical memory of the computer. If the operating system was installed by an original equipment manufacturer (OEM), this tab also displays information about technical support.
- You can view your computer's network identification by clicking the **Computer Name** tab.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
System Properties overview
Perform a local or remote shutdown
Windows Management Instrumentation overview

# Set Performance Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set performance options**

- Change processor scheduling options
- Specify memory usage
- Change virtual memory settings

# Change processor scheduling options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change processor scheduling options**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then select **Properties**.
3. On the **Advanced** tab, under **Performance**, click **Settings**.
4. Under **Processor scheduling**, select **Programs** or **Background services**. Click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify memory usage

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify memory usage**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then click **Properties**.
3. On the **Advanced** tab, under **Performance**, click **Settings**.
4. Under **Memory usage**, select **Programs** or **System cache**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.
- On all Windows Server 2003 family operating systems, the **System cache** option is selected by default.
- You must restart your computer before your changes take effect.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change virtual memory settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change virtual memory settings**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then select **Properties**.
3. On the **Advanced** tab, under **Performance**, click **Settings**.
4. Under **Virtual memory**, click **Change**.
5. In the **Drive** list, click the drive that contains the paging file you want to change.
6. Under **Paging file size for selected drive**, click **Custom size**, type new paging file sizes in the **Initial Size (MB)** and **Maximum Size (MB)** boxes, and then click **Set**. Click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.
- For best performance, set the initial size to not less than the recommended size under **Total paging file size for all drives**. The recommended size is equivalent to 1.5 times the amount of RAM on your system.
- Usually, you should leave the paging file at its recommended size, although you might increase its size if you routinely use programs that require a lot of memory.
- If you decrease the size of the paging file, you must restart your computer to see the effects of those changes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add or change environment variables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add or change environment variables**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then click **Properties**.
3. On the **Advanced** tab, under **Environment Variables**, click **Settings**.
4. Select a user in the **User variables for** list.
5. Click the name of the user or system variable you want to change or delete.
   - Click **New** to add a new variable name and value.
   - Click **Edit** to change a current variable name and value.
   - Click **Delete** to remove a variable name and value.

## Notes

- You are not required to have administrative credentials to create, edit or delete variables under **User variables for**. Therefore, as a security best practice, consider performing this task as a user without administrative credentials. You must be a member of the Administrators group on the local computer in order to create, edit or delete the variables listed under **System variables**. For more information, see Default local groups.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.
- Changes in the registry are saved so they are available automatically the next time you start your computer.
- Changes do not affect programs that are running and may not take effect until you restart your computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set Startup and Recovery Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set startup and recovery options**

- Specify the default operating system for startup
- Specify what happens when the system stops unexpectedly
- Perform a local or remote shutdown

# Specify the default operating system for startup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify the default operating system for startup**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then select **Properties**.
3. On the **Advanced** tab, under **Startup and Recovery**, click **Settings**.
4. Under **System startup**, in the **Default operating system** list, click the operating system you want to start if you do not select one from the list displayed during startup.
5. Select **Time to display list of operating systems** box, and then enter the number of seconds the list should be displayed before the default operating system starts automatically.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify what happens when the system stops unexpectedly

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify what happens when the system stops unexpectedly**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)**, and then click **Properties**.
3. On the **Advanced** tab, under **Startup and recovery**, click **Settings**.
4. Under **System startup**, select the **Time to display list of operating systems** check box, and then type the number of seconds you want the list of recovery options to display before the default recovery option is automatically selected.
5. Under **System failure**, select the check boxes that correspond to the actions you want Windows to perform if a Stop error occurs:

   - **Write an event to the system log** specifies that event information will be recorded in the system log.

     On computers running a Windows Server 2003 family operating system, you cannot disable this feature. Windows always writes event information to the system log.

   - **Send an administrative alert** specifies that your system administrator will be notified.

   - **Automatically restart** specifies that Windows will automatically restart your computer.

6. Under **Write debugging information**, choose the type of information you want Windows to record when the system stops unexpectedly:

   **Small memory dump**

   Records the smallest amount of information that will help identify the problem. This option requires a paging file of at least 2 MB on the boot volume of your computer. If you choose this option, Windows creates a new file (64 KB in size) each time the system stops unexpectedly. A history of these files is stored in the directory listed under **Small dump directory**.

   **Kernel memory dump**

   Records only kernel memory, which stores more information than small memory dump but takes less time to complete than the complete memory dump when the system stops unexpectedly. The file is stored in the directory listed under **Dump file**. If you choose this option you must have a sufficiently large paging file on the boot volume. The required size depends on the amount of RAM in your computer (although the maximum amount of space that must be available for a kernel memory dump is 2,060 MB). The following table provides guidelines:

| RAM size | Paging file should be no smaller than |
|---|---|
| 256 MB-1,373 MB | 1.5 times the RAM size |
| 1,374 MB or greater | 2,060 MB (maximum amount of data in a kernel memory dump) |

   **Complete memory dump**

   Not available on computers with 2 or more GB of RAM. Records the entire contents of system memory when the system stops unexpectedly. If you choose this option you must have a paging file on the boot volume large enough to hold all of

the physical RAM plus one megabyte (MB). The file is stored in the directory listed under **Dump file**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.

- You must have at least a 2-MB paging file on the computer's boot volume if you select **Write an event to the system log** or **Send an administrative alert**.

- If you choose **Kernel memory dump**, be sure not to set the paging file smaller than the sizes listed in the procedure, or you might not capture the information you need.

- If you choose either **Kernel memory dump** or **Complete memory dump** and select the **Overwrite any existing file** check box, Windows always writes to the same file name. To save individual dump files, clear the **Overwrite any existing file** check box and change the file name after each Stop error.

- When setting memory dump options, check your settings for the size of the paging file on the boot volume. Set the file size according to the preceding guidelines.

  It is recommended that you use the same value for both the minimum size and the maximum size of the paging file. This prevents the file from constantly growing and shrinking, which in turn prevents unnecessary disk fragmentation.

- Memory dumps might contain sensitive information, so you should store them in a secure location and limit the number of users who can access them. When you transfer a memory dump across the network or send a memory dump over the Internet, always use a secure file-transfer mechanism to guard against the file being compromised by a malicious user.

- In computers with 8 or more processors that have the maximum amount of RAM installed, you might be able to gain some incremental performance improvement by splitting the paging file into multiple paging files. Each paging file must be on a separate physical disk and for reliability, each disk must be part of a hardware RAID-5 volume. For more information about changing the size of the virtual memory paging file, see Related Topics.

- You can save memory by clearing the **Write an event to the system log** and **Send an administrative alert** check boxes. The memory saved depends on the computer, but these features typically require about 60 KB to 70 KB.

- If you contact Microsoft Product Support Services about a Stop error, they might ask for the memory dump file created when the Stop error occurred.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Perform a local or remote shutdown

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To perform a local or remote shutdown**

1. Open Computer Management.
2. In the console tree, right-click **Computer Management (Local)** , and then click **Properties**.
3. On the **Advanced** tab, click **Startup and Recovery**.
4. Click **Shut Down** to open the **Shut Down** dialog box.
5. Under **Action**, select the actions you want to perform on the computer to which you are connected.
6. Under **Force Apps Closed**, select the circumstances under which you want to force applications to close when you shut down or restart the computer, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- To perform this procedure on a remote computer, right-click **Computer Management (Local)**, click **Connect to another computer**, select **Another computer**, and then type in the name of the remote computer. You can then follow the steps in this procedure, starting at step 2, and substituting **Computer Management (*remote computername*)** for **Computer Management (Local)**. You must be a member of the Administrators group, or you must have been delegated the appropriate authority, on the computer that you specify for *remote computername*.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# System Properties Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

- System Properties overview

# System Properties overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Properties overview**

System Properties is a Windows Management Instrumentation (WMI) tool you access through **Computer Management**. Using System Properties, you can view and change system properties on a local computer or remote computer.

For more information about WMI, see Windows Management Instrumentation overview.

You can also view and change system properties on a local computer by accessing **System** in Control Panel. This is a separate tool that enables you to perform additional tasks on your local computer, but does not enable you to view or change system properties on a remote computer. For more information see System Properties Overview - Control Panel.

# Services Snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services**

You can use the Services snap-in to manage services on local or remote computers.

- For tips about using Services, see Services best practices.
- For help with specific tasks, see Services How To....
- For general background information, see Services Concepts.
- For problem-solving instructions, see Troubleshooting Services Snap-in.

**Important**

- To improve performance and security in the Microsoft® Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

# Services best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services best practices**

**Save the default state of services.**

- It is helpful to keep a list of the default service settings in the event that you need to restore these settings. For more information, see Export services information from the Services snap-in. You can also use Security Templates to define a default security template, including system service settings, for your computer or for your network. For more information, see Security Templates overview. For more information about how restore default security settings, see Reapply default security settings.

**Perform adequate testing and backup procedures before changing default settings.**

- Changing the default settings for services might prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically.

- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on an interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

**Verify service dependencies before starting or stopping services.**

- Ensure that a service you are starting does not depend on a service whose startup type is set to **Disabled** or **Manual**. Also, make sure that a service you are stopping is not required for a dependent service to function properly. For more information, see View service dependencies.

**Notify connected users before stopping or pausing services.**

- Stopping or pausing certain services affects connected users. For example, if you stop the Server service, all file, print, and named pipe sharing over the network is disabled. Also, the affected computers can no longer be administered remotely, so you must start the Server service locally.

  Stopping or pausing a service does not change the startup type of that service. For example, if you stop a service that is configured to start automatically (**Startup type** is set to **Automatic**), that service starts automatically when the computer is restarted.

**When you start disabled services, be sure to select the appropriate startup type.**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. If you want to enable any of these services, you must select the appropriate startup type. For a table that lists the default settings and provides information about the appropriate startup type for a disabled service, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

# Services How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services how to...**

- Configure how a service is started
- Start, stop, pause, resume, or restart a service
- Enable or disable a service for a hardware profile
- Access the Services snap-in on another computer
- Set up recovery actions to take place when a service fails
- Export services information from the Services snap-in
- View service dependencies

# Configure how a service is started

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure how a service is started**

- Using Services
- Using the command line

**Using Services**

1. Open Services.
2. In the details pane, right-click the service that you want to configure, and then click **Properties**.
3. On the **General** tab, in **Startup type**, click **Automatic**, **Manual**, or **Disabled**.
4. To specify the user account that the service can use to log on, click the **Log On** tab, and then do one of the following:
   - To specify that the service uses the Local System account, click **Local System account**.
   - To specify that the service uses the Local Service account, click **This account**, and then type **NT AUTHORITY\LocalService**.
   - To specify that the service uses the Network Service account, click **This account**, and then type **NT AUTHORITY\NetworkService**.
   - To specify another account, click **This account**, click **Browse**, and then specify a user account in the **Select User** dialog box. When you are finished, click **OK**.
5. Type the password for the user account in **Password** and in **Confirm password**, and then click **OK**. If you select the Local Service account or Network Service account, the password must be blank.

### Note

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

**Using the command line**

1. Open Command Prompt.
2. Type:

   **sc config***service name***start=** {**boot**|**system**|**auto**|**demand**|**disabled**}

| Value | Description |
|---|---|
| **sc config** | Modifies the value of a service's entries in the registry and in the Service Control Manager's database. |
| *service name* | Specifies the short name of the service. |

| | |
|---|---|
| **start=** | Specifies the start type for the service. |
| **boot** | A device driver that is loaded by the boot loader. |
| **system** | A device driver that is started during kernel initialization. |
| **auto** | A service that automatically starts each time the computer is restarted and runs even if no one logs on to the computer. |
| **demand** | A service that must be manually started. This is the default value if **start=** is not specified. |
| **disabled** | A service that cannot be started. To start a disabled service, change the start type to one of the other values. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- To view the complete syntax for this command, at the command prompt, type:

  **sc config help**

- For more information about the **sc** command, see Related topics.

**Caution**

- Most services are not designed to have the default account changed. Changing the default account of a service could result in the service failing to start.
- Changing the default service settings may prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically.
- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on an interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

**Important**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.
- The Local Service account and Network Service account are configured with a null password. Whatever password information you supply is ignored. For more information about service accounts, see Services permissions.
- It is recommended that user accounts that are used to log on as a service have the **Password never expires** check box selected in their properties dialog box and that they have strong passwords. For more information about creating strong passwords, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- If account lockout policy is enabled and the account is locked out, the service will not start. For more information about account lockout policy, see Related Topics.

- If you enable or disable a service and you encounter a problem starting the computer, you can start the computer in Safe Mode. In Safe Mode, core services that are required to start the operating system are started in a default scheme, regardless of any changes that are made to the service settings. After the computer is in Safe Mode, you can change the service configuration or restore the default configuration. For more information about startup options, see Related Topics.

- If you specify an account that does not have permission to log on as a service, the Services snap-in automatically grants the appropriate permissions to that account on the computer that you are managing.

- For more information about the user accounts that a service uses to log on, see "Services permissions" in Related Topics. Also, see "Managing System Services" at the Microsoft Windows Resource Kits Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start, stop, pause, resume, or restart a service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start, stop, pause, resume, or restart a service**

- Using Services
- Using the command line

**Using Services**

1. Open Services.
2. In the details panel, do one of the following:
    - Click the service, and then, on the **Action** menu, click **Start**, **Stop**, **Pause**, **Resume**, or **Restart**.
    - Right-click the service, and then click **Start**, **Stop**, **Pause**, **Resume**, or **Restart**.

### Notes

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
- To start a service with startup parameters, right-click the service, click **Properties**, type the parameters in **Start parameters**, and then click **Start**. These settings are not persistent; they are used only once, and then the default settings are restored. (A backslash (\) is treated as an escape character; type two backslashes for each backslash in a parameter.)

**Using the command line**

1. Open Command Prompt.
2. Type one of the following:
    - To start a service, type:

      **net start***service*

    - To stop a service, type:

      **net stop***service*

    - To pause a service, type:

      **net pause***service*

    - To resume a service, type:

      **net continue***service*

| Value | Description |
|---|---|

| | |
|---|---|
| **net start** | Starts a service. |
| **net stop** | Stops a service. |
| **net pause** | Pauses a service. |
| **net continue** | Continues a service that has been paused. |
| *service* | Specifies the name of service. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.
- To view the complete syntax for these commands, at the command prompt, type:

  **net help***command*

- For more information about these commands, see Related Topics.

**Caution**

- If you stop, start, or restart a service, any dependent services are also affected. Starting a service does not automatically restart its dependent services. For more information, see View service dependencies.
- Changing the default service settings may prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically.
- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on an interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

**Important**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- Some services, such as Remote Procedure Call (RPC), Event Log, and Plug and Play, cannot be stopped by using the Service snap-in or the **net stop** command. These services are required for the operating system to function properly.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable a service for a hardware profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable a service for a hardware profile**

1. Open Services.
2. In the details pane, right-click the service that you want to enable or disable, and then click **Properties**.
3. On the **Log On** tab, click the hardware profile that you want to configure.
4. Click **Enable** or **Disable**, and then click **OK**.

### Caution

- Use caution when you disable services by using this procedure. If you disable a service for a certain hardware profile, the **Hardware Profile** settings override the **Startup type** setting for that service.
- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on an interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

### Important

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
- You can use the options on the **Hardware** tab in System in Control Panel to create and manage hardware profiles. For more information about creating hardware profiles, see Related Topics.
- You may want to set up a hardware profile to test any newly installed services. For example, you can create two hardware profiles for a newly installed service: one profile in which the service is enabled and a second profile in which the service is disabled. This way, you can troubleshoot any problems that might occur, such as a driver not loading properly.
- If you receive a Connection Manager error message when you open the properties dialog box for a service, verify that the Remote Registry service is running on the specified computer. If the Remote Registry service is not running, or if the specified computer is running Windows NT 4.0, you cannot view or modify hardware profile settings, but you can perform any other actions. For more information, see Troubleshooting Services Snap-in. Also, see "Managing System Services" at the Microsoft Windows Resource Kits Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Access the Services snap-in on another computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To access the Services snap-in on another computer**

1. Open Services.
2. In the console tree, right-click **Services**, and then click **Connect to another computer**.
3. In the **Select Computer** dialog box, type the name of the computer that you want to manage, or click **Browse** to find it, and then click **OK**.

### Caution

- Changing the default service settings may prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically.
- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on an interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

### Important

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.
- If you enable or disable a service and you encounter a problem starting the computer, you can start the computer in Safe Mode. Then, you can change the service configuration or restore the default configuration. In Safe Mode, core services that are required to start the operating system are started in a default scheme, regardless of any changes that are made to the service settings. For more information about Safe Mode and other startup options, see Related Topics.

### Notes

- You must be a domain member on the specified computer to access the Services snap-in.
- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up recovery actions to take place when a service fails

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up recovery actions to take place when a service fails**

1. Open Services.
2. In the details pane, right-click the service for which you want to set up recovery actions, and then click **Properties**.
3. On the **Recovery** tab, click the action that you want in **First failure**, **Second failure**, and **Subsequent failures**, and then click **OK**:
   - If you click **Run a Program**, under **Run program**, type the absolute path for the specified computer. Universal Naming Convention (UNC) names are not supported. For example, type **C:\scripts\handlefailure.cmd**, rather than *****computername***\c$\scripts\handlefailure.cmd**.
   - If you click **Restart the Computer**, click **Restart Computer Options** to specify how long the computer waits before restarting. You can also create a message to send to remote users before the computer restarts. This message is sent automatically, using the same mechanism as the one used by the **net send** command and Send Console Message.

### Important

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
- Recovery actions are available only on computers running Windows 2000, Windows XP, or products in the Windows Server 2003 family.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Export services information from the Services snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To export services information from the Services snap-in**

1. Open Services.
2. On the **Action** menu, click **Export List**. This opens the **Export List** dialog box.
3. In **Save in**, click or type the file location where you want to save the exported file.
4. In **File name**, type the name of the file.
5. In **Save as type**, click the file type, and then click **Save**.

### Important

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

### Note

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View service dependencies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view service dependencies**

1. Open Services.
2. In the details pane, right-click the service that you want to view dependencies for, and then click **Properties**.
3. Click the **Dependencies** tab.
4. To view services that are associated dependencies of the selected service, in the list on the **Dependencies** tab, click the plus sign next to the service.

### Important

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

### Notes

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.
- The top list on the **Dependencies** tab identifies the other services that must be running for the selected service to function. The bottom list on the **Dependencies** tab identifies the services that require the selected service to be running so that the dependent services can function properly.
- For more information about service dependencies, see "Managing System Services" at the Microsoft Windows Resource Kits Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Services Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services concepts**

This section provides general background information about Services:

- Services overview
- Services permissions
- Default settings for services

**Important**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

# Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services overview**

A service is an application type that runs in the system background and is similar to a UNIX daemon application. Services provide core operating system features, such as Web serving, event logging, file serving, help and support, printing, cryptography, and error reporting. With the Services snap-in, you can manage services on local or remote computers. The operating system services that are delivered with the Microsoft® Windows Server 2003 family are designed so that only the key services that are required for common server roles are started. For more information on server roles, see Configuring Roles for Your Server.

You can use the Services snap-in to:

- Start, stop, pause, resume, or disable services on remote and local computers.
- Manage services on local and remote computers (on remote computers running Microsoft Windows NT® 4.0, Windows 2000, Windows XP, or products in the Windows Server 2003 family only).
- Set up recovery actions to take place if a service fails, for example, restarting the service automatically or restarting the computer (on computers running Windows NT 4.0, Windows 2000, Windows XP, or products in the Windows Server 2003 family only).
- Enable or disable services for a particular hardware profile.
- Export service information to a .txt or .csv file for system administration purposes.
- View the status and description of each service.

For more information about managing operating system services, see "Managing System Services" at the Microsoft Windows Resource Kits Web site.

**Important**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

# Services permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Services permissions**

There are two types of permissions that apply to services: service account permissions and service permissions. Service account permissions refer to the user rights and credentials that are granted to the service through the logon account. Service permissions refer to the permissions that are required to configure a service.

**Service account permissions**

A service must log on to an account to access resources and objects on the operating system. Most services are not designed to have their default logon account changed. Changing the default account will probably cause the service to fail.

If you select an account that does not have permission to log on as a service, the Services snap-in automatically grants that account the user rights that are required to log on as a service on the computer that you are managing. However, this does not guarantee that the service will start.

It is recommended that the user accounts that are used to log on as a service have the **Password never expires** check box selected in their properties dialog box and that they have strong passwords. For more information, see Strong passwords.

If account lockout policy is enabled and the account is locked out, the service will malfunction. For more information, see Account Lockout Policy.

The following table describes the service logon accounts and how they are used.

| Logon account | Description |
|---|---|
| Local System account | The Local System account is a powerful account that has full access to the system, including the directory service on domain controllers. If a service logs on to the Local System account on a domain controller, that service has access to the entire domain. Some services are configured by default to log on to the Local System account. Do not change the default service setting. |
| Local Service account | The Local Service account is a special, built-in account that is similar to an authenticated user account. The Local Service account has the same level of access to resources and objects as members of the Users group. This limited access helps safeguard your system if individual services or processes are compromised. Services that run as the Local Service account access network resources as a null session with no credentials. |
| Network Service account | The Network Service account is a special, built-in account that is similar to an authenticated user account. The Network Service account has the same level of access to resources and objects as members of the Users group. This limited access helps safeguard your system if individual services or processes are compromised. Services that run as the Network Service account access network resources using the credentials of the computer account. |

**Caution**

- Changing the default service settings may prevent key services from running correctly. It is especially important to use caution when changing the **Startup type** and **Log on as** settings of services that are configured to start automatically.
- In most cases, it is recommended that you not change the **Allow service to interact with desktop** setting. If you allow the service to interact with the desktop, any information that the service displays on the desktop will also be displayed on an interactive user's desktop. A malicious user could then take control of the service or attack it from the interactive desktop.

**Service permissions**

Each service has special permissions that you can grant or deny for each user or group. You can set permissions for individual services by using Security Templates or the **sc** command. For more information, see Security Templates and SC.

The following table lists the individual service permissions that you can apply.

| Permission | Allows you to |
| --- | --- |
| Full Control | Perform all functions. This permission automatically grants all service permissions to the user. |
| Query Template | Determine the configuration parameters that are associated with a service object. |
| Change Template | Change the configuration of a service. This permission is required so that the user can change the startup type. |
| Query Status | Access information about the status of the service. |
| Enumerate Dependents | Determine all the other services that depend on the specified service. |
| Start | Start a service. |
| Stop | Stop a service. |
| Pause and Continue | Pause and continue the service. |
| Interrogate | Report the current status information for the service. |
| User-Defined Control | Send a user-defined control request--or a request that is specific to the service--to the service. |
| Delete | Delete a service. |
| Read Permissions | Read the security permissions that are assigned to the service. |
| Change Permissions | Change the security permissions that are assigned to the service. |
| Take Ownership | Change a security key or change permissions on a service that is not owned by the user. |

**Important**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. For a table that lists the default settings and provides information about how to enable these services, see Default settings for services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

# Default settings for services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Default settings for services**
For a typical installation, services are configured as automatic, manual, or disabled:

- An automatic service starts automatically when the operating system starts.
- You can start a service manually by using the Services snap-in or by using the **net start** command. A manual service can also be started by a related operating system service, a system device driver, or an action in the user interface that depends on the manual service. For example, both the Telephony service and Remote Access Connection Manager service are configured as **Manual** by default, but both of these services are started during the Windows Product Activation process.
- A disabled service cannot be started automatically or manually. To start a disabled service, you must select an appropriate startup type, which is identified in the tables below. For information on enabling the services required by audio, imaging, and CD-burning peripheral devices, see Troubleshooting audio, imaging, and CD-burning peripheral devices.

For more information about how to configure service startup, see Configure how a service is started. For more information about starting a service from the command line, see Net start.

You can use the **sc** command at the command prompt to configure services and obtain information about them. For example, you can use **sc getkeyname** to obtain the key name, or short name, of the service. For more information about the **sc** command, see SC.

**Important**

- To improve performance and security in the Windows Server 2003 family, several services have been disabled by default that were previously enabled on Windows 2000. See the tables below for information about how to enable these services. Note that these settings apply only to new installations, not upgrades; all previous service configurations are preserved during upgrades to the Windows Server 2003 family.

The following tables list all the default services that may be installed as part of the Windows Server 2003 family. Your list of services may be different, depending on which Windows product is installed, which components and options are selected during installation, and whether any additional programs are installed.

**Alerter**
Short name: Alerter

This service is now disabled by default. If you want to enable this service, set **Startup type** to **Automatic**.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Disabled | Local Service |
| Windows Server 2003, Enterprise Edition | Disabled | Local Service |
| Windows Server 2003, Datacenter Edition | Disabled | Local Service |
| Windows Server 2003, Web Edition | Disabled | Local Service |

**Application Layer Gateway Service**
Short name: ALG

| Product | Startup type | Log on as |
|---|---|---|

| | | |
|---|---|---|
| Windows Server 2003, Standard Edition | Manual | Local Service |
| Windows Server 2003, Enterprise Edition | Manual | Local Service |
| Windows Server 2003, Datacenter Edition | Manual | Local Service |
| Windows Server 2003, Web Edition | Manual | Local Service |

**Application Management**
Short name: AppMgmt

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Manual | Local System |
| Windows Server 2003, Enterprise Edition | Manual | Local System |
| Windows Server 2003, Datacenter Edition | Manual | Local System |
| Windows Server 2003, Web Edition | Manual | Local System |

**Automatic Updates**
Short name: wuauserv

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Local System |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Local System |
| Windows Server 2003, Web Edition | Automatic/Started | Local System |

**Background Intelligent Transfer Service**
Short name: BITS

For information about troubleshooting problems associated with this service, see Background Intelligent Transfer Service (BITS) inactive job timeout.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Manual | Local System |
| Windows Server 2003, Enterprise Edition | Manual | Local System |
| Windows Server 2003, Datacenter Edition | Manual | Local System |
| Windows Server 2003, Web Edition | Manual | Local System |

**ClipBook**
Short name: ClipSrv

This service is now disabled by default. If you want to enable this service, set **Startup type** to **Manual**.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Disabled | Local System |
| Windows Server 2003, Enterprise Edition | Disabled | Local System |
| Windows Server 2003, Datacenter Edition | Disabled | Local System |

| | | |
|---|---|---|
| Windows Server 2003, Web Edition | Disabled | Local System |

**COM+ Event System**
Short name: EventSystem

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Manual/Started | Local System |
| Windows Server 2003, Enterprise Edition | Manual/Started | Local System |
| Windows Server 2003, Datacenter Edition | Manual/Started | Local System |
| Windows Server 2003, Web Edition | Manual/Started | Local System |

**COM+ System Application**
Short name: COMSysApp

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Manual | Local System |
| Windows Server 2003, Enterprise Edition | Manual | Local System |
| Windows Server 2003, Datacenter Edition | Manual | Local System |
| Windows Server 2003, Web Edition | Manual | Local System |

**Computer Browser**
Short name: Browser

This service is started in Safe Mode with Networking.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Local System |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Local System |
| Windows Server 2003, Web Edition | Automatic/Started | Local System |

**Cryptographic Services**
Short name: CryptSvc

This service is started in Safe Mode, Safe Mode with Networking, and Safe Mode with Command Prompt.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Local System |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Local System |
| Windows Server 2003, Web Edition | Automatic/Started | Local System |

**DCOM Server Process Launcher**
Short name: DcomLaunch

This service is started in Safe Mode, Safe Mode with Networking, and Safe Mode with Command Prompt.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Local System |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Local System |
| Windows Server 2003, Web Edition | Automatic/Started | Local System |

**DHCP Client**
Short name: Dhcp

This service is started in Safe Mode with Networking.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Network Service |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Network Service |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Network Service |
| Windows Server 2003, Web Edition | Automatic/Started | Network Service |

**Distributed File System**
Short name: Dfs

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Local System |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Local System |
| Windows Server 2003, Web Edition | Automatic/Started | Local System |

**Distributed Link Tracking Client**
Short name: TrkWks

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Local System |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Local System |
| Windows Server 2003, Web Edition | Automatic/Started | Local System |

**Distributed Link Tracking Server**
Short name: TrkSvr

This service is now disabled by default. If you want to enable this service, set **Startup type** to **Manual**.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Disabled | Local System |
| Windows Server 2003, Enterprise Edition | Disabled | Local System |

| | | |
|---|---|---|
| Windows Server 2003, Datacenter Edition | Disabled | Local System |
| Windows Server 2003, Web Edition | Disabled | Local System |

**Distributed Transaction Coordinator**
Short name: MSDTC

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Network Service |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Network Service |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Network Service |
| Windows Server 2003, Web Edition | Automatic/Started | Network Service |

**DNS Client**
Short name: Dnscache

This service is started in Safe Mode with Networking.

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Network Service |
| Windows Server 2003, Enterprise Edition | Automatic/Started | Network Service |
| Windows Server 2003, Datacenter Edition | Automatic/Started | Network Service |
| Windows Server 2003, Web Edition | Automatic/Started | Network Service |

**Error Reporting Service**
Short name: ERSvc

| Product | Startup type | Log on as |
|---|---|---|
| Windows Server 2003, Standard Edition | Automatic/Started | Local System |

# Troubleshooting Services Snap-in

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The service will not start.
- The computer will not start.
- When managing services on a remote computer, I receive a Connection Manager error message when I try to access the properties dialog box for a service.

**The service will not start.**
**Cause:** The account under which the service runs (as indicated on the **Log On** tab of the properties dialog box for the service) has changed.

**Solution:** Examine the System, Application, and Security logs in Event Viewer for "Service failed to start" error messages to identify which account the service uses. For more information about how to use Event Viewer to do this, see Search for specific events. Then, restore the default settings. For a table that lists the default settings, see Default settings for services. If you cannot access the Services snap-in to restore the settings, you can also use the **sc** command. For more information, see SC.

**Cause:** The system configuration has changed.

**Solution:** Use the System Configuration Utility (Msconfig.exe) to restart the computer using a diagnostic startup method. With the System Configuration Utility, you can select which devices and services are loaded at startup, which can help identify problem devices. For more information, see Windows interface administrative tool reference A-Z: System Configuration Utility.

**Cause:** Account lockout policy is enabled, or the password is expired.

**Solution:** If the service account is locked out or the service account password is expired, the service will not start. For more information about how to configure account lockout policy settings, see Apply or modify account lockout policy. For more information about how to apply password policy, see Apply or modify password policy.

**See also:** Account Lockout Policy.

**The computer will not start.**
**Cause:** The account under which the service runs (as indicated on the **Log On** tab of the properties dialog box for the service) has changed.

**Solution:** Start the computer in Safe Mode. In Safe Mode, you can change the service configuration or restore the default configuration. In Safe Mode, core services that are required to start the operating system are started in a default scheme, regardless of any changes that are made to the service settings. For more information, see Startup options.

**When managing services on a remote computer, I receive a Connection Manager error message when I try to access the properties dialog box for a service.**
**Cause:** The Remote Registry service is not running on the remote computer.

**Solution:** Ensure that the Remote Registry service is running on the remote computer. This is necessary only if you want to configure hardware profile settings for the service. For more information, see Start, stop, pause, resume, or restart a service. To start the service, you need the appropriate permissions on the remote computer.

**See also:** Troubleshooting Performance monitoring for System Monitor and Performance Logs and Alerts.

**Note**

- You may also receive this error message if the remote computer is running Windows 95 or Windows NT 4.0.

For information on enabling the services required by audio, imaging, and CD-burning peripheral devices, see Troubleshooting audio, imaging, and CD-burning peripheral devices.

# Event Viewer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Event Viewer**
With Event Viewer, you can monitor events recorded in event logs. Typically a computer stores the Application, Security, and System logs. It could also contain other logs, depending on the computer's role and the applications installed.

- For tips about using Event Viewer, see Event Viewer Best practices.
- For help with specific tasks, see Event Viewer How To....
- For general background information, see Event Viewer Concepts.
- For problem-solving instructions, see Event Viewer Troubleshooting.

# Event Viewer Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Enable security logging for security-critical objects and actions, and then periodically review the security logs on computers in your network.**

- By setting up an auditing policy and reviewing your security logs, you can detect unauthorized activity or intrusion attempts by malicious users or attackers on computers in your network.
- For more information about setting auditing policies, see Auditing Security Events.
- For more information about viewing event logs, see View Event Logs.

# Event Viewer How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- View Event Logs
- Manage Event Logs
- Customize Event Logs
- Use the Security Log

# View Event Logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**View event logs**

- View an event log
- Add another view of an event log
- Search for specific events
- Connect to another computer in Event Viewer
- Specify a sort order in an event log
- Filter events

# View an event log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view an event log**

1. Open Event Viewer.
2. In the console tree, click the log you want to view.
3. In the details pane, view the list of individual events.
4. If you want to see more details about a specific event, in the details pane, double-click the event.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- To refresh the view, on the **Action** menu, click **Refresh**. When you open a log, Event Viewer displays the current information for the log. While you view the log, the display is not updated unless you refresh the Event Viewer window. If you switch to another log and then return to the first log, the display for the first log is automatically refreshed. When you refresh the view of an event log, only the view is updated, no changes are made to the log. The **Refresh** command is not available for archived logs, because those files can no longer be updated.
- For more information about the event header in the details pane, click "The event header" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add another view of an event log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add another view of an event log**

1. Open Event Viewer.
2. In the console tree, click the log of which you want to add another view.
3. On the **Action** menu, click **New Log View**. A copy of the log appears in the console tree with a default name. For example, if you selected the **Application** log, the default name of the copy would be **Application (2)**.
4. If you want to change the name of the new log view, on the **Action** menu, click **Rename**.
5. Type the name as you want it to appear in the console tree, and then press ENTER.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- By creating a new log view, you can customize how Event Viewer displays the information of an existing log and then apply a new name to the new log view, while keeping the defaults or the options you set for the original log intact. Log views added to the console tree can be managed and customized in the same way as the default logs.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Search for specific events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To search for specific events**

1. Open Event Viewer.
2. In the console tree, click the log you want to search.
3. On the **View** menu, click **Find**.
4. Under **Event types**, select the types of events you want to find.
5. In **Event source**, **Category**, **Event ID**, **User**, **Computer**, or **Description**, specify additional information about the event or events you want to find.
6. Click **Find Next**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- In **Description**, you can type any text that matches a portion of an event record description.
- To restore the default search criteria, click **Restore Defaults** before clicking **Find Next**.
- Your search parameters remain in **Find** throughout the current session. The default settings are restored the next time you start Event Viewer.
- If you are looking for groups of events instead of a small number of individual events, you can also filter the log. For more information, see "Filter events" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Filter events
Specify a sort order in an event log

# Connect to another computer in Event Viewer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to another computer in Event Viewer**

1. Open Event Viewer.
2. In the console tree, right click **Event Viewer (Local)**, and then click **Connect to another computer**
3. Click **Another computer**, type the name of the computer, and then click **OK**. You can also find another computer on the network by clicking **Browse**.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the target computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- The other computer can be a workstation running Windows XP Home Edition, Windows XP Professional, Windows 2000 Professional, or Windows NT Workstation, or a server or domain controller running Windows 2000 Server, Windows NT Server, or a Windows Server 2003 family operating system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify a sort order in an event log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a sort order in an event log**

1. Open Event Viewer.
2. In the console tree, click the log you want to sort.
3. Click the column heading you want to sort by.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- To reverse the sort order, click the column heading a second time.
- To sort chronologically, on the **View** menu, click **Newest First** or **Oldest First**. The default is **Newest First**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Reset an event log to default settings
Filter events
Search for specific events

# Filter events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To filter events**

1. Open Event Viewer.
2. In the console tree, select the log you want to filter.
3. On the **View** menu, click **Filter**.
4. On the **Filter** tab, specify the characteristics you want to use in the filter.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- Filtering changes only the view, and has no effect on the actual contents of the log. All events are logged continuously, whether the filter is active or not. If you archive a log from a filtered view, all records are saved, even if you select a text format or comma-delimited text format file.
- To return to the default criteria, click **Restore Defaults**.
- To turn off event filtering, on the **View** menu, click **All Records**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Manage Event Logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage event logs**

- Clear an event log
- Archive an event log
- Open an archived event log

# Clear an event log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To clear an event log**

1. Open Event Viewer.
2. In the console tree, click the log you want to clear.
3. On the **Action** menu, click **Clear all Events**.
4. If you want to save the log before clearing it, click **Yes**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- You cannot clear archived logs; instead, delete the archived log file.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Archive an event log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To archive an event log**

1. Open Event Viewer.
2. In the console tree, right-click the log you want to archive, and then click **Save Log File As**.
3. In **File name**, enter a name for the archived log file.
4. In **Save as type**, select a file format, and then click **Save**.

## Notes

- To perform this procedure on a local computer, you must be a member of the Backup Operators group, Administrators group, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- If you archive a log in log-file format (.evt), you can reopen it in Event Viewer. If you archive a log in text (.txt) or comma-delimited (.csv) format, you can reopen the log in other programs, such as word processing or spreadsheet programs, but not with Event Viewer.
- You can only save event logs in log-file format on the computer on which the events occur; for example, when using Event Viewer to view event logs on a remote computer.
- To save a local event log in log-file format on another computer, in **File name**, type *remotecomputername**share*, and then type the path to and name for your archive file.
- When you archive a log file, the entire log is saved, regardless of filtering options. The sort order is not retained when logs are saved. However, you can filter and sort the archived log again when you open it in Event Viewer.
- Archiving has no effect on the current contents of the active log.
- To remove an archived log file from your system, delete the file in Windows Explorer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open an archived event log**

1. Open Event Viewer.
2. On the **Action** menu, click **Open Log File**.
3. Click the file you want to open. You may need to search for the drive or folder that contains the document.
4. In **Log type**, select the type of log to be opened.
5. In **Display name**, enter the name as you want it to appear in the console tree, and then click **Open**.

## Notes

- Performing this task does not require you to have administrative credentials. However, you must be a member of the Administrators group on the target computer to open the Security log, or any log when targeting a remote computer.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- You can use Event Viewer to open an archived log in log-file format (.evt). If an archived log was saved in text (.txt) or comma-delimited (.csv) format, you can open the log using other programs, such as word processing or spreadsheet programs, but not Event Viewer.
- To remove an archived log file from your system, delete the file in Windows Explorer.
- For more information about event log settings, see "Understanding event logging options" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reset an event log to default settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset an event log to default settings**

1. Open Event Viewer.
2. In the console tree, click the log you want to reset.
3. On the **Action** menu, click **Properties**.
4. On the **General** tab, click **Restore Defaults**.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the target computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- For more information about event log settings, see *Understanding event logging options* in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the maximum event log size

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the maximum event log size**

1. Open Event Viewer.
2. In the console tree, click the log you want to change.
3. On the **Action** menu, click **Properties**.
4. On the **General** tab, in **Maximum log size**, specify the new log size in kilobytes.
5. To put the new setting in effect, click **Clear Log**.

   If you want to retain the information currently in the log, click **Yes** when a message appears asking if you want to save the original log before clearing it, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.
- For more information about event log settings, see *Understanding event logging options* in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use the Security Log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use the security log**

- View the security log
- Define or modify auditing policy settings for an event category
- Apply or modify auditing policy settings for a local file or folder
- Apply or modify auditing policy settings for an object using Group Policy

# View the security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the security log**

1. Open Event Viewer.
2. In the console tree, click **Security**. The details pane lists individual security events.
3. If you want to see more details about a specific event, in the details pane, double-click the event.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Event Viewer, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Event Viewer**.

# Define or modify auditing policy settings for an event category

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define or modify auditing policy settings for an event category**

- For your local computer
- For only domain controllers, when you are on a domain controller or on a workstation that hasWindows Server 2003Administration Tools Pack installed
- For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed
- For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain

**For your local computer**

1. Open Local Security Settings.
2. In the console tree, click **Audit Policy**.

   **Where?**

   - Security Settings/Local Policies/Audit Policy

3. In the details pane, double-click an event category that you want to change the auditing policy settings for.
4. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.
   - To audit unsuccessful attempts, select the **Failure** check box.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For only domain controllers, when you are on a domain controller or on a workstation that has Windows Server 2003 Administration Tools Pack installed**

1. Open Domain Controller Security Policy.
2. In the console tree, click **Audit Policy**.

   **Where?**

- Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

3. In the details pane, double-click an event category that you want to change the auditing policy settings for.

4. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

5. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.

   - To audit unsuccessful attempts, select the **Failure** check box.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Domain Controller Security Policy, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Domain Controller Security Policy**.

**For a domain or organizational unit, when you are on a domain controller or on a workstation that has Administration Tools Pack installed**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click **Edit** to open the Group Policy object (GPO) that you want to edit. You can also click **New** to create a new GPO, and then click **Edit**.

5. In the console tree, click **Audit Policy**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

6. In the details pane, double-click an event category that you want to change the auditing policy settings for.

7. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

8. Do one or both of the following, and then click **OK**.

   - To audit successful attempts, select the **Success** check box.

   - To audit unsuccessful attempts, select the **Failure** check box.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**For a domain or organizational unit, when you are on a member server or on a workstation that is joined to a domain**

1. Open Microsoft Management Console (MMC).

2. In the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.

3. Click **Group Policy Object Editor**, and then click **Add**.

4. On the **Select Group Policy Object** page in the Group Policy Wizard, click **Browse**.

5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, click **OK**, and then click **Finish**.

6. Click **Close**, and then click **OK**.

7. In the console tree, click **Audit Policy**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Local Policies/Audit Policy

8. In the details pane, double-click an event category that you want to change the auditing policy settings for.

9. If you are defining auditing policy settings for this event category for the first time, select the **Define these policy settings** check box.

10. Do one or both of the following, and then click **OK**.

    - To audit successful attempts, select the **Success** check box.

    - To audit unsuccessful attempts, select the **Failure** check box.

    **Notes**

    - To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

    - To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

**Notes**

- To audit object accesses, enable auditing of the object access event category by following the steps above. Then, enable auditing on the specific object. For information about how to enable auditing on an object, see "Apply or modify auditing

policy settings for a local file or folder" or "Apply or modify auditing policy settings for an object using Group Policy" in Related Topics.

- After your audit policy is configured, events will be recorded in the security log. Open the security log to view these events. For information about the security log, see "Use the security log" in Related Topics.

- The default auditing policy setting for domain controllers is **No Auditing**. This means that even if auditing is enabled in the domain, the domain controllers do not inherit auditing policy locally. If you want domain auditing policy to apply to domain controllers, you must modify this policy setting.

# Apply or modify auditing policy settings for a local file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify auditing policy settings for a local file or folder**

1. Open Windows Explorer.
2. Right-click the file or folder that you want to audit, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Auditing** tab.
4. Do one of the following:
   - To set up auditing for a new user or group, click **Add**. In **Enter the object name to select**, type the name of the user or group that you want, and then click **OK**.
   - To remove auditing for an existing group or user, click the group or user name, click **Remove**, click **OK**, and then skip the rest of this procedure.
   - To view or change auditing for an existing group or user, click its name, and then click **Edit**.
5. In the **Apply onto** box, click the location where you want auditing to take place.
6. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes:
   - To audit successful events, select the **Successful** check box.
   - To stop auditing successful events, clear the **Successful** check box.
   - To audit unsuccessful events, select the **Failed** check box.
   - To stop auditing unsuccessful events, clear the **Failed** check box.
   - To stop auditing all events, click **Clear All**.
7. If you want to prevent subsequent files and subfolders of the original object from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

**Important**

- Before setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files or folders will be audited. For more information about how to enable object access auditing, see "Define or modify auditing policy settings for an event category" in Related Topics.

**Notes**

- You must be logged on as a member of the Administrators group or you must have been granted the **Manage auditing**

**and security log** right in Group Policy to perform this procedure.

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- For information about how to audit local registry keys, see "Audit activity on a registry key" in Related Topics.
- After object access auditing is enabled, view the security log in Event Viewer to review the results of your changes.
- You can set up file and folder auditing only on NTFS drives.
- If you see the following:
    - In the **Auditing Entry for *File or Folder*** dialog box, in the **Access** box, the check boxes are unavailable ...
    - In the **Advanced Security Settings for *File or Folder*** dialog box, the **Remove** button is unavailable ...

  auditing has been inherited from the parent folder.
- Because the security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the security log. The maximum size for the security log is defined in Event Viewer.

# Apply or modify auditing policy settings for an object using Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify auditing policy settings for an object using Group Policy**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. On the **Select Group Policy Object** page in the Group Policy Wizard, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. Do one or more of the following:

| To audit | Do this |
|---|---|
| System services | In the console tree, click **System Services**.<br>Where?<br>• Computer Configuration/Windows Settings/Security Settings/System Services<br>In the details pane, right-click the service that you want to apply or modify auditing policy settings for, and then click **Properties**.<br>If it is not already selected, select the **Define this policy setting** check box, and then select the appropriate setting.<br>Click **Edit security**. |
| Registry keys | In the console tree, click **Registry**.<br>Where?<br>• Computer Configuration/Windows Settings/Security Settings/Registry<br>If you want to add a registry key to this GPO to audit, right-click **Registry**, and then click **Add Key**. Browse to the key that you want, and then click **OK**.<br>If you want to apply or modify auditing settings on a registry key that has already been added to this GPO, in the details pane, right-click the registry key, click **Properties**, and then click **Edit Security**. |

| | |
|---|---|
| Files or folders | In the console tree, click **File System**.<br><br>Where?<br><br>• Computer Configuration/Windows Settings/Security Settings/File System<br><br>If you want to add a file or folder to this GPO to audit, right-click **File System**, and then click **Add File**. Browse to the file that you want, or make a new folder, and then click **OK**.<br><br>If you want to apply or modify auditing settings on a file or folder that has already been added to this GPO, in the details pane, right-click the file or folder, click **Properties**, and then click **Edit Security**. |

8. Click **Advanced**, and then click the **Auditing** tab.

9. Do one of the following:

   - To set up auditing for a new user or group, click **Add**. In **Name**, type the name of the user or group that you want, and then click **OK**.
   - To view or change auditing for an existing group or user, click the name that you want, and then click **Edit**.
   - To remove auditing for an existing group or user, click the name that you want, click **Remove**, click **OK**, and then skip the rest of this procedure.

10. Select the appropriate entry in the **Apply onto** list.

11. In the **Access** box, indicate what actions you want to audit by selecting the appropriate check boxes:

    - To audit successful events, select the **Successful** check box.
    - To stop auditing successful events, clear the **Successful** check box.
    - To audit unsuccessful events, select the **Failed** check box.
    - To stop auditing unsuccessful events, clear the **Failed** check box.
    - To stop auditing all events, click **Clear All**.

12. If you want to prevent files and subfolders in the tree from inheriting these audit entries, select the **Apply these auditing entries to objects and/or containers within this container only** check box.

**Important**

- Before setting up auditing for files and folders, you must enable object access auditing by defining auditing policy settings for the object access event category. If you do not enable object access auditing, you will receive an error message when you set up auditing for files and folders, and no files or folders will be audited. For more information about how to enable object access auditing, see "Define or modify auditing policy settings for an event category" in Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- For more information on selecting where to apply auditing entries, see Related Topics.
- You can set up file and folder auditing only on NTFS drives.
- If you see the following:
    - In the **Auditing Entry for *File or Folder*** dialog box, in the **Access** box, the check boxes are unavailable ...
    - In the **Advanced Security Settings for *File or Folder*** dialog box, the **Remove** button is unavailable ...

  auditing is inherited from the parent folder.
- After object access auditing is enabled, view the security log in Event Viewer to review the results of your changes.
- Because the security log is limited in size, select the files and folders to be audited carefully. Also, consider the amount of disk space that you want to devote to the security log. The maximum size for the security log is defined in Event Viewer.

# Event Viewer Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Event Viewer:

- Event Viewer overview
- Auditing Security Events
- Event log overview
- Using the Event Viewer snap-in
- Managing event logs from the command line

# Event Viewer overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Event Viewer overview**
Using Event Viewer, you can view and set logging options for event logs in order to gather information about hardware, software, and system problems.

- For information about event logs, see Event log overview.
- For information about events, see The event header or Types of events.
- For information about event logging options you can set using Event Viewer, see Understanding event logging options.
- For information about setting up auditing policies, see Auditing Security Events.

# Auditing Security Events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Auditing security events**
You can set up audit policy so that user or system activity in specified event categories is recorded. You can monitor security-related activity, such as who accesses an object, if a user logs on to or logs off from a computer, or if changes are made to an auditing policy setting.

- Before defining auditing policy settings in the object access event category, see Checklist: Setting up object access auditing.
- For tips about auditing, see Auditing Security Events Best practices.
- For help with specific tasks, see Auditing Security Events How To....
- For general background information, see Auditing Security Events Concepts.

# Event log overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Event log overview**
By default, a computer running a Windows Server 2003 family operating system records events in three kinds of logs:

**Application log**
The application log contains events logged by applications or programs. For example, a database program might record a file error in the application log. Application developers decide which events to log.

**Security log**
The security log records events such as valid and invalid logon attempts, as well as events related to resource use such as creating, opening, or deleting files or other objects. For example, if logon auditing is enabled, attempts to log on to the system are recorded in the security log.

**System log**
The system log contains events logged by Windows system components. For example, the failure of a driver or other system component to load during startup is recorded in the system log. The event types logged by system components are predetermined by the server.

A computer running a Windows Server 2003 family operating system which is configured as a domain controller records events in two additional logs:

**Directory service log**
The directory service log contains events logged by the Windows Active Directory service. For example, connection problems between the server and the global catalog are recorded in the directory service log.

**File Replication service log**
The File Replication service log contains events logged by the Windows File Replication service. For example, file replication failures and events that occur while domain controllers are being updated with information about system volume changes are recorded in the file replication log.

A computer running Windows configured as a Domain Name System (DNS) server records events in an additional log:

**DNS server log**
The DNS server log contains events logged by the Windows DNS service.

Other types of events and event logs might be available on a computer, depending on what services are installed.

The Event Log service starts automatically when you start Windows.

If you are a member of the Administrators group on the local computer, you can set access permissions on event logs using Group Policy. For more information about security groups, see Default groups. For more information, see Settings for Event Logs.

For more information about viewing events, see Types of events and Interpreting an Event.

# The event header

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The event header**

The event header contains the following information:

| Information | Meaning |
|---|---|
| Date | The date the event occurred. The date and time of an event are stored in Universal Time Coordinate (UTC) but always display in the viewer's locale. |
| Time | The time the event occurred. The date and time of an event are stored in UTC but always display in the viewer's locale. |
| User | The name of the user on whose behalf the event occurred. This name is the client ID if the event was actually caused by a server process, or the primary ID if impersonation is not taking place. Where applicable, a security log entry contains both the primary and impersonation IDs. Impersonation occurs when the server allows one process to take on the security attributes of another. |
| Computer | The name of the computer where the event occurred. This is usually the name of your own computer, unless you are viewing an event log on another computer. |
| Source | The software that logged the event, which can be either a program name such as SQL Server, or a component of the system (such as a driver name) or of a large program. For example, "Elnkii" indicates an EtherLink II driver. The Source always remains in its original language. |
| Event | A number identifying the particular event type for this source. The first line of the description usually contains the name of the event type. For example, 6005 is the ID of the event that occurs when the Event log service is started. The first line of the description of such an event is "The Event log service was started." Using the values of Source and Event together, product support representatives can troubleshoot system problems. |
| Type | A classification of the event severity: Error, Information, or Warning in the system and application logs; Success Audit or Failure Audit in the security log. In the Event Viewer normal list view, these are represented by a symbol. |
| Category | A classification of the event by the event source. This information is primarily used in the security log. For example, for security audits, this corresponds to one of the event types for which success or failure auditing can be enabled in Group Policy by a member of the Administrators group. |

For more information, see

- Event log overview
- View an event log
- Types of events
- Understanding event logging options

# Types of events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Types of events**

Event Viewer displays five types of events:

| Event type | Description |
|---|---|
| Error | A significant problem, such as loss of data or loss of functionality. For example, if a service fails to load during startup, an Error will be logged. |
| Warning | An event that is not necessarily significant, but might indicate a possible future problem. For example, when disk space is low, a Warning might be logged. |
| Information | An event that describes the successful operation of an application, driver, or service. For example, when a network driver loads successfully, an Information event will be logged. |
| Success Audit | Any audited security event that succeeds. For example, a user's successful attempt to log on the system will be logged as a Success Audit event. |
| Failure Audit | Any audited security event that fails. For example, if a user tries to access a network drive and fails, the attempt will be logged as a Failure Audit event. |

For more information, see:

- Event log overview
- View an event log
- The event header
- Understanding event logging options

# Linking to Microsoft for Help and Support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Linking to Microsoft for Help and Support**
For more details about an event, you can double-click it in the details pane to open the **Event Properties** dialog box. The **Event Properties** dialog box contains a Uniform Resource Locator (URL) link in the **Description** dialog box.

If you click the URL in the **Event Properties** dialog box of an event generated by a Microsoft application or service, information related to the event display is sent over the Internet to Microsoft in the form of a query, which locates more detailed information from the Microsoft Web site. The collected data is limited to only what is needed to retrieve more information about the event. User names and e-mail addresses, names of files unrelated to the logged event, machine addresses, and any other forms of personally identifiable information are not collected.

### Notes

- Events not generated by Microsoft applications or services might also contain a URL, and might take you to non-Microsoft web sites.

- Administrators can use a Group Policy setting to prevent the URL link in the **Description** dialog box from appearing.

# Viewing and Archiving Log Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing and archiving log files**
This section covers:

- Understanding event logging options
- File formats for archived logs

# Understanding event logging options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding event logging options**

Using Event Viewer, you can define logging parameters for each kind of event log. To define parameters, right-click a log in the console tree, and then click **Properties**. On the **General** tab, you can set the maximum size of the log and specify whether the events are overwritten or stored for a certain period of time.

The default logging policy is that if a log is full, the oldest events are deleted to make room for new events, provided events are at least seven days old. You can customize this policy, or event log wrapping options, for different logs.

Event log wrapping options include the following.

| Use | To |
|---|---|
| **Overwrite events as needed** | Have new events continue to be written when the log is full. Each new event replaces the oldest event in the log. This option is a good choice for low-maintenance systems. |
| **Overwrite events older than** [*x*] **days** | Retain the log for the number of days you specify before overwriting events. The default is seven days. This option is the best choice if you want to archive log files weekly. This strategy minimizes the chance of losing important log entries and at the same time keeps log sizes reasonable. |
| **Do not overwrite events** | Clear or archive the log manually rather than automatically. Select this option only if you cannot afford to miss an event (for example, for the security log at a site where security is extremely important). |

You can also use Group Policy to set the maximum log sizes and log wrapping options, as well as set access permissions on event logs. For more information, see Settings for Event Logs.

Application and system logging start automatically when you start the computer. For information about configuring security logging, see Auditing Security Events.

**Notes**

- To perform these procedures, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform these procedures. For more information, see Default local groups, Default groups, and Using Run as.

- For information about how to set event logging options using Event Viewer, see Set event logging options.

# File formats for archived logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File formats for archived logs**

When you archive an event log, you save it in one of three file formats:

- **Log-file format** (.evt), which enables you to view the archived log again in Event Viewer.
- **Text-file format** (.txt), which enables you to use the information in a program such as a word processing program. You cannot use Event Viewer to open a log file saved in .txt format.
- **Comma-delimited text-file format** (.csv), which enables you to use the information in a program such as a spreadsheet or a flat-file database. You cannot use Event Viewer to open a log file saved in .csv format.

The event description is saved in all archived logs. The data within each individual event record is recorded in the following order:

1. Date
2. Time
3. Source
4. Type
5. Category
6. Event
7. User
8. Computer
9. Description

For more information, see:

- Archive an event log
- Open an archived event log
- Event log overview
- Types of events

# Managing event logs from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing event logs from the command line**

**Opening Event Viewer from the command line**
You can launch Event Viewer from the command-line using `eventvwr.exe` or `mmc.exe`. Either command opens Event Viewer.

**Syntax for eventvwr.exe**

```
eventvwr.exe
```

**Parameters**

```
computername
```

Specifies the computer you want to target, where `computername` is the name of the target computer. If you do not specify a computer, Event Viewer displays the logs on the local computer. You can specify a remote computer for `computername`, if you are a member of the Administrators group, or have been delegated the appropriate authority, on the remote computer.

**or**

**Syntax for mmc.exe**

```
mmc.exe X:\WINDOWS\system32\eventvwr.msc
```

Where `X:\WINDOWS\System32` is the default path to `eventvwr.msc`, and `X` is the folder where Windows is installed.

**Parameters**

```
/computer=computername
```

Specifies the computer you want to target, where `computername` is the name of the target computer. If you do not specify a computer, Event Viewer displays the logs on the local computer. You can specify a remote computer for `computername`, if you are a member of the Administrators group, or have been delegated the appropriate authority, on the remote computer.

```
/auxsource=computername
```

Enables Event Viewer to obtain the information about events from a computer on which the event log service is installed. This can be the computer that generated the log or another computer on the network. You can use the `/auxsource=computername` parameter on computers running a Windows XP or later operating system. To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**Using command-line tools to manage events and event logs**
You can also use command-line utilities to create and query event logs and associate programs with particular logged events. For example, you can use Eventcreate to customize an event entry to a specified event log. Eventquery.vbs is used to list the events and event properties from one or more event logs. Eventtriggers enables you to create event triggers that will run programs upon the occurrence of specific events.

For information about other command-line utilities, see Command-line reference A-Z.

# Event Viewer Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- When viewing an event in a saved event log on a remote computer, you are unable to view the Description or Category fields in the properties dialog box. Instead of a description in the Description field, you see an error message, or instead of a category in the Category field, you see a number.
- When viewing an event in the details pane, you see a globally unique identifier (GUID) or security ID (SID) in the User field. You should see a user name.
- You are unable to view the Security log, but can view other logs.
- You are able to view the Security log, but are unable to view other logs.
- You cannot access the Computer Management extension snap-ins on a remote computer.

**When viewing an event in a saved event log on a remote computer, you are unable to view the Description or Category fields in the properties dialog box. Instead of a description in the Description field, you see an error message, or instead of a category in the Category field, you see a number.**
**Cause:** Event Viewer obtains event description and category information from the computer that contains the log. The event log might have been copied from the computer on which it was generated, to another computer, on which the service that logged these events is not installed.

**Solution:** Open Event Viewer from the command-line using **mmc.exe**, and use the **/auxsource=***computername* parameter. The **/auxsource=***computername* parameter enables Event Viewer to obtain the information about events from a computer on which the event log service is installed. This can be the computer which generated the log or another computer on the network. You can use the **/auxsource=***computername* parameter on computers running a Windows XP or later operating system. To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**Syntax**

**mmc.exe X:\WINDOWS\system32\eventvwr.msc /auxsource=** *computername*

Where X:\WINDOWS\System32 is the default path to eventvwr.msc, and X is the drive where Windows is installed.

**Note**

- To run a command-line utility, click **Start**, and then click **Run**. In the **Open** box, enter the command-line utility and parameters, and then click **OK**.
- If category information is not available, you will also see a number instead of text in the **Category** field in the Event Viewer details pane for an event listing.

**See also:** Mmc; Managing event logs from the command line

**Cause:** You are attempting to view a log on a remote computer and are not a member of the Administrators group, or have not been delegated the appropriate authority on the remote computer.

**Solution:** To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

You might also be able to obtain the same information from a different computer on your network. To do this, run Event

Viewer at a command prompt (Eventvwr.msc) with the **auxsource=***ComputerName* parameter. You can use this parameter to enable Event Viewer to obtain information from a computer on which the service is installed. This can be either the computer that generated the log or another computer on the network.

**Cause:** You are attempting to view a log on a remote computer and the Remote Registry service on the remote computer is stopped. If the remote computer is running a Windows XP or later operating system, the Remote Registry service must be started for you to be able to see the **Description** or **Category** fields in the property page for an event log.

**Solution:** On the remote computer, start the Remote Registry Service. You can manage the Remote Registry service through the **Services and Applications** snap-in in **Computer Management**.

To start the Remote Registry service

1. In **Computer Management**, verify that you are in the console for the remote computer.

2. In the console tree, under **Services and Applications**, click **Services**.

3. In the details pane, double-click **Remote Registry**.

4. In the **General** tab, under **Service status**, click **Start**. Click **OK**.

You might also be able to obtain the same information from a different computer on your network. To do this, run Event Viewer at a command prompt (Eventvwr.msc) with the **auxsource=***ComputerName* parameter. You can use this parameter to enable Event Viewer to obtain information from a computer on which the service is installed. This can be either the computer that generated the log or another computer on the network.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- This parameter is available on computers running Windows XP or a product in the Windows Server 2003 family.

**See also:** Remote Administration;Computer Management; Microsoft Management Console

**When viewing an event in the details pane, you see a globally unique identifier (GUID) or security ID (SID) in the User field. You should see a user name.**
**Cause:** The computer on which you are running Event Viewer is unable to translate the GUID or SID into the user name.

**Solution:** Run Event Viewer on the computer on which the event log was generated.

**Cause:** The user account referenced by the event has been deleted.

**Solution:** You will not be able to retrieve this information through Event Viewer.

**You are unable to view the Security log, but can view other logs.**
**Cause:** You are not a member of the Administrators group, or have not been delegated the appropriate authority on the target computer.

**Solution:** To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**See also:** Use the Security Log

**You are able to view the Security log, but are unable to view other logs.**
**Cause:** Your account has been added to the Guests group on the target computer, and is also a member of the Administrators group.

**Solution:** Remove your account from the **Guests** group on the target computer:

1. Open **Computer Management**. If the target computer is a remote computer, right-click **Computer Management (Local)**, and then click **Connect to another computer**.

2. Under **Local Users and Groups**, click **Groups**.

3. In the details pane, double-click **Guests**.

4. Select the account, and then click **Remove**.

5. Click **OK**.

### Notes

- This problem typically develops when an administrator adds a group containing a broad category of users (such as the **Everyone**, **INTERACTIVE**, OR **Authenticated users** group) to the **Guests** group.

- By default, members of the **Guests** group are explicitly denied access to resources such as event logs. Therefore, avoid adding groups containing users with administrative privileges to the **Guests** group.

- You might need to log off, and then log back on for these changes to take effect.

**See also:** Connect to another computer in Event Viewer.

**You cannot access the Computer Management extension snap-ins on a remote computer.**
**Cause:** The Remote Registry service is not running on the remote computer.

**Solution:** Ensure that the Remote Registry service is started on the remote computer. For more information, see Start, stop, pause, resume, or restart a service. You need appropriate permissions on the remote computer to start the service.

### Note

- You might also receive this error message if the remote computer is running Windows 95. Computer Management does not support remote access to computers that are running Windows 95.

# Network Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network Monitor**
Network administrators use Network Monitor to view and detect problems on local area networks (LANs).

- Before using Network Monitor, see Checklist: Monitoring network traffic on your local computer.
- To find features that have been moved in Microsoft® Windows Server 2003 family operating systems, see New ways to do familiar Network Monitor tasks.
- For tips about using Network Monitor, see Network Monitor Best practices.
- For help with specific tasks, see Network Monitor How To ....
- For general background information, see Network Monitor Concepts.
- For problem-solving instructions, see Troubleshooting Network Monitor.

# Checklist: Monitoring network traffic on your local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Monitoring network traffic on your local computer**

| Step | Reference |
|---|---|
| Review key concepts. | Network Monitor overview;<br><br>Network Monitor Best practices |
| Confirm that you are a member of the Administrators group. | Default local groups;<br><br>Edit local security settings |
| Install Network Monitor tools. | Install Network Monitor |

# New ways to do familiar Network Monitor tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for configuring Network Monitor. The user interface for performing these tasks is almost identical in this version of Windows to the way it was in Windows NT version 4.0.

### Note

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Install Network Monitor | Network in Control Panel. | Open Windows Components wizard.<br><br>For more information, see Install Network Monitor. |
| Install the Network Monitor driver | Network in Control Panel. | Open Network Connections; go to **Local Area Connection Properties**.<br><br>For more information, see Install the Network Monitor driver. |

# Network Monitor Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Running Network Monitor during low-usage times**

  Run Network Monitor at low-usage times or for short periods of time. This decreases the effect that Network Monitor might have on the performance of your computer.

- **Capturing minimum amount of network statistics**

  Use capture filters and capture only as many statistics as you need for evaluation. This prevents you from capturing too much information to make a reasonably quick diagnosis of the problem.

- **Viewing Network Monitor captures**

  Use display filters when viewing captured frames to omit extraneous captured frames.

- **Capturing frames on token ring networks**

  Token ring adapters reject frames larger than a size specified in their configuration settings. If you capture frames on token ring networks, set your network adapter to accept the largest possible token-ring frame size, which is 17 KB. For more information, see the documentation for your network adapter.

# Network Monitor How To ...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install and Configure Network Monitor
- Capture Network Data
- Display Network Data
- Print Network Data

# Install and Configure Network Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install and configure Network Monitor**

- Install Network Monitor
- Modify capture buffer settings
- Install the Network Monitor driver

# Install Network Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Network Monitor**

1. Open Windows Components wizard.
2. In the Windows Components wizard, click **Management and Monitoring Tools**, and then click **Details**.
3. In **Subcomponents of Management and Monitoring Tools**, select the **Network Monitor Tools** check box, and then click **OK**.
4. If you are prompted for additional files, insert the installation CD for your operating system, or type a path to the location of the files on the network.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- This procedure automatically installs the Network Monitor driver.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify capture buffer settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify capture buffer settings**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Buffer Settings**.
4. Specify the maximum size of the capture buffer. If necessary, also adjust the maximum size of frames to be captured, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- If your buffer setting exceeds the available memory on your computer, frames might be dropped.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install the Network Monitor driver

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the Network Monitor driver**

1. Open Network Connections.
2. In **Network Connections**, click **Local Area Connection**, click the **File** menu, and then click **Properties**.
3. In the **Local Area Connection Properties** dialog box, click **Install**.
4. In the **Select Network Component Type** dialog box, click **Protocol**, and then click **Add**.
5. In the **Select Network Protocol** dialog box, click **Network Monitor Driver**, and then click **OK**.
6. If you are prompted for additional files, insert the installation CD for your operating system, or type a path to the location of the files on the network.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- **Network Monitor Driver** does not appear in the **Select Network Protocol** dialog box if the Network Monitor driver is already installed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Capture Network Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture network data**

- Capture network frames
- Save captured frames to a file
- Set a capture trigger
- Capture data in dedicated capture mode
- Identify the largest broadcaster on the network
- Use a Capture Filter

# Capture network frames

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To capture network frames**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Buffer Settings**, and then set the buffer and frame size as appropriate.
4. On the **Capture** menu, click **Start**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- If you add a network interface, you must restart Network Monitor before you can capture data on that interface.
- To pause, stop, or display the data capture, on the **Capture** menu, click **Pause**, **Stop**, or **Display Captured Data**. You can also stop and display the capture by clicking **Stop and View**.
- Network Monitor displays session statistics of the first 100 unique network sessions that it detects. To reset statistics and view information about the next 100 detected network sessions, click the **Capture** menu, and then click **Clear Statistics**.
- If you want to capture data from multiple local networks at the same time, install an adapter and start an instance of Network Monitor for each network. In each instance, specify the network from which you want to capture data by, on the **Capture** menu, clicking **Networks** and selecting a network.
- If prompted for additional files, insert the installation CD for your operating system, or type a path to the location of the files on the network.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save captured frames to a file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save captured frames to a file**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Buffer Settings**, and then set the buffer and frame size as appropriate.
4. On the **Capture** menu, click **Start**.
5. To halt the data capture temporarily, on the **Capture** menu, click **Pause**.
6. To stop and view the data capture, on the **Capture** menu, click **Stop and View**.
7. On the **File** menu, click **Save As**.
8. Open the folder in which you want to store the file.
9. In the **File Name** box, specify a file name.
10. If necessary, do one of the following:
    - To save a range of frames, in the **From** box, type the beginning frame number, and in the **To** box, type the ending frame number.
    - To save only the frames that appear when the current display filter is in use, select the **Filtered** check box.
11. Click **Save**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- If you add a network interface, you must restart Network Monitor before you can capture data on that interface.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- To change the default network, on the **Capture** menu, click **Networks**, and then choose the network on which you are trying to capture data.
- If you want to use Network Monitor to load the file you saved, use the .cap file extension. Network Monitor automatically uses this file extension if you do not specify one.

- Network Monitor cannot open capture files larger than 1 GB (1,024 MB).

- When you save a range of frames or apply a display filter and then save the filtered frames, Network Monitor renumbers the saved frames, starting with 1. However, you can create a file with the original frame numbers preserved. To do this, on the **File** menu, click **Print**, click the **General** tab, and then select the **Print to file** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Design a capture filter

# Set a capture trigger

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set a capture trigger**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Trigger**.
4. Do one of the following to specify trigger criteria:
   - To initiate a trigger action when a specific ASCII or hexadecimal string appears in a frame, click **Pattern match**. In the **Pattern** box, type the string you want Network Monitor to detect, and then specify whether the pattern is in hexadecimal or ASCII. If you want, specify where Network Monitor should search for the pattern.
   - To initiate a trigger action when a specific percentage of the capture buffer is full, click **Buffer space**, and then specify the percentage needed.
   - To initiate a trigger action when Network Monitor detects a specific pattern in a frame after a specific percentage of the capture buffer becomes full, click **Buffer space then pattern match**, and specify the percentage and pattern needed.
   - To initiate a trigger action when a specific percentage of the capture buffer becomes full after Network Monitor detects a specific pattern in a frame, click **Pattern match then buffer space**, and specify the pattern and percentage needed.
   - To clear any capture triggers that have been set, click **Nothing**.
5. Do one of the following to specify a trigger action:
   - To have the computer beep, click **Audible Signal Only**.
   - To stop the capture, click **Stop Capture**.
   - To run a command or a program, click **Execute Command Line** and specify the command or program that runs when the conditions for the trigger are met. To specify a program, type the path and the name of the program file, or click **Browse** and navigate to the program file. To use an MS-DOS command, such as **copy**, type **CMD /K**, and then type the command.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- If you click **Pattern match then buffer space** and set **Buffer Space** to **100%**, Network Monitor starts monitoring the capture buffer size with the frame after the frame that contained the pattern match. This means that when the buffer is

100% full, the frame containing the pattern match has been overwritten. If you use the **Pattern match then buffer space** option and need to view the frame that contains the pattern match in order to analyze your network traffic issues, set **Buffer Space** to 75% or smaller.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Capture data in dedicated capture mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To capture data in dedicated capture mode**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Dedicated Capture Mode**.
4. On the **Capture** menu, click **Start**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- If you add a network interface, you must restart Network Monitor before you can capture data on that interface.
- During the capture, select options in the Dedicated Mode dialog box.
- In dedicated capture mode, Network Monitor does not display or refresh capture statistics when frames are copied to the temporary capture file. This frees more resources for capturing data.
- Use dedicated capture mode if Network Monitor drops frames due to a lack of resources.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Identify the largest broadcaster on the network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To identify the largest broadcaster on the network**

1. Open Network Monitor.
2. On the **Capture** menu, click **Start**.
3. When you finish capturing data, on the **Capture** menu, click **Stop** (or **Pause**).
4. In the Station Statistics pane (the lowest pane on the screen), double-click the **Broadcasts Sent** column header.

   Or, right-click in the **Broadcasts Sent** column and then click **Sort Column**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- If the Graph pane indicates a high percentage of network use and if network operations are unusually slow, an abrupt increase in broadcasts may be the source of the problem.
- The row containing the highest number of broadcasts that were sent appears at the top of the list. The network address in this row represents the highest broadcaster on your network.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use a Capture Filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use a capture filter**

- Design a capture filter
- Load a capture filter
- Specify frame data patterns to capture
- Specify capture filter protocols
- Save a capture filter
- Filter Data by Address

# Design a capture filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To design a capture filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Filter**.
4. In the Capture Filter dialog box, do the following:
   - Specify capture filter protocols.
   - Specify address pairs in a capture filter.
   - Specify frame data patterns to capture.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Specify capture criteria to identify the frames that you want to capture on the network.
- Build a complete capture filter expression by specifying the protocols, address pairs, and data patterns of the frames that you want to include or exclude from the capture.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Load a capture filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To load a capture filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Filter** and then click **Load**.
4. Select the capture file you want and then click **Open**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- The decision tree that appears reflects the contents of the filter file that you have loaded. Network Monitor applies this filter when the data capture begins.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify frame data patterns to capture

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify frame data patterns to capture**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Filter**.
4. In the capture filter decision tree, double-click the **AND (Pattern Matches)** line.
5. Complete the Pattern Match dialog box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- You can define up to four data patterns in a capture filter.
- To capture frames that match any of multiple patterns, create a logical branch by selecting one of the patterns in the decision tree and clicking **OR**.
- To exclude frames that match a pattern, select the pattern in the decision tree and then click **NOT**.
- If you specify more than one pattern in the capture filter decision tree, by default, Network Monitor treats each as a logical OR branch.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify capture filter protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify capture filter protocols**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Filter**.
4. Double-click the **SAP/ETYPE=** line.
5. Enable and disable protocols in the Capture Filter SAPs and ETYPES dialog box and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- All the protocols that you specified in your filter appear on the **SAP/ETYPE=** line in the capture filter decision tree.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save a capture filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save a capture filter**

1. Open Network Monitor.
2. On the **Capture** menu, click **Filter**.
3. When you finish editing the filter, click **Save**.
4. In the **File name** text box, type a name for the filter.
5. Click **Save**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access.
- Use a .cf file name extension for a capture filter or use a .df file name extension for a display filter.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Filter Data by Address

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Filter data by address**

- Specify address pairs in a capture filter
- Create an address database
- Edit an address in an address database
- Save the address database to a file
- Load an address file

# Specify address pairs in a capture filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify address pairs in a capture filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Filter**.
4. Double-click the **AND (Address Pairs)** line in the decision tree.

   Or, double-click the address pair you want to edit.
5. In the **Address Expression** dialog box, specify address pair properties, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- You can define up to three address pairs in a capture filter.
- In a capture filter, EXCLUDE statements take logical precedence over INCLUDE statements. Regardless of the sequence in which statements appear in the **Capture Filter** dialog box, Network Monitor evaluates EXCLUDE statements first. Therefore, in a filter containing both an EXCLUDE and an INCLUDE statement, if a frame meets the criteria specified in an EXCLUDE statement, Network Monitor discards the frame. Network Monitor does not test that frame against the INCLUDE statement to see if the frame also meets the criteria of the INCLUDE statement.
- When you close the capture filter, Network Monitor optimizes the logic you used in the **(Pattern Matches)** branch of the capture filter decision tree. Therefore, when you re-open the capture filter, it might look different from the way it did when you created it. For example, if you define multiple pattern match statements, Network Monitor automatically processes them with an implicit OR operator and removes any explicit OR operators between such statements.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create an address database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an address database**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Start**.
4. On the **Capture** menu, click **Stop and View**.
5. On the **Display** menu, click **Find All Names**.
6. In the **Find All Names** dialog box, click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- After the frames are processed, a message appears telling you how many unique addresses were added to the database. To display a list of the addresses in the database you just created, on the **Display** menu, click **Addresses**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit an address in an address database

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit an address in an address database**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Addresses**.
4. Click the address that you want to edit.
5. Click **Edit**.
6. Edit the address in the **Address Information** dialog box and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access.
- When you include the edited address in a capture or display filter, your changes are reflected in the filter.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save the address database to a file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save the address database to a file**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Addresses**.
4. In the **Address Database** dialog box, click **Save**.
5. Specify the file name and location.
6. Click **Save**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- The next time that you design a capture or display filter that includes address pairs, you can use this database. If you assign the database the Default.adr file name, it becomes your default address database.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Load an address file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To load an address file**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Capture** menu, click **Addresses**.
4. Click **Load**.
5. If a message box that asks you whether you want to cancel your changes and load another address database appears, click **Yes**.
6. Specify the file name of the address file (.adr) that you want to load.
7. Click **Open**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access.
- If you load an address database while another address database is open, you will lose unsaved changes made to the open database.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display Network Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Display network data**

- Open an existing capture file
- Change the Frame Viewer window label
- Display network adapter vendor names
- Display address names
- Add a comment frame to a capture
- Specify the protocol header to display
- Select a protocol color scheme
- Display Frames
- Use a Display Filter

# Open an existing capture file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To open an existing capture file**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **File** menu, click **Open**.
4. Select the capture file that you want to open, and then click **Open**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- You can open several capture files at one time; Network Monitor opens a separate Frame Viewer window for each capture file.
- Network Monitor can also open capture files created by some other programs. Some of the other file formats Network Monitor can read are:
    - Ethernet (files with an .ENC extension)
    - Token Ring (files with a .TRC extension)
    - FDDI (files with an .FDC extension)

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the Frame Viewer window label

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the Frame Viewer window label**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Window** menu, click **Label**.
5. In the Label Window dialog box, type the text that you want to appear in the window title bar, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display network adapter vendor names

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display network adapter vendor names**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. On the **Options** menu, click **Show Vendor Names**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- When **Show Vendor Names** is active, Network Monitor replaces computer addresses with a twelve-byte code. The first six bytes of the code display the name of the vendor that produced the network adapter on the remote computer. The last six bytes are a host ID.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display address names

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To display address names**

1. Open Network Monitor.
2. On the **Options** menu, click **Show Address Names**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- When **Show Address Names** is active, a check mark appears next to the command name.
- User-assigned address names are displayed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Display network adapter vendor names

# Add a comment frame to a capture

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a comment frame to a capture**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Tools** menu, click **Insert Comment Frame**.
5. Complete the settings in the Insert Comment Frame dialog box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- The comment frame contains the Trail protocol, which includes statistics such as the amount of frames and bandwidth consumed. These statistics are based on a block of frames bounded by the current comment frame and the next comment frame of the same type (or the end of the capture).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify the protocol header to display

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify the protocol header to display**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Display Captured Data** when you are done capturing frames.
4. On the **Display** menu, click **Options**.
5. In the Display Options dialog box, click **Auto**, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.

**Information about functional differences**

# Select a protocol color scheme

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select a protocol color scheme**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Colors**.
5. In the Protocol Colors dialog box, click the protocol names and the color combination you want, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- If you want to specify more than one color combination, repeat this procedure for each protocol color scheme that you want.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Display Frames

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Display frames**

- View a specific frame
- Search for a frame by its properties
- Expand and collapse frame details
- Specify the frame time stamp
- Set the frame data display font

# View a specific frame

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view a specific frame**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Go To Frame**.
5. In the Go To dialog box, type the number of the frame that you want to view, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- The frame number is listed in the **Frame** column.
- Frames are numbered in the order that Network Monitor captures them.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Search for a frame by its properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To search for a frame by its properties**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Find Next Frame**.
5. In the **Find Frame Expression** dialog box, do one of the following:
   - To search for a frame on the basis of its source or destination address, open and complete the Expression dialog box: Address tab.
   - To search for a frame on the basis of the protocols that were used to send it, open and complete the Expression dialog box: Protocol tab.
   - To search for a frame on the basis of protocol properties, open and complete the Expression dialog box: Property tab.
6. To begin searching for the expression displayed near the top of the dialog box, click **OK**.
7. To find the next frame that has the specified properties, on the **Display** menu, click **Repeat Find Next Frame**.
8. To find the previous frame that has the specified properties, on the **Display** menu, click **Repeat Find Previous Frame**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- If the property is found, the frame automatically expands to display the property that you specified in your search.
- The search remains active until you close the active window or begin a new search.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Expand and collapse frame details

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To expand and collapse frame details**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. Double-click the frame you want to view.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- To expand or collapse a list of frame data, in the Detail pane, double-click the line you want to expand or collapse.
- By default, frame data displayed in the Frame Viewer window Detail pane are collapsed.
- All other lines using the expanded protocol automatically expand as they appear.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify the frame time stamp

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify the frame time stamp**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Options**.
5. In the Display Options dialog box, specify one of the available time options, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- The time setting appears under **Time** in the Frame Viewer window Summary pane.
- The **Seconds From Previous Frame** option provides very useful data for troubleshooting performance issues, because it helps you pinpoint gaps in time that can occur in a network transaction.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use a Display Filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use a display filter**

- Design a display filter
- Load a display filter
- Modify the display filter decision tree structure
- Specify address pairs in a display filter
- Specify display filter protocol properties
- Specify display filter protocols
- Save a display filter

# Design a display filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To design a display filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Filter**.
5. In the Display Filter dialog box, do the following:
   - Specify display filter protocols.
   - Specify display filter protocol properties.
   - Specify address pairs in a display filter.
6. If needed, you can Modify the display filter decision tree structure.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- A Network Monitor display filter functions like a database query. You can use it to specify the types of captured data you want to examine. You also can use display filters to specify the types of displayed data, such as protocols and computer addresses, that you want to save to a file.
- You can add only one expression at a time. If you specify an expression and then click another tab in the Expression dialog box, that expression is lost. To save the specified expression and add it to the decision tree, you must click **OK**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Load a display filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To load a display filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Filter**.
5. Click **Load**.
6. Specify the display filter file (.df), and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- The new display filter decision tree appears in the Display Filter dialog box.
- If you load a display filter, you will overwrite any unsaved changes to the current display filter.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify the display filter decision tree structure

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify the display filter decision tree structure**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Filter**.
5. To add a logical operator to the decision tree in the Display Filter dialog box, click the line below the row where you want to add the operator. Then:
   - To find frames that satisfy all expressions in the branch, click **AND**.
   - To find frames that satisfy one or more of the expressions in the branch, click **OR**.
   - To exclude frames that satisfy the expressions in the branch, click **NOT**.
6. To change a logical operator, click it and then click **Change Operator** until the operator you want appears.
7. To modify an expression, click it and then click **Edit Expression**.
8. To add an expression to a branch, click the line beneath the row where you want to insert the new expression. Then, in the **Add** group, click **Expression**. You can:
   - Specify display filter protocols.
   - Specify display filter protocol properties.
   - Specify address pairs in a display filter.
9. To delete a single expression or logical operator, click the line, and then click **Line** in the **Delete** group.
10. To delete a branch, click the top branch that you want to delete, click **Branch** in the **Delete** group, and click **Yes** to confirm that you want to delete the branch and all the branches underneath it.
11. To clear the decision tree and start over, click **All** in the **Delete** group. Click **Yes** to confirm that you want to start over and clear the decision tree contents.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have

been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.

- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.

- When you add an operator, a new decision tree branch appears.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify address pairs in a display filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify address pairs in a display filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **Display** menu, click **Filter**.
5. In the **Add** group box, click **Expression**.
6. Click the Expression dialog box: Address tab, specify the address pair, and click **OK**.
7. To make the address pair one of many display criteria, click it and then click **OR**.
8. To exclude the address pair from the display, click it and then click **NOT**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. # Print Network Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Print network data**

- Print captured frames
- Print all data in a capture file
- Set the print filter

# Print captured frames

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print captured frames**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **File** menu, click **Print**.
5. In the Print dialog box: Netmon tab, specify the print options, and then click **Print**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.
- When you print frames, columns that do not fit on the page horizontally are truncated. To avoid losing important information, resize the columns before printing so they display only essential information. On the **Layout** tab, select **Landscape**. If you resize a column to its smallest possible size, it does not print at all.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Print all data in a capture file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print all data in a capture file**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Display Captured Data** when you are done capturing frames.
4. On the **File** menu, click **Print**.
5. In the Print dialog box: Netmon tab, click **All** as the print range.
6. Click the **Netmon** tab.
7. Clear the **Apply Display Filter** check box, and then click **Print**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Set the print filter

# Set the print filter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the print filter**

1. Open Network Monitor.
2. If prompted, select the local network from which you want to capture data by default.
3. Do one of the following:
   - On the **File** menu, click **Open**, and then double-click a saved capture file to open it.
   - On the **Capture** menu, click **Start**, and then click **Stop and View** when you are done capturing frames.
4. On the **File** menu, click **Print**.
5. In the Print dialog box: Netmon tab, click the **Netmon** tab.
6. Select the **Apply Display Filter** check box.
7. Click **Edit Filter**.
8. In the Edit Display Filter dialog box, edit the filter, and then click **OK**.
9. To print the filtered frames, click **Print**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To start Network Monitor, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and double-click **Network Monitor**.
- Network Monitor runs with reduced access in which administrative privileges have been removed. If you receive an Access Denied message when you follow this procedure, add your user name to the permissions list of the file or folder that you want to access. See Related Topics for more information about setting permissions on files and folders.

# Network Monitor overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network Monitor overview**

By using Network Monitor, you can gather information that helps you keep your network running smoothly, from identifying patterns to preventing or solving problems. Network Monitor provides information about the network traffic that flows to and from the network adapter of the computer on which it is installed. By capturing and analyzing that information, you can prevent, diagnose, and solve many types of network problems. For more information about troubleshooting networks, see Network Monitor Resources.

You can configure Network Monitor to provide specific types of information that are most relevant to you. For example, you can set up triggers so that Network Monitor starts or stops capturing information when a circumstance or set of circumstances arises. You can also set up filters to control what types of information Network Monitor captures or displays. To make analyzing the information easier, you can modify how information appears on the screen, and you can save or print the information for review at a later time. For more information about customizing Network Monitor, see Capturing Data and Filtering data.

The Network Monitor component that ships with Microsoft® Windows Server 2003 family operating systems can capture frames that are sent to or from the computer on which Network Monitor is installed. If you want to capture frames that are sent to or from a remote computer, you must use the Network Monitor component that ships with Microsoft Systems Management Server, which can capture frames sent to or from any computer on which the Network Monitor driver is installed. For more information on Systems Management Server, go to the Microsoft Web site.

The information that Network Monitor provides comes from the network traffic itself, which is divided into frames. These frames contain information such as the address of the computer that sent the frame, the address of the computer to which the frame was sent, and the protocols that exist within the frame. For more information about frames, see How Network Monitor works.

- Frame Viewer Window

# How Network Monitor works

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How Network Monitor works**

Data sent over a network is divided into frames. Each frame contains the following information:

- **Source address** The address of the network adapter from which the frame originated.
- **Destination address** The address of the network adapter that is meant to receive the frame. This address can also specify a group of network adapters.
- **Header information** Information specific to each protocol used to send the frame.
- **Data** The information (or a portion of it) being sent.

Every computer on a network segment receives frames transmitted on that segment. The network adapter in each computer retains and processes only those frames that are addressed to that adapter. The rest of the frames are dropped and no longer processed. The network adapter also retains broadcast (and potentially multicast) frames.

After installing Network Monitor, users can capture to a file all the frames sent to, or retained by, the network adapter of the computer on which it is installed. These captured frames can then be viewed or saved for later analysis. Users can design a capture filter so that only certain frames are captured. This filter can be configured to capture frames based on criteria such as source address, destination address, or protocol. Network Monitor also makes it possible for a user to design a capture trigger to initiate a specified action when Network Monitor detects a particular set of conditions on the network. This action can include starting a capture, ending a capture, or starting a program.

By default, the size of the capture buffer is 1 MB. You can reduce the amount of data you capture by shrinking the capture buffer.

# Capturing Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capturing data**
This section covers:

- The capture process
- Capture filters
- Capture triggers

# The capture process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The capture process**

The process by which Network Monitor copies frames is referred to as capturing. You can capture all network traffic to and from the local network adapter, or you can set a capture filter and capture a subset of frames. You can also specify a set of conditions that trigger an event. If you create triggers, Network Monitor can respond to events on your network. For example, you can make the operating system start an executable file when Network Monitor detects a particular set of conditions on the network. After you have captured data, you can view it. Network Monitor translates the raw capture data into its logical frame structure.

While Network Monitor captures frames from the network, statistics about the frames appear in the Capture window, which has four panes:

| Pane | Displays |
|---|---|
| Capture window: Graph pane | A graphical representation of frames sent to or from the local computer. |
| Capture window: Session Statistics pane | Statistics about current individual sessions. |
| Capture window: Station Statistics pane | Statistics about frames sent to or from the computer running Network Monitor. |
| Capture window: Total Statistics pane | Summary statistics about frames sent to or from the local computer since the capture process began. |

Network Monitor uses the Network Driver Interface Specification (NDIS) facility to copy all frames it detects to its capture buffer.

For detailed instructions on capturing network data, see Capture network frames.

# Capture filters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture filters**
A capture filter functions like a database query that you can use to specify the types of network information you want to monitor. For example, to see only a specific subset of computers or protocols, you can create an address database, use the database to add addresses to your filter, and then save the filter to a file. By filtering frames, you save both buffer resources and time. Later, if necessary, you can load the capture filter file and use the filter again.

**Designing a capture filter**
To design a capture filter, specify decision statements in the **Capture Filter** dialog box. This dialog box displays the filter's decision tree, which is a graphical representation of a filter's logic. When you include or exclude information from your capture specifications, the decision tree reflects these specifications.

**Filtering by protocol**
To capture frames sent using a specific protocol, specify the protocol on the **SAP/ETYPE=** line of the capture filter. For example, to capture only IP frames, disable all protocols and then enable **IP ETYPE 0x800** and **IP SAP 0x6**. By default, all of the protocols that Network Monitor supports are enabled. You can only specify protocols with ETYPE or SAP.

**Filtering by address**
To capture frames sent from a specific computer on your network to your computer or sent from your computer to a specific computer on your network, specify one or more address pairs in a capture filter. You can monitor up to four address pairs simultaneously.

An address pair consists of:

- The addresses of the two computers you want to monitor traffic between.
- Arrows that specify the traffic direction you want to monitor.
- The INCLUDE or EXCLUDE keyword, indicating how Network Monitor should respond to a frame that meets a filter's specifications.

Regardless of the sequence in which statements appear in the **Capture Filter** dialog box, EXCLUDE statements are evaluated first. Therefore, if a frame meets the criteria specified in an EXCLUDE statement in a filter containing both an EXCLUDE and INCLUDE statement, that frame is discarded. Network Monitor does not test that frame by INCLUDE statements to see if it meets that criterion also.

For example, to capture all the traffic from Joe's computer *except* the traffic from Joe to Anne, use the following capture filter address section:

**Addresses**

**include Joe <----> Any**

**exclude Joe <----> Anne**

If there are no INCLUDE lines, *YourComputer* <----> Any is used implicitly.

**Filtering by data pattern**
By specifying a pattern match in a capture filter, you can:

- Limit a capture to only those frames containing a specific pattern of ASCII or hexadecimal data.
- Specify how many bytes (offsets) of the frame must be ignored before the search begins.

When you filter based on a pattern match, you must specify where, in the frame, the search for the pattern should begin. This setting specifies, in bytes, the distance from the beginning of the frame or the end of the topology header to the point at which the pattern might occur. If your network medium has a variable size in the media access control protocol, such as Ethernet or

token ring, specify to count from the end of the topology header.

# Capture triggers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture triggers**
If you create capture triggers, Network Monitor can respond to events on your network. By default, no trigger is set.

**Types of triggers**
Network Monitor can detect how full your capture buffer is, and whether a specific pattern appears in a captured frame. You can create capture triggers that depend on either or both of these criteria.

If you specify a trigger that depends on a specific pattern appearing in a captured frame, Network Monitor performs the action you specify when it detects a frame that contains the pattern you specify. The pattern can be an ASCII string or a hexadecimal string. You can also specify a trigger which depends on a specific pattern appearing in a captured frame and a certain percentage of the capture buffer being filled. You can also specify whether Network Monitor should start its search at the beginning of each frame, after the end of the header of each frame, or some number of bytes after either of these locations. By default, Network Monitor searches the entire frame for the pattern.

**Trigger actions**
You can choose one of the following actions to occur when the trigger criteria are met:

- The computer beeps.
- Network Monitor stops capturing frames.
- A command that you specify runs.

  To specify a command that starts a program, type the path and the name of the program file, or click **Browse** and navigate to the program file. To use an MS-DOS command, such as **copy**, type **CMD /K**, and then type the command.

# Displaying Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Displaying data**
This section covers:

- The Frame Viewer window
- Filtering data
- Protocol parsers included with Network Monitor

# The Frame Viewer window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The Frame Viewer window**

Network Monitor simplifies data analysis by interpreting raw data collected during the capture and displaying it in the Frame Viewer window.

The Frame Viewer window includes the following panes:

| Pane | Displays |
|---|---|
| Frame Viewer window: Summary pane | General information about the captured frames in the order that they were captured in. |
| Frame Viewer window: Detail pane | The contents of the frame, including the protocols that were used to send it. |
| Frame Viewer window: Hexadecimal pane | Hexadecimal and ASCII representations of the captured data. |

# Filtering data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Filtering data**
Like a capture filter, a display filter helps you to isolate specific types of information. Unlike a capture filter, however, a display filter operates on data that has already been captured. You can use a display filter to configure how much captured data appears in the Frame Viewer Window, or you can use it to save data to a capture file.

Use display filters to determine which frame to display. You can filter a frame by:

- Its source or destination address.
- The protocols it contains.
- The properties and values that it contains. The properties of a protocol collectively indicate the purpose of the protocol.

The structure of the display-filter decision tree is flexible. You can define a simple, rather flat structure, or you can make it complex, as your needs dictate.

**Protocols Used**
When you display captured data, all available information about the captured frames appears in the Frame Viewer window. You can display only the frames which contain a specific protocol by editing the **Protocol ==** line in the Display Filter dialog box.

Network Monitor processes the filter you have designed and applies it to the contents of the Frame Viewer window.

**Protocol Properties**
You can use a display filter to isolate frames that contain specific protocol properties. Protocol properties consist of the elements of information that define the purpose of a protocol. Because the purposes of protocols vary, properties differ from one protocol to another.

As an example, you might capture a large number of frames with SMB protocol but want to examine only those frames in which the SMB protocol was used to create a directory on a remote computer. In this situation, you could isolate frames that include the **Make Directory** SMB command property.

Network Monitor identifies the protocols used to send a frame on the network by using a protocol parser. Each protocol that Network Monitor supports has a corresponding parser.

**Computer Addresses**
When you display captured data, by default all addresses that you capture information from appear in the Frame Viewer window. You can display only those frames that originate or are sent to a specific computer by editing the **ANY <--> ANY** line in the **Edit Display Filter** dialog box.

**Filtering and address databases**
Often, you need to capture only those frames that originate with or are sent to specific computers. To do this, you must know the addresses of the computers on your network.

You can use the **ping** command to find the IP address of a computer if you know its computer name. For more information, see the section "Testing connections by using ping" in Command-line utilities.

# Protocol parsers included with Network Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protocol parsers included with Network Monitor**

Each protocol that Network Monitor supports has a corresponding parser. The following is a list of the protocols whose parsers are included with Network Monitor.

| Protocol | Description |
|---|---|
| AARP | AppleTalk Address Resolution Protocol (Atalk.dll) |
| ADSP | AppleTalk Data Stream Protocol (Atalk.dll) |
| AFP | AppleTalk File Protocol (Atalk.dll) |
| AH | IP Authentication Header (Tcpip.dll) |
| ARP_RARP | Internet Address Resolution Protocol/Reverse Address Resolution Protocol (Tcpip.dll) |
| ASP | AppleTalk Session Protocol (Atalk.dll) |
| ATMARP | ATM Address Resolution Protocol (Atmarp.dll) |
| ATP | AppleTalk Transaction Protocol (Atalk.dll) |
| BONE | Bloodhound-Oriented Network Entity Protocol (Bone.dll) |
| BOOKMARK | Network Monitor BOOKMARK Protocol (Trail.dll) |
| BPDU | Bridge Protocol Data Unit (Llc.dll) |
| BROWSER | Microsoft Browser (Browser.dll) |
| CBCP | Callback Control Protocol (Ppp.dll) |
| CCP | Compression Control Protocol (Ppp.dll) |
| COMMENT | Network Monitor COMMENT Protocol (Trail.dll) |
| DDP | AppleTalk Datagram Delivery Protocol (Atalk.dll) |
| DHCP | Dynamic Host Configuration Protocol (Tcpip.dll) |
| DNS | Domain Name System (Tcpip.dll) |
| EAP | PPP Extensible Authentication Protocol (Ppp.dll) |
| ESP | IP Encapsulating Security Payload (Tcpip.dll) |
| ETHERNET | Ethernet 802.3 topology (Mac.dll) |
| FDDI | FDDI topology (Mac.dll) |
| FINGER | Internet Finger protocol (Tcpip.dll) |
| FRAME | Base frame properties (Frame.dll) |
| FTP | File Transfer Protocol (Tcpip.dll) |
| GENERIC | Network Monitor GENERIC Protocol (Trail.dll) |

| | |
|---|---|
| GRE | Generic Routing Encapsulation Protocol (Ppp.dll) |
| ICMP | Internet Control Message Protocol (Tcpip.dll) |
| IGMP | Internet Group Management Protocol (Tcpip.dll) |
| IP | Internet Protocol (Tcpip.dll) |
| IPCP | Internet Protocol Control Protocol (Ppp.dll) |
| IPX | NetWare Internetwork Packet eXchange protocol (Ipx.dll) |
| IPXCP | NetWare Internetwork Packet eXchange Control Protocol (Ppp.dll) |
| IPXWAN | NetWare Internetwork Packet eXchange Protocol for Wide Area Networks (Ppp.dll) |
| ISAKMP | Internet Security Association and Key Management Protocol (Ppp.dll) |
| L2TP | Level 2 Tunneling Protocol (L2tp.dll) |
| LAP | AppleTalk Link Access Protocol (Atalk.dll) |
| LCP | Link Control Protocol (Ppp.dll) |
| LLC | Logical Link Control 802.2 Protocol (LLC.dll) |
| LPR | BSD Printer (Ppp.dll) |
| MESSAGE | Network Monitor MESSAGE Protocol (Trail.dll) |
| MSRPC | Microsoft Remote Procedure Call Protocol (Msrpc.dll) |
| NBFCP | NetBIOS Frames Control Protocol (Ppp.dll) |
| NBIPX | NetBIOS on IPX (Ipx.dll) |
| NBP | AppleTalk Name Binding Protocol (Atalk.dll) |
| NBT | Internet NetBIOS Over TCP/IP (Tcpip.dll) |
| NCP | NetWare Core Protocol (Ncp.dll) |
| NDR | NetWare Diagnostic Redirector (Ipx.dll) |
| NETBIOS | Network Basic Input/Output System Protocol (Netbios.dll) |
| NETLOGON | Microsoft Netlogon Broadcasts (Netlogon.dll) |
| NFS | Network File System (Tcpip.dll) |
| NMPI | Microsoft Name Management Protocol on IPX (Ipx.dll) |
| NSP | NetWare Serialization Protocol (Ipx.dll) |
| NWDP | NetWare WatchDog Protocol (Ipx.dll) |
| ODBC | Network Monitor ODBC Protocol (Trail.dll) |
| OSPF | Open Shortest Path First (Tcpip.dll) |
| PAP | AppleTalk Printer Access Protocol (Atalk.dll) |
| PPP | Point-to-Point Protocol (Ppp.dll) |
| PPPCHAP | PPP Challenge Handshake Authentication Protocol (Ppp.dll) |

| | |
|---|---|
| PPPML | Point-to-Point Multilink Protocol (Ppp.dll) |
| PPPPAP | PPP Password Authentication Protocol (Ppp.dll) |
| PPTP | Point-to-Point Tunneling Protocol (Ppp.dll) |
| R_LOGON | Generated RPC for interface logon (Logon.dll) |
| R_LSARPC | Generated RPC for Interface Lsarpc (Lsarpc.dll) |
| R_WINSPOOL | Generated RPC for Interface Winspool (Winspl.dll) |
| RADIUS | Remote Authentication Dial-In User Service Protocol (Ppp.dll) |
| RIP | Internet Routing Information Protocol (Tcpip.dll) |
| RIPX | NetWare Routing Information Protocol (Ipx.dll) |
| RPC | Remote Procedure Call (Tcpip.dll) |
| RPL | Remote Program Load (Llc.dll) |
| RSVP | Resource Reservation Protocol (Rsvp.dll) |
| RTMP | AppleTalk Routing Table Maintenance Protocol (Atalk.dll) |
| SAP | NetWare Service Advertising Protocol (Ipx.dll) |
| SMB | Server Message Block Protocol (Smb.dll) |
| SMT | FDDI MAC Station Management (Mac.dll) |
| SNAP | Sub-Network Access Protocol (Llc.dll) |
| SNMP | Simple Network Management Protocol (Snmp.dll) |
| SPX | NetWare Sequenced Packet eXchange Protocol (Ipx.dll) |
| SSP | Security Support Provider Protocol (Msrpc.dll) |
| STATS | Network Monitor Capture Statistics Protocol (Trail.dll) |
| TCP | Transmission Control Protocol (Tcpip.dll) |
| TMAC | Token Ring MAC layer (Mac.dll) |
| TOKENRING | Token Ring 802.5 Topology (Mac.dll) |
| TPCTL | Test Protocol Control Language (Tpctl.dll) |
| TRAIL | Network Monitor TRAIL Protocol (Trail.dll) |
| UDP | User Datagram Protocol (Tcpip.dll) |
| VINES_FRAG | Banyan Vines Fragmentation Protocol (Vines.dll) |
| VINES_IP | Banyan Vines Internet Protocol (Vines.dll) |
| VINES_TL | Banyan Vines Transport Layer Protocols (Vines.dll) |
| XNS | Xerox Network System (Xns.dll) |
| ZIP | AppleTalk Zone Information Protocol (Atalk.dll) |

**Note**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows

Server 2003 family.

# Managing Network Monitor from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Network Monitor from the command line**

By using the **start netmon** command, you can start the Network Monitor user interface from the command line. You can also specify parameters for capturing and filtering frames from network traffic going to and coming from the computer on which you have Network Monitor installed.

**Syntax**

**start netmon** [**/net** *Number*] [**/capturefilter** *Path*] [**/displayfilter** *Path*] [**/buffersize** *Number*] [**/quickfilter** {**ATM** | **ETHERNET** | **IP** | **IPX** | **VINES** | **TOKENRING** | **FDDI**}**,** *Address*] [**/quickfiltername** *FilterName*] [**/autostart**] [**/autostop**]

**Parameters**

**/net *Number***

Specifies the number of the network from which you want to capture frames. You can specify any of the network segments to which your computer is connected.

**/capturefilter *Path***

Specifies a capture filter to be used when Network Monitor starts. You can abbreviate **/capturefilter** as **/cf**.

**/displayfilter *Path***

Specifies a display filter to be used when Network Monitor starts. You can abbreviate **/displayfilter** as **/df**.

**/buffersize: *Number***

Specifies the size (in megabytes) of the capture buffer.

**/quickfilter{ ATM| ETHERNET| IP| IPX| VINES| TOKENRING| FDDI} , *Address***

Specifies that Network Monitor should capture frames only of a particular type and from a particular address. You can specify up to three types at a time. You can abbreviate **/quickfilter** as **/qf**. The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

**/quickfiltername *FilterName***

Specifies the name of the filter that you describe with the **/quickfilter** command. This parameter is ignored if you do not specify any **/quickfilter** options. You can abbreviate **/quickfiltername** as **/qfn**.

**/autostart**

Specifies that Network Monitor should begin to capture data at interface startup.

**/autostop**

Specifies that Network Monitor should stop capturing data when the capture buffer is full.

**/?**

Displays help at the command prompt.

**Remarks**

- Network Monitor is not installed by default. To use this command, you must have installed Network Monitor on your computer, and you must run the command from the directory where Network Monitor is installed.

**Examples**

To set the size of your capture buffer to 4 megabytes, type:

**start netmon /buffersize:4**

To load a specific capture filter when you start Network Monitor, type:

**start netmon /capturefilter d:\captures\http.cf**

**Formatting legend**

| Format | Meaning |
|---|---|

| | |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture window: Graph pane**

The Graph pane graphically represents the total capture statistics of the current capture data. This pane appears in the upper-left corner of the Capture Window, and it is on by default.

**% Network Utilization**

The percentage of your network adapter's capacity that the current capture uses. This percentage is calculated by dividing the rate at which your adapter is sending and receiving frames by the maximum rate at which your adapter can process those frames.

**Frames Per Second**

The number of frames that the adapter is capturing every second.

**Bytes Per Second**

The number of bytes that the adapter is capturing every second.

**Broadcasts Per Second**

The number of broadcasts that the adapter is capturing every second.

**Multicasts Per Second**

The number of multicasts that the adapter is capturing every second.

Capture Window

How Network Monitor works

# Capture window: Session Statistics pane

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture window: Session Statistics pane**
A session designates the data that is sent to or from the local computer. The Session Statistics pane displays statistics on a per-session basis. The pane also identifies both participants in a session and displays how much information passed in either direction between them.

This pane appears in the left-center portion of the Capture Window, and it is on by default.

**Network Address 1**
The network address of the first participant in a network session.

**1 --> 2**
The number of frames sent from the address listed in the **Network Address 1** column to the address listed in the **Network Address 2** column.

**1 <-- 2**
The number of frames sent from the address listed in the **Network Address 2** column to the address listed in the **Network Address 1** column.

**Network Address 2**
The network address of the second participant in a network session.

**Note**

- Network Monitor reflects session statistics of only the first 100 unique addresses that it detects. To gather statistics on a specific workstation, design a capture filter. To reset statistics and view information about the next 100 detected network sessions, click the **Capture** menu, and then click **Clear Statistics**.

# Capture window: Station Statistics pane

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture window: Station Statistics pane**

The Station Statistics pane displays statistics that describe the network activity of your workstation. This pane appears at the bottom of the Capture Window, and it is on by default.

**Network Address**

The network address of the computer on which the frames were captured.

**Frames Sent**

The number of frames sent from the address listed in the **Network Address** column.

**Frames Rcvd**

The number of frames received by the address listed in the **Network Address** column.

**Bytes Sent**

The number of bytes sent by the address listed in the **Network Address** column.

**Bytes Rcvd**

The number of bytes received by the address listed in the **Network Address** column.

**Directed Frames Sent**

The number of non-broadcast, non-multicast frames transferred over the network from the associated address.

**Multicasts Sent**

The number of times the address listed in the **Network Address** column has sent frames to a subset of computers on the network, by sending "FFFFFFFFFFFF."

**Broadcasts Sent**

The number of times that the address listed in the **Network Address** column has sent frames to all computers on the network.

**Note**

- Network Monitor reflects station statistics of only the first 128 unique addresses that it detects. To gather statistics on a specific workstation, design a capture filter.

Capture filters

# Capture window: Total Statistics pane

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture window: Total Statistics pane**

The Total Statistics pane provides an overall view of network traffic sent to or from the local computer. This pane appears in the upper-right corner of the Capture Window, and it is on by default.

**Network Statistics**

The total amount of traffic that has been sent to or from the local computer since the current capture began. These statistics include:

- The total number of frames sent to or from the local computer.
- The total number of broadcasts sent to or from the local computer.
- The total number of multicasts sent to or from the local computer.
- The total number of bytes sent to or from the local computer.
- The total number of frames dropped.
- The network status. On an Ethernet network, this entry will always be **Normal**. On a token ring network, this entry reflects whether the token is present locally.

**Captured Statistics**

Total statistics that describe the current capture, including:

- The total number of captured frames.
- The total number of frames in the temporary capture file.
- The number of frames dropped when the buffer was exceeded.
- The total number of captured bytes.
- The total number of bytes in the temporary capture file.
- The percentage of allotted buffer space that is in use.
- The number of frames dropped by Network Monitor.

**Per Second Statistics**

Statistical averages of current activity and continual updates of this average to reflect current per-second activity. The statistics in this panel include all frames (even frames that were excluded by a capture filter). Per-second statistics include:

- The average number of frames per second detected since the capture began.
- The average number of bytes per second detected since the capture began.
- The average number of broadcast messages per second detected since the capture began.
- The average number of multicast messages per second detected since the capture began.
- The percentage of network utilization. This statistic shows the percentage of your network adapter's capacity that the

current capture uses. This percentage is calculated by dividing the rate at which your adapter is sending and receiving frames by the maximum rate at which your adapter can process those frames.

**Network Card (MAC) Statistics**

Statistics that reflect average activity detected by your network adapter since the current capture began. The statistics in this pane reflect all the network activity that your network adapter can receive. These statistics include:

- Total frames detected by the network adapter.
- Total broadcast frames detected by the network adapter.
- Total multicast frames detected by the network adapter.
- Total bytes detected by the network adapter.

**Network Card (MAC) Error Statistics**

Statistics that reflect adapter-related errors that have occurred since the capture began. These statistics include:

- Number of errors that occurred because the cyclical redundancy check (CRC) did not match the actual bytes received.
- Number of frames that the network adapter detected but that were dropped because Network Monitor lacked sufficient buffer space.
- Number of frames that the network adapter detected but that were dropped because of hardware constraints.

**Note**

- Not all network adapters support these statistics. If your network adapter does not support a statistic, the value is replaced with **Unsupported**.

# Capture Window Dialog Boxes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dialog boxes**
This section covers:

- Address Database dialog box
- Address Expression dialog box
- Address Information dialog box
- Capture Buffer Settings dialog box
- Capture Filter dialog box
- Capture Filter SAPs and ETYPEs dialog box
- Capture Trigger dialog box
- Dedicated Mode dialog box
- Open File dialog box
- Pattern Match dialog box
- Print dialog box: Netmon tab
- Protocol Parsers dialog box
- Select a Network dialog box

# Address Database dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Address Database dialog box**

Use this dialog box to add, delete, or edit address database information. You can also use this dialog box to save the current address database or load a different one.

**Name**

The user-defined name of the computer.

**Address**

The 4-byte (IPv4) or 16-byte (IPv6) address of the network adapter.

**Type**

The network adapter address type (MAC or IP, for example).

**Comment**

Comments or additional address information.

**Vendor**

Name of the vendor that created the network adapter.

**Add**

Click to open the Address Information dialog box, which you can use to add a new computer address to the address database.

**Edit**

Click to open the Address Information dialog box, which you can use to change the currently selected computer address.

**Delete**

Click to remove the currently selected computer address from the address database.

**Load**

Click to open the **Open Address file** dialog box, which you can use to load a different address database instead of the one currently displayed.

**Save**

Click to open the **Save Addresses as** dialog box, which you can use to save the currently displayed address database to a file. Unless you save any changes that you made, you lose them when you load a new address database or close Network Monitor.

**See Also**

**Concepts**

Create an address database

How Network Monitor works

# Address Expression dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Address Expression dialog box**

Use this dialog box to create a new address expression that is added to the **Address Pairs** section of the current capture filter.

**Include**

Includes capture data that travels between the members of the current address pair. By default, this option is selected.

**Exclude**

Excludes capture data that travels between the members of the address pair.

**Station 1**

The list of first addresses in the address pair. Depending on the arrow that you select in **Direction**, **Station 1** can be the originating or the destination address.

**Direction**

Specify an arrow that indicates the direction of the traffic between the two addresses.

**<-->**

Click to specify frames that travel in either direction between the computers that you specified in **Station 1** and **Station 2**. By default, this arrow is selected.

**-->**

Click to specify frames that travel from **Station 1** to **Station 2**.

**<--**

Click to specify frames that travel from **Station 2** to **Station 1**.

**Station 2**

The list of second addresses in the address pair. Depending on the arrow that you select in **Direction**, **Station 2** can be the originating or the destination address.

**Edit Addresses**

Click to open the Address Database dialog box, which you can use to modify the current address database.

**Note**

- When you specify **Direction**, you cannot construct a statement in which the source address is either Broadcast or Multicast because Broadcast and Multicast are always destination addresses.

**See Also**

**Concepts**

Specify address pairs in a capture filter

Address Database dialog box

# Address Information dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Address Information dialog box**

Use this dialog box to edit individual address entries or add a new entry.

**Name**

The friendly name (computer name, for example) for the **Address**.

**Permanent Name**

Uses the text in the **Name** text box as the friendly name of the computer in the local address database (.adr). By default, this check box is cleared.

**Address**

The address that identifies the computer to the network.

**Type**

The address type that associates with **Address**. By default, the detected address type appears in this list.

For example, suppose that the network associates a name with an Ethernet address and you want to associate the name with an IP address. You select **IP** and then type the IP address in the **Address** text box. Associating a name with a new address type removes its association with the previous address type.

**Comment**

Any additional information that you want to include in the address description. For example, you might enter the type of CPU or network adapter or mention some problem the computer has exhibited.

**See Also**

**Concepts**

How Network Monitor works

# Capture Buffer Settings dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture Buffer Settings dialog box**

Use this dialog box to adjust the size of the data frame and the total amount of frames you want to capture.

**Buffer Size (MB)**

The size of your capture buffer. By default, the buffer size is set to 1.0 MB.

**Frame Size (bytes)**

The number of bytes that you want Network Monitor to capture from each frame. By default, the frame size is **Full** (65,535).

The drop-down list contains numbers in increments of 64, up to 65,472. You can select one of these numbers, or you can type a specific number between 32 and 65,535, inclusive.

# Capture Filter dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture Filter dialog box**
This dialog box displays the capture filter decision tree and helps you to specify the frames that you want to capture. You can also load filters that were previously designed and saved to a file. By doing this, you avoid creating filters every time you want to capture filtered data.

You can use the following controls to make changes to the decision tree.

- **SAP/ETYPE =**

  Double-click this line to specify protocols that you want to capture in frames.

- **AND (Address Pairs)**

  Double-click this line to filter on computer address pairs.

  You can specify as many as three address pairs.

- **AND (Pattern Matches)**

  Double-click this line to capture only frames that contain a specified pattern at a specified offset.

  You can specify as many as four pattern matches.

- **Add**

  Use the buttons in this group box to add criteria to the capture filter.

  - **Address**

    Click to open the Address Expression dialog box, which you can use to specify the address pairs of the computers between which you want to capture data.

  - **Pattern**

    Click to open the Pattern Match dialog box, which you can use to capture only those frames containing a specific pattern of ASCII or hexadecimal data.

- **Insert**

  Use the buttons in this group box to add operators to the capture filter.

  - **OR**

    Click to add an OR branch to the capture filter decision tree. This option is available only for pattern matches.

  - **NOT**

    Click to add a NOT branch to the decision tree or to remove a branch of the tree. This option is available only for pattern matches.

- **Edit**

Click to edit the line that is currently selected in the capture filter.

- **Delete**

  Click to delete the line that is currently selected in the capture filter.

- **Load**

  Click to open the **Load Capture Filter** dialog box, which you can use to replace the current capture filter with one that has been saved to a file.

- **Save**

  Click to open the **Save Capture Filter** dialog box, which you can use to save the current capture filter as a file.

## Notes

- In the address portion of a capture filter, EXCLUDE statements take logical precedence over INCLUDE statements. Regardless of the sequence in which statements appear in the **Capture Filter** dialog box, Network Monitor evaluates EXCLUDE statements first. Therefore, in a filter containing both an EXCLUDE and an INCLUDE statement, if a frame meets the criteria specified in an EXCLUDE statement, Network Monitor discards the frame without testing it against the INCLUDE statement to see whether the frame also meets the criteria of the INCLUDE statement.

- When you close the capture filter, Network Monitor optimizes the logic you used in the **Pattern Matches** branch of the capture filter decision tree. Therefore, when you re-open the capture filter, it might look different from when you created it. For example, if you define multiple pattern match statements, Network Monitor automatically processes them with an implicit OR operator and removes any explicit OR operators between such statements.

How Network Monitor works

# Capture Filter SAPs and ETYPEs dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture Filter SAPs and ETYPEs dialog box**
Use this dialog box to specify the protocols that Network Monitor captures while your capture filter runs. The choices that you make in this dialog box are reflected in the line that begins with **SAP/ETYPE=** in the decision tree in the Capture Filter dialog box. Only protocols that use an SAP or an ETYPE can be filtered in the capture filter.

- **Enabled Protocols**

  The protocols that Network Monitor uses to capture frames from the network. By default, all protocols are enabled.

  Double-click any protocol in this box to move it to the **Disabled Protocols** table.

  - **Protocol**

    The names of all currently enabled protocols.

  - **Comment**

    A brief description of each enabled protocol.

  - **Type**

    The enabled protocol ETYPE or SAP.

  - **Values**

    Possible values of enabled protocols.

- **Disable**

  Click to move the protocols that you select in the **Enabled Protocols** table to the **Disabled Protocols** table.

- **Disable All**

  Click to disable all available protocols.

- **Enable**

  Click to move protocols that you selected in the **Disabled Protocols** table to the **Enabled Protocols** table.

- **Enable All**

  Click to enable all available protocols.

- **Disabled Protocols**

  The currently disabled protocols, which will not be used to capture network data.

  - **Protocol**

    The names of all currently disabled protocols.

- **Comment**

  A brief description of each disabled protocol.

- **Type**

  The disabled protocol type (ETYPE or SAP).

- **Values**

  Possible values of disabled protocols.

# Capture Trigger dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Capture Trigger dialog box**

Use this dialog box to specify the event that acts as a trigger and the action that results from the event.

- **Trigger On**

  Specify the conditions that induce the trigger action. By default, no trigger is set.

  - **Nothing**

    Turns off trigger actions during data capture.

  - **Pattern match**

    Engages the trigger when a specified hexadecimal or ASCII pattern match occurs.

  - **Buffer space**

    Engages the trigger when a capture fills a specific percentage of the capture buffer.

  - **Pattern match then buffer space**

    Requires Network Monitor to monitor the buffer space after the specific matched pattern occurs and to perform the trigger action when both specified conditions exist.

  - **Buffer space then pattern match**

    Requires Network Monitor to detect when a capture has filled a specified percentage of the capture buffer and then to perform the trigger action when both conditions exist.

- **Buffer Space**

  The percentage of capture buffer that is filled before the trigger action occurs. For example, if you want to trigger action to occur when the capture buffer is three-quarters full, select **75%**. The only accepted values are multiples of 25%.

- **Pattern**

  The pattern you select for the pattern match.

  - **Offset (Hex)**

    The number of hexadecimal bytes from the beginning of the frame to where Network Monitor begins looking for a pattern match. By default, the pattern triggers if the pattern occurs anywhere in the frame.

    The pattern offset can be measured from the beginning of the frame or from the end of the topology header.

  - **From Start of Frame**

    Starts the search for the pattern at the beginning of the frame.

  - **From End of Topology Header**

Starts the pattern search beyond the topology header.

- **Pattern**

  The pattern that you select to engage the trigger.

- **Hex**

  A hexadecimal pattern.

- **ASCII**

  An ASCII pattern.

- **Trigger Action**

  Specify the action that you want to occur when the trigger criteria (pattern match, buffer space, or both) are met.

  - **Audible Signal Only**

    The computer beeps when the trigger condition is met and the capture process continues without interruption. By default, this option is selected.

  - **Stop Capture**

    The capture process stops when the trigger condition is met.

  - **Execute Command Line**

    Runs a command or opens a file when the trigger specifications are met. You can use as many as 259 characters for the command line. Click **Browse** to specify a file you want to run.

### Note

- If you click the **Pattern match then buffer space** option and set **Buffer Space** to **100%**, Network Monitor will overwrite the frame that has the pattern match because it does not start counting the buffer space until after the pattern match is found.

How Network Monitor works

# Pattern Match dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Pattern Match dialog box**
Use this dialog box to specify that you want to capture only those frames that contain a specific pattern of hexadecimal or ASCII data. You can specify that the pattern can start at the beginning of the frame or that it must be a specified number of bytes (offset) away from the beginning of the frame or the end of the topology header. Specify the offset by using the following controls.

- **Pattern**

  The hexadecimal or ASCII data pattern that you want captured frames to match.

  - **Hex**

    The specified pattern is read in hexadecimal format. By default, this option is selected.

  - **ASCII**

    The specified pattern is read in ASCII format.

- **Offset (in hex)**

  The hexadecimal number that specifies where the search should begin. The way Network Monitor interprets this number depends upon whether you click the **From Start Of Frame** or the **From End Of Topology Header** option.

  - **From Start of Frame**

    The offset you specify is measured from the beginning of the frame. By default, this option is selected.

  - **From End of Topology Header**

    The offset you specify is measured from the end of the topology header.

**See Also**
**Concepts**
Specify frame data patterns to capture
Capture Filter dialog box
How Network Monitor works

# Print dialog box: Netmon tab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Print dialog box: Netmon tab**
Use this tab to specify printing options specific to your Network Monitor capture file.

- **Output Detail**

  Specify the amount of detailed information that you want to print for each frame.

  - **Print Frame Summary Lines**

    Prints information that appears in the Frame Viewer window Summary pane. By default, this check box is selected.

    **Print Protocol Details**

    Prints information that appears in the Frame Viewer window Details pane. By default, this check box is selected.

| | |
|---|---|
| **Indent Levels** | Indents each successive protocol level when frames are printed. By default, this check box is selected. |
| **Indent Spaces per Level** | The number of spaces that you want to indent each level of detail. By default, this value is set to 0. |
| **Print Same as View** | The printed document reflects exactly the structure of the Frame Viewer window. |
| **Expand All Levels** | The printed document contains an expanded view of all of the protocols listed in the Frame Viewer window Detail pane. By default, this option is selected. |

  - **Print Hex Data**

    Prints the data that appears in the Hexadecimal pane of the Frame Viewer window. By default, this check box is selected.

| | |
|---|---|
| **Lines of Hex Data to Print** | The number of lines of hexadecimal data that you want to print. By default, this value is set to "All."<br><br>If you want to print all the data in a frame, set this option to "All." (This is useful if you are printing only a few frames.) |

- **Filtering**

  Specify whether to print only those frames that match the display filter, which is described in Filtering data.

  - **Apply Display Filter**

    Applies a display filter to the data that you want to print. By default, this check box is cleared.

  - **Edit Filter**

    Click to open the Display Filter dialog box, which you can use to edit the display filter before applying it to the data that you want to print.

- **Add Page Breaks**

  Adds page breaks to the printed material. By default, this check box is cleared.

On the **General** tab, the following options are specific to Network Monitor:

- **Print Range**

  Specify which frames that you want to print.

  Network Monitor preserves the original frame numbers. Saving the filtered frames to a capture (.cap) file causes the original frame numbering to be lost; in a capture file, frame numbers always begin with 1.

  - **All**

    All displayed frames. By default, this option is selected.

  - **Frame**

    A portion of the displayed frames. Specify the range of frames that you want to print in the **From** and **To** boxes.

**See Also**
**Concepts**
Print captured frames
Frame Viewer Window

# Protocol Parsers dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protocol Parsers dialog box**
Use this dialog box to enable or disable the parsers that read and interpret data sent to or from your computer with various protocols. When you disable a parser, Network Monitor does not attach the properties of the disabled parser to the captured data in the associated protocol. Any protocol that follows the disabled protocol in the frame will not be parsed.

- **Enabled Protocol Parsers**

  The names and descriptions of all currently enabled parsers. By default, all Network Monitor protocols are enabled.

  - **Name**

    The names of enabled protocols.

  - **Description**

    The descriptions of enabled protocols.

- **Disable**

  Click to move the protocol selected in the **Enabled Protocol Parsers** list to the **Disabled Protocol Parsers** list.

- **Disable All**

  Click to move all protocols to the **Disabled Protocol Parsers** list.

- **Enable**

  Click to move the protocol selected in the **Disabled Protocol Parsers** list to the **Enabled Protocol Parsers** list.

- **Enable All**

  Click to move all protocols to the **Enabled Protocol Parsers** list.

- **Disabled Protocol Parsers**

  All of the parsers that are loaded into the \Parsers subdirectory but that are not enabled. As long as a parser appears in this list, Network Monitor cannot interpret frames using the associated protocol.

  - **Name**

    The names of disabled protocols.

  - **Description**

    The descriptions of disabled protocols.

- **Save as Default**

  Saves the parsers that appear in the **Enabled Protocol Parsers** list as your default configuration.

  By default, this check box is cleared (Network Monitor enables all parsers in the \Parsers subdirectory).

**See Also**

# Select a Network dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Select a Network dialog box**
This dialog box displays information about the current network configuration. Use this dialog box to:

- Find information about your local configuration.
- Use a different network adapter on the local computer to capture network data.

**Local Computer**
A tree control that displays information about one or more network adapters on the local computer. Select the network adapter for which you want to display information.

**Properties**
This control describes the following information about the network adapter you selected:

- whether the network configuration supports delayed capture.
- whether the network configuration supports Expert Stats (ESP interface).
- whether the network configuration supports real time capture.
- whether the network configuration supports network statistics.
- the type of network connection (for example, a dial-up connection).
- the manufacturer name and model information for the network adapter.
- the MAC address of your network adapter. This is the address assigned by the manufacturer of the adapter.
- the current address of your network adapter. Unless the permanent address of the adapter has been overridden, this listing is identical to the MAC address.
- the Link speed, in bits per second (bps). This is the rate at which you can transfer bits over the network. This information is supplied by the manufacturer of the network adapter.
- the type of network (for example, Ethernet) to which the network adapter can connect. This information is supplied by the manufacturer of the network adapter.
- the maximum number of bytes per frame that the selected network adapter can handle. This information is supplied by the manufacturer of the network adapter.
- whether the network adapter supports promiscuous mode.

# Frame Viewer window: Summary pane

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Frame Viewer window: Summary pane**

The Frame Viewer Window, Summary pane, displays a list of the frames in the order in which they were captured.

**Frame**

The frame number, which is listed in the order that the frame was captured. Frame numbers begin with 1.

**Time**

The time that the frame was captured. The way that the capture time is expressed depends on the display options that you specify. The time is expressed as one of the following:

- The absolute system time that the frame was captured.
- The time that the frame was captured relative to the beginning of the capture. This value is expressed in microseconds.
- The time that the frame was captured relative to the capture completion time of the frame that precedes it. This value is specified in microseconds.

**Src MAC Addr**

The network address of the computer that sent the frame.

**Dst MAC Addr**

The network address of the computer that the frame was sent to.

**Protocol**

The primary protocol that was used to send the frame.

**Description**

A brief description of the contents of the frame.

**Src Other Addr**

The IP or IPX/XNS address associated with the address displayed in the **Src MAC Addr** column.

**Dst Other Addr**

The IP or IPX/XNS address associated with the address displayed in the **Dst MAC Addr** column.

**Type Other Addr**

The types of the addresses displayed in the **Src Other Addr** and **Dst Other Addr** columns.

**Note**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

# Frame Viewer window: Detail pane

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Frame Viewer window: Detail pane**

The Frame Viewer window Detail pane displays information about the frame that is currently selected in the Frame Viewer window: Summary pane. This information includes details about the selected frame and about the protocols that were used to send it.

You can expand or collapse the levels of detail that appear in this pane by double-clicking the lines that appear next to plus (+) or minus (-) signs.

**Frame**

The base properties of the selected frame. These properties include:

- The date and time that the frame was captured.
- The time (measured in milliseconds) that elapsed between the capture of the current frame and the capture of the frame that precedes it.
- The frame number in the sequence of total frames captured.
- The length of the frame (in bytes).
- The amount of the frame (in bytes) that was captured.
- The number of bytes in the frame not parsed by the base parser.

**Protocol**

The protocol section of the Detail pane consists of all information that appears below the end of the **Frame** section. The length of the section varies, depending on the number of protocols used to send the frame. Network Monitor displays the protocols from the lowest-level protocol to the highest-level protocol.

When you click a line in this pane, Network Monitor selects the raw representation of this line (which appears in the Hexadecimal pane) automatically.

# Frame Viewer window: Hexadecimal pane

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Frame Viewer window: Hexadecimal pane**
The Frame Viewer Window Hexadecimal pane consists of two sections.

- The hexadecimal section displays the contents of the frame in hexadecimal form.
- The ASCII section displays an alphabetical representation of the ASCII contents of the frame.

When you select a line in the Detail pane, the section of the frame that the line represents is selected automatically in both sections of the Hexadecimal pane.

# Frame Viewer Dialog Boxes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dialog boxes**
This section covers:

- Display Options dialog box
- Expression dialog box
- Expression dialog box: Address tab
- Expression dialog box: Protocol tab
- Expression dialog box: Property tab
- Font dialog box
- Go To dialog box
- Insert Comment Frame dialog box
- Label Window dialog box
- No Networks Found dialog box
- Protocol Colors dialog box
- Save dialog box
- Display Filter dialog box

# Display Options dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Display Options dialog box**
Use this dialog box to specify the time data and the protocols that you want to appear in the Frame Viewer window: Summary pane of the Frame Viewer window.

- **Time**

  Specify how you want the time to display in the **Time** column of the Summary pane.

  - **Time of day**

    Display the system time at which the frame was captured (for example, 10:35:48.358).

  - **Seconds from beginning of capture**

    Display the time (in microseconds) that elapsed between the beginning of the capture and the capture of the frame.

    By default, this option is selected.

  - **Seconds from previous frame**

    Display the time (in microseconds) that elapsed between the capture of a frame and the capture of the frame that precedes it.

- **Summary Protocol**

  Specify the protocol summary information that appears in the **Protocol** column of the Summary pane.

  - **Last protocol in frame**

    Display information about the final protocol that appears in the captured frame. By default, this option is selected.

  - **Auto (Based on protocols in display filter)**

    Display the protocol information that Network Monitor selects for you. The selection is based on the current display filter settings.

**See Also**
**Concepts**
Specify the frame time stamp
Specify the protocol header to display

# Expression dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Expression dialog box**
Use this dialog box to:

- Write or edit an expression in a display filter decision tree. For more information about display filters, see Filtering data.
- Search for a frame in the Frame Viewer Window with criteria that you provide.

The main categories that you can specify options for are represented by tabs.

- Expression dialog box: Address tab
- Expression dialog box: Protocol tab
- Expression dialog box: Property tab

**Note**

- Only one expression string at a time can be added to a display filter or be used as a search criterion.

**See Also**
**Concepts**
Specify address pairs in a display filter
Specify display filter protocols
Specify display filter protocol properties
Search for a frame by its properties

# Expression dialog box: Address tab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Expression dialog box: Address tab**

Use this tab to specify the address you want to find or to add or edit an address expression in a display filter decision tree. The **Station 1** and **Station 2** boxes display all of the addresses contained in the currently loaded address database. For each address, the friendly name, address, type of address (protocol), and associated comments are included.

**Expression**

The address expression that you want to locate or to add to a display filter decision tree. The display changes as you select items in other areas of the dialog box. When you click **OK**, the displayed expression is added to the display filter decision tree or used as the search criteria for frames. Any other changes you make are lost.

The **Expression** text box appears regardless of which tab you select. You cannot edit the expression directly.

**Station 1 (and Station 2)**

The computer addresses between which you want to monitor traffic or that you want to locate. If you do not specify the local computer as either Station 1 or Station 2, no data will appear when you apply the filter.

**Direction**

An arrow that indicates the traffic direction that you want to monitor or locate. For example, to identify traffic that travels from Computer 1 to Computer 2, select the Computer 1 name, the **-->** symbol, and then the Computer 2 name.

**Edit Addresses**

Click to open the Address Database dialog box, which you can use to edit the selected address.

Other tabs in this dialog box: Expression dialog box: Protocol tab, Expression dialog box: Property tab

**Note**

- You should specify BROADCAST, MULTICAST, and FUNCTIONAL only as destination addresses. If you construct a statement in which the source address is either broadcast or multicast, you filter out all frames. Broadcast and multicast are always destination addresses.

Display Filter dialog box

Open an existing capture file

# Expression dialog box: Protocol tab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Expression dialog box: Protocol tab**

Use this tab to specify the protocols that you want to find in the Frame Viewer window or to specify protocols in the display filter decision tree.

By default, all protocols are enabled, and the **Expression** box shows **Protocol == Any**. The protocols listed in this tab are those whose parsers are currently available to Network Monitor.

**Expression**

The address expression to search for in frames or to add to a display filter decision tree. As you select items in other areas of the dialog box, the display changes. When you click **OK**, the displayed expression is added to the display filter decision tree or is used as the frame search criterion. Any other changes you make are lost.

The **Expression** box appears regardless of which tab you select. You cannot edit the expression directly.

**Enabled Protocols**

The protocols to include in the display filter or to use to search for a frame.

**Disabled Protocols**

The protocols excluded from the display filter, which will not be used to search for a frame. If there are protocols in the frame in addition to the disabled protocols, then the frame will still be found. For example, if you disable the SMB protocol, SMB frames will be found if they contain enabled protocols.

**Disable**

Click to move selected protocols to the **Disabled Protocols** box.

**Enable**

Click to move the selected protocols to the **Enabled Protocols** box.

**Disable All**

Click to move all protocols to the **Disabled Protocols** box.

**Enable All**

Click to move all protocols to the **Enabled Protocols** box.

Other tabs in this dialog box: Expression dialog box: Address tab, Expression dialog box: Property tab

**Note**

- To exclude all frames that contain the SMB protocol, create a line that states **Protocol == SMB** and put a "**Not**" in front of it.

**See Also**

**Concepts**

Open an existing capture file

# Expression dialog box: Property tab

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Expression dialog box: Property tab**

Use this tab to specify which protocol properties you want to find or to add or edit a protocol property expression in the display filter decision tree.

**Expression**

The address expression that you want to locate or to add to a display filter decision tree. As you select items in other areas of the dialog box, the display changes. When you click **OK**, the displayed expression is added to the display filter decision tree or is used as the frame search criterion. Any other changes that you make are lost.

The **Expression** box appears regardless of which tab you have selected. You cannot edit the expression directly.

**Protocol:Property**

The names and properties of protocols available to Network Monitor. If a plus (+) sign appears next to a protocol name, you double-click the sign to expand the protocol and select a property.

**Relation**

A relational operator used to specify the connection between the protocol property and its possible values. The relational value can be one of the following:

**==**
Equal to

**<>**
Not equal to

**>**
Greater than

**<**
Less than

**>=**
Greater than or equal to

**<=**
Less than or equal to

**contains**
Contains (value)

**exists**
Exists (value)

**Value**

The possible values that the highlighted property is compared to.

When the **Hex** and the **Decimal** or **Ascii** options are visible, you can specify whether the number in the **Value** box is displayed in hexadecimal, decimal, or ASCII form.

Other tabs in this dialog box: Expression dialog box: Address tab, Expression dialog box: Protocol tab

# Font dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Font dialog box**

Use this dialog box to change the fonts used to display or print captured frame data.

**Font**

The fonts you can use to display or print captured frame data. You might prefer a monospace font such as Courier or Fixedsys rather than a proportional font such as MS Sans Serif. Depending on your printer configuration, some fonts might not be available for printing. By default, the font is Courier New.

**Font Style**

The font style, such as bold or italic, that you use to display or print captured frame data. By default, the font style is Regular.

**Size**

The type size that gives you the best combination of readability and quantity of data per screen. By default, the type size is 8 points. (Other ways to fit data onto the screen include maximizing the window and rearranging columns.)

**See Also**

**Concepts**

Set the frame data display font

Capture network frames

Network Monitor overview

# Go To dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Go To dialog box**
Use this dialog box to open a specific frame in the currently displayed capture file.

### Frame Number

The number of the frame that you want to highlight.

### Note

- The second field in the Frame Viewer window status bar lists the number of the frame that is currently highlighted, followed by a slash mark (**/**) and the total number of frames in the current capture file.

**See Also**
**Concepts**
View a specific frame
Display Filter dialog box
How Network Monitor works

# Insert Comment Frame dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Insert Comment Frame dialog box**

Use this dialog box to add a frame that contains comments and other information into a capture file. The comment frame contains the Trail protocol, which includes statistics such as the number of frames and bandwidth consumed. These statistics are calculated for a block of frames bounded by the current comment frame and the next comment frame of the same type (or by the end of the capture).

**Frame Number**

The frame position in the capture where Network Monitor inserts the comment frame. By default, the frame number is the current location. Network Monitor places the inserted frame in front of the frame number specified and increases the other frame numbers by one.

The maximum frame number ranges from one more than the number of the final frame in the capture.

**Type of Frame to Insert**

The parser that processes the comment frame after the Trail protocol runs.

If you modify the %netmon%\Parsers\Trail.ini file and map a parser to an integer, you can type that number in this field.

**No Statistics**

Disables the generating of statistics for the comment frame. When **No Statistics** is selected, Network Monitor does not use the comment frame to define a block of any other inserted comment frames for statistics. By default, this check box is selected.

**Apply Current Filter to Statistics**

Uses the current display filter to calculate statistics. By default, this check box is selected.

If you clear this check box, the output shows data for all frames in the capture, including those that have been filtered from the display.

**Enter in a comment for this new frame**

The text that you attach to the frame by using the protocol specified in **Type of Frame to Insert**.

**See Also**

**Concepts**

Add a comment frame to a capture
Design a display filter
Load a capture filter

# Label Window dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Label Window dialog box**

Use this dialog box to change the text that appears in the Frame Viewer Window title bar.

### Description

The new window label.

**See Also**

**Concepts**

Change the Frame Viewer window label

Design a display filter

Network Monitor overview

# No Networks Found dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**No Networks Found dialog box**
This dialog box appears when Network Monitor cannot find installed network drivers on the local computer or if the Network Monitor driver is not installed.

**Do not notify me of this in the future**
Hides this message box the next time you open Network Monitor. Select this check box if you plan to work only with existing Network Monitor capture files. By default, this check box is cleared.

If you receive this message, Install the Network Monitor driver.

**See Also**
**Concepts**
Select a Network dialog box
Install the Network Monitor driver
Network Monitor overview

# Protocol Colors dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protocol Colors dialog box**
Use this dialog box to specify colors that appear in the panes in the Frame Viewer window. You can use the colors to highlight frames, properties, and hexadecimal data pertaining to that protocol.

- **X**

  Selected protocols apply the current color selection. Click anywhere in the protocol line to select or clear it.

- **Name**

  The names of currently supported protocols.

- **Description**

  A description of each supported protocol.

- **Colors**

  Specifies the colors of the selected protocols.

  - **Foreground**

    The color to apply to the protocol text.

  - **Background**

    The color to apply to the text background.

- **Select All**

  Click to select all listed protocols.

- **Clear All**

  Click to clear all listed protocols.

  This button does not reset the background and foreground colors.

- **Save as Default**

  Automatically uses the specified color combination every time you display data in the Frame Viewer window. By default, this check box is cleared.

**See Also**
**Concepts**
Select a protocol color scheme
Change the Frame Viewer window label
Specify capture filter protocols
Frame Viewer Window

# Save dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Save dialog box**

Use this dialog box to:

- Save captured data in a file (.cap) that you can view in Network Monitor at a later time.
- Save a capture or display filter that you have designed or edited.
- Save an address database to a file.
- Save a text file to which you can print frame data.

**Save in**

The drive and directory that you want to save the file to.

**File name**

The name to save the file as.

**Save as type**

The file format of the information that you want to save. Network Monitor uses these default file types and file name extensions:

| File type | File name extension |
|---|---|
| Capture files | .cap |
| Capture filters | .cf |
| Display filters | .df |
| Address files | .adr |
| Print files | .txt |

**Range**

In the **From** and **To** boxes, specify the numerical range of the frames that you want to save in the capture file.

When you save a range of frames to a capture file, the numbers associated with the frames are changed. In a capture file, frame numbers always begin with 1, regardless of the number associated with the original frame. Similarly, if you apply a display filter and then save the filtered frames, the frame numbers in the capture file begin with 1. If, on the other hand, you select **Print To File** in the **Print** dialog box, the original frame numbers associated with the frames are preserved.

**Filtered**

Applies the current display filter to the capture data when the data is being saved. When you select this check box, the saved frames are renumbered so that no gaps appear in the sequence. By default, this check box is cleared.

**Note**

- The **From**, **To**, and **Filtered** options are available only when you are saving a capture file from the Frame Viewer window.

**See Also**

**Concepts**

Save captured frames to a file
Save a capture filter
Save a display filter
Save the address database to a file

# Display Filter dialog box

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Display Filter dialog box**

Use this dialog box to limit your display to frames that have the properties that you specify. For example, you can specify the protocols, computer addresses, and protocol properties that you want to display in the Frame Viewer Window. The following controls help you to make changes to the display filter decision tree.

- **Protocol ==**

  The decision tree branch that lists the protocols that you want to display. By default, this branch is set to **Protocol == Any**. To modify the protocol list, double-click the branch to open the Expression dialog box: Protocol tab.

- *address* **<->** *address*

  The decision tree branch that lists the computer address pairs that you want to display. By default, this branch is set to **Any <-> Any**. To modify the address pairs list, double-click the branch to open the Expression dialog box: Address tab. You must specify the local computer as the data source or destination.

- **Add**

  Decision tree criteria.

  - **Expression**

    Click to open the Expression dialog box, which enables you to specify the computer address pairs, protocols, and protocol properties that you want to display.

- **Insert**

  Logical operators for the decision tree. You can use as many as 4,000 decision tree operators.

  - **AND**

    Click to add an AND branch to the currently selected branch of the decision tree.

  - **OR**

    Click to add an OR branch to the decision tree.

  - **NOT**

    Click to add a NOT branch to the decision tree or to negate a branch of the tree.

- **Edit Expression (Change Operator)**

  If you select an expression in the decision tree, the label on the button in this group is **Edit Expression**. Click this button to open the Expression dialog box, which you can use to edit the selected data.

  If you select a logical operator in the decision tree, the label on the button in this group is **Change Operator**. Click this button to cycle through the logical operators for the selected line.

- **Delete**

  Decision criteria that you want to delete from the tree.

- **Line**

  Click to delete the selected line in the decision tree.

- **Branch**

  Click to delete the currently selected branch in the decision tree.

- **All**

  Click to delete the entire decision tree.

- **Load**

  Click to open the **Open** dialog box, which you can use to replace the current display filter with a display filter that has previously been saved to a file.

- **Save**

  Click to open the **Save Display Filter** dialog box, which you can use to save the current display filter as a file (.df). To open this display filter again later, you can click the **Load** button to open the file.

**See Also**
**Concepts**
Design a display filter
Save a capture filter

Filtering data

# Network Monitor Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

For more information about Network Monitor, consult the following resources:

- Windows Server 2003 Resource Kit at the Microsoft Windows Resource Kits Web site.
- Microsoft TechNet at the Microsoft Web site.
- Microsoft Product Support Services at the Microsoft Web site.

# Troubleshooting Network Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Network Monitor will not start.
- Not enough disk space to create a capture buffer.
- Access denied to default capture directory on computers with lockdown policies in place.
- "No NPPs found" error message.

**Network Monitor will not start.**
**Cause: Authenticated Users** has been manually removed from the **Users** group.

**Solution:** Add the Network Monitor user to the **Users** group following the steps described in Add a member to a local group. After the user has been added, they must log-off the computer, and then log back on.

**Cause:** The Discretionary Access Control List (DACL) of the system directory is changed to disallow normal user's access.

**Solution:** Add the Network Monitor user to the DACL of the system directory and assign permissions to allow normal user access by following the steps described in Assign, change, or remove permissions on Active Directory objects or attributes.

**Not enough disk space to create a capture buffer.**
**Cause:** When you set a capture buffer, Network Monitor reserves disk space equal to the size of the capture buffer. If not enough disk space is free, you will get an error.

**Solution:** Make sure that the temporary capture directory has enough free disk space (at least 1 MB free + buffer size).

**Access denied to default capture directory on computers with lockdown policies in place.**
**Cause:** Lockdown computers will not allow you to write to files in the \Windows folder and subfolders, but the default folder for Network Monitor capture files is a subfolder of the \Windows folder.

**Solution:** After you create a capture, save the capture into a folder to which you have read and write access. This folder becomes the new default location for saving capture files.

**"No NPPs found" error message.**
**Cause:** Network Monitor, the Network Monitor driver, or neither is installed properly.

**Solution:** Make sure that the Network Monitor components are installed properly.

1. If the Network Monitor driver is not installed, install it using the steps described in Install the Network Monitor driver.
2. If the Network Monitor driver is installed, delete it and then reinstall it.
3. If reinstalling the Network Monitor driver does not solve the problem, remove Network Monitor and then reinstall it using the steps described in Install Network Monitor.

# Monitoring Performance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring performance**

System Monitor and Performance Logs and Alerts support detailed monitoring of the utilization of operating system resources.

- To find features that have been changed in the Windows Server 2003 family, see New ways to do familiar performance monitoring tasks.
- For tips about monitoring performance, see Performance monitoring best practices.
- For help with specific tasks, see Performance monitoring How To....
- For general background information, see Performance monitoring Concepts.
- For problem solving instructions, see Troubleshooting Performance monitoring.

# New ways to do familiar performance monitoring tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for System Monitor and Performance Logs and Alerts (hosted in the Performance console, named Perfmon.msc). The user interface for performing these tasks is different in the Windows Server 2003 family and Windows 2000 from the way it was in Windows NT version 4.0. Many of the toolbar buttons remain the same among the three operating systems and can be used instead of the steps listed in this table.

| **If you want to** | **In Windows NT 4.0 use** | **In Windows 2000 or the Windows Server 2003 family use** |
|---|---|---|
| Create a chart of performance data: See Work with Monitoring Views. | Performance Monitor on the **Administrative Tools** menu. | Open System Monitor. |
| Create a report of performance data: See Change from graph view to histogram or report views. | Performance Monitor on the **Administrative Tools** menu. | Open System Monitor. |
| Create a log: See Create a counter log or Create a trace log. | Performance Monitor on the **Administrative Tools** menu. | Open Performance. |
| Create an alert: See Create an alert. | Performance Monitor on the **Administrative Tools** menu. | Open Performance. |

# Performance monitoring best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Set up a monitoring configuration.** Configure Performance Logs and Alerts to report data for the recommended counters at regular intervals, such as every 10 to 15 minutes. Retain logs over extended periods of time, store data in a database, and query the data to report on and analyze the data as needed for overall performance assessment, trend analysis, and capacity planning.

  For best results, do the following before starting System Monitor or Performance Logs and Alerts on the computer you want to monitor for diagnostic purposes:

  - If the server in question has halted or is not responding, run System Monitor from another computer.

- **Keep monitoring overhead low.** In general, the performance tools are designed for minimal overhead. However, you might find that the overhead increases under the following conditions:

  - You are running System Monitor in graph view.
  - You have selected an option other than the default (current value) for either the System Monitor graph or report views.
  - You are sampling at very frequent intervals (less than three seconds apart).
  - You have selected many different objects and counters.

- Other aspects of performance tool operation that affect performance include file size and disk space taken up by log files. To reduce file size and related disk space usage, extend the update interval. Also, log to a disk other than the one you are monitoring. Frequent logging also adds demand on disk input and output (I/O).

  If monitoring overhead is a concern, run only the Performance Logs and Alerts service and do not monitor using a System Monitor graph.

  During local logging of remote counters, frequent updating can slow performance due to network transport. In this case, it is recommended that you log continuously on remote computers but upload logs infrequently -- for example, once a day.

- **Analyze performance results, and establish a performance baseline.** Review logged data by graphing it using the System Monitor display or exporting it for printing. Compare the values against the counter thresholds shown in Analyzing performance data to verify that resource usage or other activity is within acceptable limits. Set your baseline according to the level of performance that you consider satisfactory for your typical workload.

- **Set alerts.** Set alerts according to the counter values you consider to be unacceptable, as defined by baseline evaluation.

- **Tune performance.** Tune system settings and workload to improve performance and repeat monitoring to examine tuning results. For more information on ways to improve performance, see Solving performance problems.

- **Plan ahead.** Monitor trends for capacity planning and add or upgrade components as needed. Maintain logged data in a database and observe changes to identify changes in resource requirements. After you observe changes in activity or resource demand, you can identify areas that might require additional resources.

# Performance monitoring How To...

Updated: January 21, 2005

# Work with Counters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with counters**

- Add counters to System Monitor
- Delete counters from System Monitor
- Get counter descriptions

# Add counters to System Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add counters to System Monitor**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Add Counters**.
3. To monitor any computer on which the monitoring console is run, click **Use local computer counters**.

   Or, to monitor a specific computer, regardless of where the monitoring console is run, click **Select counters from computer** and specify a computer name or IP address.
4. In **Performance object**, click an object to monitor.
5. To monitor all counters, click **All counters**.

   Or, to monitor only selected counters, click **Select counters from list** and select the counters you want to monitor.
6. To monitor all instances of the selected counters, click **All instances**.

   Or, to monitor only selected instances, click **Select instances from list** and select the instances you want to monitor.
7. Click **Add**, and then click **Close**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- By default, the following three counters are displayed in System Monitor -- Memory\Pages/sec, PhysicalDisk(_Total)\Avg. Disk Queue Length, and Processor(_Total)\%Processor Time.
- If you select an object on a remote computer, you might notice a short delay as System Monitor refreshes the list to reflect objects present on that computer.
- Unless you are configuring data from a log, you can select only active instances in the list box.
- Some object types have several instances. For example, if a system has multiple processors, the Processor object type will have multiple instances. The Physical Disk object type has two instances if a system has two disks. Some object types such as Memory and Server have only a single instance. If an object type has multiple instances, you can add counters to track statistics for each instance, or in many cases, for all instances at once.
- To monitor the sum of the values all of a particular counter's instances, select the _Total instance.
- By default, process and thread instances have a #n appended (where n is an integer). To append the process ID instead, create a DWORD value called ProcessNameFormat under the

HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\PerfProc\Performance subkey and set its value to 2. Likewise, to append the thread ID instead, create a DWORD value called ThreadNameFormat under the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\PerfProc\Performance subkey and set its value to 2. To turn off any of these options and return to the default, set the value of the appropriate DWORD to 1.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

- By default, counters are shown with both the instance name and an instance index. To turn off this feature, right-click the details pane, click **Properties**, select the **General** tab, and clear the **Allow duplicate counter instances** check box.

- When you select two instance indexes of the same counter, for example, if you are monitoring multiple threads of a process, note that the instance index number assigned to that instance changes over time as the instance, such as a thread, starts and stops. The index number does not necessarily correspond to the same thread over the life of the process.

- When creating a monitoring console for export, make sure to select **Use local computer counters**. Otherwise, System Monitor will obtain data from the computer named in the text box, regardless of where the console file is installed.

- For a description of a particular counter, click the name of the counter in **Add counters**, and then click **Explain**.

- You can change the default display characteristics assigned to a counter such as the color, line style and width, and graph scale by using the **Data** tab in the **System Monitor Properties** dialog box. To access the **Data** tab, right-click the details pane, and click **Properties**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete counters from System Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete counters from System Monitor**

1. Open Performance.
2. In the System Monitor details pane, click the name of the counter in the legend.
3. Press DELETE.

## Notes

To perform this procedure, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- You can also delete counters by using the **Remove** button on the **Data** tab in the **System Monitor Properties** dialog box. The **Remove** button is helpful for deleting a group of counters at once.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Get counter descriptions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To get counter descriptions

1. Open Performance.
2. Right click the System Monitor details pane and click **Add Counters**.
3. In **Performance object**, click an object.
4. In **Select counters from list**, click the counter for which you want information.
5. Click **Explain**, and then click the Close button.

### Notes

- To perform this procedure, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Monitoring Views

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with monitoring views**

- Use logged data
- Change counters and counter properties
- Change sampling options
- Monitor a different computer
- Highlight counter data
- Change from graph view to histogram or report views
- Add titles, grids, and other attributes to a graph
- Change background, chart, text, and font properties

# Use logged data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use logged data**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Properties**.
3. On the **Source** tab under **Data Source**, click **Log files**, and then add the file(s) you want to use as a data source.

   To specify a SQL server data source, click **Database**.
4. Click **Time Range**.
5. Click the **Data** tab and click **Add** to open the **Add Counters** dialog box. The counters you selected during log configuration appear.

## Notes

- You do not need administrative credentials to view counters from log files on the local computer.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- Unless you specifically want to monitor start-up events, you should exclude times that include such events from your time window because these temporary high values tend to skew overall performance results.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change counters and counter properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change counters and counter properties**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Properties**.
3. On the **Data** tab, specify the options you want to use:
   - **Add.** Opens the **Add Counters** dialog box, where you can select other counters to add.
   - **Remove.** Removes the counter selected in the counter list.
   - **Color.** Changes the color of the selected counter.
   - **Scale.** Changes the displayed scale of a selected counter in the graph or histogram view. Counter values can be scaled linearly from .0000001 to 1000000.0. You can adjust the counter scale settings to enhance the visibility of counter data in the graph. Changing the scale does not affect the statistics displayed in the value bar.
   - **Width.** Changes the line width of a selected counter. Note that defining a line width can determine the line styles that are available.
   - **Style.** Changes the line style for a selected counter. You can select a style only when you are using the default line width.
4. Click **Apply** and then click **OK**.

## Notes

- If you want to view counters in real-time mode, or set up a monitoring configuration, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If you want to simply work with data from log files, you do not need administrative credentials on the local computer.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- By default, System Monitor displays Pages/sec, Avg. Disk Queue Length, and % Processor Time counter data for the local computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change sampling options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change sampling options**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Properties**.
3. On the **General** tab, specify the sampling option you want:
   - To sample automatically at regular intervals, select the **Sample automatically every** check box and in **seconds** type the length of the interval in seconds. The default interval is one second.
   - To sample manually, clear the **Sample automatically every** check box.

     When manual sampling is selected, click the Update Data button to collect a sample.
4. Click **Apply**, and then click **OK**.

**Note**

- To perform this procedure, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

# Monitor a different computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To monitor a different computer**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Add Counters**.
3. Click **Select counters from computer**, and in the text box, type the name of the computer that you want to monitor (*computer_name*), or enter the IP address of the computer you want to monitor.
4. In **Performance object**, click an object to monitor.
5. In **Select counters from list**, click one or more counters, or click **All counters** to use all counters for that object.
6. To use all counter instances available when System Monitor is in use, click **All instances**.

   Or, to use only selected counter instances, click **Select instances from list**, and select the instances you want to use.
7. Click **Close**.

## Notes

- You do not need administrative credentials to simply view counters on a remotely managed computer unless you use Perfmon with the /WMI option. To use the Windows Management Instrumentation (WMI) interface, you must be a member of the Administrators group on the remotely managed computer.
- To monitor (rather than simply view) counters on remotely managed computers, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- If you select an object on a remote computer, you might notice a short delay as System Monitor refreshes the list to reflect objects present on that computer.
- If you do not see a counter that you want to monitor, it could be because the service or feature that provides the counter object is not installed or enabled on that computer and you might need to add it before you can monitor related data.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Highlight counter data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To highlight counter data**

1. Open Performance.
2. In the legend, click the counter you want to highlight.
3. Click the Highlight button, or press CTRL+H.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- When you highlight a counter, a thick line replaces the colored chart line. For white or light-colored backgrounds (defined by the Graph Background property), this line is black; for other backgrounds, this line is white.
- When using the System Monitor control in an application that supports Active-X controls, note that the CTRL+H combination used for System Monitor highlighting may conflict with the default key settings in the application. You may need to change the default key settings to support highlighting when you use the System Monitor control (Sysmon.ocx in the systemroot\System32 folder) in other applications.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change from graph view to histogram or report views

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change from graph view to histogram or report views**

1. Open Performance.
2. On the toolbar, click the View Histogram button to view a histogram or bar graph.

   Click the View Report button to view a report.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- You can also change the display by clicking the View Log Data button to open the **System Monitor Properties** dialog box. Click the **General** tab, and use the **View** setting to specify your display preference.
- Graph view displays counter data over a given time period in line graph format. The histogram view displays counter data in bar chart format, showing only a single value per counter instance. Report view displays counter data in table format, also showing only a single value per counter instance. In report view, counter names and data values appear in rows beneath their associated performance objects, and a separate column displays each instance and its data.
- For both the histogram and report views, choosing average, minimum, or maximum statistics causes the statistic to be calculated at each sample interval. This incurs some additional performance overhead for realtime data only.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add titles, grids, and other attributes to a graph

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add titles, grids, and other attributes to a graph**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Properties**.
3. On the **Graph** tab, specify the graph options you want to use:
   - To change the grid color, use the **Appearance** tab.
   - To add or remove the legend, statistics, or the toolbar, use the **General** tab.
   - To change border style or appearance, use the **General** tab.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change background, chart, text, and font properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change background, chart, text, and font properties**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Properties**.
3. Click the **Appearance** tab.
4. To change the color elements, in **Color**, select the graph element for which you want to change the color. To change the color used for the selected graph element, click the **Change** button.

   Or, to change the font used for the text or numbers on your graph, in **Font**, click the **Change** button. In **Font**, set any font options you want. The options include **Font**, **Font style**, **Size**, and **Script**.
5. The available elements in **Color** are:

   - **Graph Background**. The background color of the window area where counter data is charted.
   - **Control Background**. The background color that surrounds the window area where data is charted.
   - **Text**. The text color.
   - **Grid**. The color used for vertical and horizontal grid lines.
   - **Time Bar**. The color used for the timer bar.
6. Click **Apply**, and then click **OK**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with data**

- Collect performance data using Microsoft SQL Server
- Collect performance data using WMI
- Copy counter data between instances of System Monitor
- Print performance data
- Save graph settings as an HTML page
- Insert the System Monitor control in a Web page
- Save data to a log file

# Collect performance data using Microsoft SQL Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Collect performance data using Microsoft SQL Server**

- Set up a user account on a SQL server
- Set up the System DSN on each test computer

# Set up a user account on a SQL server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up a user account on a SQL server**

1. Open Enterprise Manager.
2. In the console tree, double-click **Microsoft SQL Servers**, click **SQL Server Group**, and then **SQLComputerName (Windows NT)**.
3. Double-click **Databases**, and then double-click your database of choice.
4. Right-click **Users**, and then click the **New Database User** menu.
5. Next to **Login name**, type:

   *domain**username*
6. Next to **User name**, type your user name.
7. Select the **Public** check box, and then select all of the following objects:

   - **db_owner**
   - **db_accessadmin**
   - **db_securityadmin**
   - **db_ddladmin**
   - **db_datareader**
   - **db_datawriter**
   - **db_backupoperator**

   **Important**

   - Do not select **db_denydatareader** or **db_denydatawriter**. These objects allow members to deny Read or Write permissions to data in the database.

**Notes**

- To open Enterprise Manager, click **Start**, point to **Programs**, click **Microsoft SQL Server**, and then click **Enterprise Manager**.
- Before you begin, confirm that a domain and your administrative credentials are set up:
  - You have permissions to read from and write to the SQL Server database.
  - Your user name has administrative credentials on each of the above computers; you will use it to log on at all

times.

- This is a quick start procedure only. Consult your Microsoft SQL Server documentation for detailed instructions on setting up and configuring a SQL database.

- Windows Server 2003 family, not Microsoft SQL Server, authentication is used when you connect to a SQL server for performance monitoring purposes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Set up the System DSN on each test computer
Create and Configure Counter Logs

# Set up the System DSN on each test computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up the System Data Source Name (DSN) on each test computer**

1. Open ODBC Data Source Administrator.
2. Click the **SystemDSN tab**.
3. Click **Add**.
4. In the **Create New Data Source** wizard, click **SQL Server**, and then **Finish**.
5. In the **Create a New Data Source to SQL Server** dialog box, fill in the **Name** and **Description** text boxes. In the **Server** box, type or select the name of the computer.

   **Important**

   - If you previously configured an **ODBC data source** for the same SQL server, a dialog box may appear which reads, "A new data source will be created with the following configuration." Click **Finish** if you do not want to change databases. Otherwise, follow steps 6 through 9.

6. Click **Next** to accept the following default settings:

   - **With Windows NT authentication using the network login ID.**
   - **Connect to SQL Server to obtain default settings for the additional configuration options.**

7. Click **Next** a second time to accept the following default settings:

   - **Use ANSI quoted identifiers.**
   - **Use ANSI nulls, paddings and warnings.**

   **Important**

The **Change the default database to** check box should be cleared. If, when setting up a user account, you selected a database other than **master**, you should now select the **Change the default database to** check box, and then click that database in the list.

1. Click **Finish** to accept the default setting, **Perform translation for character data.**
2. In the **ODBC Microsoft SQL Server Setup** dialog box, click **Test Data Source**, and verify that the "Tests completed successfully!" message appears.

**Notes**

- Before you begin, confirm that your computer is connected to the domain, and that you are logged into the domain as a user. See Related Topics for more information.
- To open Data Sources (ODBC), click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-

click **Data Sources (ODBC)**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Collect performance data using WMI

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To collect performance data using WMI**

- Open Command Prompt and type:
- **perfmon.exe /wmi**

## Notes

- To perform this procedure, you must be a member of the Administrators group, the Performance Log Users group, or the Performance Monitor Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- When this option is specified, the program obtains performance data by means of Windows Management Instrumentation (WMI) instead of the registry. WMI Hi-Perf providers can then expose performance counters, which in turn appear in System Monitor or are logged by the Performance Logs and Alerts Service. For Windows XP and the Windows Server 2003 family, all WMI counters now appear through the use of a reverse adapter regardless of whether you use the **/wmi** option.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Copy counter data between instances of System Monitor

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy counter data between instances of System Monitor**

1. Open Performance.
2. In the System Monitor details pane, click the Copy Properties button on the toolbar.
3. Open another instance of System Monitor and click the Paste Counter List button on the toolbar to load the counter path data from the Clipboard into the current window.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Print performance data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print performance data**

1. Open Performance.
2. Press ALT+PRINT SCREEN to copy a view of the active window.
3. To open **Paint**, click **Start**, point to **All programs**, point to **Accessories**, and then click **Paint**.
4. On the **Edit** menu, click **Paste**.

   If prompted with the alert message "The image in the Clipboard is larger than the bitmap. Would you like the bitmap enlarged?", click **Yes**.
5. On the **File** menu, click **Print**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- For the best quality prints, choose one of the following options:
  - Add the System Monitor control to a Microsoft Office application such as Microsoft Word or Microsoft Excel and print from that program.
  - Save the System Monitor control data as an HTML file and print it from Internet Explorer or another program using **Save As**.
  - Import a log file in comma-separated (.csv) or tab-separated (.tsv) format into a Microsoft Excel spreadsheet and print from that application.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Insert the System Monitor control in a Web page
Save graph settings as an HTML page

# Save graph settings as an HTML page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save graph settings as an HTML page**

1. Open Performance.
2. Add counters to a graph.
3. Right-click the displayed graph, and click **Save As**.
4. In the **Save As** dialog box, select a path and type the name of the new HTML file.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- The System Monitor configuration is saved to the HTML file, including View type (graph, histogram, report), graph title, and so on.
- You can apply the counter settings that are saved as an HTML file by dragging the HTML file from Windows Explorer onto a System Monitor graph.
- You can print a static System Monitor graph by opening the HTML file in a browser. The graph will display the data at the time the HTML file was saved. If you click on the graph, it will become live.
- You can use the Copy Properties button in the toolbar to transfer all System Monitor settings to the Windows Clipboard as a System Monitor HTML object. You can paste this HTML object into any HTML page.
- Use the Paste Counter List button on the toolbar (or drag and drop) to transfer the counter settings from the saved System Monitor object configuration in the Clipboard or HTML file to the System Monitor.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Insert the System Monitor control in a Web page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To insert the System Monitor control in a Web page**

1. Open Performance.
2. In the System Monitor toolbar, click the Copy Properties button.
3. Open your Web page in Notepad or a different text editor.
4. Insert the cursor at the point you want the control to appear, right-click, and select **Paste**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- When you open your Web page in the browser, the System Monitor graph will appear static. It represents the performance data as it appeared the moment you copied the graph. To monitor performance in real time, go to the toolbar and click the Freeze Display button.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Save data to a log file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save data to a log file**

1. Open Performance.
2. Right-click the System Monitor details pane and click **Save Data As**.
3. Type the name of the saved log file and select the format.
4. Enter the data filter (value *n*) for the saved log file in **Reduce log file size by only writing one out of every*n*original log records**.

   By default, *n* is set to 1, and the saved log file contains the same number of data points as the original log file.
5. Click **Save**.

## Notes

- To perform this task, you do not need administrative credentials on the local computer.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- To select a log file or a SQL server as the data source, see Related Topics.
- The **Save Data As** feature only works on log files and not on real-time data.
- Only the counters that are currently loaded from the log and are displayed in the current view will be relogged, or resampled.
- Although the extension for a log file is .blg, the file format is changed in the Windows Server 2003 family and therefore cannot be read on an earlier version of the operating system. For example, if you copy a binary file from Windows Server 2003, Standard Edition, to Windows 2000, you will be unable to read it on the latter system.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with settings**

- Save a monitoring console
- Save log or alert settings as an HTML page
- Create a custom monitoring console
- Use a Windows NT Server 4.0 Performance Monitor settings file

# Save a monitoring console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save a monitoring console**

1. Open Performance.
2. Using System Monitor or a tool under Performance Logs and Alerts, configure the tool with the settings you want.
3. On the **File** menu, click **Save As**, and then type the name you want for this console. The default directory for storing this file is System32 on the root volume.
4. Click **Save**.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- Only modifications to the System Monitor are saved.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Add counters to System Monitor
Create a counter log
Create an alert

# Save log or alert settings as an HTML page

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To save log or alert settings as an HTML page**

1. Open Performance.
2. Create a log or an alert.
3. In the details pane, right-click the name of the log or the alert and click **Save Settings As**. By default, the settings are saved in the user's personal default directory; this is typically My Documents.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- As a security precaution, the RunAs user name and password are not copied to the HTML file when you save a log or alert configuration to it.
- A second security feature is that you can use this HTML settings file to create a new log or alert, not to modify the settings of an existing log or alert. In the existing log or alert file, right-click the details pane, and click **New Log Settings From** or **New Alert Settings From**. This is an easy way to generate log settings from an alert configuration.
- For counter logs and alerts, you can open the HTML page in a browser, displaying a System Monitor object. The System Monitor object will specify the current log file as the data source.

  Or, you can drag the HTML file and drop it on a System Monitor object. In this case, the counters specified in the HTML file will be added to the System Monitor display.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a custom monitoring console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a custom monitoring console**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**.
3. On the **Standalone** tab, click **Add**.
4. In the snap-in list, click **ActiveX Control**, and then click **Add**.
5. In the **Insert ActiveX Control** wizard, click **Next**.

   There is a short delay before the next dialog box appears; this is normal.
6. In **Control category**, click **All Categories**.
7. In **Control type**, click **System Monitor Control**.
8. Click **Next**.

   The System Monitor control provides the functionality of System Monitor.
9. In **Select a name for the ActiveX control**, type a name for the control, and then click **Finish**.

## Notes

- To open MMC, click **Start**, click **Run**, and then type **mmc**.
- Creating a custom console is useful if you want to have System Monitor hosted in the same console with Event Viewer or another tool.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use a Windows NT Server 4.0 Performance Monitor settings file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use a Windows NT Server 4.0 Performance Monitor settings file**

- At a command prompt, type

  **perfmon.exe***file_name*

  where *file_name* is the name of the settings file you want to use.

## Notes

- This procedure will open a Performance console configured with the settings from the Windows NT Server 4.0 version of Performance Monitor settings file.

- This procedure works for the following types of Windows NT Server 4.0 version of Performance Monitor settings files: chart (.pmc), report (.pmr), alert (.pma), and log (.pml). Workspace (.pmw) files that were created with Windows NT Server 4.0 version of Performance Monitor are not fully compatible with System Monitor. Only one of the views previously saved in the workspace will be available in System Monitor.

- To display the Windows NT Server 4.0 settings file in System Monitor, the system temporarily converts the file for use with System Monitor but discards the converted version after the console starts. If you want to save the settings file for permanent use with System Monitor, type the following command:

  **perfmon.exe /HTMLFILE:***converted_filesettings_file*

  where *converted_file* is the name you are giving to the converted file and *settings_file* is the name of the original Windows NT Server 4.0 settings file.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Configure Counter Logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and configure counter logs**

- Create a counter log
- Add objects to a log
- Add counters to a log
- Get details about objects and counters
- Set parameters for a log

# Create a counter log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a counter log**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs**.

   Any existing counter logs will be listed in the details pane. A green icon indicates that a log is running; a red icon indicates that a log has stopped.
3. Right-click a blank area of the details pane, and click **New Log Settings**.
4. In **Name**, type the name of the counter log, and then click **OK**.
5. On the **General** tab, click **Add Objects** and select the performance objects you want to add, or click **Add Counters** to select the individual counters you want to log.

   - You must use the Run as text box and Password button to collect counter data from a remotely managed computer. These features enable you to specify the logon account name for the log. You can access them from the **General** tab.
6. If you want to change the default file and schedule information, make the changes on the **Log Files** tab and the **Schedule** tab.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- To save the settings for a counter log, trace log, or alert, right-click the log or alert in the details pane and click **Save Settings As**. You can then specify an .htm file in which to save the settings. To reuse the saved settings for a new log or alert, right-click the details pane, and then click **New Log Settings From** or **New Alert Settings From**. This is an easy way to generate new settings from a log or alert configuration. You can also open the HTML file in Internet Explorer to display a System Monitor graph.
- Although the extension for a log file is .blg, the file format is changed in the Windows server 2003 family and therefore cannot be read on an earlier version of the operating system. For example, if you copy a binary file from Windows Server 2003, Standard Edition, to Windows 2000, you will be unable to read it on the latter system.

#### Using a command line

1. Open Command Prompt

2. Type:

   **logman create counter***collection_name***-c** {*path* [*path*...]} | {**-cf***filename*}

| Value | Description |
|---|---|
| **create counter** *collection_name* | Creates a counter collection query named *collection_name*. |
| **-c** {*path* [*path*...]} \| **-cf** {*filename*} | Specifies the performance counter path to log (*path*), or specifies the path name of the log file that lists these counters (**-cf***filename*). To list multiple counter paths, separate the command line by a space, or use the **-cf** option to list counter paths in an input file, one per line. Use this format [*computer*]*object*[*instance*]*counter*] for each counter path where:<br><br>*Computer* is the optional computer name or the IP address of a remote computer. If a computer name is not supplied, the local computer will be used by default.<br><br>*Object* is the performance counter object (process or memory).<br><br>*Instance* (if any) is the performance object (process).<br><br>*Counter* is the performance counter for the object (processor time). |

For example, to create a collection query named perf_log to collect Total % Processor Time counter data, type:

**logman create counter perf_log -c "\Processor(_Total)\% Processor Time"**

### Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add objects to a log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add objects to a log**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then double-click **Counter Logs** or **Alerts**.
3. In the details pane, double-click the log or alert you want to modify.
4. On the **General** tab, click **Add Objects**. For each object that you want to add to the log, perform the following steps:

   - To log objects from the computer on which the Performance Logs and Alerts service will run, click **Use local computer counter objects**.

     Or, to log objects from a specific computer regardless of where the service is run, click **Select counter objects from computer:** and specify the Universal Naming Convention (UNC) name, such as *MyLogServer*, of the computer you want to monitor.

   - In **Performance object**, click an object to monitor, and then click **Add**. Objects are added to the **Counters** list on the **General** tab.
   - When you are finished adding objects to monitor, click **Close**.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- When creating counter log settings for export, make sure to select **Use local computer counter objects**. Otherwise, counter logs will obtain data from the computer named in the text box.
- For a description of an object, click the object in **Performance counters** and then click **Explain**.
- When you specify the name of a remote computer using **Select counter objects from computer**, only the name of the local computer and those computer names entered during the current Performance session are listed. Computer names entered in previous sessions will not be listed.
- The Run as feature enables you to run log collections under different accounts. For example, if you need to log data from a remote computer that requires administrative credentials, you can use the feature to specify an account with the

necessary permissions.

#### Using a command line

1. Open Command Prompt

2. Type:

   **logman update** *collection_name* **-c** {*path* [*path*...]} | {**-cf***filename*}

| Value | Description |
|---|---|
| **update** *collection_name* | Updates the collection query named *collection_name*. For counter collections, modifications to the query will stop, and then restart the collections. |
| **-c** {*path* [*path*...]} \| **-cf** {*filename*} | Specifies the performance object path to log (*path*), or specifies the path name of the log file that lists these objects (**-cf***filename*). To list multiple object paths, separate the command line by a space, or use the **-cf** option to list object paths in an input file, one per line. Use this format [*computer**object*] for each object path where: *Computer* is the optional computer name or the IP address of a remote computer. If a computer name is not supplied, the local computer will be used by default.<br><br>*Object* is the performance counter object (process or memory). |

For example, to add the PhysicalDisk object to the collection query named perf_log on computer \\COMP1, type:

**logman update perf_log -c "\\COMP1\PhysicalDisk(*)*"**

### Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add counters to a log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add counters to a log**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs**.
3. In the details pane, double-click the log you want to modify.
4. On the **General** tab, click **Add Counters**. For each counter or group of counters that you want to add to the log, perform the following steps:

   - To log counters from the computer on which the Performance Logs and Alerts service will run, click **Use local computer counters**.

     Or, to log counters from a specific computer regardless of where the service is run, click **Select counters from computer** and specify the Universal Naming Convention (UNC) name, such as *MyLogServer*, of the computer you want to monitor.

   - In **Performance object**, select an object to monitor.
   - In **Select counters from list**, click one or more counters to monitor.
   - To monitor all instances of the selected counters, click **All Instances**. (Binary logs can include instances that are not available at log startup but subsequently become available.)

     Or, to monitor particular instances of the selected counters, click **Select Instances From List**, and then click an instance or instances to monitor.

   - Click **Add**.
   - When you are finished adding counters, click **Close**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- When creating a monitoring console for export, make sure to select **Use local computer counters**. Otherwise, counter

logs will obtain data from the computer named in the text box, regardless of where the console file is installed.

- For a description of a counter, click the counter in **Performance counters** and then click **Explain**.

- Some object types have several instances. For example, if a system has multiple processors, the Processor object type will have multiple instances. The PhysicalDisk object type has two instances if a system has two disks. Some object types, such as Memory and Server, have only a single instance. If an object type has multiple instances, you can add counters to track statistics for each instance, or in many cases, for all instances at once. By default, counters are shown with both the instance name and an instance index. To turn off this feature, right-click the System Monitor graph, click **Properties**, and click the **General** tab.

- When you specify the name of a remote computer using **Select counters from computer**, only the name of the local computer and those computer names entered during the current Performance session are listed. Computer names entered in previous sessions will not be listed.

**Using a command line**

1. Open Command Prompt

2. Type:

   **logman update** *collection_name* **-c** {*path* [*path*...]} | {**-cf***filename*}

| Value | Description |
|---|---|
| **update** *collection_name* | Updates the collection query named *collection_name*. For counter collections, modifications to the query will stop, and then restart the collections. |
| **-c** {*path* [*path*...]} \| **-cf** {*filename*} | Specifies the performance counter path to log (*path*), or specifies the path name of the log file that lists these counters (**-cf***filename*). To list multiple counter paths, separate the command line by a space, or use the **-cf** option to list counter paths in an input file, one per line. Use this format [*computer*]*object*[*instance*]*counter*] for each counter path where:<br><br>*Computer* is the optional computer name or the IP address of a remote computer. If a computer name is not supplied, the local computer will be used by default.<br><br>*Object* is the performance counter object (process or memory).<br><br>*Instance* (if any) is the performance object (process).<br><br>*Counter* is the performance counter for the object (processor time).<br><br>**Note**<br><br>• An asterisk (*) can be used as a wild card when specifying the counter path. For example, to specify all instances of the % Processor Time, use "\Processor(*)\% Processor Time". |

For example, to add all instances of the % Interrupt Time to the collection query named perf_log on computer \\COMP1, type:

**logman update perf_log -c "\\COMP1\Processor(*)\% Interrupt Time"**

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command**

**prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Get details about objects and counters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To get details about objects and counters**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs**.
3. In the details pane, double-click the counter log.
4. Click the **Add Objects** button to open the **Add Objects** dialog box or click the **Add Counters** button to open the **Add Counters** dialog box.
5. In the **Add Objects** dialog box, select **Performance objects**, click an object, then click **Explain**.
6. In the **Add Counters** dialog box, select **Performance object**, click an object, and in **Performance counters**, click a counter and then click **Explain**.

## Notes

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- Clicking **Explain** opens a pop-up window that contains information about the selected object or counter. For more information on counters, including detailed descriptions of how each counter is calculated and guidelines on using counters to diagnose performance problems, see the Performance Counter Help Reference at the Microsoft Windows Resource Kits Web site.

**Information about functional differences**

# Set parameters for a log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set parameters for a log**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**.
3. To set parameters for a counter log, double-click **Counter Logs**.

   Or, to set parameters for a trace log, double-click **Trace Logs**.
4. In the details pane, double-click the log.
5. On the **Log Files** tab, complete the following options:

   - **Log file type.** In the list, select the format you want for this log file, complete the options, and then click the **Configure** button. See "Quick reference to log file formats" under Related Topics for more information.
   - **End file names with.** Select this and choose the suffix style you want from the list. Use **End file names with** to distinguish between individual log files with the same log file name that are in a group of logs that have been automatically generated.
   - **Start numbering at.** Set this to the start number for automatic file numbering, when you select **nnnnnn** as the **End file names with**.
   - **Comment.** If appropriate, type a comment or description for the log file.
   - **Overwrite existing log file.** Select this check box if the log file should overwrite and replace the existing log file.
   - **Configure.** Select the configuration parameters using the following options for either **Configure Log Files** or **Configure SQL Logs, based on the log file type selected from the drop-down menu.**

| Option | Description | Applies to |
|---|---|---|
| **Location** | Type the name of the folder where you want the log file created, or click **Browse** to search for the folder. | Configure Log Files |
| **File name** | Type a partial or base name for the log file. You can use **File name** in conjunction with **End file names with** if appropriate. | Configure Log Files |
| **Repository name** | Select the **System DSN** (Data Source Name) from the drop-down list, and then type the **Log set name.** The **Log set name** will be stored in the database within the **System DSN.** | Configure SQL Logs |

6. **Log file size.** Decide, using the following options, whether or not you want to limit the size of the log file.

7. Or, under **Log set size.** Decide, using the following options, whether or not you want to limit the size of the log set.

    - **Maximum limit.** When you select this option, data is continuously collected in a log file until it reaches limits set by disk quotas or the operating system. (For SQL logs, data is collected in a database until it reaches its limits set by the number of records written.)

    - **Limit of.** To define a size limit for the log file, specify the size. For counter and trace logs, specify the maximum size in megabytes. For SQL logs, specify the maximum size in records.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

- If you choose to allow the log file to grow to its maximum size, consider the available space on your disk and any quotas that may be in effect. An error might occur if you run out of disk space due to logging. The **Log file size** option works in conjunction with the **When the log file is full** option on the **Schedule** tab.

- When you select a log file limit or log set size limit, the stop option **When the log file is full** reflects the size limit typed here.

- The **File name** can identify a group of log files with similar parameters.

- The **End file names with** suffix can be a numeric sequence or a character string indicating the date and time the log was started. For example, you might define the **File name** "DailyLog" and the Performance Logs and Alerts service would append the date as a suffix for each file so that you might have a series of files named as follows: DailyLog_19990715, DailyLog_19990716, for each day the log is run.

- The comment text and the file name appear in the details pane in the Performance Logs and Alerts console window.

- Sequential counter or trace log files can grow to a size larger than the maximum file size specified by the user. This can occur for different reasons, depending on the type of log configured. For counter logs, the log service postpones checking the log's file size until after it has collected the last data sample, at which point the file size might already have exceeded the defined limit. For trace logs, the log service writes additional buffers to the log when the log service stops, which can cause the final log file size to be slightly larger than the defined limit.

**Using a command line**

1. Open Command Prompt

2. Type the appropriate command below:

| Command | Action |
|---|---|
| **logman update** *collection_name* **-f** {*bin* \| *bincirc* \| *csv* \| *tsv* \| *SQL*} | Defines the log file format. |

| | |
|---|---|
| **logman update** *collection_name* **-v** {*nnnnn* \| *mmddhhmm*} | Specify the file suffix. |
| **logman update** *collection_name* **-v** *nnnnn* | Set the automatic file numbering start number. |
| **logman update** *collection_name* **-o** *path* | Specify the location of the log file. |
| **logman update** *collection_name* **-o** *DSN!counter_log* | Specify the location of the SQL database and log set where output data will be written. |

| Value | Description |
|---|---|
| **update** *collection_name* | Updates the collection query named *collection_name*. For counter collections, modifications to the query will stop, and then restart the collections. |
| **-f** *bin* \| *bincirc* \| *csv* \| *tsv* \| *SQL* | Specifies the file format used for collecting performance counter and trace data. You can use binary (bin), circular binary (circbin), comma (csv) and tab (tsv) separated, or SQL database (SQL) formats when collecting performance counters.<br><br>**Note**<br><br>• For SQL database formats, you must use the **-o** option in the command line with the DNS!counter_log option, the System Database System Name (System DSN) must be predefined, and you must have Write permissions to the database. The log set *counter_log* is created in the database, and is specified by the DSN.<br><br>If a file format is not specified, it defaults to binary. |
| **-v** *nnnnn* \| *mmddhhmm* | Attaches the version control information to the end of the output file and path name. Use numeric *nnnnn* format, or date format *mmddhhmm* (month, day, 24-hour, minute) for version control. |
| **-o** *path* | Specifies the path name of the output file that collects performance counter or trace data. By default, the collection log file name is the collection query name suffixed by either .blg for performance counters, or .etl for trace data. |
| **-o** *DSN!counter_log* | Specifies the location of the SQL database and log set. |

For example, to specify that the output for counter collection perf_log be written to a SQL log set named daily_log in the perfdb database, type:

**Logman update perf_log -f sql -o perfdb!daily_log**

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

#### Information about functional differences

# Create and Configure Trace Logs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and configure trace logs**

- Create a trace log
- Select trace log providers and events
- Define trace log buffers

# Create a trace log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a trace log**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Trace Logs**.

   Any existing trace logs will be listed in the details pane. A green icon indicates that a log is running; a red icon indicates that a log has stopped.
3. Right-click a blank area of the details pane, and click **New Log Settings**.
4. In **Name**, type the name of the trace log, and then click **OK**.

   By default, the log file is created in the PerfLogs folder in the root directory on your system drive, a sequence number is appended to the file name you entered, and the sequential trace file type with the .etl extension. Use the **Log Files** and **Advanced** tabs to modify these parameters or define other parameters for your log. To define providers and events to log, use the **General** tab. To specify when you want logging to occur, use the **Schedule** tab.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- To save the settings for a counter log, trace log, or alert, right-click the log or alert in the details pane and click **Save Settings As**. You can then specify an .htm file in which to save the settings. To reuse the saved settings for a new log or alert, right-click the details pane, and then click **New Log Settings From** or **New Alert Settings From**. This is an easy way to generate new settings from a log or alert configuration. You can also open the HTML file in Internet Explorer to display a System Monitor graph.

**Using a command line**

1. Open Command Prompt.
2. To create a trace log type:

   **Logmancreate***tracecollection_name*

| Value | Description |
| --- | --- |
| **create** *trace* | Creates a trace log collection query. |
| *collection_name* | Specifies the name of the collection query. |

For example, to create a trace log collection query named perf_log, type:

**logman create trace perf_log**

Once the collection query is created, providers then need to be enabled.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **Logman /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Select trace log providers and events

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To select trace log providers and events**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Trace Logs**.
3. In the details pane, double-click the log.
4. For a list of the installed providers and their status (enabled or not), click **Provider Status**.

   Only one instance of each trace provider can be enabled at any given time.

   By default, the **Nonsystem providers** option is selected to keep trade logging overhead to a minimum.
5. If you click **Events logged by system provider**, a default provider (the Windows kernel trace provider) is used to monitor processes, threads, and other activity. To define events for logging, click the check boxes as appropriate.
6. If you click **Nonsystem providers**, you can select the data providers you want--for example, if you have written your own providers. Use the **Add** or **Remove** buttons as needed.

## Notes

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- Trace logging of file details and page faults can generate an extremely large amount of data. It is recommended that you limit trace logging using the file details and page fault options to a maximum of two hours.
- The Windows kernel trace provider and some other providers require you to run the collection under the authority of an account with administrative credentials. By default, the service runs under the NT Authority\NetworkService account. Use the Run as text box to specify an administrator account to do this.

**Using a command line**

1. Open Command Prompt.
2. Type the appropriate command below:

| Action | Command |
|---|---|
| To view each installed provider and its status. | **logman query providers** |

| | |
|---|---|
| To specify that data collected by the system trace provider is logged. | **logman update** *collection_name* **-P** "Windows kernel trace" (*process*, *thread*, *disk*, *net*, *page*, *file*) |
| To specify that data collected by a provider other than the Windows kernel trace provider is logged. | **logman update** *collection_name* **-P** *provider* |

| Value | Description |
|---|---|
| **query providers** | Queries the providers installed on the local system. |
| **update** *collection_name* | Updates the collection query named *collection_name*. |
| **-P** "Windows kernel trace" (*process*, *thread*, *disk*, *net*, *page*, *file*) | Specifies "Windows kernEl trace" as the provider that collects data for the trace log. *Process*, *thread*, *disk*, *net*, *pf*, *hf*, *registry*, *image*, and *file* are optional events to include in the trace log.<br><br>Use *process* to include data on the creating and ending processes.<br><br>Use *thread* to include data on the creating and ending threads.<br><br>Use *disk* to include data on disk input/output operations.<br><br>Use *net* to include data on TCP/IP send or receive requests.<br><br>Use *pf* to enable soft page fault tracing.<br><br>Use *hf* to enable hard page fault tracing.<br><br>Use *registry* to include data on registry operations.<br><br>Use *image* to include data on the program name for the loaded process.<br><br>Use *file* to include file I/O data. |
| **-P** *provider* | Specifies the non-system provider that collects data for the trace log. |

For example, to specify that a provider named Nonsystem01 is used to collect data for a trace log named perf_log, type:

**logman update perf_log -P Nonsystem01**

**Notes**

- The Windows kernel trace provider and some other providers require you to run the collection under the authority of an account with administrative credentials. By default, the service runs under the NT Authority\NetworkService account. Use the **-u** option to specify an account with administrative credentials.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define trace log buffers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define trace log buffers**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and click **Trace Logs**.
3. In the details pane, double-click the log, and click the **Advanced** tab on the dialog box that appears.
4. In **Buffer size**, specify the size of the buffer you want to use in kilobytes for trace data collection.
5. In **Minimum**, specify the smallest number of buffers you want to use for trace data.
6. In **Maximum**, specify the largest number of buffers you want to use for trace data.
7. To have the trace provider periodically flush the buffers, select the **Transfer data from buffers to log file at least every** check box and specify the transfer interval in seconds.

**Note**

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

**Using a command line**

1. Open Command Prompt.
2. Type:

   **logmanupdate***collection_name***-bs** {*value*} **-nb** {*minmax*} **-ft***[[hh:]mm:]ss*

| Value | Description |
|---|---|
| **update** *collection_name* | Updates the collection query named *collection_name*. |
| **-bs** {*value*} | Specifies the buffer size in *n* kilobytes for the trace log. |
| **-nb** {*minmax*} | Specifies the minimum and maximum number of buffers for the trace log. |
| **-ft** *[[hh:]mm:]ss* | Specifies whether the buffer will be flushed and the interval at which the buffer will be flushed. |

For example, to specify a buffer size of 128 kilobytes, a minimum of 10 buffers, and a maximum of 25 buffers for a trace log named perf_log, type:

**logman update perf_log -bs 128 -nb 10 25**

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create and Configure Alerts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Create and configure alerts**

- Create an alert
- Define counters and thresholds for an alert
- Define actions for an alert

# Create an alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an alert**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Alerts**.

   Any existing alerts will be listed in the details pane. A green icon indicates that an alert is running; a red icon indicates that an alert has stopped.
3. Right-click a blank area of the details pane and click **New Alert Settings**.
4. In **Name**, type the name of the alert, and then click **OK**.
5. To define a comment for your alert, along with counters, alert thresholds, and a sample interval, use the **General** tab.

   To define actions that should occur when counter data triggers an alert, use the **Action** tab. To define when the service should begin scanning for alerts, use the **Schedule** tab.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- To save the settings for a counter log, trace log, or alert, right-click the log or alert in the details pane and click **Save Settings As**. You can then specify an .htm file in which to save the settings. To reuse the saved settings for a new log or alert, right-click the details pane, and then click **New Log Settings From** or **New Alert Settings From**. This is an easy way to generate new settings from a log or alert configuration. You can also open the HTML file in Internet Explorer to display a System Monitor graph.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define counters and thresholds for an alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define counters and thresholds for an alert**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Alerts**.
3. In the details pane, double-click the alert.
4. In **Comment**, type a comment to describe the alert as needed, and click **Add**.
5. For each counter or group of counters that you want to add to the log, perform the following steps:
   a. To monitor counters from the computer on which the Performance Logs and Alerts service will run, click **Use local computer counters**.

      Or, to monitor counters from a specific computer regardless of where the service is run, click **Select counters from computer** and type the Universal Naming Convention (UNC) name, such as *MyLogServer*, of the computer you want to monitor in the text box.

   b. In **Performance object**, click an object to monitor.
   c. In **Select counters from list**, click one or more counters to monitor.
   d. To monitor all instances of the selected counters, click **All Instances**. (Binary logs can include instances that are not available at log startup but subsequently become available.)

      Or, to monitor particular instances of the selected counters, click **Select Instances From List**, and then click an instance or instances to monitor.

   e. Click **Add**. When you are through adding counters, click **Close**.
6. In **Alert when the value is**, specify **Under** or **Over**, and in **Limit**, specify the value that triggers the alert. Perform this step for each counter or group of counters that you added to the log.
7. In **Sample data every**, specify the amount and the unit of measure for the update interval.
8. Complete the alert configuration using the **Action** and **Schedule** tabs.
9. Click **Apply**, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

- You can add a counter to an alert multiple times, and specify different thresholds for each instance.

- To save the settings for a counter log, trace log, or alert, right-click the log or alert in the details pane and click **Save Settings As**. You can then specify an .htm file in which to save the settings. To reuse the saved settings for a new log or alert, right-click the details pane, and then click **New Log Settings From** or **New Alert Settings From**. This is an easy way to generate new settings from a log or alert configuration. You can also open the HTML file in Internet Explorer to display a System Monitor graph.

- Some object types have several instances. For example, if a system has multiple processors, the Processor object type will have multiple instances. The PhysicalDisk object type has two instances if a system has two disks. Some object types, such as Memory and Server, have only a single instance. If an object type has multiple instances, you can add counters to track statistics for each instance, or in many cases, for all instances at once.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define actions for an alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define actions for an alert**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Alerts**.
3. In the details pane, double-click the alert.
4. Click the **Action** tab.
5. To have Performance Logs and Alerts create an entry visible in Event Viewer, select **Log an entry in the application event log**. This option is selected by default.
6. To have Performance Logs and Alerts trigger the Messenger service to send a message, select **Send a network message to** and type the IP address or name of the computer on which the alert message should be displayed.
7. To run a counter log when an alert occurs, select **Start performance data log** and specify the counter log you want to run.
8. To have a program run when an alert occurs, select **Run this program** and type the file path and name, or click **Browse** to locate the file. Click **Command Line Arguments** and select the appropriate check boxes for arguments to include when the program is run.

## Notes

- To perform this procedure, you must be a member of the Administrators group or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

  **Important**

  - Note the security implications running an interactive program: When an alert stops, it will run the program on the desktop. If you schedule a collection to run on a system that other users have access to under an account with administrative credentials, then the program will appear on the desktop under the authentication of the administrator account, possibly when other users are logged onto the system.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- When you select **Run this program**, by default, the program runs in the background.
- When an alert occurs, the service creates a process and runs the specified executable or command file. The service also copies any command line arguments that you define to run the file to the command line.
- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start or stop a counter log, trace log, or alert manually

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start or stop a counter log, trace log, or alert manually**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and click **Counter Logs**, **Trace Logs**, or **Alerts**.
3. In the details pane, right-click the name of the log or alert you want to start or stop, and click **Start** to begin the logging or alert activity you defined, or click **Stop** to terminate the activity.

   Or, click the **Start** or **Stop** buttons in the toolbar.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- There might be a slight delay before the log or alert starts or stops, indicated when the icon changes color (from green for started to red for stopped, and vice versa). This delay might reflect the startup time for a service or the fact that you have added many counters. If a log or alert does not start, you can view the Application Log for errors.

**Using a command line**

1. Open Command Prompt
2. Type:

   **logman start***collection_name*

   or

   **logman stop***collection_name*

| Value | Description |
|---|---|
| **start** *collection_name* | Starts the data collection query *collection_name*. Use this option to change from scheduled collections to manual ones. Use the **update** parameter in the command line with begin-time (**-b**), end-time (**-e**), or repeat-time (**-rt**) to reschedule collections. |

| | |
|---|---|
| **stop** *collection_name* | Stops the data collection query collection_name. Use this option to change from scheduled collections to manual ones. Use the **update** parameter in the command line with begin-time (**-b**), end-time (**-e**), or repeat-time (**-rt**) to reschedule collections. |

For example, to stop the collection query named perf_log, type:

**logman stop perf_log**

## Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove counters from a log or alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove counters from a log or alert**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs** or **Alerts**.
3. In the details pane, double-click the name of the log or alert.
4. Under **Counters**, click the counter you want to remove, and then click **Remove**.

## Notes

- To perform this procedure, you must be a member of the Administrators group or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Add counters to a log

# View or change properties of a log or alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view or change properties of a log or alert**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**.
3. Click **Counter Logs**, **Trace Logs**, or **Alerts**.
4. In the details pane, double-click the name of the log or alert.
5. View or change the log properties as needed.

### Notes

To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.
- To start or stop a log or alert, right-click its name in the details pane, and click **Start** or **Stop** as appropriate. This overrides any scheduled start and stop settings, resetting the start and stop mode to manual.

**Using a command line**

1. Open Command Prompt.
2. Type the appropriate command below:

| Action | Command |
|---|---|
| To update counter log counters and the update interval. | **logman update** *collection_name* **-c** {*path* [*path*...]} \| **-cf** {*filename*} **-si***[[hh:]mm:]ss* |
| To update a counter log collection, file type, file size limits, path and name, and automatic naming parameters. | **logman update** *collection_name***-f** {*bin* \| *bincirc* \| *csv* \| *tsv* \| *SQL*} **-max***value***-o***path***-v** {*nnnnn* \| *mmddhhmm*} |
| To update manual to automated start and stop methods and schedule. | **logman update** *collection_name***-b** *M/d/I h:mm:ss* [*AM* \| *PM*] **-e** *M/d/yyyy h:mm:ss* [*AM* \| *PM*] **-r** |
| To update trace log providers and events to log. | **logman update** *collection_name***-p** *provider* |

| | |
|---|---|
| To update a trace log collection, file type, file size limits, path name, and automatic naming parameters. | **logman update** *collection_name* **-f** {*bin* \| *bincirc*} **-max***value* **-o***path* **-v** {*nnnnn* \| *mmddhhmm*} |
| To update a trace log's buffer size, limits, and transfer interval. | **logman update** *collection_name* **-bs** {*value*} **-nb** {*min max*} **-ft** *[[hh:]mm:]ss* |

| Value | Description |
|---|---|
| **update** *collection_name* | Updates the collection query named *collection_name*. For counter collections, modifications to the query will stop, and then restart the collections. |
| **-c** {*path* [*path*...]} \| **-cf** {*filename*} | Specifies the performance counter path to log (*path*), or specifies the path name of the log file that lists these counters (**-cf***filename*). To list multiple counter paths, separate the command line by a space, or use the **-cf** option to list counter paths in an input file, one per line. Use this format [*computer*]*object*[*instance*]*counter*] for each counter path where:<br><br>*Computer* is the optional computer name or the IP address of a remote computer. If a computer name is not supplied, the local computer will be used by default.<br><br>*Object* is the performance counter object (process or memory).<br><br>*Instance* (if any) is the performance object (process).<br><br>*Counter* is the performance counter for the object (processor time). |
| **-si** *[[hh:]mm:]ss* | Specifies the update interval for counter collection in hours, minutes, and seconds. |
| **-f** *bin* \| *bincirc* \| *csv* \| *tsv* \| *SQL* | Specifies the file format used for collecting performance counter and trace data. You can use binary (bin), circular binary (circbin), comma (csv) and tab (tsv) separated, or SQL database (SQL) formats when collecting performance counters. If a file format is not specified, it defaults to binary. Binary (bin) and circular binary (circbin) are the only types supported for trace collections. |
| **-max** {*value*} | Specifies the maximum size of the collected log file in megabytes. If the log file exceeds the maximum size, the collection will stop. For a SQL database, the maximum size is the number of records to be written. |
| **-o** *path* | Specifies the path name of the output file that collects performance counter or trace data. By default, the collection log file name is the collection query name suffixed by either .blg for performance counters, or .etl for trace data. |
| **-v** {*nnnnn* \| *mmddhhmm*} | Attaches the version control information to the end of the output file and path name. Use numeric *nnnnn* format, or date format *mmddhhmm* (month, day, 24-hour, minute) for version control. |
| **-b** *M/d/yyyy h:mm:ss*[*AM* \| *PM*] | Specifies the begin-time for collections in a 24-hour format. You can also specify begin-time for collections in a 12-hour format by adding AM or PM in the command line. By default, the current day and time is used unless otherwise specified. |
| **-e** *M/d/yyyy h:mm:ss*[*AM* \| *PM*] | Specifies the end-time for collections in a 24-hour format. You can also specify end-time for collections in a 12-hour format by adding AM or PM in the command line. By default, the current day and time is used unless otherwise specified. |
| **-r -[-]r** | Repeats the collection every day at the time periods specified by the **-b** and **-e** options. This is valid only for begin- and end-times specified on the same day, month, and year.<br><br>**-[-]r** turns off the repeat option. |
| **-p** {*provider* [flags [level]]} | Specifies the name of the provider. |
| **-bs** {*value*} | Specifies the buffer size in *n* kilobytes for the trace log. |
| **-nb** {*minmax*} | Specifies the minimum and maximum number of buffers for the trace log. |

| | |
|---|---|
| **-ft** *[[hh:]mm:]ss* | Specifies whether the buffer will be flushed, and the interval at which the buffer will be flushed. |

**Notes**

To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Define start or stop parameters for a log or alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To define start or stop parameters for a log or alert**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Performance.
2. Double-click **Performance Logs and Alerts**, and then click **Counter Logs**, **Trace Logs**, or **Alerts**.
3. In the details pane, double-click the name of the log or alert.
4. Click the **Schedule** tab.
5. Under **Start log**, click one of the following options:
   - To start the log or alert manually, click **Manually**. When this option is selected, to start the log or alert, right-click the log name in the details pane, and click **Start**.
   - To start the log or alert at a specific time and date, click **At**, and then specify the time and date.
6. Under **Stop log**, select one of the following options:
   - To stop the log or alert manually, click **Manually**. When this option is selected, to stop the log or alert, right-click the log or alert name in the details pane, and click **Stop**.
   - To stop the log or alert after a specified duration, click **After**, and then specify the number of intervals and the type of interval (days, hours, and so on).
   - To stop the log or alert at a specific time and date, click **At**, and then specify the time and date. (The year box accepts four characters; the others accept two characters.)
   - To stop a log when the log file becomes full, select options as follows: For counter logs and trace logs, click **When the log file is full**. The file will continue to accumulate data according to the file-size limit you set on the **Log Files** tab. When setting this option, take into consideration your available disk space and any disk quotas that are in place. An error might occur if your disk runs out of disk space due to logging.
7. Complete the properties as appropriate for logs or alerts:
8. For logs, under **When a log file closes**, select the appropriate option:
   - If you want to configure a continuous (automated) counter or trace logging, select **Start a new log file**.
   - If you want to run a program after the log file stops (for example, a copy command for transferring completed logs to an archive site), select **Run this command**. Also, type the path and file name of the command to run, or click **Browse** to locate the command.

- For alerts, under **When an alert scan finishes**, select **Start a new scan** if you want to configure continuous alert scanning.

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the group on the local computer, or you must have been delegated the appropriate Performance Log Users authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

- When you schedule a log to close at a specific time and date or close the log manually, the **Start a new log file** option is unavailable.

- If the log is set to start at a scheduled time using **Start At**, the log will restart if the system reboots during the scheduled time. The scheduled time is based on the **Stop** settings.

- When you select **Run this command**, by default, the command runs in the background.

- To open Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Services**.

**Important**

- Note the security implications running an interactive program: When log stops, it will run the program on the desktop. If you schedule a collection to run on a system that other users have access to under an account with administrative credentials, then the program will appear on the desktop under the authentication of the administrator account, possibly when other users are logged onto the system.

- To run an interactive program, open **Services** and double-click **Performance Logs and Alerts**. Click the **Log On** tab, and fill the Local System account and **Allow service to interact with desktop** check boxes.

- When creating a monitoring console for export, make sure to select **Use local computer counters**. Otherwise, System Monitor will obtain data from the computer named in the text box, regardless of where the console file is installed.

- For a description of a particular counter, click the name of the counter in **Add counters**, and then click **Explain**.

- To monitor the sum of the values all of a particular counter's instances, select the _Total instance.

- Unless you are configuring data from a log, you can select only active instances in the list box.

- By default, counters are shown with both the instance name and an instance index. To turn off this feature, right-click the details pane, click **Properties**, select the **General** tab, and clear the **Allow duplicate counter instances** check box.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **logmanupdate***collection_name***-mstartstop**

| Value | Description |
| --- | --- |
| **update** *collection_name* | Updates the collection query named *collection_name*. |
| **-m start stop** | Specifies that the logging will start and stop manually. **Start** specifies the time you want logging to start. **Stop** specifies the time you want logging to stop. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command Prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a log or alert

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To delete a log or alert

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Open Performance.
2. Double-click **Performance Logs and Alerts**.
3. Click **Counter Logs**, **Trace Logs**, or **Alerts**.
4. In the details pane, right-click the name of the log or alert, and click **Delete**.

### Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Performance, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Performance**.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **logmandelete***collection_name*

| Value | Description |
|---|---|
| **delete** *collection_name* | Deletes the collection query named *collection_name*. If *collection_name* does not exist, you will receive an error. |

For example, to delete a log named perf_log, type:

**logman delete perf_log**

### Notes

- To perform this procedure, you must be a member of the Administrators group, or the Performance Log Users group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To view the complete syntax for this command, at a command prompt, type:

  **logman /?**

- This command is used only for deleting logs. You cannot use this command to delete an alert.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Performance monitoring Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information on performance-monitoring tools in the Windows Server 2003 family:

- Performance console overview
- Understanding the Performance console
- Using the Performance console
- Performance monitoring resources

# Performance console overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance console overview**
The Windows Server 2003 family provides the following tools as part of the Performance console:

- System Monitor
- Performance Logs and Alerts
- Task Manager

Monitoring system performance is an important part of maintaining and administering your operating system. You use performance data to do the following:

- Understand your workload and the corresponding effect on your system's resources.
- Observe changes and trends in workloads and resource usage so you can plan for future upgrades.
- Test configuration changes or other tuning efforts .
- Diagnose problems and target components or processes for optimization.

System Monitor and Performance Logs and Alerts provide detailed data about the resources that are used by specific components of the operating system and by programs that have been designed to collect performance data. Graphs provide a display for performance-monitoring data. Logs provide recording capabilities for the data. Alerts send notification to users when a counter value reaches, rises above, or falls below a defined threshold.

Task Manager is another tool that provides performance information about systems running the Windows Server 2003 family. Task Manager provides information about programs and processes that are running on your computer, plus a summary of its processor and memory usage. For information about Task Manager, see Task Manager overview.

Microsoft technical support often uses the results of performance monitoring in problem diagnosis. Therefore, Microsoft recommends that you monitor system performance as part of your administrative routine.

For information on server reliability, availability, and performance and tuning features in the Windows Server 2003 family, see Features for Management, Security, and Best Performance.

For overviews of the performance-monitoring tools, see the following topics:

- System Monitor overview
- Performance Logs and Alerts overview

# System Monitor overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Monitor overview**

With System Monitor, you can measure the performance of your own computer or other computers on a network in the following ways:

- Collect and view the real-time performance data of a local computer or several remote computers: Usability has been modified in the Windows Server 2003 family. For example, you can delete multiple counters at once and display the data properties page for a counter directly from the list window. You can save selected data from a performance log file or an SQL database to a new file for analysis at a later time.

- Also new in the Windows Server 2003 family are two new security groups that help you to ensure that only trusted users can access and manipulate sensitive performance data. These are the Performance Log Users group and the Performance Monitor Users group.

- View data collected either currently or previously in a counter log. With the Windows Server 2003 family, you can now simultaneously view data from multiple log files.

- Present data in a printable graph, histogram, or report view.

- Incorporate System Monitor functionality into applications that support ActiveX controls, for example, Web pages, and Microsoft Word or other applications in Microsoft Office

- Create HTML pages from performance views. Views stored in HTML format can be displayed by a browser.

- Create reusable monitoring configurations that can be installed on other computers using Microsoft Management Console (MMC).

With System Monitor, you can collect and view extensive data about the usage of hardware resources and the activity of system services on computers you administer. You can define the data you want System Monitor to collect in the following ways:

- **Type of data.** To select the data to be collected, you specify performance objects, performance counters, and performance object instances.

  Some objects provide data on system resources (such as memory); others provide data on the operation of applications (for example, system services).

- **Source of data.** System Monitor can collect data from your local computer or from other computers on the network for which you have administrative credentials. By default, administrative credentials are required. In addition, you can include real-time data or data collected previously using counter logs. With the Windows Server 2003 family, you can now view performance data that was previously collected and stored in an SQL database by the Performance Logs and Alerts service.

- **Sampling parameters.** System Monitor supports manual, on-demand sampling or automatic sampling based on a time interval you specify; this functionality applies to real-time data only. When viewing logged data, you can also choose starting and stopping times so that you can view data spanning a specific time range.

In addition to options for defining data content, you have considerable flexibility in designing the appearance of your System Monitor views:

- **Type of display.** System Monitor supports graph, histogram, and report views. The graph view is the default view; it offers the widest variety of optional settings.

- **Display characteristics.** For any of the three views, you can define the colors and fonts for the display. In graph and histogram views, you can select from many different options when you view performance data:
    - Provide a title for your graph or histogram and label the vertical axis.
    - Set the range of values depicted in your graph or histogram.
    - Adjust the characteristics of lines or bars plotted to indicate counter values, using color, width, style, and other graphical features.

For more information about the performance-monitoring process and interface, see Performance console overview and System Monitor interface.

# Performance Logs and Alerts overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance Logs and Alerts overview**

With Performance Logs and Alerts you can collect performance data automatically from local or remote computers. You can view logged counter data using System Monitor or export the data to spreadsheet programs or databases for analysis and report generation. The following list explains the capabilities of Performance Logs and Alerts:

- New in the Microsoft® Windows Server 2003 family is the ability to run log collections under different accounts. For example, if you need to log data from a remote computer that requires administrative credentials, you can specify an account with the necessary credentials.

- Also new in the Windows Server 2003 family are two new security groups that help you to ensure that only trusted users can access and manipulate sensitive performance data. These are the Performance Log Users group and the Performance Monitor Users group.

- The Windows Server 2003 family supports log files greater than 1 GB in size, and with its new log-file format, you can append performance data to an existing log file.

- Performance Logs and Alerts collects data in a comma-separated or tab-separated format for easy import to spreadsheet programs. A binary log-file format is also provided for circular logging or for logging instances such as threads or processes that may begin after the log starts collecting data. (Circular logging is the process of continuously logging data to a single file, overwriting previous data with new data.)

- You can also collect data in an SQL database format. This option defines the name of an existing SQL database and log set within the database where the performance data will be read or written. This file format is useful when collecting and analyzing performance data at an enterprise level rather than on a per-computer basis. Logging data directly to a SQL database is supported through open database connectivity (ODBC).

- Counter data collected by Performance Logs and Alerts can be viewed during collection as well as after collection has stopped.

- Because logging runs as a service, data collection occurs regardless of whether any user is logged on to the computer being monitored.

- You can define start and stop times, file names, file sizes, and other parameters for automatic log generation.

- You can manage multiple logging sessions from a single console window.

- You can set an alert on a counter, thereby defining that a message be sent, a program be run, an entry made to the application event log, or a log be started when the selected counter's value exceeds or falls below a specified setting.

Similar to System Monitor, Performance Logs and Alerts supports defining performance objects, performance counters, and performance object instances. It also supports setting sampling intervals for monitoring data about hardware resources and system services. Performance Logs and Alerts also offers other options related to recording performance data:

- **Start and stop logging** either manually on demand or automatically based on a user-defined schedule.

- **Configure additional settings** for automatic logging, such as automatic file renaming, and set parameters for stopping and starting a log file based on the elapsed time or the file size.

- **Create trace logs**. Using the default Windows Server 2003 family data provider or another application provider, trace logs record detailed system application events when certain activities, such as a disk I/O operation or a page fault, occurs. When the event occurs, your operating system logs the system data to a file specified by the Performance Logs and

Alerts service. This differs from the operation of counter logs; when counter logs are in use, the service obtains data from the system when the update interval has elapsed, rather than waiting for a specific event. A parsing tool is required to interpret the trace log output. Developers can create such a tool using application programming interfaces (APIs) provided in the MSDN Library on the Microsoft Web site.

- You can also produce trace analysis reports from trace log output files using the Tracerpt tool. Use this tool to process kernel, Active Directory, and other transactional based trace event logs, and to generate trace analysis reports and .csv files from binary logs.

- Define a program that runs when a log is stopped.

- If you want to export log data to Microsoft Excel, the Performance Logs and Alerts service must be stopped because Microsoft Excel requires exclusive access to the log file. Most other programs are not known to require this exclusive access; therefore, in general you can work with data from a log file while the service is collecting data to that file.

For more information about the Performance Logs and Alerts user interface, see Performance Logs and Alerts interface.

# Understanding the Performance console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding the Performance console**

This section describes the design and operation of System Monitor and Performance Logs and Alerts:

- Performance objects and counters
- Performance tool architecture

# Performance objects and counters

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance objects and counters**

The Windows Server 2003 family of operating systems obtains performance data from components in your computer as those components are utilized. That data is described as a performance object and is typically named for the component generating the data. For example, the Processor object is a collection of performance data about processors on your system.

Performance objects are built into the operating system, typically corresponding to the major hardware components such as memory, processors, and so on. Other programs might install their own performance objects. For example, services such as Windows Internet Name Service (WINS) or server programs such as Microsoft Exchange provide performance objects, and performance graphs and logs can monitor these objects.

Each performance object provides performance counters that represent data on specific aspects of a system or service. For example, the Pages/sec counter provided by the Memory object tracks the rate of memory paging.

Although your system might typically make available many more objects, following are the most frequently used objects:

- Cache
- Memory
- Objects
- Paging File
- PhysicalDisk
- Process
- Processor
- Server
- System
- Thread

The following table describes the services or features of your operating system that you might be using in your configuration and their corresponding performance objects:

| Feature or service to monitor | Performance object available |
|---|---|
| TCP/IP | ICMP, IP, NBT, TCP, and UDP objects |
| Browser, Workstation, and Server services | Browser, Redirector, and Server objects |
| Windows Internet Name Service (WINS) | WINS object |
| Connection Point Services | PBServer Monitor object |
| Indexing Service | Indexing Service, Indexing Service Filter, and HTTP Indexing Service objects |
| Directory service | NTDS object |
| Print server activity | Print Queue object |

For a description of the data provided by a particular counter that is associated with a performance object, click **Explain** in the **Add Counters** dialog box. For information about adding counters, see Add counters to System Monitor.

Although some objects (such as Memory and Server) have only a single performance object instance, some performance objects can have multiple instances. If an object has multiple instances, you can add counters to track statistics for each instance or for all instances at once.

Depending on how the counter was defined, its value may be:

- The most recent measurement of an aspect of resource utilization. These are called instantaneous counters.

  An example is Process\Thread Count, which shows the number of threads for a particular process as of the last time this was measured.

- The average of the last two measurements over the period between samples.

  An example is Memory\Pages/sec, a rate per second based on the average number of memory pages during the last two samples.

Other types of counters can be defined as described in the Platform Software Development Kit (SDK).

The combination of computer name, object, counter, instance, and instance index is known as the *counter path*. The counter path is typically shown in the tools as follows:

*Computer_name**Object_name*(*Instance_name*#*Index_Number*)*Counter_name*

The *computer_name* is optional. If you do not supply a name, your operating system will use the name of the local computer by default.

# Performance tool architecture

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance tool architecture**

Various architectural levels of the Windows Server 2003 family support the operation of System Monitor and Performance Logs and Alerts. For example, these performance tools obtain data by default by means of the registry. You can optionally collect performance data by means of the Windows Management Instrumentation (WMI) interface for hardware resources or applications installed on the system. The Performance Data Helper dynamic-link library (DLL) acts as an intermediary between the WMI and the performance tools to format the data and make calculations, where necessary, to convert raw data for display or reporting. For information about configuring performance tools to collect data using WMI, see Collect performance data using WMI.

DLLs supplied by the operating system provide counters for monitoring the behavior of resources such as memory, processors, disks, and network adapters and protocols. In addition, many services in the Windows Server 2003 family provide their own DLLs that install counters that you can use to monitor their operation.

System Monitor and Performance Logs and Alerts use the Remote Registry service process that manages user logon and logoff operations for remote monitoring connections. The Messenger service in the Windows Server 2003 family sends users alert notification. This service must be running for alert notifications to be received.

# Using the Performance console

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the Performance console**

This section covers the following topics:

- Setting up a monitoring configuration
- Quick reference to System Monitor settings
- System Monitor buttons and keyboard shortcut reference
- System Monitor interface
- Performance Logs and Alerts interface
- Quick reference to log file formats
- Analyzing performance data
- Solving performance problems
- Monitoring performance from the command line

# Setting up a monitoring configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting up a monitoring configuration**
Setting up a monitoring configuration is the first step in evaluating your system's performance. To monitor your Windows Server 2003 family operating system, you can choose to view data in a graph or collect the data in log files for use in other applications.

**Note**

- For best results, read the following sections for setting up your monitoring configuration. To get started quickly, however, you can use the predefined log settings under Counter Logs. These settings, named System Overview, are configured to create a binary log that, after manual startup, updates every 15 seconds and logs continuously until it achieves a maximum size. If you start logging with these settings, data is saved to the Perflogs folder on the root directory and includes the counters: Memory\Pages/sec, PhysicalDisk(_Total)\Avg. Disk Queue Length, and Processor(_Total)\% Processor Time.

**Choosing the monitoring method**
Graphs are useful for short-term, real-time monitoring of a local or remote computer--for example, when you want to observe a system event while it is happening. Choose the update interval to best capture the type of activity you are interested in. Logs are useful for record-keeping and for extended monitoring, especially of a remote computer; logged data can be exported for report generation and presented as graphs or histograms using System Monitor. Logging is the most practical way to monitor multiple computers.

**Choosing how often to monitor**
For routine monitoring, start by logging activity over 15-minute intervals. If you are monitoring for a specific problem, you might want to vary the interval. If you are monitoring the activity of a specific process at a specific time, set a frequent update interval; however, if you are monitoring a problem that manifests itself slowly, such as a memory leak, use a longer interval.

Also consider the overall length of time you want to monitor when choosing this interval. Updating every 15 seconds is reasonable if you plan to monitor for no more than four hours. If you plan to monitor a system for eight hours or more, set an interval longer than 300 seconds (five minutes). Setting the update interval to a frequent rate (low value) can cause the system to generate a large amount of data. This can be difficult to work with and can increase the overhead of running Performance Logs and Alerts.

Monitoring a large number of objects and counters can also generate large amounts of data and consume disk space. Try to strike a balance between the number of objects you monitor and the sampling frequency to keep log file size within manageable limits.

**Choosing the data to monitor**
Start by monitoring the activity of the following components in order:

1. Memory
2. Processors
3. Disks
4. Network

The following table shows the types of counters recommended for server monitoring. When examining specific resources, you should include other counters for the associated performance object.

| Component | Performance aspect being monitored | Counters to monitor |
|---|---|---|

| | | |
|---|---|---|
| Disk | Usage | Physical Disk\Disk Reads/sec Physical Disk\Disk Writes/sec LogicalDisk\% Free Space Interpret the % Disk Time counter carefully. Because the _Total instance of this counter may not accurately reflect utilization on multiple-disk systems, it is important to use the % Idle Time counter as well. Note that these counters cannot display a value exceeding 100%. |
| Disk | Bottlenecks | Physical Disk\Avg. Disk Queue Length (all instances) |
| Memory | Usage | Memory\Available Bytes Memory\Cache Bytes |
| Memory | Bottlenecks or leaks | Memory\Pages/sec Memory\Page Reads/sec Memory\Transition Faults/sec Memory\Pool Paged Bytes Memory\Pool Nonpaged Bytes Although not specifically Memory object counters, the following are also useful for memory analysis: Paging File\% Usage object (all instances) Cache\Data Map Hits % Server\Pool Paged Bytes and Server\Pool Nonpaged Bytes |
| Network | Throughput | Protocol transmission counters (varies with networking protocol); for TCP/IP: Network Interface\Bytes total/sec Network Interface\Packets/sec Server\Bytes Total/sec or Server\Bytes Transmitted/sec and Server\Bytes Received/sec |
| Processor | Usage | Processor\% Processor Time (all instances) |
| Processor | Bottlenecks | System\Processor Queue Length (all instances) Processor\Interrupts/sec System\Context switches/sec |

If some of the counters listed in the preceding table are not available on your computer, verify that you have installed the necessary services or activated the counters.

**Choosing the computer to use for monitoring**

When monitoring computers remotely, you have some options for collecting data. For example, you can run performance logging on the administrator's computer, drawing data continuously from each remote computer. In another case, you can have each computer running the service to collect data and, at regular intervals, run a batch program to transfer the data to the administrator's computer for analysis and archiving. Note that Performance Logs and Alerts allows you to specify a batch file that will run whenever a given log file is closed for a specified log.

Centralized data collection (that is, collection on a local computer from remote computers that you are monitoring) is simple to implement because only one logging service is running. You can collect data from multiple systems into a single log file. It causes additional network traffic, however, and might be restricted by available memory on the administrator's computer. To do centralized data collection, use the Add Counters dialog box to select a remote computer while running Performance Logs and Alerts on your local computer.

Distributed data collection (that is, data collection that occurs on the remote computers that you are monitoring) does not incur the memory and network traffic problems of centralized collection. It does result in delayed availability of the data, however, requiring that the collected data be transferred to the administrator's computer for review. To do distributed data collection, use the Performance Logs and Alerts node within Computer Management on a local computer to select a remote computer on which to collect data.

**Remote monitoring**

If you plan to monitor remote computers, you must have the appropriate administrative credentials to gain access to them. In order to monitor remote systems from your computer, you must specify a Run as account that has access to the remote computer. The Run as option sets the account for the specified log or alert, not for the entire Performance Logs and Alerts service. By default, the service is started under the local computer's NTAuthority\NetworkService account, which generally has permission only to access services and resources on the local computer. To start the service under a different account, use the Run as option when configuring data collection, or use Services under Computer Management, and update the properties of the Performance Logs and Alerts service.

**Keeping records of performance data**

Performance Logs and Alerts provides you with the ability to log performance data to an SQL database. When you retain your logged data in a database, you can query the information and include it in reports. Using database analysis tools, you can query results and examine the results in detail using a variety of parameters. You can also use logs for trend analysis and capacity planning.

**Exporting your monitoring configuration**

After configuring the performance tools with the counters, update intervals, and other settings you want, you can save those settings on your local computer or for export to another computer. System Monitor settings are saved to the .msc file, while Performance Logs and Alerts settings are stored in the registry. If you save the settings under the name Perfmon.msc, note that

you are permanently changing the configuration of the tools on the computer. Therefore, it is recommended that you save the file under another name. You can also save the settings for a single log or alert to an HTML file, which you can later use as a starting point to create new logs or alerts.

In addition to saving monitoring settings, you can add other tools or add multiple copies of System Monitor; for example, if you want to monitor graph and report views simultaneously. For information about adding tools to a console, see Create a custom monitoring console.

# Quick reference to System Monitor settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quick reference to System Monitor settings**

For all of the following settings, start by right-clicking the System Monitor details pane and clicking **Properties**.

| To add or change this | Use this tab |
|---|---|
| View type: graph, histogram, or report | **General** |
| Objects, counters, and instances (add or delete) | **Data**<br><br>**Note**<br><br>• You can also add counters by right-clicking in the details pane of the System Monitor (as opposed to the **System Monitor Properties** dialog box) and clicking **Add Counters**, or by clicking the Add button on the toolbar. You can also delete counters by pressing the **DELETE** key. This works only if you are using the System Monitor (as opposed to the **System Monitor Properties** dialog box). To remove all counters and specify new ones, click the New Counter Set button on the toolbar. |
| Source of data displayed: current data input to the graph, current data input from a log, archived data input from a log | **Source**<br><br>**Note**<br><br>• You can also use the View Log File Data button on the toolbar to use a log file as the data source or the View Current Activity to view real-time data. |
| Time range for a log and view time range | **Source** |
| Update frequency | **General**<br><br>**Note**<br><br>• You can also use the Freeze Display and Update Data buttons on the toolbar to take samples manually. |
| Report or histogram value type (minimum, maximum, average) | **General** |
| Display of counter legend | **General** |
| Display of last, minimum, and maximum values for a selected counter (the value bar); allow multiple counter instances | **General** |
| Color, width, style, or graph line | **Data** |

| | |
|---|---|
| Scale of counter data values | **Data** |
| Background color of results pane surrounding the graph area, color of graph data-display area | **Appearance** |
| Title of graph | **Graph** |
| Label on value axis, vertical or horizontal grid lines, and upper and lower limits of graph axes | **Graph** |
| Font color in graph display or legend | **Appearance** |
| Font type, size, and style | **Appearance** |
| Grid color, timer bar color | **Appearance** |
| Border style, appearance of graph window | **General** |
| Toolbar | **General** |

# System Monitor buttons and keyboard shortcut reference

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Monitor buttons and keyboard shortcut reference**

Many commonly used functions can be easily accessed by icons found on the System Monitor toolbar, or by using keystroke combinations. The following table displays these functions and their corresponding buttons or keystroke combinations.

| Function | Button | Keyboard Shortcut |
|---|---|---|
| New Counter Set | | Ctrl+E |
| Clear Display | | Ctrl+D |
| View Current Activity | | Ctrl+T |
| View Log File Data | | Ctrl+L |
| View Graph | | Ctrl+G |
| View Histogram | | Ctrl+B |
| View Report | | Ctrl+R |
| Add | | Ctrl+I |
| Delete | | Delete Key |
| Paste Counter List | | Ctrl+V |
| Copy Properties | | Ctrl+C |
| Properties | | Ctrl+Q |
| Freeze Display | | Ctrl+F |
| Update Data | | Ctrl+U |
| Highlight | | Ctrl+H |
| Help | | F1 |

# System Monitor interface

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System Monitor interface**
When you open Performance, a toolbar appears and the graph view area displays the same set of counters as the system overview query in Performance Logs and Alerts. System Monitor begins charting counter values in this graph area immediately. By default, data is updated automatically. Switch to manual update by using the **Freeze Display** button in the toolbar. Use the **Update Data** button to collect each sample on demand. One collection is made per click. To remove all data from the display, click the **Clear Display** button.

The names and associated information for the counters you select are shown in the legend beneath the graph, as follows:

- Computer on which System Monitor is running
- Performance object
- Performance counter
- Performance object instance. Note that by default counter instances are listed by name and numerical index. This index appears after the instance name, represented by a number sign (#) and a number. This index makes it easier to monitor multiple instances, for example, when you are monitoring threads of a process.

  To turn off the index display, right-click the graph, click **Properties**, and clear the **Allow duplicate counter instances** check box. By default, process and thread instances have a #n appended (where n is an integer). To append the process ID instead, create a DWORD value called ProcessNameFormat under the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\PerfProc\Performance subkey and set its value to 2. Likewise, to append the thread ID instead, create a DWORD value called ThreadNameFormat under the HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\PerfProc\Performance subkey and set its value to 2. To turn off any of these options and return to the default, set the value of the appropriate DWORD to 1.

  **Caution**

  - Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. For more information, see Registry Editor overview.

- Graphical properties of each counter.

**Note**

- To match a line in a graph with the counter for which it is charting values, select a counter in the legend and double-click a position in the line. When highlighting is in effect, the bar or line representing data for the selected counter changes color to black for most background colors. If chart lines are close together, try to find a point in the graph where they diverge. Otherwise, System Monitor may not be able to pinpoint the value you are interested in.

Above the legend columns is the value bar, where you see the last, minimum, maximum, and average values for the counter that is currently selected. These values are calculated over the time period and number of samples displayed in the graph (reflected by the **Duration** value), not over the time that has elapsed since monitoring was started. The **Duration** value in the value bar indicates the total elapsed time displayed in the graph (based on the update interval). The movement of the timer bar across the graph indicates the passing of each update interval. Regardless of the update interval, the view will show up to 100 samples. System Monitor compresses log data as necessary to fit it in the display.

You can define the following attributes of the graph:

- Type of display, with options for graph, histogram, or report.

- Background color of the details pane and of the data-display area.
- Size, type, and style of font used to show text in the display.
- Color, width, and style of line used to chart data.

**Note**

- Default key settings in Microsoft Word may conflict with the CTRL+H combination used for System Monitor highlighting. You may need to change these to support highlighting when the System Monitor control (Sysmon.ocx in the *system_root*\System32 folder) is used in Microsoft Word.

Clicking **Object**, **Counter**, **Instance**, or **Computer** in the counter legend sorts entries in ascending or descending order for that category. For example, to sort all counters by name, click **Counter**.

For more information, see Quick reference to System Monitor settings.

# Performance Logs and Alerts interface

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance Logs and Alerts interface**

In Performance Logs and Alerts you define settings for counter logs, trace logs, and alerts. The details pane of the console window shows logs and alerts that you have created. You can define multiple logs or alerts to run simultaneously. Each log or alert is a saved configuration that you define. If you have configured the log for automatic starting and stopping, a single log can generate many individual log data files. For example, if you were generating a log file for each day's activity, one file would close at 11:59 P.M. today, and a new file would open at 12:00 A.M. tomorrow. The following table explains the query summary information provided by the columns in the details pane.

| Column | Description |
|---|---|
| **Name** | This is the name of the log or alert. It describes the type of data you are collecting or the condition you are monitoring. One log can generate multiple log files.<br><br>**Note**<br><br>• Sample settings, named System Overview, have been predefined for counter logging. You can start logging using these settings or define your own settings, as appropriate. |
| **Comment** | This can be any descriptive information about the log or alert. |
| **Log File Type** | This is the log-file format you define. For alert, the type will always be **alerts**. For trace logs, the type can be **sequential** or **circular**. For logs, this can be **binary**, **binary circular**, **text file (comma delimited)**, **text file (tab delimited)** or **SQL**. |
| **Log File Name** | This is the path and base file name you defined for the files generated by this log. The base file name is used for automatically naming new files. |

To see the parameters defined for each log, double-click the list entry for the log. In the dialog box that appears, you can choose how to name your log files, when logging is scheduled to occur, and what performance objects and counters you want to monitor in your log.

If a log is currently running and collecting data (based on the schedule you defined for the log or alert), a green data icon appears next to the log or alert. If a red icon appears, the log or alert has been defined but is not currently running.

**Note**

- You can configure more than one type of log to run at a time. One log can generate multiple log files if the restart option is selected or if the user starts and stops the log multiple times. However, you will not see these individual log files listed in the console window. Use Windows Explorer to view a listing of these files.

# Quick reference to log file formats

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Quick reference to log file formats**

The following table provides a description of each log file format. For step-by-step guidance on selecting a format, see Set parameters for a log.

| Log file format | Description | Applies to |
|---|---|---|
| Text File (Comma delimited) | This option defines a comma-delimited log file (with a .csv extension). Use this format, for example, to export the log data into a spreadsheet program. | Counter logs |
| Text File (Tab delimited) | This option defines a tab-delimited log file (with a .tsv extension). Use this format, for example, to export the log data into a spreadsheet program. | Counter logs |
| Binary File | This option defines a sequential, binary-format log file (with a .blg extension). Use this file format if you want to be able to record data instances that are intermittent--that is, stopping and resuming after the log has begun running. Only binary file formats can accommodate instances that are not persistent throughout the duration of the log. | Counter logs |
| Binary Circular File | This option defines a circular, binary-format log file (with a .blg extension). Use this file format to record data continuously to the same log file, overwriting previous records with new data when the file reaches its maximum size. | Counter logs |
| Circular Trace File | This option defines a circular trace log file (with an .etl extension). Use this file format to record data continuously to the same log file, overwriting previous records with new data when the file reaches its maximum size. | Trace logs |
| Sequential Trace File | This option defines a sequential trace log file (with an .etl extension) that collects data until it reaches a user-defined limit and then closes and starts a new file. | Trace logs |
| SQL Database | This option defines the name of an existing SQL database and log set within the database where the performance data will be read or written. Use this file format to collect performance data at an enterprise level rather than a per computer basis. | Counter logs |

# Analyzing performance data

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Analyzing performance data**

Analyzing your monitoring data consists of examining counter values that are reported while your system is performing various operations. You should determine which processes are most active and which programs or threads, if any, are monopolizing a resource. Using this type of performance data analysis, you can understand how your system is responding to workload demands.

As a result of this analysis, you may find that your system performs satisfactorily at some times and unsatisfactorily at others. Depending on the causes of these variations and the degree of difference, you may choose to take corrective action or to accept these variations and delay tuning or upgrading resources for a later time.

The level of system performance that you consider acceptable when your system is handling a typical workload and running all required services is its baseline. The baseline performance is a subjective standard that the administrator determines based on the work environment. It may correspond to a range of counter values, including some that are temporarily unacceptable but which generally indicate the best possible performance under the administrator's specific conditions. The baseline can be the measure used for setting performance standards for your users and can be included in any service agreements you put in place.

**Determining acceptable values for counters**

In general, deciding whether or not performance is acceptable is a subjective judgment that varies significantly with variations in user environments. The following table containing threshold values for specific counters can, however, help you determine whether values reported by your system indicate a problem. If System Monitor consistently reports these values, it is likely that bottlenecks exist on your system and you should take action to tune or upgrade the affected resource. Counters that show usage ratios over an interval are a more informative measurement than averages of instantaneous counter values. In performance data measurements, one or two data points that fall outside normal operating conditions for a brief period of time, for example, during the startup period of a service, can skew the average. This gives a false impression of the overall operating performance during the collection period.

| Resource | Object\Counter | Suggested threshold | Comments |
|---|---|---|---|
| Disk | Physical Disk\% Free Space<br>Logical Disk\% Free Space | 15% | |
| Disk | Physical Disk\% Disk Time<br>Logical Disk\% Disk Time | 90% | |
| Disk | Physical Disk\Disk Reads/sec, Physical Disk\Disk Writes/sec | Depends on manufacturer's specifications | Check the specified transfer rate for your disks to verify that this rate does not exceed the specifications. In general, Ultra Wide SCSI disks can handle 50 to 70 I/O operations per second. Note that whether or not the I/O is sequential or random can have a strong impact on values for disk reads/sec and disk writes/sec. |
| Disk | Physical Disk\Current Disk Queue Length | Number of spindles plus 2 | This is an instantaneous counter; observe its value over several intervals. For an average over time, use Physical Disk\Avg. Disk Queue Length. |
| Memory | Memory\Available Bytes | For larger memory computers, greater than 4 MB | Research memory usage and add memory if needed. |
| Memory | Memory\Pages/sec | *n* pages/sec per pagefile | Research paging activity. Note the amount of I/O going to the disks with pagefiles. |
| Paging file | Paging File\% Usage | Above 70% | Review this value in conjunction with Available Bytes and Pages/sec to understand paging activity on your computer. |
| Processor | Processor\% Processor Time | 85% | Find the process that is using a high percentage of processor time. Upgrade to a faster processor or install an additional processor. |

| | | | |
|---|---|---|---|
| Processor | Processor\Interrupts/sec | Depends on processor; 1,000 interrupts per second is a good starting point | A dramatic increase in this counter value without a corresponding increase in system activity indicates a hardware problem. Identify the network adapter, disk, or other hardware causing the interrupts. |
| Server | Server\Bytes Total/sec | | If the sum of Bytes Total/sec for all servers is roughly equal to the maximum transfer rates of your network, you may need to segment the network. |
| Server | Server\Work Item Shortages | 3 | If the value reaches this threshold, consider adding the DWORD entries **InitWorkItems** (the number of work items allocated to a processor during startup) or **MaxWorkItems** (the maximum number of receive buffers that a server can allocate) to the registry (under HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\LanmanServer\Parameters). The entry **InitWorkItems** can range from 1 to 512 while **MaxWorkItems** can range from 1 to 65,535. Start with any value for **InitWorkItems** and a value of 4,096 for **MaxWorkItems** and keep doubling these values until the Server\Work Item Shortages threshold stays below 3. For information about modifying the registry, see Registry Editor overview.<br>**Caution**<br>• Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |
| Server | Server\Pool Paged Peak | Amount of physical RAM | This value is an indicator of the maximum paging file size and the amount of physical memory. |
| Server | Server Work Queues\Queue Length | 4 | If the value reaches this threshold, there may be a processor bottleneck. This is an instantaneous counter; observe its value over several intervals. |
| Multiple processors | System\Processor Queue Length | 2 | This is an instantaneous counter; observe its value over several intervals. |

For tuning and upgrade suggestions, see Solving performance problems.

For a more detailed discussion of performance-data analysis, see "Part One: Operating System Performance" in the System Performance and Troubleshooting Guide, available at the Microsoft Windows Resource Kits Web site.

# Solving performance problems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Solving performance problems**
Analysis of your monitoring data can reveal problems such as excessive demand on certain resources resulting in bottlenecks. This section discusses common causes for bottlenecks and a recommended strategy for tuning and testing.

**Causes of bottlenecks**
Demand may become extreme enough to cause resource bottlenecks for the following reasons:

- Resources are insufficient and additional or upgraded components are required.
- Resources are not sharing workloads evenly and need to be balanced.
- A resource is malfunctioning and needs to be replaced.
- A program is monopolizing a particular resource; this might require substituting another program, having a developer rewrite the program, adding or upgrading resources, or running the program during periods of low demand.
- A resource is incorrectly configured and configuration settings need to be changed.

**Strategy for tuning and testing**
Insufficient memory is the most common cause of serious performance problems in computer systems. If you suspect other problems, check memory counters to rule out a memory shortage. Poor response time on a workstation is most likely to result from memory and processor problems; servers are more susceptible to disk and network problems.

Before you start tuning, consider the following recommendations:

- Make one change at a time. In some cases, a problem that appears to relate to a single component might be the result of bottlenecks involving multiple components. For this reason, it is important to address problems individually.

  Making multiple changes simultaneously may make it impossible to assess the impact of each individual change.

- Repeat monitoring after every change. This is important for understanding the effect of the change and to determine whether additional changes are required. Proceed methodically, making one change to the identified resource at a time and then testing the effects of the changes on performance. Because tuning changes can affect other resources, it is important to keep records of the changes you make and to review after you make a change.
- In addition to monitoring, review event logs, because some performance problems generate output you can display in Event Viewer. For more information about using Event Viewer, see Event Viewer.
- To see whether network components are playing a part in performance problems, compare the performance of programs that run over the network with locally run programs.

**Tuning and upgrade tips by component**
This section lists tuning tips for resources you are monitoring:

**Memory:**

- Increase physical memory above the minimum required.
- Create multiple paging files when you use multiple disks.
- Determine the correct size for the paging files. The recommended initial size of the paging file is between 1 and 1.5 times the amount of RAM available, based on your system; the size needed depends on the workload.

- Ensure that memory settings are properly configured.
- Run memory-intensive programs on your highest performing computers or when system workload is light.

**Disk:**

- Upgrade to a higher speed disk, or add disks. If possible, upgrade the disk controller and the bus.
- On servers, use Disk Management to create striped volumes on multiple physical disks. This solution increases throughput because I/O commands can be issued concurrently.
- Distribute programs among servers. Distributed File System (DFS) can be used to balance workload.
- Isolate tasks that heavily utilize disk I/O on separate physical disks or disk controllers.
- Use Disk Defragmenter to consolidate files optimizing data access and disk space.
- If you want to improve the efficiency of disk access, consider installing the latest driver software for your host adapters or motherboard drivers. Contact your adapter or motherboard manufacturer for information.

**Processor:**

- Add a processor (especially for multithreaded programs). Upgrade to a faster processor, or one with a larger cache.
- On multiprocessor computers, manage the processor affinity with respect to process threads and interrupts.

**Network:**

- Configure your network so that systems shared by the same group of people are on the same subnet.
- Unbind infrequently used network adapters. See Modify the protocol bindings order for more information.
- If you are using more than one protocol, you can set the order in which the workstation and NetBIOS software bind to each protocol. See Network and Dial-up Connections Help for more information. Some reasons for changing the list order are as follows:
    - If the protocol you use most frequently is first in the binding list, average connection time decreases.
    - Some protocols are faster than others for certain network topologies. If you are optimizing a client computer, putting the faster protocol first in the bindings list improves performance. Because the server accepts incoming connections using the protocol chosen by the client computer, there is no reason to reorder server computer bindings.
- Use multiple network adapters. The Windows Server 2003 family of operating systems supports multiple adapters for a given protocol and multiple protocols for a given adapter. Although this configuration can create distinct networks that cannot communicate with one another, it is a way to increase file sharing throughput.

For information on server reliability, availability, and performance and tuning features in the Windows Server 2003 family, see Features for Management, Security, and Best Performance.

For detailed guidance on solving performance problems, see "Part One: Operating System Performance" in the System Performance and Troubleshooting Guide, available at the Microsoft Windows Resource Kits Web site.

# Monitoring performance from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring performance from the command line**

In addition to using the Performance graphical interface, you can use the following command line utilities:

- Logman manages and schedules performance counter and event trace log collections on local and remote systems.
- Perfmon allows you to open a Performance console configured with the System Monitor ActiveX control and Performance Logs and Alerts Service.
- Relog extracts performance counters from performance counter logs into other formats, such as **text file (tab delimited)**, **text file (comma delimited)**, **binary-BIN**, or **SQL**.
- Tracerpt processes event trace logs or real-time data from instrumented event trace providers and allows you to generate trace analysis reports and **CSV** (comma-delimited) files for the events generated.
- Typeperf writes performance counter data to the command window, or to a supported log file format.
- Lodctr registers new Performance counter names and Explain text for a service or device driver, and saves and restores counter settings and Explain text.
- Unlodctr removes Performance counter names and Explain text for a service or device driver from the system registry.

For more information about incorporating these Performance commands into your Windows Management Instrumentation (WMI), see "Part One: Operating System Performance" in the System Performance and Troubleshooting Guide, available at the Microsoft Windows Resource Kits Web site.

For information about other command-line utilities, see Command-line reference. For more information about manageability, see Management Strategies and Tools.

# Performance monitoring resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

- For a more detailed discussion of performance data and its analysis, and on troubleshooting your computer using performance-monitoring tools, see "Part One: Operating System Performance" in the System Performance and Troubleshooting Guide, available at the Microsoft Windows Resource Kits Web site.

- For information about optimizing programs or writing performance counters for programs, and about tuning network and service parameters in the registry to optimize performance, see the MSDN library at the Microsoft Web site.

# Troubleshooting Performance monitoring

Updated: April 25, 2012

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Counter values consistently equal zero.
- System Monitor shows gaps in its line graphs.
- Values recorded in a log do not appear in the graph view.
- Objects, counters, or instances seem to be missing or invalid.
- I sometimes see an extremely high value for one instance and not another while I am monitoring processes of the same name.
- While monitoring several threads, if one thread stops, its data appears to be reported for another.
- An error message is displayed if I try to export log data to Microsoft Excel while the Performance Logs and Alerts service is actively collecting data to that log.
- I lost my connection to a remote computer from which I was logging data and I cannot resume logging.
- Help for System Monitor does not appear in MMC Help; only Performance Logs and Alerts is displayed.
- I cannot log performance counters from a remote computer.
- My counters used to work, but since I installed a new application they do not work. Is there a way to restore the old counter settings?
- A remote performance counter query might return incorrect zero value for process elapsed time.

**Counter values consistently equal zero.**
**Cause:** The process being monitored has stopped so there is no data in the performance tools.

**Solution:** If you stopped the process manually, restart it to see the process in System Monitor. Otherwise, check Event Viewer for concurrent entries. You may find an error associated with this process.

**Cause:** The counter DLL was disabled after you selected the corresponding counters in a log or display. The performance tools will not detect that the counter was removed or disabled but will report the counter data as zeros.

**Solution:** Enable the corresponding counter DLL.

**Cause:** You lack the appropriate administrative credentials on the computer being monitored.

**Solution:** An administrator must ensure that your user account has the appropriate administrative credentials to use the performance tools.

**System Monitor shows gaps in its line graphs.**
**Cause:** This could be because data collection was subordinated to a processing activity with a higher priority on a system with a heavy load. When the system has adequate resources to continue with data collection, the graphing will resume as usual. A message appears describing this.

**Solution:** Reduce the performance overhead of system monitoring.

**See also:** Performance monitoring best practices

**Values recorded in a log do not appear in the graph view.**
**Cause:** The graph is limited to 100 samples.

**Solution:** Reduce the selected time range. For more information, see Use logged data.

**Cause:** You did not add counters to the graph view.

**See also:** For more information, see Add counters to System Monitor.

**Objects, counters, or instances seem to be missing or invalid.**
**Cause:** Test routines that run when you open the Performance console have detected a problem with installed counters and have disabled the counters automatically to prevent them from slowing the system. Disabled objects and counters do not appear in the **Add Counters** dialog box.

**Solution #1:** You can enable the disabled counters. Using Registry Editor, change the value under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services***Service_name***\Performance\Disable Performance Counters** from **1** for disable to **0** for enable. Note that counters that have been disabled after initial testing are likely to contain errors and may cause system problems. For information about debugging problems with counter DLLs, see the Microsoft Web site.

**Solution #2:** You can turn off the automatic testing feature for the counter DLL or adjust the level of testing. Using Registry Editor, locate the **Configuration Flags** subkey under **HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Perflib** and change the value of the **REG_DWORD** entry for this subkey:

| REG_DWORD value | Performance counter DLL test level |
|---|---|
| 0x00 | Test for buffer alignment errors and report any critical error detected. |
| 0x01 | Do not test for data buffer alignment errors. |
| 0x02 | Do not disable DLLs when errors are detected.<br>**Note**<br>• Your operating system will still write messages to the Event Log if this option is used. |
| 0x04 | Disable all performance counter function testing. |
| 0x08 | Enable the disabling of performance objects if they exceed a time-out value.<br>**Note**<br>• Normally your operating system will merely write a message to the Event Log. |
| 0x10 | Enable the collection of performance and error statistics for each performance object. This is the default setting.<br>**Caution**<br>• Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer. |

**Cause:** The process that starts the object counters is not started or installed.

**Solution:** Use Task Manager to verify that the process is running. If not, use Exctrlst.exe.

**See also:** Windows Resource Kit Tools Help.

**Cause:** The counters have not been enabled.

**Solution:** Make sure that the service or feature that provides the counter has been installed or configured.

**Cause:** The DLL that installs the counters is generating errors. An example is possible problems with localization functions by the counter.

**Solution:** Check Event Viewer to see whether the counter DLL or the Performance Data Helper reported any errors. If necessary, you can disable counter DLLs that are causing errors by using Exctrlst.exe.

**See also:** Windows Resource Kit Tools Help.

**Cause:** You are trying to monitor a 16-bit or MS-DOS application. Only 32-bit processes appear in the instances list. Active 16-bit processes appear as threads running in a Windows Virtual DOS Machine (NTVDM) process.

**Solution:** Monitor the application through the NTVDM process.

**Cause:** The instance you want to monitor is not currently active. If you are configuring System Monitor to collect real-time data, you can only select active instances for data collection. (If you are viewing logged data, you can select inactive instances for which the log contains data.) If you select the process and it stops after you've selected it, it will continue to appear in the list box but the reported data will be zeros.

**Solution:** Make sure the instance is active.

**I sometimes see an extremely high value for one instance and not another while I am monitoring processes of the same name.**
**Cause:** The performance tools sometimes misrepresent data for separate instances of processes with the same name by reporting the combined values of the instances as the value of a single instance.

**Solution:** Use the instance index and track the Process\ID Process and Process\Creating Process ID counters.

**While monitoring several threads, if one thread stops, its data appears to be reported for another.**
**Cause:** This is caused by the way threads are numbered. For example, assume you are monitoring three threads, numbered 0, 1, and 2. If thread 0 stops, the remaining threads get renumbered. The original thread 0 is now gone and the original thread 1 is renamed 0. As a result, data for the stopped thread 0 could be reported along with data for the running thread 1 because the previous thread 1 is now the current thread 0.

**Solution:** Use the instance index with Thread ID to track these threads.

**An error message is displayed if I try to export log data to Microsoft Excel while the Performance Logs and Alerts service is actively collecting data to that log.**
**Cause:** Microsoft Excel requires exclusive access to the log file. Most other programs do not require this exclusive access; therefore, in general, you can work with data from a log file while the service is collecting data to that file.

**Solution:** Stop the log collection using Performance Logs and Alerts before trying to use the log data with Microsoft Excel.

**I lost my connection to a remote computer from which I was logging data and I cannot resume logging.**
**Cause:** Logging data from a remote computer requires the use of Remote Registry Service. If the service stops due to failure, by default the system restarts it automatically only once.

**Solution:** If Remote Registry service stops more than once, you must restart the service manually on the second and any subsequent failures. To change this default behavior, use Computer Management or Services (on the **Administrative Tools** menu) to modify the properties for Remote Registry service.

**Help for System Monitor does not appear in MMC Help; only Performance Logs and Alerts is displayed.**
**Cause:** Because System Monitor is designed as an ActiveX control, its behavior differs from other Microsoft Management Console (MMC) snap-ins. For example, System Monitor Help is not available when you right-click System Monitor and then click **Help** on the shortcut menu, or when you click **Help Topics** on the **Help** menu.

**Solution:** Click the **Help** button on the System Monitor toolbar.

**I cannot log performance counters from a remote computer.**
**Cause:** You may not have administrative credentials to view the counters on the remote computer.

**Solution:** Ask the administrator of the remote computer to give you read access to the remote computer.

**Cause:** You may not have the correct administrative credentials granted through Group Policy.

**Solution:** Ask the administrator of the remote computer to grant you access through the following User Rights policies: **Profile System Performance** and **Profile a Single Process**.

**See also:** Group Policy (pre-GPMC).

**Cause:** The Performance Logs and Alerts service may not have permission to log on to the remote computer or to create and update the log file.

**Solution:** Use the Run as text box and **Password** button to specify the logon account name with the necessary permissions for the Performance Logs and Alerts service. You can access these features from the **General** tab.

**Cause:** The Remote Registry service is not running on the remote computer.

**Solution:** Ensure that the Remote Registry service is started on the remote computer. You need appropriate permissions on the remote computer to start the service.

**Note**

- You might also receive this error message if the remote computer is running Windows 95. Computer Management does not support remote access to computers that are running Windows 95.

**See also:** Start, stop, pause, resume, or restart a service.

**Cause:** The size limit of the log file may not be large enough to collect your requested data.

**Solution:** Increase the limit of the log file size or set the file size to the maximum limit allowed.

**See also:** Set parameters for a log.

**Cause:** The log update interval may be too short to allow the server to respond to each periodic data request.

**Solution:** Increase the log update interval.

**See also:** View or change properties of a log or alert.

**My counters used to work, but since I installed a new application they do not work. Is there a way to restore the old counter settings?**

**Cause:** Whenever you install a new application that installs performance counters on your operating system, the operating system creates a backup copy of the performance counter registry entries taken prior to the addition of the new application's performance counters file. This backup is saved as a file named PerfStringBackup.ini. If your operating system successfully adds the new application's performance counters file, it then replaces the previous version of the PerfStringBackup.ini file with the file that it just created.

**Solution:** Restore the performance counter registry to the state described in the uncorrupted backup file by using the following command: **LODCTR /R:***filename* where *filename* is the name of the backup file of the performance counter registry entries.

**Note**

- To make a backup copy at any time of the performance counter registry settings, use the following command:

  **LODCTR /S:***filename*

  where *filename* is any name. You can save these backup files anywhere on your computer.

**A remote performance counter query might return incorrect zero value for process elapsed time.**

**Cause:** If an application queries performance counters through remote registry, some performance counters might appear with zero values.This is caused by a remote registry design limitation. The issue will occur if your application calls WNetAddConnection2W with a CONNECT_UPDATE_PROFILE flag prior to opening a remote registry handle.

**Solution:** This is a known issue that is resolved in Windows Server 2008.

# Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shutdown Event Tracker**
Shutdown Event Tracker is a routine part of the shutdown process, providing a way for IT professionals to uniformly document why users restart or shut down their computers. The data recorded by Shutdown Event Tracker help to create a comprehensive picture of an organization's system environment. Shutdown Event Tracker is enabled by default and supported on all Microsoft® Windows Server 2003 family operating systems. It is disabled by default and unsupported on Microsoft® Windows® XP Professional.

- For tips on using Shutdown Event Tracker, see Shutdown Event Tracker Best practices.
- For help with specific tasks, see Shutdown Event Tracker How To....
- For general background information, see Shutdown Event Tracker Concepts.
- For problem-solving instructions, see Troubleshooting Shutdown Event Tracker.

# Shutdown Event Tracker Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Plan to use Shutdown Event Tracker as a best practice.**

- You can use the data provided by Shutdown Event Tracker to create a more complete picture of your system environment. For more information, see Shutdown Event Tracker overview.

- To identify patterns of system restarts and shutdowns, review the event logs in Event Viewer on a regular basis. This information serves as a starting point for isolating system problems. For more information, see Event Viewer.

- To create a record of which system resources reached or exceeded their limits just before an unplanned shutdown, use the System State Data feature. When you decide to restart a server running a Windows Server 2003 family operating system, and you select an unplanned reason for doing so, this feature records information about each process, page file, and disk running on the system. It also records data on overall system usage. You can opt to send this information in a System State Data file to Microsoft using the error reporting functionality in the Windows Server 2003 family of operating systems. For more information, see Configure the System State Data feature on your local computer, Configure the System State Data feature on a domain or organizational unit, and Enable notification and reporting of unplanned shutdowns on your local computer. To access Microsoft's privacy policy on error reporting, see Shutdown Event Tracker Resources.

**Consider security when assigning shutdown user rights.**

- In addition to physically securing your server, use Active Directory to uniformly assign shutdown user rights to trusted users. For guidance, see the Access control overview and Best practices for security for security.

**Use standard reasons instead of custom reasons.**

- Using the standard restart and shutdown reasons provided by Microsoft enables you to remotely browse event logs, and to use automated tools that will be available. in the future. In addition, using predefined reasons is a simpler approach than defining your own reasons. For guidance on how to define custom reasons, as well as a comprehensive list of the standard reasons, see "Tools for Troubleshooting" at the Microsoft Windows Resource Kits Web site.

**Establish guidelines across your organization for choosing reasons and making comments.**

- Users should consistently use the restart and shutdown reasons displayed in the graphical user interface (GUI) to ensure the validity of the data collected. As a system administrator, you should establish and communicate specific guidelines for using each reason. You should also provide standards for information that users type in the **Comment** box, including when a comment is required, what information it should contain, and what form that information should take.

  For example, you may want to establish guidelines such as these:

  - If installing new software involves restarting a computer, use the reason **Application: Installation (Planned)**. Always supply the name of the new software in the **Comment** box.

  - If repairing hardware forces you to immediately restart or shut down a computer, use the reason **Hardware: Maintenance (Unplanned)**. Always supply the name of the hardware in the **Comment** box.

# Shutdown Event Tracker How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Configure Shutdown Event Tracker
- Work with Shutdown Event Tracker

# Configure Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure Shutdown Event Tracker**

- Configure Shutdown Event Tracker on your local computer
- Configure Shutdown Event Tracker on a domain or organizational unit
- Configure the System State Data feature on your local computer
- Configure the System State Data feature on a domain or organizational unit

# Configure Shutdown Event Tracker on your local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Shutdown Event Tracker on your local computer**

1. Open Group Policy.
2. Navigate to the **Display Shutdown Event Tracker** policy, and double-click it.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/System

3. On the **Setting** tab, click **Not Configured**, **Enabled**, or **Disabled**.
4. Click **Apply**, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Group Policy, click **Start**, click **Run**, type **gpedit.msc**, and then click **OK**.
- The **Server Only** and **Workstation Only** settings that appear in the user interface (UI) have an impact on the local computer, but they are intended primarily for use by domain administrators.
- To apply the policy setting to a remote computer, see "Group Policy" under Related Topics, below.
- You cannot use Group Policy to manage computers running Windows NT 4.0, Windows 95, Windows 98, Windows Millennium Edition, and Windows XP Home Edition.
- Shutdown Event Tracker is enabled by default on all Windows Server 2003 family operating systems. It is disabled by default on Windows XP Professional. It is not a functional component of Windows XP Home Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Shutdown Event Tracker on a domain or organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Shutdown Event Tracker on a domain or organizational unit**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

   **Where?**

   - Active Directory Users and Computers [*domain_controller_name.domain_name*]/*domain organizational unit/child organizational unit*

3. Click **properties**, and then click the **Group Policy** tab.
4. Click an existing Group Policy object (GPO) in the list box, and then click **Edit**.

   or

   Click **New** to create a new Group Policy object, and then click **Edit**.

5. Click **Display Shutdown Event Tracker**

   **Where?**

   - *Group policy object name*/Computer Configuration/Administrative Templates/System

6. On the **Setting** tab, click **Not Configured**, **Enabled**, or **Disabled**.
7. Click **Apply**, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- If you choose to enable the Group Policy for **Server Only**, Shutdown Event Tracker appears when you shut down a computer running a Windows Server 2003 family operating system.
- If you choose to enable the Group Policy for **Workstation Only**, the Shutdown Event Tracker appears when you shut down a computer running Windows XP Professional.
- To apply the Group Policy setting to a site, see "Group Policy" under Related Topics, below.
- You cannot use Group Policy to manage computers running Windows NT 4.0, Windows 95, Windows 98,

Windows Millennium Edition, and Windows XP Home Edition.

- Shutdown Event Tracker is enabled by default but not configured on all Windows Server 2003 family operating systems. It is disabled by default on Windows XP Professional. It is not a functional component of Windows XP Home Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure the System State Data feature on your local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the System State Data feature on your local computer**

1. Open Group Policy.
2. Navigate to the **Activate Shutdown Event Tracker System State Data feature** policy, and double-click it.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/System

3. On the **Setting** tab, click **Not Configured**, **Enabled**, or **Disabled**.
4. Click **Apply**, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Group Policy, click **Start**, click **Run**, type **gpedit.msc**, and then click **OK**.
- When this policy is enabled, Shutdown Event Tracker writes out a system state data file when a user with shutdown user rights designates a restart or shutdown as unplanned. This file is stored in the *%windir%\system32\LogFiles\Shutdown* directory, and only members of the Administrators group may view it or optionally send it to Microsoft.
- You can configure the number of days a system state data file will be saved to the *%windir%\system32\LogFiles\Shutdown* directory using the registry. See "Resources" in Related Topics for more information.
- To view Microsoft's privacy policy on error reporting, see "Resources" in Related Topics.
- When this policy is disabled, Shutdown Event Tracker will not create a system state data file in the event of an unplanned restart or shutdown.
- If you do not configure the System State Data feature, the default behavior occurs: By default, this feature is always enabled on the Windows Server 2003 family operating systems.
- To apply the policy setting to a remote computer, see "Group Policy" under Related Topics, below.
- You cannot use Group Policy to manage computers running Windows Server 4.0, Windows 95, Windows 98, Windows Millennium Edition, and Windows XP Home Edition.
- Administrative Templates provide a friendlier user interface (UI) for editing the registry than does Registry Editor (Regedit.exe), as well as an added degree of security: They expose only the registry keys that Microsoft has determined to be frequently useful.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure the System State Data feature on a domain or organizational unit

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the System State Data feature on a domain or organizational unit**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.

   **Where?**

   - Active Directory Users and Computers [*domain_controller_name.domain_name*]/*domain/organizational unit/child organizational unit*

3. Click **properties**, and then click the **Group Policy** tab.

4. Click an existing Group Policy object in the list box, and then click **Edit**.

   or

   Click **New** to create a new Group Policy object, and then click **Edit**.

5. Click **Activate Shutdown Event Tracker System State Data feature**

   **Where?**

   - *Group policy object name*/Computer Configuration/Administrative Templates/System

6. On the **Setting** tab, click **Not Configured**, **Enabled**, or **Disabled**.

7. Click **Apply**, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- When this policy is enabled, Shutdown Event Tracker writes out a system state data file when a user with shutdown rights designates a restart or shutdown as unplanned. This file is stored in the *%windir%\system32\LogFiles\Shutdown* directory, and only members of the Administrators group may view it or, optionally, send it to Microsoft.

- You can configure the number of days a system state data file will be saved to the *%windir%\system32\LogFiles\Shutdown* directory using the registry. See "Resources" in Related Topics for more information.

- To view Microsoft's privacy policy on error reporting, see "Resources" in Related Topics.

- When this policy is disabled, Shutdown Event Tracker does not create a system state data file.
- This policy is not configured by default on Windows XP Professional and Windows Server 2003 family operating systems.
- To apply the policy setting to a site, see "Group Policy" under Related Topics, below.
- You cannot use Group Policy to manage computers running Windows Server 4.0, Windows 95, Windows 98, Windows Millennium Edition, and Windows XP Home Edition.
- Administrative Templates provide a friendlier user interface (UI) for editing the registry than does Registry Editor (Regedit.exe), as well as an added degree of security: They expose only the registry keys that Microsoft has determined to be frequently useful.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with Shutdown Event Tracker**

- Restart or shut down locally and document the reason
- Restart or shut down remotely and document the reason
- Cancel a restart or shutdown
- Document the reason for an unexpected restart or shutdown of your local computer
- Document the reason for unexpected restarts or shutdowns of remote computers
- Enable notification and reporting of unplanned shutdowns on your local computer

# Restart or shut down locally and document the reason

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To restart or shut down locally and document the reason

- Using the Windows interface
- Using a command line

#### Using the Windows interface

1. Click **Start**, and then click **Shut Down** or **Restart**.
2. Under **What do you want the computer to do**, click **Restart** or **Shut down**.
3. If you did not anticipate having to restart or shut down the computer at this time, clear the **Planned** check box.
4. Select the appropriate reason from the list.
5. If a comment is required, the **OK** button will not function until you type at least one character in the text box.

### Important

- Do not turn off your computer until a message appears telling you that it is safe to do so. Windows Server 2003 family operating systems store important data in memory while the system is running and need to write the data to the hard disk before you turn off the computer. After the data is saved, the operating system notifies you that it is okay to turn off the computer.

### Notes

- To perform this procedure, you must have the user rights to shut down the local system. For a list of security groups that have this permission by default on computers running Windows Server 2003 family operating systems, see "Privileges" under Related Topics.
- An alternative way to open the expected shutdown dialog box is to press CTRL+ALT+DELETE and then click **Shut Down**.
- Shutdown Event Tracker records data only for the **Restart** and **Shutdown** options.
- If the System State Data feature is enabled and you specify an unplanned reason for the restart or shutdown, a file containing relevant system data will be created in the *%windir%\system32\LogFiles\Shutdown* directory. The System State Data feature is enabled by default on all Windows Server 2003 family operating systems.
- For information on defining custom reasons, see "Best practices" under Related Topics.

#### Using a command line

1. Open Command Prompt.
2. Type:

   **shutdown /s /d 1:1** to initiate an unplanned shut down after a default wait period of 30 seconds, with the major reason, **Hardware**, and the minor reason, **Maintenance**.

Or,

Type:

**shutdown /r /t 60 /d p:4:2** to initiate a planned startup after waiting one minute, with the major reason, **Application**, and the minor reason, **Installation**.

Or,

Type:

**shutdown /p /d p:1:2** to turn off the power to your computer with no time-out period or warning and to indicate that the action was planned with the major reason **Hardware** and the minor reason **Installation**.

| Value | Description |
|---|---|
| **/s** | Shuts down the computer. |
| **/r** | Restarts the computer after shutdown. |
| **/p** | Turns off the local computer with no time-out period or warning. You can use **/p** only with **/d**. If your computer does not support power off functionality, it will shut down when you use **/p**, but the power to the computer will remain on. |
| **/t** *nnn* | Sets the wait period before a restart or shutdown to *xxx* seconds, causing a warning to display on the local console. You can specify from 0 through 600 seconds. If you omit **/t**, the wait period defaults to 30 seconds. |
| **/d**[**p:**]*xx*:*yy* | Lists the reason for the system restart, shutdown, or power off. The following rows describe the parameter values. |
| **p:** | Indicates that the restart or shutdown is planned. If you do not use the **p:** option, Shutdown Event Tracker assumes that the restart or shutdown is unplanned. |
| *xx* | Specifies the major reason number (0-255). |
| *yy* | Specifies the minor reason number (0-65535). |

**Notes**

- To perform this procedure, you must have the user rights to shut down the local system. For a list of security groups that have this permission by default on computers running Windows Server 2003 family operating systems, see "Privileges" under Related Topics.
- For the complete command line syntax, see "Shutdown" under Related Topics, below.
- If the System State Data feature is enabled and you specify an unplanned reason for the restart or shutdown, a file containing relevant system data will be created in the *%windir%\system32\LogFiles\Shutdown* directory. The System State Data feature is enabled by default on all Windows Server 2003 family operating systems.
- For information on defining custom reasons, see "Best practices" under Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Restart or shut down remotely and document the reason

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To restart or shut down remotely and document the reason**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Command Prompt.
2. Type:

   **shutdown /i** to display the Remote Shutdown dialog box (Shutdown.exe).
3. Under **Computers**, click **Add** to enter computer names, or click **Browse** to open the **Find Computers** dialog box.
4. Under **What do you want these computers to do**, click **Restart** or **Shut down**.
5. If you did not anticipate restarting or shutting down the target computers at this time, clear the **Planned** check box.
6. Select the appropriate reason from the list.
7. If a comment is required, the **OK** button will not function until you type at least one character one in the text box.

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To perform this procedure, you must have the user rights to force a shutdown from a remote system. For a list of security groups that have this permission by default on computers running Windows Server 2003 family operating systems, see "Privileges" under Related Topics.
- The Remote Shutdown dialog box can be displayed only by typing **shutdown /i** at the command prompt.
- If the remote computer is functioning properly, but Shutdown.exe fails to restart it or shut it down, wait for two minutes before making a second attempt: Either the log on dialog box or the unexpected shutdown dialog box is open on the remote computer, causing an error.
- Shutdown Event Tracker records data only for the **Restart** and **Shutdown** options.
- If the System State Data feature is enabled and you specify an unplanned reason for the restart or shutdown, a file containing relevant system data will be created in the *%windir%\system32\LogFiles\Shutdown* directory. The System State Data feature is enabled by default on all Windows Server 2003 family operating systems.
- For information on defining custom reasons, see "Best practices" under Related Topics.
- The **Warn users of the action** check box is selected by default.

**Using a command line**

1. Open Command Prompt.

2. Type:

   **shutdown /s /m ***ComputerName***/d 1:1** to initiate an unplanned shutdown after a default wait period of 30 seconds, with the major reason, **Hardware**, and the minor reason, **Maintenance**.

   Or,

   Type:

   **shutdown /r /m ***ComputerName***/t 60 /d p:4:2** to initiate a planned startup after waiting for one minute, with the major reason, **Application**, and the minor reason, **Installation**.

| Value | Description |
|---|---|
| **/s** | Shuts down the computer. |
| **/r** | Restarts the computer after shutdown. |
| **/m ** *ComputerName* | Specifies the target computer. |
| **/t** *nnn* | Sets the wait period before a restart or shutdown to *nnn* seconds, causing a warning to display on the local console. You can specify from 0 through 600 seconds. If you omit **/t**, the wait period defaults to 30 seconds. |
| **/d**[**p:**]*xx***:***yy* | Lists the reason for the system restart, shutdown, or power off. The following rows describe the parameter values. |
| **p:** | Indicates that the restart or shutdown is planned. If you do not use the **p:** option, Shutdown Event Tracker assumes that the restart or shutdown is unplanned. |
| *xx* | Specifies the major reason number (from 0 through 255). |
| *yy* | Specifies the minor reason number (from 0 through 65535). |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- To perform this procedure, you must have the user rights to force a shutdown from a remote system. For a list of security groups that have this permission by default on computers running Windows Server 2003 family operating systems, see "Privileges" under Related Topics.

- For the complete command line syntax, see "Shutdown" under Related Topics, below.

- If the remote computer is functioning properly, but Shutdown.exe fails to restart it or shut it down, wait for 2 minutes before making a second attempt: Either the log on dialog box or the unexpected shutdown dialog box is open on the remote computer, causing an error.

- If the System State Data feature is enabled and you specify an unplanned reason for the restart or shutdown, a file containing relevant system data will be created in the *%windir%\system32\LogFiles\Shutdown* directory. The System State Data feature is enabled by default on all Windows Server 2003 family operating systems.

- For information on defining custom reasons, see "Best practices" under Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Cancel a restart or shutdown

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To cancel a restart or shutdown**

1. Open Command Prompt.
2. Type:

   **shutdown/a** within the time-out period.

## Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To perform this procedure on a local computer, you must have user rights to shut down the computer. To perform this procedure on a remotely managed computer, you must have the user rights to force a shutdown from a remote system.
    - You can set the time-out period before a restart or shutdown to *nnn* seconds using the **/t***nnn* option. The valid range is from 0 through –600 seconds, with a default of 30 seconds.
    - You cannot cancel a restart or shutdown using the Shutdown Event Tracker user interface (UI). It is possible to perform this task only from the command line.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Document the reason for an unexpected restart or shutdown of your local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To document the reason for an unexpected restart or shutdown of your local computer**

1. Under **Why did the computer shut down unexpectedly,** specify the appropriate reason from the list.
2. If your organization has a trouble-ticketing system, you can enter a **Problem Id**.
3. If a comment is required, the **OK** button will not function until you type at least one character in the text box.

### Note

- To perform this procedure, you must have the user rights to shut down the local system. For a list of security groups that have this right by default on computers running the Windows Server 2003 family operating systems, see "Privileges" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Document the reason for unexpected restarts or shutdowns of remote computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To document the reason for unexpected restarts or shutdowns of remote computers**

- Using the Windows interface
- Using a command line

**Using the Windows interface**

1. Open Command Prompt.
2. Type:

   **shutdown /i** to display the Remote Shutdown dialog box (Shutdown.exe).
3. Under **Computers**, click **Add** to enter computer names, or click **Browse** to open the **Find Computers** dialog box.
4. Under **What do you want these computers to do**, click **Annotate Unexpected Shutdown**.
5. Select the appropriate reason for the unexpected shutdown from the list.
6. If a comment is required, the **OK** button will not function until you type at least one character one in the text box.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- The Remote Shutdown dialog box (Shutdown.exe) can only be displayed by typing **shutdown /i** at the command prompt.
- For information on defining custom reasons, see "Best practices" in Related Topics.

**Using a command line**

1. Open Command Prompt.
2. Type: **shutdown/e/m**_ComputerName_**/c "**_Comment_**" /d** xx**:**yy

| Value | Description |
|---|---|
| **/e** | Enables you to document the reason for the unexpected shutdown on the remote computer. |

| | |
|---|---|
| **/m** *ComputerName* | Specifies the target computer. |
| **/c** | Enables you to comment in detail about the reason for the shutdown. You can use a maximum of 511 characters. Comments must be enclosed in quotation marks. |
| **/d** *xx* **:** *yy* | Lists the reason for the system restart or shutdown, where *xx* specifies a major reason number from 0 through 255 and *yy* specifies a minor reason number from 0 through 65,535. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- For the complete command line syntax, see "Shutdown" under Related Topics, below.
- For information on defining custom reasons, see "Best practices" under Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable notification and reporting of unplanned shutdowns on your local computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable notification and reporting of unplanned shutdowns on your local computer**

1. Enable Shutdown Event Tracker. See "Configure Shutdown Event Tracker on your local computer" in Related Topics for instructions.

2. Open Group Policy.

3. Navigate to **Activate Shutdown Event Tracker System State Data feature**, and double-click it.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/System

4. On the **Setting** tab, click **Enabled**.

5. Click **Apply**, and then click **OK**.

6. Navigate to the **Configure Error Reporting** policy, and double-click it.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/System/Error Reporting

7. On the **Setting** tab, click **Enabled**.

8. Click **Apply**, and then click **OK**.

9. Navigate to the **Report unplanned shutdown events** policy, and double-click it.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/System/Error Reporting/Advanced Error Reporting settings

10. On the **Setting** tab, click **Enabled**.

11. Click **Apply**, and then click **OK**.

12. Navigate to the **Display Error Notification** policy, and double-click it.

    **Where?**

    - Local Computer Policy/Computer Configuration/Administrative Templates/System/Error Reporting

13. On the **Setting** tab, click **Enabled**.

14. Click **Apply**, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- The above procedure causes a system state data file to be created in the *%windir%\system32\LogFiles\Shutdown* directory prior to an unplanned restart or shutdown. The first user with administrative credentials who subsequently logs on to the computer will see a dialog box notification reading "The system has restarted after an unplanned shutdown. A log of this event has been created." From this dialog box, the administrator can navigate to a more detailed description of the system state data file, its contents, and Microsoft's privacy policy for data collection on the Web. The administrator can choose whether or not to send the system state data file to Microsoft by clicking either the **Send Error Report** or **Don't Send** button.

- To enable the creation of the system state data file and notification, but disable error reporting, set all of the policies to **Enabled** except for the **Configure Error Reporting** policy, which should be set to **Disabled**.

- To bypass the administrator and send the error report automatically, set all of the policies to **Enabled** except for the **Display Error Notification** policy, which should be set to **Disabled**.

- You have the option of enabling Corporate Error Reporting by setting a path for uploading data to a central location on your network. You can also customize the error reporting dialogs by replacing instances of the word "Microsoft" with your company's name. For more information, double-click the **Configure Error Reporting** policy and click the **Explain** tab.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Shutdown Event Tracker Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Shutdown Event Tracker and the System State Data feature:

- Shutdown Event Tracker overview
- Using Shutdown Event Tracker
- Shutdown Event Tracker Resources

# Shutdown Event Tracker overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shutdown Event Tracker overview**
Shutdown Event Tracker provides a way for IT professionals to consistently track why users restart or shut down their computers. It does not document why users choose other options, such as **Log off** and **Hibernate**. It gathers the reasons users give for restarts and shutdowns to help create a comprehensive picture of an organization's system environment. Shutdown Event Tracker is enabled by default and supported on all Microsoft® Windows Server 2003 family of operating systems. It is disabled by default and unsupported on Microsoft® Windows® XP Professional.

**"Expected" and "unexpected" startups and shutdowns**
When Shutdown Event Tracker is enabled, the "expected" shutdown dialog box appears when users click **Start** and then **Shutdown**, or when they press CTRL+ALT+DELETE and then click **Shutdown**. This dialog box is different from the standard Windows shutdown dialog box in that it prompts users to supply a reason and a comment to explain the action. An expected startup or shutdown provides the operating system time to complete its usual shutdown routine. By contrast, the computer cannot anticipate an "unexpected" startup or shutdown. If Shutdown Event Tracker is enabled, the unexpected shutdown dialog box appears to the first person with shutdown user rights who logs on to the computer after the startup or shutdown. Like the expected shutdown dialog box, it prompts this user to supply a reason and a comment.

**Planned and unplanned startups and shutdowns**
From the user's point of view, an expected system startup or shutdown can be planned or unplanned. When users have control over the timing of a startup or shutdown, the task is planned. For example, the IT department may reserve a specific time at which to install new applications. By contrast, an unplanned restart or shutdown forces users to immediately perform the task. For example, unresponsive applications might suddenly force users to restart their computers.

Unexpected restarts or shutdowns can also be planned or unplanned. For example, users sometimes choose to shut down their computers by pressing the power button instead of clicking **Start** and then **Shutdown**, or by pressing CTRL+ALT+DELETE and then clicking **Shutdown**. In this case, the shutdown is unexpected by the computer and planned by the user. However, if the computer's power cord is accidentally disconnected, the shutdown is both unexpected and unplanned. In each case, the unexpected dialog box appears to the first person with shutdown user rights to log on to the computer after the event.

For step-by-step guidance and specific examples, see Restart or shut down locally and document the reason and Restart or shut down remotely and document the reason.

**Local and remote startups and shutdowns**
Shutdown Event Tracker and the Shutdown.exe tool enable users to restart or shut down a local computer and one or more remote computers by using either the graphical user interface (GUI) or the Shutdown command. Additionally, IT professionals can perform remote bulk annotations of unexpected shutdowns, an alternative to the time-consuming task of logging on to each computer to record a reason for an unexpected shutdown.

**Root-cause analysis of startups and shutdowns**
Shutdown Event Tracker records the reason for each shutdown or startup through the Event Log service. You can use Event Viewer to open the system log and look for a pattern of events to find the cause of frequent system restarts and shutdowns. For more information, see Event Viewer.

The System State Data feature gathers information for root-cause analysis of unplanned shutdowns. System state data is recorded in a log file when a user who has shutdown user rights specifies an unplanned reason for shutting down a computer. Regardless of who gathers the data, only users with administrative credentials can view it or, optionally, send it to Microsoft. The first person with administrative credentials to log on to the computer after the unplanned shutdown encounters a Windows error reporting dialog box with a link to the system state data file. This file is stored in the *%windir%\system32\LogFiles\Shutdown* directory.

The System State Data feature is available on all Windows Server 2003 family of operating systems. It is not available on Windows XP Professional. For step-by-step guidance, see Configure the System State Data feature on your local computer and Configure the System State Data feature on a domain or organizational unit.

# Using Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Shutdown Event Tracker**

This section covers:

- Enabling or disabling Shutdown Event Tracker
- Using Shutdown Event Tracker with non-English Windows Server 2003 family products
- Managing Shutdown Event Tracker from the command line

# Enabling or disabling Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling or disabling Shutdown Event Tracker**

You can use either Group Policy to enable or disable Shutdown Event Tracker on your system. For details on how to configure Shutdown Event Tracker by setting the **Display Shutdown Event Tracker** policy, see Configure Shutdown Event Tracker on your local computer or Configure Shutdown Event Tracker on a domain or organizational unit.

When Shutdown Event Tracker is enabled, the expected shutdown dialog box appears when you click **Start** and then click **Shutdown**, or when you press CTRL+ALT+DELETE and then click **Shutdown**. Should an unexpected restart or shutdown occur, the unexpected shutdown dialog box will appear to the first person with shutdown user rights who logs on to the computer.

When Shutdown Event Tracker is disabled, the standard Windows shutdown dialog box appears. It provides a way to restart or shut down your computer; however, it does not provide a way to record whether or not the event is planned or unplanned, or a way to record a reason for it. Should an unexpected restart or shutdown occur, the unexpected shutdown dialog box will *not* appear to the first person with shutdown rights who logs on to the computer. For definitions of planned and unplanned, and expected and unexpected startups and shutdowns, see Shutdown Event Tracker overview.

# Using Shutdown Event Tracker with non-English Windows Server 2003 family products

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Shutdown Event Tracker with non-English Windows Server 2003 family products**

You can configure Shutdown Event Tracker to display standard and custom reasons in languages other than English by modifying the registry. For example, to display the standard shutdown reasons supplied by Microsoft in a language such as Romanian, your operating system's Locale must also be in Romanian, and the Windows Server 2003 family operating system on your computer must also be Romanian. However, custom reasons that you store under a designated subkey will appear in whatever language they are stored. For example, if you define reasons under this subkey in Chinese characters, Shutdown Event Tracker will attempt to display the Chinese characters on the Romanian Windows Server 2003 family operating system. If you have installed the appropriate code page, the Chinese characters will appear. If you have not installed the code page, question marks (?) will appear instead.

For information on how to edit the registry to enable multilanguage support, see "Tools for Troubleshooting" at the Microsoft Windows Resource Kits Web site.

# Managing Shutdown Event Tracker from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Shutdown Event Tracker from the command line**
In addition to using the graphical user interface (GUI) to record restart and shutdown reasons, you can use the command line. For details, see the following:

- Restart or shut down locally and document the reason
- Restart or shut down remotely and document the reason
- Document the reason for unexpected restarts or shutdowns of remote computers

See Shutdown for specific usage information.

# Shutdown Event Tracker Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

See "Tools for Troubleshooting" at the Microsoft Windows Resource Kits Web site for the following information:

- How to manage Shutdown Event Tracker using the registry
- How to turn off the standard restart and shutdown reasons provided by Microsoft
- How to define your own reasons

To view Microsoft's privacy policy in relation to the System State Data feature, see Microsoft Error Reporting.

For information on error and event log messages, technical support, and tools, see Support resources.

# Troubleshooting Shutdown Event Tracker

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Shutdown Event Tracker does not appear when you attempt to shut down your computer. (The standard Windows shutdown dialog box appears. It does not allow you to supply a reason or a comment.)
- A System State Data file is not created before an unplanned shutdown: Upon checking the Event Log for the corresponding 1074 event, you see that the System State Data file name does not appear in the event description.
- You initiated the shutdown sequence using the command line, but the shutdown reason text in the event description is incorrect.
- When you log on to a computer, the error reporting dialog box appears even though the previous shutdown was planned.
- The OK button is disabled after you choose a shutdown reason.
- After you upgrade a server from Windows NT to a Windows Server 2003 family operating system, users who were previously able to shut down the computer can no longer do so.
- When you attempt to shut down a remote computer, you are denied access.
- The Shutdown tool (Shutdown.exe) fails to restart or shut down a remote computer, although the target computer is functioning properly.

**Shutdown Event Tracker does not appear when you attempt to shut down your computer. (The standard Windows shutdown dialog box appears. It does not allow you to supply a reason or a comment.)**
**Cause:** Shutdown Event Tracker is disabled.

**Solution:** If you have not yet enabled Shutdown Event Tracker using Group Policy, do so.

**See also:** Configure Shutdown Event Tracker on your local computer and Configure Shutdown Event Tracker on a domain or organizational unit.

**Cause:** You do not have the rights to shut down the computer.

**Solution:** Assign yourself the rights to shut down each computer that you manage or have your system administrator assign you the appropriate user rights.

**See also:** Privileges and Security overview

**Cause:** An out-of-date shutdown tool from an earlier Resource Kit is installed.

**Solution:** Uninstall any out-of-date shutdown tool.

**Cause:** The Shutdown Event Tracker Group Policy setting has not yet taken effect.

**Solution:** Allow more time for the Group Policy setting to update itself. If this strategy does not yield results, use the gpupdate.exe tool.

**See also:** Group Policy (pre-GPMC) and Gpupdate.

**Cause:** A higher-level Group Policy configuration takes precedence.

**Solution:** If the Group Policy settings are at a higher level and you do not have the proper administrative credentials to change it, contact your system administrator.

**See also:** Windows Server 2003 Technical Reference at the Microsoft Web site, Group Policy (pre-GPMC), and Configure Shutdown Event Tracker on a domain or organizational unit.

**A System State Data file is not created before an unplanned shutdown: Upon checking the Event Log for the corresponding 1074 event, you see that the System State Data file name does not appear in the event description.**
**Cause:** The System State Data feature is disabled.

**Solution:** If you have not yet enabled the System State Data feature using Group Policy, do so. If the problem persists, consult the Microsoft Resource Kit chapter, below.

**See also:** Configure the System State Data feature on your local computer, Configure the System State Data feature on a domain or organizational unit, and "Tools for Troubleshooting" at the Microsoft Windows Resource Kits Web site.

**Cause:** You initiated the shutdown on a computer running Windows XP Professional.

**Solution:** Windows XP Professional does not include the System State Data feature.

**You initiated the shutdown sequence using the command line, but the shutdown reason text in the event description is incorrect.**
**Cause:** The appropriate reason code was not defined on the computer you shut down.

**Solution:** Add the same set of reasons to all the computers in your organization.

**See also:** "Tools for Troubleshooting" at the Microsoft Windows Resource Kits Web site.

**When you log on to a computer, the error reporting dialog box appears even though the previous shutdown was planned.**
**Cause:** The person who performed the previous shutdown specified it as unplanned. This is likely if the shutdown was initiated from the command line, because omitting **p:** causes Shutdown Event Tracker to record an unplanned event.

**Solution:** You cannot use Shutdown Event Tracker to change or annotate the details of an unplanned shutdown that was expected by the computer, after the fact. In other words, the user who initiated the shutdown did so through the Shutdown Event Tracker user interface (UI) or the command line instead of pulling the power cord or pushing the power button. If the unplanned shutdown was initiated through a different tool, contact that vendor to see if an updated version exists, and whether it supports planned and unplanned shutdown flagging.

**See also:** Shutdown Event Tracker overview, Restart or shut down locally and document the reason, and Restart or shut down remotely and document the reason.

**The OK button is disabled after you choose a shutdown reason.**
**Cause:** A comment is required for this reason.

**Solution:** Type explanatory text in the **Comment** box.

**After you upgrade a server from Windows NT to a Windows Server 2003 family operating system, users who were previously able to shut down the computer can no longer do so.**
**Cause:** The shutdown user rights assigned to users on Windows NT systems will be automatically revoked during an upgrade to a Windows Server 2003 family operating system. This is done for security purposes, to ensure that user rights are uniformly assigned.

**Solution:** Use group accounts in Active Directory to ensure that shutdown user rights are uniformly assigned to trusted users.

**See also:** Privileges, Security overview, and Restart or shut down remotely and document the reason.

**When you attempt to shut down a remote computer, you are denied access.**
**Cause:** You must have the appropriate user rights on the remote computer before you attempt to shut it down.

**Solution:** Establish the appropriate user rights on all computers that you must remotely manage. Being able to shut down a computer locally does not mean that you have the right to shut it down remotely.

**See also:** Privileges, Security overview, and Restart or shut down remotely and document the reason.

**The Shutdown tool (Shutdown.exe) fails to restart or shut down a remote computer, although the target computer is functioning properly.**
**Cause:** There are four possible causes:

- The target computer has just restarted and is applying policies.
- A shut down of the target computer is in progress or has already occurred.

- The log on dialog box is open on the target computer.
- An expected or unexpected shutdown dialog box is open on the target computer.

**Solution:** In all of these cases, the operating system is functioning properly. For the last two causes, wait for a few minutes before making another attempt to restart or shut down the target computer.

**See also:** Restart or shut down remotely and document the reason.

# SNMP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SNMP**
Simple network management protocol (SNMP) provides the ability to monitor and communicate status information between a variety of hosts.

- Before installing SNMP, see Checklist: Implementing the SNMP service.
- To find features that have been moved in the Microsoft® Windows Server 2003 family, see New ways to do familiar SNMP tasks.
- For tips about using SNMP, see SNMP Best practices.
- For help with specific tasks, see SNMP How To...
- For general background information, see SNMP Concepts.
- For problem-solving instructions, see Troubleshooting SNMP.

# Checklist: Implementing the SNMP service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Implementing the SNMP service**

| Step | Reference |
|---|---|
| Obtain, install, and configure SNMP management software. | The SNMP service |
| Gather information required to implement SNMP on your network. Requirements include contact persons (administrator), physical computer location, configured SNMP community names, and IP or IPX addresses, or computer names of SNMP management systems on your network. | Using SNMP |
| Install SNMP on this computer. | Install the SNMP service |
| Configure SNMP agent properties. | Configure agent properties |
| If you have an additional TCP/IP service in your network, such as a bridge or router, you should consult RFC 1213 for additional configuration information before proceeding. | "Simple Network Management Protocol" at the Microsoft Windows Resource Kits Web site |
| Configure trap destinations. | Configure traps |
| Configure SNMP security properties. | Configure SNMP security properties |

**Note**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

# New ways to do familiar SNMP tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for configuring Simple Network Management Protocol (SNMP). The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Install the SNMP service. | The SNMP Service option in Windows NT TCP/IP Installation Options. | Windows Components wizard. For more information, see Install the SNMP service. |
| Configure the SNMP agent. | Control Panel, Network, **Services** tab. | **Services** in the Computer Management console. For more information, see Configure agent properties. |
| Configure SNMP traps. | Control Panel, Network, **Services** tab. | **Services** in the Computer Management console. For more information, see Configure traps. |
| Configure SNMP security. | Control Panel, Network, **Services** tab. | **Services** in the Computer Management console. For more information, see Configure SNMP security properties. |

# SNMP Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Update settings regularly.**

- Make sure that you monitor and update the host name settings on an ongoing basis. This will help ensure timely detection of any unauthorized access.

**Allow hosts to accept packets only from specific hosts.**

- When you configure security options, do not click **Accept packets from any host**.

**Configure authentication traps.**

- Take advantage of SNMP security checking by configuring authentication traps on all SNMP agents.

**Verify proper functioning of service-specific components.**

- If you will be monitoring service-specific components, such as Dynamic Host Configuration Protocol (DHCP) or Windows Internet Name Service (WINS), verify that these services have been successfully installed and configured.

**Use IPSec to secure SNMP messages.**

- Reduce the risk of internal attacks by configuring the SNMP agent systems to reject request messages from unauthorized management systems. For security purposes, use Internet Protocol security (IPSec) to secure SNMP messages by creating filter specifications in the appropriate IP filter list between SNMP management systems and agents.

- Remember that SNMP is an insecure protocol.

- If you decide to use SNMP to manage networks, remember that SNMP is an insecure protocol whose effectiveness depends solely on how you implement it.

# SNMP How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install the SNMP service
- Configure agent properties
- Configure traps
- Configure SNMP security properties
- Start or stop the SNMP service
- Configure event to trap translator

# Install the SNMP service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the SNMP service**

1. Open Windows Components wizard.
2. In **Components**, click **Management and Monitoring Tools** (but do not select or clear its check box), and then click **Details**.
3. Select the **Simple Network Management Protocol** check box, and click **OK**.
4. Click **Next**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the Windows Components Wizard, click **Start**, click **Control Panel**, double-click **Add or Remove programs**, and then click **Add/Remove Windows Components**.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.
- SNMP starts automatically after installation.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure agent properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure agent properties**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Services and Applications/Services

3. In the details pane, click **SNMP Service**.
4. On the **Action** menu, click **Properties**.
5. On the **Agent** tab, in **Contact**, type the name of the user or administrator for this computer.
6. In **Location**, type the physical location of the computer or the contact.
7. Under **Service**, select the appropriate check boxes for this computer, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- If you change **Contact** or **Location** SNMP settings, your changes take effect within a few minutes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure traps

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure traps**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Services and Applications/Services

3. In the details pane, click **SNMP Service**.
4. On the **Action** menu, click **Properties**.
5. On the **Traps** tab, under **Community name**, type the case-sensitive community name to which this computer will send trap messages, and then click **Add to list**.
6. In **Trap destinations**, click **Add**.
7. In **Host name, IP or IPX address**, type information for the host, and click **Add**.
8. Repeat steps 5 through 7 until you have added all the communities and trap destinations you want.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- If you change existing SNMP settings, your changes take effect immediately. The SNMP service does not need to be restarted for your settings to take effect.
- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

**Information about functional differences**

# Configure SNMP security properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure SNMP security properties**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Services and Applications/Services

3. In the details pane, click **SNMP Service**.
4. On the **Action** menu, click **Properties**.
5. On the **Security** tab, select **Send authentication trap** if you want a trap message sent whenever authentication fails.
6. Under **Accepted community names**, click **Add**.
7. Under **Community Rights**, select a permission level for this host to process SNMP requests from the selected community.
8. In **Community Name**, type a case-sensitive community name, and then click **Add**.
9. Specify whether or not to accept SNMP packets from a host:

   - To accept SNMP requests from any host on the network, regardless of identity, click **Accept SNMP packets from any host**.
   - To limit acceptance of SNMP packets, click **Accept SNMP packets from these hosts**, click **Add**, type the appropriate host name, IP or IPX address, and then click **Add** again.

**Important**

- By default, SNMP does not respond to any community names presented.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can add additional community and host names as necessary.
- You can make changes to an entry by clicking the entry, and then clicking **Edit**. You can delete a selected entry by clicking **Remove**.

- If you change existing SNMP settings, your changes take effect immediately. The SNMP service does not need to be restarted for your settings to take effect.

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# SNMP defined

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SNMP defined**

The Simple Network Management Protocol (SNMP) is a network management standard widely used in TCP/IP networks.

SNMP provides a method of managing network hosts such as workstation or server computers, routers, bridges, and hubs from a centrally-located computer running network management software. SNMP performs management services by using a distributed architecture of management systems and agents.

Because network management is critical for both auditing and resource management, SNMP can be used to:

- **Configure remote devices.** Configuration information can be sent to each networked host from the management system.
- **Monitor network performance.** You can track the speed of processing and network throughput, and collect information about the success of data transmissions.
- **Detect network faults or inappropriate access.** You can configure trigger alarms on network devices when certain events occur. When an alarm is triggered, the device forwards an event message to the management system. Common types of alarms include a device being shut down and restarted, a link failure being detected on a router, and inappropriate access.
- **Audit network usage.** You can monitor both overall network usage to identify user or group access, and types of usage for network devices and services.

# The SNMP service

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The SNMP service**
The simple network management protocol (SNMP) service supports computers running TCP/IP and IPX protocols. It is an optional service that can be installed after the TCP/IP protocol has been successfully configured.

The SNMP service provides an SNMP agent that allows remote, centralized management of computers running:

- Microsoft® Windows® XP
- Microsoft Windows 2000
- Microsoft Windows Server 2003 family

The SNMP agent also allows management of the following services:

- Windows XP or the Windows Server 2003 family and Microsoft Windows 2000-based WINS
- Windows XP or the Windows Server 2003 family and Windows 2000-based DHCP
- Windows XP or the Windows Server 2003 family and Windows 2000-based Internet Information Services
- Microsoft LAN Manager

To access the information that the SNMP agent service provides, you need at least one SNMP management system software application. The SNMP service supports but does not currently include SNMP management software. SNMP management software must be running on the host which acts as the management system.

**Note**

- The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

# Understanding SNMP

# SNMP management systems and agents

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SNMP management systems and agents**

Using SNMP requires two components:

- **An SNMP management system.**

  The management system, also called *management console*, sends information and update requests to an SNMP agent. Any computer running SNMP management software is an SNMP management system. The management software application does not need to run on the same host as the SNMP agent.

  The SNMP management system requests information from a managed computer, called an SNMP agent, such as the amount of hard disk space available or the number of active sessions. If the management system has been granted write access to an agent, that management system can also initiate a change to the agent's configuration.

- **An SNMP agent.**

  The SNMP agent responds to management system requests for information. Any computer running SNMP agent software is an SNMP agent. The SNMP service, which is agent software, responds to information requests from one or multiple management systems. The SNMP service can be configured to determine which statistics are tracked and which management systems are authorized to request information.

  In general, agents do not originate messages, but only respond to them. A trap message is the only agent-initiated SNMP communication, and it enhances security. A trap is an alarm-triggering event, such as a system reboot or illegal access, on an agent.

  Management hosts and agents belong to an SNMP community, which is a collection of hosts grouped together for administrative purposes. Defining communities provides security by allowing only management systems and agents within the same community to communicate.

# SNMP messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SNMP messages**

When simple network management protocol (SNMP) management programs send requests to a network device, the agent software on that device receives the requests and retrieves information from MIBs. The agent then sends the requested information back to the initiating SNMP management program. To perform these tasks, the agent uses the following message types:

| SNMP Message | Description |
|---|---|
| Get | The basic SNMP request message. Sent by an SNMP management system, it requests information about a single MIB entry on an SNMP agent. For example, the amount of free drive space. |
| Get-next | An extended type of request message that can be used to browse the entire tree of management objects. When processing a Get-next request for a particular object, the agent returns the identity and value of the object which logically follows the object from the request. The Get-next request is useful for dynamic tables, such as an internal IP route table. |
| Set | If write access is permitted, this message can be used to send and assign an updated MIB value to the agent. |
| Getbulk | Requests that the data transferred by the host agent be as large as possible within given restraints of message size. This minimizes the number of protocol exchanges required to retrieve a large amount of management information. The maximum message size should not be larger than the path maximum transmission unit (MTU), the largest frame size allowed for a single frame on your network, or fragmentation can occur. |
| Trap | An unsolicited message sent by an SNMP agent to an SNMP management system when the agent detects that a certain type of event has occurred locally on the managed host. The SNMP management console that receives a trap message is known as a trap destination. For example, a trap message might be sent on a system restart event. |

Four of these message types are simple request-reply protocols where SNMP uses User Datagram Protocol (UDP). This means that a request from the management system might not arrive at the agent, and the agent's reply might not make it back to the management system. Because SNMP is a connectionless network protocol, SNMP messages are not guaranteed to arrive at their destinations.

You can use Internet Protocol security (IPSec) to secure traffic between SNMP management systems and agents. For more information, see Securing SNMP messages with IPSec.

# Using SNMP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using SNMP**

- Defining communities
- Agent properties
- Trap properties
- SNMP security properties
- Securing SNMP messages with IPSec
- SNMP service properties
- Managing SNMP from the command line

# Defining communities

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Defining communities**

You can assign groups of hosts to Simple Network Management Protocol (SNMP) communities for limited security checking of agents and management systems or for administrative purposes. Communities are identified by community names that you assign. A host can belong to multiple communities at the same time, but an agent does not accept a request from a management system outside its list of acceptable community names.

For more information, see SNMP Best practices.

Define communities logically to take advantage of the basic authentication service provided by SNMP. In the following example, there are two communities: Public 1 and Public 2.

- Agent 1 can send traps to Manager 2 and respond to requests from Manager 2 because they are both members of the Public 2 community.
- Agents 2-4 can send traps to Manager 1 and respond to requests from Manager 1 because they are all members, by default, of the Public 1 community.

### Important

- Community names are sent across the network as plaintext. Because attackers can read plaintext with network analysis software, sending SNMP community names across the network represents a potential security risk. You can help protect SNMP messages by configuring Internet Protocol security (IPSec). For more information about configuring SNMP for IPSec, see Securing SNMP messages with IPSec.

### Notes

- There is no relationship between community names and domain or workgroup names. Community names represent a shared password for groups of network hosts, and should be selected and changed as you would change any password.
- Use community names primarily as an element for organization, not security.
- You should not create a community that is named Public and grant it read access. You should also specify hosts from which packets can be accepted, rather than clicking **Accept packets from any host**.

# Agent properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Agent properties**

The simple network management protocol (SNMP) agent provides the related management system with information on activities that occur at the Internet Protocol (IP) network layer.

The SNMP service sends MIB information in response to an SNMP request or in an SNMP trap message.

You can configure the following agent properties by using the **Agent** tab on the **SNMP Service Properties** dialog box:

| **Agent Service** | **Select if this computer:** |
|---|---|
| Physical | Manages physical devices, such as a hard disk partition. |
| Applications | Uses any applications that send data using the TCP/IP protocol suite. This service should always be enabled. |
| Datalink and Subnet | Manages a bridge. |
| Internet | Is an IP gateway (router). |
| End-to-end | Is an IP host. This service should always be enabled. |

You can also configure agent properties such as:

- The location of the contact person.
- The name of the person to contact, such as the network administrator.

For more information on how to configure SNMP agent properties, see Configure agent properties.

# Trap properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Trap properties**

The SNMP service, when configured for an agent, generates trap messages if any specific events occur. These messages are sent to a trap destination. For example, an agent can be configured to initiate an authentication trap if a request for information is sent by an unrecognized management system.

Trap destinations consist of the computer name or the IP or IPX address of the management system. The trap destination must be a network-enabled host that is running SNMP management software. Trap destinations can be configured by a user, but the events (such as a system reboot) that can generate a trap message are internally defined by the SNMP agent.

The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

You can configure trap destinations by using the **Traps** tab in **SNMP Service Properties**.

For more information on how to configure SNMP traps, see Configure traps.

# SNMP security properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SNMP security properties**

Simple network management protocol (SNMP) provides security through the use of authentication traps and community names. In addition, you can restrict SNMP communications for the agent, allowing it to communicate with only a specified list of SNMP management systems. Because the SNMP protocol provides minimal security, you should use SNMP only on trusted networks.

You can configure certain features of SNMP security on the **Security** tab in the **SNMP Service Properties** dialog box. These features provide a minimal level of security to your network, and you should use them in conjunction with other stronger methods of secure network management.

The following options can be configured to enable SNMP security:

- **Accepted community names**. The service has no default community name. By default, SNMP will not respond to any community names presented. You can add, delete, or change multiple community names. If an SNMP request is received from a community that is not on this list, it will generate an authentication trap.

  You can define community rights for a community name. A permission level can be selected in the **SNMP Service Configuration** dialog box, that determines how the SNMP agent processes requests from a selected community. For example, you can configure the permission level to block the SNMP agent from processing any requests from a specific community.

- **Accept SNMP packets from any host**. In this context, no SNMP packets are rejected on the basis of the name or address of the source host or the list of acceptable hosts.

- **Accept SNMP packets from these hosts**. In this context, the list of acceptable hosts means the acceptable SNMP management systems. This option is selected by default with *localhost* as the only hostname. Only SNMP packets received from *localhost* are accepted. SNMP messages from all other hosts are rejected and an authentication trap is sent. This option provides a higher level of security than using a community name, which might contain many hosts.

- **Send authentication trap**. Authentication is the process of verifying that a host name or address is valid. When the SNMP agent receives a request that does not contain the correct community name or is not sent from a member of the acceptable host list, the agent sends an authentication trap message to one or more trap destinations (management systems), indicating the failure of authentication. This option is selected by default.

For more information on how to configure SNMP security, see Configure SNMP security properties.

**Note**

- The default Security tab settings are no communities listed under **Accepted community names** and one host name, *localhost*, under **Accept SNMP packets from these hosts**. The term *localhost* refers to the loopback interface on the local computer. You must add a community name of your choice to **Accepted community names**. For security reasons, naming a community Public is not recommended. You should monitor and update the settings on an ongoing basis to ensure timely detection of any unauthorized access.

# Securing SNMP messages with IPSec

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Securing SNMP messages with IPSec**

By configuring IPSec policies on all SNMP agents and managers, you can help prevent malicious users and attackers from intercepting SNMP messages. If you cannot configure IPSec policies on all SNMP hosts but you want to ensure that all hosts can communicate with each other, you must configure IPSec policies that allow plaintext communication. However, allowing plaintext communication is not recommended.

IPSec does not automatically encrypt the SNMP traffic. You must create filter specifications in the appropriate IP filter list for traffic between the SNMP managers and agents.

To make SNMP messages more secure, you must add two sets of filter specifications to a new or existing IPSec policy on the SNMP-enabled host. The first set of filter specifications regulates typical SNMP traffic or SNMP messages between the SNMP managers and the SNMP agents. This set of filter specifications typically consists of one filter specification for inbound traffic and one for outbound traffic. You must create these specifications in the **IP Filter Properties** dialog box. For more information about creating filter specifications, see Filter list, Set an active IP filter list for a rule, and Add, edit, or remove IP filter lists.

On the **Addresses** tab:

- In **Source address**, click **A specific IP address** and type the address of the SNMP manager.
- In **Destination address**, click **My IP Address**, which refers to the IP address of the SNMP agent to which the policy is assigned.
- Select the **Mirrored** check box to automatically create the filter specification for outbound traffic.

On the **Protocol** tab:

- Under **Select a protocol type**, click **TCP** or **UDP**. If you require both these protocols, create an additional filter specification.
- Click **From any port**, click **To this port**, and type **161**.

The second set of filter specifications regulates trap messages, and it consists of one filter specification for inbound traffic and one for outbound traffic:

On the **Addresses** tab:

- Under **Source address**, click **A specific IP address** and type the IP address of the SNMP agent.
- Under **Destination address**, click **My IP Address**, which refers to the IP address of the SNMP manager to which the policy is assigned.
- Select the **Mirrored** check box to automatically create the outbound filter specification.

On the **Protocol** tab:

- Under **Select a protocol type**, click **TCP** or **UDP**. If you require both these protocols, create an additional filter specification.
- Click **From any port**, click **To this port**, and type **162**.

For more information on SNMP messages, see SNMP messages.

To send secure SNMP messages, you must configure IPSec policies on SNMP managers as well as SNMP agents. The Windows Server 2003 family supports but does not include SNMP management software.

# SNMP service properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SNMP service properties**

You can use the **General**, **Log On**, and **Recovery** tabs in **SNMP Service Properties** to configure how the SNMP service starts, logs on to the system, and recovers from an abnormal program termination of the service or operating system.

For information on changing these properties, see Services Snap-in.

# Managing SNMP from the command line

Published: January 21, 2005

Updated: November 28, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing SNMP from the command line**

You can use the **evntcmd** command to configure SNMP traps based on events recorded in system logs. You can also use this command to specify where trap messages are sent within an SNMP community. For information on how to use the **evntcmd** command to configure traps and trap destinations, see evntcmd at http://www.microsoft.com/resources/documentation/windows/xp/all/proddocs/en-us/evntcmd.mspx. For information on identifying the events from which you can configure traps, see Event Viewer.

You can use the **evntwin** command to start Event to Trap Translator, which is a graphical utility you can use to configure the translation of events to traps. However, you cannot use Event to Trap Translator to configure trap destinations. For information on configuring trap destinations using the SNMP console, see Configure traps.

You must install SNMP before either the **evntcmd** command or the **evntwin** command will work.

For information about other command-line utilities, see Command-line reference. For more information about manageability, see Management Strategies and Tools.

# Troubleshooting SNMP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- My SNMP agent is not functioning.
- My SNMP management system keeps timing out while querying the WINS server.

**My SNMP agent is not functioning.**
**Cause:** An unknown network or SNMP problem.

**Solution:** SNMP error handling is integrated with Event Viewer. Use Event Viewer if you suspect there is a problem with the SNMP service. You can configure a **View** filter to display only SNMP messages.

**See also:** Event Viewer.

**My SNMP management system keeps timing out while querying the WINS server.**
**Cause:** The SNMP time-out period is too short or the WINS server is off-line or unreachable.

**Solution:** Increase the SNMP time-out period on the SNMP management system. If that does not work contact your system administrator to check the WINS server.

# Device Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Device Manager**
You can use Device Manager to update the drivers (or software) for hardware devices, modify hardware settings, and troubleshoot problems.

- For help with specific tasks, see Device Manager How To....
- For general background information, see Device Manager Concepts.

**Caution**

- Incorrectly altering your hardware configuration can damage your system. Be sure to read the appropriate instructions before making changes to your hardware configuration.

# Device Manager How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- View Device Information
- Configure Device Properties and Settings
- Uninstall and Reinstall Devices
- Update and View Device Drivers

# View Device Information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**View device information**

- View devices and resource settings
- View hidden devices
- View the status of a device
- View power allocations for USB hubs
- View bandwidth allocations for a USB host controller
- Print information about a specific device

# View devices and resource settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view devices and resource settings**

1. Open Device Manager.
2. On the **View** menu, click one of the options listed in the following table:

| Option | Description |
|---|---|
| **Devices by type** | Displays devices by the type of device installed, such as monitor or mouse. This is the default view. After you double-click the device type, the connection name is listed below the type. |
| **Devices by connection** | Displays devices by how they are connected in your computer. Each device is listed under the hardware to which it is connected. For example, if a small computer system interface (SCSI) card is listed, the devices attached to the SCSI card are listed beneath it. |
| **Resources by type** | Displays all allocated resources by the type of device using these resources. The resources are as follows:<br>• Direct memory access (DMA) channels<br>• Input/output ports (I/O ports)<br>• Interrupt request (IRQ<br>• Memory addresses |
| **Resources by connection** | Displays all allocated resources by connection type. The resources are: DMA channels, I/O ports, IRQ, and memory addresses. |

**Notes**

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- For information on how to view hidden devices, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View hidden devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view hidden devices**

1. Open Device Manager.
2. On the **View** menu, click **Show hidden devices**.

## Notes

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- If you no longer want to view hidden devices, click **Show hidden devices** to remove the check mark.
- Hidden devices include non-Plug and Play devices (devices with earlier Windows device drivers).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the status of a device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the status of a device**

1. Open Device Manager.
2. Double-click the type of device you want to view.
3. Right-click the specific device you want, and then click **Properties**.
4. On the **General** tab, under **Device status** is a description of the device status.

## Notes

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- If the device is experiencing a problem, the type of problem is displayed. You might also see a problem code and number and a suggested solution. If you call a support line, this problem code and number can be useful for determining and diagnosing the problem.
- For information on how to resolve hardware device problems, click **Troubleshoot** to start the Hardware Troubleshooter.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View power allocations for USB hubs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view power allocations for USB hubs**

1. Open Device Manager.
2. Double-click **Universal serial bus controller**.
3. Right-click **USB Root Hub**, and then click **Properties**.
4. On the **Power** tab, view the power required by each device in the **Attached devices** list.

## Notes

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- Hubs for universal serial bus (USB) devices are self-powered or bus-powered. A self-powered hub (a hub that is plugged into an electrical outlet) provides maximum power to the device. A bus-powered hub (a hub that is plugged into another USB port) provides minimum power. Devices requiring a lot of power, such as cameras, should be plugged into self-powered hubs.
- You can check the power allocations for a USB hub to detect situations in which too many devices are using the hub.
- **Universal serial bus controller** only appears if you have a USB port on your computer.
- The **Power** tab only appears for USB hubs.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View bandwidth allocations for a USB host controller

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view bandwidth allocations for a USB host controller**

1. Open Device Manager.
2. Double-click **Universal serial bus controller**.
3. Right-click a **USB Universal Host Controller** for your system, and then click **Properties**.
4. On the **Advanced** tab, in the **Bandwidth-consuming devices** list, view the bandwidth used by each device.

## Notes

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- You can view bandwidth only for a universal serial bus (USB) controller. Some USB devices (for example, modems) might not appear because they do not report bandwidth requirements to the operating system.
- Each USB controller has a fixed amount of bandwidth that all attached devices must share. If you suspect a bandwidth shortage for a USB controller, you can confirm this by viewing the bandwidth allocations currently being used by each device.
- **Universal serial bus controller** appears only if you have a USB port on your computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Print information about a specific device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To print information about a specific device**

1. Open Device Manager.
2. Double-click the type of device you want to print information about, and then click the specific device to select it.
3. On the **Action** menu, click **Print**.
4. In the **Print** dialog box, under **Report type**, click **Selected class or device**.

   You can also print other types of reports from this dialog box. The following table describes the types of reports you can print:

| Option | Description |
|---|---|
| **System summary** | Prints a summary of the devices that are installed on your computer or on the remote computer you are managing. The summary includes the product version number, bus type, registered owner, and resource information such as interrupt request (IRQ) usage or input/output (I/O) port usage. |
| **Selected class or device** | Prints a report for the device or the hardware type you have selected. The report includes device name, device driver location, version and manufacturer information, and resources allocated to the device, such as I/O ports and memory addresses. |
| **All devices and system summary** | Prints a report for each device or hardware type that is installed on your computer and a summary of your system. If you have many devices installed on your system, this could be a large document. |

**Notes**

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- You can print to a .prn file by selecting the **Print to file** check box.
- **Selected class or device** is the default setting for the type of report to be printed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Device Properties and Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure device properties and settings**

- Enable a device
- Disable a device
- Change resource settings for a device
- Change network adapter settings
- Change port settings
- Change PS/2 mouse settings
- Change IDE controller settings
- Change region settings for DVD drives
- Change ISDN adapter settings
- Change power management settings for a device
- Enable or disable digital CD audio
- Configure multimedia devices
- Upgrade from a uniprocessor to a multiprocessor computer

# Enable a device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable a device**

1. Open Device Manager.
2. Double-click the type of device that you want to enable.
3. Right-click the specific device you want, and then click **Enable**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- If you are prompted to restart the computer, the device will not be enabled until the computer has been restarted.
- **Enable** will only be listed if the device is disabled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable a device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable a device**

1. Open Device Manager.
2. Double-click the type of device that you want to disable.
3. Right-click the specific device you want, and then click **Disable**.

### Important

- If you disable a device that is required to start the system, such as your hard disk drive, these devices will not work, and your system might not start.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- When you disable a device, the physical device stays connected to your computer, but the device driver is disabled. The drivers are available again when you enable the device. It can be useful to disable devices if you want to have more than one hardware configuration for your computer, or if you have a portable computer that you use at a docking station.
- If you are prompted to restart the computer, the device will not be disabled and will continue to function until the computer is restarted.
- After you disable a device and restart your computer (if necessary), the resources allocated to the device are free and can be allocated to another device.
- Some devices cannot be disabled, such as devices for disk drives and processors.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change resource settings for a device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change resource settings for a device**

1. Open Device Manager.
2. Double-click the type of device you want to change.
3. Double-click the specific device you want to change. If the device has resources settings that you can change, the **Resources** tab will appear in the dialog box.
4. Click the **Resources** tab, and then clear the **Use automatic settings** check box. This check box might be unavailable if you cannot assign a specific resource to the device.
5. In **Setting based on**, click the hardware configuration you want to change.
6. In **Resource settings**, under **Resource type**, click the resource type you want to change. Your choices are as follows:
   - Direct memory access (DMA)
   - Interrupt request (IRQ)
   - Input/output (I/O) port
   - Memory address
7. Click **Change Setting**, and then type a new value for the resource type.
8. Repeat as necessary.

**Caution**

- Changing resource settings improperly can disable your hardware and cause your computer to malfunction or become inoperable. Resource settings should be changed only by users who have expert knowledge of computer hardware and hardware configuration settings.

**Important**

- You must be certain that the new values you apply do not conflict with any other devices. If you have any device conflicts, they appear under **Conflicting device list**.

  **Use automatic settings** is unavailable for devices that have no other settings to configure. It is also unavailable on devices that are controlled by Plug and Play resources and should not be changed by the user.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer**

**Management**, and then click **Device Manager**.

- You should need to assign resources manually only for some older Industry Standard Architecture (ISA) and Plug and Play basic input/output system (BIOS) devices. It is not usually necessary for you to change resource settings because resources are automatically allocated by the system when the hardware is installed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change IDE controller settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change IDE controller settings**

1. Open Device Manager.
2. Double-click **IDE ATA/ATAPI controllers**, right-click the Integrated Device Electronics (IDE) device for which you want to change advanced settings, and then click **Properties**.
3. On the **Advanced Settings** tab, make the appropriate changes, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- The **Advanced Settings** tab might not appear for all IDE controller devices.
- Some of the advanced settings for IDE controllers are device dependent. Read the device manufacturer's instruction manual to determine which settings you can change.
- You will not be able to change the setting in **Device Type** if the system has already detected an IDE device on an IDE channel. This prevents you from selecting **None**, which would disable the IDE device. If you want to disable the device, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change region settings for DVD drives

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change region settings for DVD drives**

1. Open Device Manager.
2. Double-click **DVD/CD-ROM drives**, right-click the DVD drive for which you want to change region settings, and then click **Properties**.
3. On the **DVD Region** tab, make the appropriate changes.

### Important

- Because many software decoders require Direct Memory Access (DMA) in order to function, you should check the settings of your Integrated Device Electronics (IDE) ATA/ATAPI controllers to ensure that **DMA if available** is selected in **Transfer Mode**. If applicable, you should also check this setting for the Secondary IDE Channel.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- The **DVD Region** tab might not be available for all DVD drives.
- To configure your DVD drive to play discs from other regions, select a geographic area from the list of regions. Typically, you would select the region in which you reside. It is not usually necessary to change the setting again.
- The region settings can be changed only a limited number of times. When **Changes remaining** equals 1, and you select a new region, an alert will be displayed warning you that after this, you will only be able to play DVDs from that region. Be aware that you might not be able to change the region setting for some DVD hardware and software decoders.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change ISDN adapter settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change ISDN adapter settings**

1. Open Device Manager.
2. Double-click **Network adapters**, right-click the Integrated Services Digital Network (ISDN) adapter card for which you want to change settings, and then click **Properties**.
3. On the **ISDN** tab, in the **Select the switch type or D-channel protocol** list, click a switch type or a D-channel protocol, and then click **Configure**.
4. Make the appropriate changes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- Your telephone company or hardware manufacturer should provide the information you need to configure ISDN adapter settings.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change power management settings for a device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change power management settings for a device**

1. Open Device Manager.
2. Double-click the type of device for which you want to change power management settings.
3. Right-click the specific device you want, and then click **Properties**.
4. On the **Power Management** tab, change the power management settings.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- You can use the power management settings to specify that the operating system return from a low-power state to service an event. One example of the effect of doing so is that an incoming modem call will alert the system to service the call even if the system is in hibernation. You can also specify whether the operating system should turn off a particular device if it is not doing something, such as servicing a call.
- The **Power Management** tab appears only for device drivers that support the power management standards, such as network adapters.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable digital CD audio

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable digital CD audio**

1. Open Device Manager.
2. Double-click **DVD/CD-ROM drives**, right-click the CD-ROM drive, and then click **Properties**.
3. On the **Properties** tab, select or clear the **Enable digital CD audio for this CD-ROM device** check box.

   This check box enables some CD-ROM drives to read the audio data from an audio CD digitally and send it to either a sound card or a pair of universal serial bus (USB) speakers.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- It might be necessary to restart your computer after changing this setting.
- Enabling this feature can improve audio quality because Windows reads the CD directly, bypassing the CD-ROM drive's digital-to-analog converters. Directly accessing the CD improves quality because it eliminates extraneous electrical interference that can leak through the shielding on the cable that connects the CD-ROM drive to the sound card.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure multimedia devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure multimedia devices**

1. Open Device Manager.
2. Double-click **Sound, video and game controllers**.
3. Right-click the device that you want to configure, and then click **Properties**.
4. On the **Properties** tab, locate the specific device, and then double-click it.
5. Change the configurations for the device.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- The **Properties** button is available only if you have drivers other than Windows Driver Model (WDM) drivers on your computer. If The **Properties** button appears dimmed, use the **Resources** tab to configure the device.
- Multimedia devices can include audio or video codecs, game ports, and MIDI devices.
- You might want to reconfigure multimedia settings to adjust compression settings and allow a device driver to be used by a program

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Upgrade from a uniprocessor to a multiprocessor computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To upgrade from a uniprocessor to a multiprocessor computer**

1. Open Device Manager.
2. Double-click **Computer**.
3. Right-click the computer model, and then click **Properties**.
4. On the **Driver** tab, click **Update Driver**. This starts the Hardware Update Wizard.
5. Click **Install from a list or specific location**, and then click **Next**.
6. From the **Please choose your search and installation options** page, click **Don't search. I will choose the driver to install**, and then click **Next**.
7. From the **Select a Device Driver** page, click the appropriate computer type from the **Models** list.
8. Click **Next**, click **Next** again, and then click **Finish**.

### Caution

- Upgrading from a uniprocessor to a multiprocessor computer can improperly disable your hardware and cause your computer to malfunction or become inoperable. Upgrading should be done only by users who have expert knowledge of computer hardware and hardware configuration settings.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Uninstall and Reinstall Devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Uninstall and reinstall devices**

- Uninstall a device
- Reinstall a Plug and Play device
- Reinstall a non-Plug and Play device
- Roll back to the previous version of a driver
- Undock a portable computer
- Unplug or eject devices

# Uninstall a device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To uninstall a device**

1. Open Device Manager.
2. Double-click the type of device that you want to uninstall.
3. Right-click the specific device you want to uninstall, and then click **Uninstall**.
4. In the **Confirm Device Removal** dialog box, click **OK**.
5. When you are done uninstalling the device, remove it from the computer.

## Notes

- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- If you are prompted to restart the computer, the device will not be removed and will continue to function until the computer is restarted.
- You do not usually need to use Device Manager to uninstall a Plug and Play device. Simply disconnect the Plug and Play device from your computer. You might have to restart your computer, however, depending on the type of device. Check the device manufacturer's instructions for more information.
- Uninstalling a device does not remove the device drivers from your computer's hard disk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reinstall a Plug and Play device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reinstall a Plug and Play device**

1. Open Device Manager.
2. Double-click the type of device that you want to reinstall.
3. Right-click the specific device you want, and then click **Uninstall**.
4. In the **Confirm Device Removal** dialog box, click **OK**. If you are prompted to restart the computer, the device will be reinstalled when the computer starts again. If you are not prompted to restart the computer, continue to the next step.
5. To reinstall the device, on the **Action** menu, click **Scan for hardware changes**.
6. Follow the instructions on the screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- You should reinstall a Plug and Play device only if it is working improperly or it has stopped working altogether. Before you reinstall a device, you should try to restart your computer and check the device to determine whether it is functioning properly. If it is not, try reinstalling the device.
- You do not usually need to reinstall or uninstall a Plug and Play device. With Plug and Play devices, you can simply remove the device from your computer. To remove a device properly, you should follow the device manufacturer's installation/removal instructions.
- **Scan for hardware changes** will not reinstall a Plug and Play device if it detects the device and its driver. If the device has not been uninstalled, **Scan for hardware changes** will not detect it as a change. You must uninstall a Plug and Play device before scanning for hardware changes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reinstall a non-Plug and Play device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reinstall a non-Plug and Play device**

1. In **Control Panel**, open Add Hardware.
2. In the **Add Hardware Wizard**, click **Next**, and then follow the instructions on your screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

# Roll back to the previous version of a driver

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To roll back to the previous version of a driver**

1. Open Device Manager.
2. Right-click the device for which you want to reinstall the previous version of the driver, then click **Properties**.
3. Click the **Drivers** tab.
4. Click **Roll Back Driver**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.

# Undock a portable computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To undock a portable computer**

1. Click **Start**, and then click **Eject PC**. A message appears saying that it is safe to undock your computer.

2. Undock your portable computer, or, if you have a motorized docking station, your portable computer will undock automatically.

### Warning

- Removing a portable computer without using **Eject PC** is not supported and can result in data loss or even hardware damage. To avoid loss or damage, use **Eject PC** to undock your computer, or shut down the system and undock the portable computer while your system is off. Undocking a portable computer while it is in either standby mode or hibernate mode is also not supported as this is likely to result in data loss and system instability.

### Notes

- **Eject PC** appears on the **Start** menu only if a computer is Advanced Configuration and Power Interface (ACPI)-enabled. If **Eject PC** does not appear on the **Start** menu, your computer is not ACPI-enabled, might not support undocking, or you might lack the security permissions required to undock your portable computer. See your administrator for these permissions.

- Some computers have an eject button on the docking station. Pressing the eject button button instead of following this procedure also undocks the laptop. Read the manufacturer's instructions for more information.

- To work on a file or folder that is located on the network, ensure that you make the item available on your undocked laptop. For more information on using offline folders, see **Offline Files overview** in Related Topics.

- For optimal laptop performance, you should change your power scheme using **Power Options** in **Control Panel**.

- Programs located on a network will not be available on your laptop when you undock.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Unplug or eject devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To unplug or eject devices**

1. In the notification area next to your task bar, double-click the **Safe Removal** icon. Safe Removal displays a list of Plug and Play devices that support safe removal and that are currently attached to the system.

   If you do not see the **Safe Removal** icon, your device does not support safe removal, and you cannot unplug or eject your device using Safe Removal.

2. In **Safely Remove Hardware**, in the list of devices, select the device that you want to unplug or eject, and then click **Stop**. This tells the system that you will be unplugging or ejecting the device.

3. In **Stop a Hardware device**, click **OK**.

   A notification appears stating that it is now safe to unplug or eject the device.

### Caution

- Unplugging or ejecting a device that supports safe removal without first using the Safe Removal application to warn the system can cause data to be lost or your system to become unstable. For example, if a device is unplugged during a data transfer, data loss is likely. If you use Safe Removal, however, you can warn the system before you unplug or eject a device, preventing possible loss of data.

### Note

- For removable storage devices that can safely be removed while the system is on, the system disables write caching by default. It does this so the devices can be removed without loss of data. When write caching is disabled, however, the system will likely experience slower performance, so be sure to enable write caching when you have finished removing the device.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Update and View Device Drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Update and view device drivers**

- Update or change a device driver
- View information about a device driver
- Start and stop non-Plug and Play drivers
- Change the startup type for non-Plug and Play drivers

# Update or change a device driver

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To update or change a device driver**

1. Open Device Manager.
2. Double-click the type of device you want to update or change.
3. Right-click the specific device driver you want to update or change, and then click **Update Driver** to open the Hardware Update Wizard. Follow the instructions in the wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- When you are upgrading a driver or installing new hardware, and your computer has access to the Internet, your computer will automatically check Windows Update for an appropriate device driver. For more information on Windows Update, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Start and stop non-Plug and Play drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start and stop non-Plug and Play drivers**

1. Open Device Manager.
2. Click the **View** menu, and then click **Show hidden devices**.
3. In the list of devices, double-click **Non-Plug and Play Drivers**, right-click a device, and then click **Properties**.
4. On the **Driver** tab, click **Start** or **Stop** to start or stop the device driver, and then click **OK**.

### Caution

- Starting or stopping a non-system device incorrectly can cause it to stop working.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- If the **Start** button on the **Driver** tab is unavailable, the driver is already loaded.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the startup type for non-Plug and Play drivers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the startup type for non-Plug and Play drivers**

1. Open Device Manager.
2. Click the **View** menu, and then click **Show hidden devices**.
3. Double-click **Non-Plug and Play Drivers**, right-click a device, and then click **Properties**.
4. On the **Driver** tab, in **Startup** select a **Type**, and then click **OK**.

### Caution

- Improperly changing the startup type of a boot device or system device can cause the system to become unstable or to no longer boot, or cause the device to stop working altogether. You should fully understand the instructions before changing this setting.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Device Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, double-click **Computer Management**, and then click **Device Manager**.
- The **Startup Type** defaults to the type required by the driver when the driver is first installed. You can use the options described in the following table to change the default. Use caution when changing the startup type; be sure that you fully understand the instructions before you change this setting.

| Type | Description |
|---|---|
| **Automatic** | Starts every time the system starts, after the boot and system devices start. Click this option for devices that are not critical to basic system operation. |
| **Boot** | Starts every time the system starts, before any other devices start. Click this option for critical devices that are essential to system operation. |
| **Demand** | Starts when the device is detected or it is needed for a specific event. Click this option for devices that are not critical to basic system operation or required for device detection. |
| **System** | Starts every time the system starts, after the boot devices start. Click this option for critical devices that are essential to system operation. |

**Information about functional differences**

# Device Manager overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Device Manager overview**
Device Manager provides a graphical view of the hardware that is installed on your computer. You can use Device Manager to update the drivers (or software) for hardware devices, modify hardware settings, and troubleshoot problems.

**Warning**

- Incorrectly altering your hardware configuration can damage your system. Be sure to read the appropriate instructions before making changes to your hardware configuration.

You can use Device Manager to do the following:

- Determine whether the hardware on your computer is working properly.
- Change hardware configuration settings.
- Identify the device drivers that are loaded for each device and obtain information about each device driver.
- Change advanced settings and properties for devices.
- Install updated device drivers.
- Disable, enable, and uninstall devices.
- Roll back to the previous version of a driver.
- Print a summary of the devices that are installed on your computer.

Device Manager is usually used to check hardware status and update device drivers on the computer. Advanced users with thorough understanding of computer hardware might also use Device Manager's diagnostic features to resolve device conflicts and change resource settings, but this should be done with extreme caution.

**Caution**

- Changing resource settings improperly can disable your hardware and cause your computer to malfunction or become inoperable. Only users who have expert knowledge of computer hardware and hardware configurations should change resource settings.

You will not usually use Device Manager to change resource settings because resources are allocated automatically by the system during hardware setup.

You must be a member of the Administrators group to manage device drivers.

You can use Device Manager to manage devices only on a local computer. On a remote computer, Device Manager will work only in read-only mode.

**Notes**

- If you cannot access Device Manager from the Computer Management extension snap-ins on a remote computer, ensure that the Remote Registry service is started on the remote computer. For more information, see Start, stop, pause, resume, or restart a service. You must have appropriate permissions on the remote computer to start the service.
- You might also receive this error message if the remote computer is running Microsoft® Windows 95. Computer Management does not support remote access to computers that are running Windows 95.

For more information, see the "Device Management" chapter that is provided on the Microsoft Resource Kits Web site.

# Configuring devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring devices**
When you install a Plug and Play device, Windows automatically configures the device so it will work properly with the other devices that are installed on your computer. As part of that configuration process, Windows assigns a unique set of system resources to the device you are installing. These resources can include one or more of the following:

- Interrupt request (IRQ) line numbers.
- Direct memory access (DMA) channels.
- Input/output (I/O) port addresses.
- Memory address ranges.

Each resource that is assigned to your device must be unique or the device will not function properly. For Plug and Play devices, Windows automatically ensures that these resources are configured properly.

Occasionally, two devices require the same resources, resulting in a device conflict. If this occurs, you can manually change the resource settings to be sure each setting is unique. However some resources, such as interrupts on PCI devices, can be shared, depending on the drivers and computer.

When you install a non-Plug and Play device, the resource settings for the device are not automatically configured. Depending on the type of device you are installing, you may have to manually configure these settings. Instructions for doing so should be supplied in the manual that came with your device.

Generally, you should not change resource settings manually, because when you do, the settings become fixed, and Windows will then have less flexibility when allocating resources to other devices. If too many resources become fixed, Windows may not be able to install new Plug and Play devices.

You can manually configure devices using Device Manager.

**Warning**

- Changing resource settings improperly can disable your hardware and cause your computer to malfunction or become inoperable. Resource settings should only be changed if you are certain the new settings do not conflict with other hardware, or if a hardware manufacturer has provided you with specific resource settings for a device.

# Uninstalling devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Uninstalling devices**

Although you can usually uninstall a plug and play device by disconnecting or removing the device, some devices might require that you turn off the computer first. To ensure that you do this properly, consult the device manufacturer's instructions for device installation and removal.

Uninstalling a non-Plug and Play device typically involves two steps:

- Using Device Manager to uninstall the device.
- Removing the device from your computer.

You can use Device Manager to notify the system that you want to uninstall a non-Plug and Play device. After you notify the system that you are uninstalling a device, you must physically disconnect or remove the device from your computer. For example, if the device is connected to a port on the outside of your computer, you shut down your computer, disconnect the device from the port, and then unplug the power cord for the device.

You need not uninstall a device that you want to disable but that you want to remain attached to the computer--a modem, for example. Instead of uninstalling it, you can simply disable the Plug and Play device. When you disable such a device, it stays physically connected to your computer, but Windows updates the system registry so that the device drivers for the device you have disabled are no longer loaded when you start your computer. The drivers are available again, however, when you enable the device. This is useful if you need to switch between two hardware devices, such as a networking card and a modem, or if you need to troubleshoot a hardware problem.

For instructions on how to uninstall, reinstall, and roll back devices, see Uninstall and Reinstall Devices.

For background information on hardware and instructions for installing devices, see Hardware profiles overview and Configuring devices.

# Hardware profiles overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware profiles overview**

A hardware profile is a set of instructions that tells Windows which devices to start when you start your computer or which settings to use for each device. When you first install Windows, a hardware profile called Profile 1 (for laptops, the profiles are Docked Profile or Undocked Profile) is created. By default, every device that is installed on your computer at the time you install Windows is enabled in the Profile 1 hardware profile.

Hardware profiles are especially useful if you have a portable computer. Most portable computers are used in a variety of locations, and hardware profiles will let you change which devices your computer uses when you move it from location to location. For example, you may have one profile named Docking Station Configuration for using your portable computer at a docking station with hardware components such as a CD-ROM drive and a network adapter. And you may have a second profile named Undocked Configuration for using your portable computer in a hotel or on an airplane, when you are not using a network adapter or a CD-ROM but you are using a modem and a portable printer.

If there is more than one hardware profile on your computer, you can designate a default profile that will be used every time you start your computer. You can also have Windows ask you which profile to use every time you start your computer. Once you create a hardware profile, you can use Device Manager to disable and enable devices that are in the profile. When you disable a device in a hardware profile, the device drivers for the device are not loaded when you start your computer.

This section covers:

- Task Scheduler
- Logon Scripts
- Windows Script Host

# Task Scheduler

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Task Scheduler**

You can use Task Scheduler to schedule commands, programs, or scripts to run at specific times.

- For tips about using Task Scheduler, see Task Scheduler Best practices.
- For help with specific tasks, see Task Scheduler How To....
- For general background information, see Task Scheduler Concepts.
- For problem-solving instructions, see Troubleshooting Task Scheduler.

# Task Scheduler Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Set appropriate permissions on the file your scheduled task will run.**

- To avoid a malicious user from corrupting a program set to run by a scheduled task, restrict access for the program file to only the specific users who need access.

- For more information about setting permissions on a file, see Set, view, change, or remove permissions on files and folders.

**Make sure you have correct password information for your users.**

- Before creating a scheduled task, check that the account and password information you have for the user that you will enter in the **Add Scheduled Task** wizard or **Run as** box in the scheduled task's property dialog box is accurate. If an account password expires any scheduled task for which that user has been specified will not run. For more information, see Task Scheduler and security.

**Encourage your users to use strong passwords.**

- Scheduled tasks always run under the context of a specific account, and the set of permissions for which the group it belongs to provides. To prevent a malicious user from modifying a scheduled task using another user's account name and password, encourage the use of strong passwords. For more information about strong passwords, see Strong passwords.

**Choose carefully when deciding which tasks to schedule under the System account.**

- Tasks scheduled under the System (or AT Service account) will run regardless of which user is logged on to a computer. Often these tasks will run in the background, unnoticed by the user.

  For more information about the implications of running a task under the System account, see Act as part of the operating system.

**Before stopping a scheduled task that is running, check for other scheduled tasks that are dependent on the task.**

- If you stop a scheduled task that is running without checking for dependent tasks, other tasks might not run or run incorrectly.

**Only create scheduled tasks on domain controllers if absolutely necessary.**

- If you are a member of the Administrators group, and the local computer on which you create a scheduled task is a domain controller, the scheduled task could affect objects in the entire domain.

**Avoid entering a member of the Domain group in the Add Scheduled Task wizard or Run as box when creating a scheduled task.**

- It is possible that a malicious user who is a member of the Administrators group could obtain those credentials and access the entire domain.

# Task Scheduler How To...

Updated: January 21, 2005

# Schedule Tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Schedule tasks**

- Schedule a new task
- Modify a scheduled task
- Remove a scheduled task
- Stop a scheduled task that is running
- Run a scheduled task immediately
- Schedule a task on a remote computer

# Schedule a new task

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To schedule a new task**

1. Open Task Scheduler.
2. Double-click **Add Scheduled Task**.
3. Follow the instructions in the Scheduled Task wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- When creating a scheduled task, you must enter a user name and password, either in the **Add Scheduled Task Wizard** or in the **Run as** box in the **Task** tab of the scheduled task's property dialog box. When the scheduled task runs, the program you've scheduled runs as if it were started by the user you specified, with that user's security context.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- Confirm that the system date and time on your computer are accurate, as Task Scheduler relies on this information to run scheduled tasks. To verify or change this information, double-click the time indicator on the taskbar.
- If you want to configure advanced settings for the task, select the **Open advanced properties for this task when I click Finish** check box in the final page of the wizard. This opens the properties dialog box for the task. You can then change the program being run in the **Task** tab, fine-tune the schedule in the **Schedule** tab, customize settings in the **Settings** tab, or set user and group permissions in the **Security** tab.
- If the task program requires command-line options, type them in **Run**, after the task path.
- If the path to the task program includes spaces, type double quotation marks ("") around the entire task path. For example:

  **"C:\Program Files\Windows Media Player\Mplayer2.exe"**

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Modify a scheduled task

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To modify a scheduled task**

1. Open Task Scheduler.
2. Right-click the task you want to modify, and then click **Properties**.
3. Do one or more of the following:
   - To change the program being run, in **Run**, type the path for the new program.
   - To change the user account name and password that the scheduled task will run as, edit or enter a new name in the **Run as** box, and then click **Set password**.
   - To change the schedule for the task, click the **Schedule** tab.
   - To customize the settings for the task, click the **Settings** tab.
   - To set user and group permissions for the task, click the **Security** tab.

## Notes

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- Confirm that the System date and time on your computer are accurate, as Task Scheduler relies on this information to run scheduled tasks. To verify or change this information, double-click the time indicator on the taskbar.
- If the task program requires command-line options, type them in **Run**, after the task path.
- If the path to the task program includes spaces, type double quotation marks ("") around the entire task path. For example:

  **"C:\Program Files\Windows Media Player\Mplayer2.exe"**

# Remove a scheduled task

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a scheduled task**

1. Open Task Scheduler.
2. Right-click the task that you want to remove, and then click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- You can also remove a scheduled task by selecting a task in the details pane, and then clicking **Delete** on the **File** menu.
- Removing a scheduled task removes only the .job file from the schedule. The program file the task runs is not removed from the hard disk.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Stop a scheduled task that is running

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To stop a scheduled task that is running**

1. Open Task Scheduler.
2. Click the task that you want to stop.
3. From the **File** menu, click **End Scheduled Task**.

### Notes

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- If you stop a scheduled task that is currently running, you might experience a delay (up to 3 minutes) before the task shuts down.
- To restart a stopped task, right-click the task, and then click **Run**.

### Note

- Before stopping a scheduled task that is running, make sure you check for other scheduled tasks that are dependent on the task. If you stop a scheduled task that is running without checking what other tasks are dependent on it, other tasks might not run or run incorrectly.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Schedule a task on a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To schedule a task on a remote computer**

1. Open My Network Places.
2. Click **Search for Computers**.
3. In the **Computer name** box, enter the computer name, and then click **Search**.
4. In the details pane, double-click the remote computer on which you want to view scheduled tasks.
5. Double-click **Scheduled Tasks**.
6. On the **File** menu, point to **New**, and then click **Scheduled Task**.
7. Type a name for the new task, and then press ENTER.
8. Right-click the new task, and then click **Properties**.
9. Do the following:
    - To specify the program being run, in **Run**, type the path for the new program.
    - To set the user account name and password that the scheduled task will run as, type a new name in **Run as**, and then click **Set password**.
    - To set the schedule for the task, click the **Schedule** tab.
    - To customize the settings for the task, click the **Settings** tab.
    - To set user and group permissions for the task, click the **Security** tab.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the remote computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open My Network Places, click **Start**, and then click **My Computer**. Under **Other Places**, click **My Network Places**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Receive notification of missed tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To receive notification of missed tasks**

1. Open Task Scheduler.
2. On the **Advanced** menu, click **Notify Me of Missed Tasks**.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If you enable the **Notify Me of Missed Tasks** setting, the missed tasks dialog box displays at the foreground of the computer display, in front of the logon screen, when there are missed tasks to report. Anyone who sits at the computer can view the list of missed tasks.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- A check mark next to **Notify Me of Missed Tasks** indicates that the feature is turned on. You can click **Notify Me of Missed Tasks** again to clear the check mark and turn off the feature.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the AT Service Account

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the AT Service Account**

1. Open Task Scheduler.
2. On the **Advanced** menu, click **AT Service Account**.
3. Click **This Account**, and then type the user account that will run tasks that are scheduled by using the **at** command.
4. In the **Password** and **Confirm Password** boxes, type the password for the account.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- The AT service account is used by tasks that have been scheduled by using the **at** command.
- By default, tasks scheduled using the **at** command stop after 72 hours. For more information, see **At** in Related Topics.
- Unless you click **This Account** and type the user account name and password, tasks are scheduled using **System Account**, which is the default selection in the **AT Service Account Configuration** dialog box. If you run the **at** command for tasks by using the System Account, the scheduled tasks run using the default System account.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View a log of past scheduled tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view a log of past scheduled tasks**

1. Open Task Scheduler.

2. On the **Advanced** menu, click **View Log**.

## Notes

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.

- The Task Scheduler log file lists all past scheduled tasks under all users, including members of the Administrators group and the System account. The file is located in the \Windows\Tasks folder, and is named SchedLgU.txt. In the SchedLgU.txt file, to see the most recent task that has run, find the following text:

  **[ ***** Most recent entry is above this line ***** ]**. The most recent task that has run is the entry directly above this text.

- The default log file size is 32 kilobytes.

- When the log file reaches its maximum size, it automatically starts recording new information at the beginning of the log file and writes over old log file information.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set power management options for a scheduled task

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set power management options for a scheduled task**

1. Open Task Scheduler.
2. Right-click the task for which you want to set power management options, and then click **Properties**.
3. On the **Settings** tab, under **Power Management**, do one or more of the following:
   - To conserve the battery power of your computer, select the **Don't start the task if the computer is running on batteries** check box.
   - To stop the task if the computer starts running on battery power, select the **Stop the task if battery mode begins** check box.
   - To wake your computer from hibernation or standby to run a task, select the **Wake the computer to run this task** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Task Scheduler, click **Start**, click **Control Panel**, and then double-click **Scheduled Tasks**.
- By default, power management is set to refrain from starting scheduled tasks if the computer is running on battery power. If you are using a portable computer that runs on batteries and you want a scheduled task to run, clear the default check boxes.
- If the power is interrupted or if the battery fails, the scheduled task that is running might not complete.
- The **Wake the computer to run this task** check box is only displayed on computers that support it.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Task Scheduler using Computer Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Task Scheduler using Computer Management**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Computer Management (Local)/Services and Applications

3. In the details pane, double-click **Task Scheduler**.
4. Edit the appropriate settings in the **General**, **Log On**, **Recovery**, or **Dependencies** tab.

### Note

- To perform this procedure, you must be a member of the Administrators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Task Scheduler overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Task Scheduler overview**

Using Task Scheduler, you can schedule any script, program, or document to run at a time that is most convenient for you.

When you first install your Windows Server 2003 family operating system, the Task Scheduler service is enabled. By default, you must be a member of the Administrators, Backup Operators, or Server Operators group on the local computer, to view, add, edit, or delete scheduled tasks, or to disable, pause, or restart the Task Scheduler service. For more information, see Task Scheduler and Security.

With Task Scheduler, you can:

- Schedule a task to run daily, weekly, monthly, or at certain times (such as system startup).
- Change the schedule for a task.
- Stop a scheduled task.
- Customize how a task runs at a scheduled time.

Each scheduled task you create is stored as a .job file in the \Windows\Tasks folder. The .job file contains the properties and configuration information for the task. You can create a scheduled task on your computer and then drag the .job object over to a remote computer. After you drag a task from one computer to another, you must update the account information for the task before it will run. Removing a scheduled task removes only the .job file from the schedule. The program file the task runs is not removed from the hard disk.

For tips on using Task Scheduler, see Task Scheduler Best practices.

# Task Scheduler and security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Task Scheduler and security**

When creating a scheduled task, you must enter a user name and password, either in the **Add Scheduled Task Wizard** or in the **Run as** box in the **Task** tab of the scheduled task's property dialog box. When the scheduled task runs, the program you've scheduled runs as if it were started by the user you specified, with that user's security context. For example, if the user specified for a scheduled task is a member of the Backup Operators group on the local computer, the program specified in the scheduled task file runs as if a member of the Backup Operators group is logged onto the local computer. If another user is logged on to the computer at the time a scheduled task specified for a different user runs, the task runs but is not visible to the current user.

By default, to schedule a task, you must be a member of the Administrators, Backup Operators, or Server Operators group on the local computer. By default, when creating a scheduled task, you cannot enter a user who belongs to a group that has more rights than the group you belong to. For example, if you are a member of the Backup Operators group on the local computer, you cannot specify a member of the Administrators group when creating a scheduled task. However, a member of the Administrators group can enable a member of any group to create or modify scheduled tasks, by using the **cacls** command to modify the discretionary access control list (DACL) of the **Tasks** folder. By default, the **Tasks** folder is located in the **\Windows** folder on the hard drive of the local computer, for example **C:\Windows\Tasks**. For more information about using **cacls**, see Cacls. For more information about groups, see Default local groups and Default groups.

**Note**

- A user for whom you assign permissions to the **Tasks** folder using **cacls** will be able to access scheduled tasks for all users. Choose which users to give access to the **Tasks** folder judiciously.

In Windows Server 2003 family operating systems, passwords have an expiration date. If you are scheduling recurring tasks that run indefinitely, you need to be aware of the expiration date on your passwords. If the password changes for an account on a domain, then you must update the tasks scheduled to run under that account.

When a job is created through Task Scheduler, account information for all tasks that use the same **run as** account is stored only once. Task Scheduler validates the **run as** account when a job is created, which prevents incorrect **run as** account information from being saved and, as a result, prevents other existing jobs that use the same account from being affected. If the password validation fails, a job file is created, but it will not run.

If the **run as** account password has expired or the account has been deleted and recreated, the password must be updated for jobs to run. Updating the password for one job automatically updates it for all jobs that use the same **run as** account.

When you create a scheduled task, the user credentials you specify for that specific task are securely stored on the local computer.

For security-related tips on using Task Scheduler, see Task Scheduler Best practices.

**Notes**

- To view the user and group permissions for a scheduled task, right-click the task, click **Properties**, and then click the **Security** tab.
- To view or change advanced user and group permissions, on the **Security** tab, click **Advanced**, click the user for whom you want to view or change permissions, and then click **View/Edit**.
- For information about viewing past scheduled tasks, see View a log of past scheduled tasks.
- For general information about Task Scheduler, see Task Scheduler overview.

# Administering Task Scheduler using Computer Management

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Task Scheduler using Computer Management**

Using Computer Management, you can do the following to a local or remote computer console:

- Stop, start, or pause the Task Scheduler service
- Specify start parameters for the Task Scheduler service
- Specify logon settings for the Task Scheduler service
- Select the computer's response if the Task Scheduler service fails
- Set or verify dependencies for the Task Scheduler service

For more information, see Configure Task Scheduler using Computer Management.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- The **Task Scheduler Properties (*computername*)** dialog box is in the **Services** snap-in. To make the dialog box available in MMC, you must add the **Services** snap-in to your Computer Management console.

# Creating and managing scheduled tasks from the Command Line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating and managing scheduled tasks from the Command Line**

In addition to using Task Scheduler, you can use the **at** and **schtasks** command-line utilities to create and manage scheduled tasks.

For more information about the **at** command, including all available parameters, see At. For more information about the **schtasks** command, including all available parameters, see Schtasks. For information about other command-line utilities, see Command-line reference A-Z.

# Troubleshooting Task Scheduler

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- Task does not run at the scheduled time.

**Task does not run at the scheduled time.**
**Cause:** The password for the user you specified when creating the scheduled task might have changed.

**Solution:** Open the scheduled task, and then update the password for the user.

**Note**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**See also:** Modify a scheduled task; Schedule a new task; Task Scheduler and security; Task Scheduler Best practices

or

**Cause:** The password for the user you specified when creating the scheduled task might be blank.

**Solution:** Assign a password for the user account for which you are scheduling the task. For more information, see User and Group Accounts. After the user has a password, modify the scheduled task to include the password.

**Note**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

**See also:** Modify a scheduled task; Schedule a new task; Task Scheduler and security; Task Scheduler Best practices

or

**Cause:** Task Scheduler cannot find the executable for the program that is supposed to run at the scheduled time because the path to it is set incorrectly.

**Solution:**

1. Open Task Scheduler.
2. Double-click the scheduled task.
3. In the **Task** tab, verify that the paths to the program executable are correct in the **Run** and **Start in** boxes.

**Note**

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

**See also:** Task Scheduler Best practices; Schedule a new task; Creating and managing scheduled tasks from the Command Line; Configure Task Scheduler using Computer Management

or

**Cause:** The task was scheduled to run under another user account than the user currently logged on.

**Solution:**

1. Open Task Scheduler.

2. In the **Task** tab, in the **Run as** box, and then type the correct user name.

**Note**

- To perform this procedure, you must be a member of the Administrators, Backup Operators, or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

or

**Cause:** The Task Scheduler service might be stopped.

**Solution:**

1. Open Task Scheduler.

2. In the **Advance** menu, click **Start Using Task Scheduler**.

**Note**

- To perform this procedure, you must be a member of the Administrators or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

**See also:** Administering Task Scheduler using Computer Management

or

**Cause:** The Task Scheduler service might be disabled.

**Solution:**

1. Open Computer Management.

2. In the console tree, click **Services**.

   **Where?**

   - Computer Management (Local)/Services and Applications

3. In the details pane, double-click **Task Scheduler**.

4. In the **General** tab, in **Startup type** list box, select **Automatic** or **Manual**. Click **OK**.

**Note**

- To perform this procedure, you must be a member of the Administrators or Server Operators group, or have been delegated the appropriate authority, on the local computer. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

You can also stop and start the Task Scheduler service in the Microsoft Management Console: open the **Task Scheduler Properties (*computername*)** dialog box, and then under the **General** tab, under **Service status**, click **Start** or **Stop**.

**See also:** Administering Task Scheduler using Computer Management

# Logon Scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logon Scripts**
Logon scripts are groups of commands that run when a user logs on to a computer. Administrators design logon scripts to automate the process of configuring a user environment. Administrators use the tools described below to manage logon scripts for individual user accounts, especially those defined locally.

- For help with specific tasks, see Logon Scripts How To....
- For general background information, see Logon Scripts Concepts.

Administrators use a different set of tools to manage scripts for groups of users and computers defined in Active Directory®. For more information about Group Policy startup, shutdown, logon, and logoff scripts, see Group Policy (pre-GPMC).

# Logon Scripts How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Assign a logon script to a user or group
- Assign a logon script to a user in the Active Directory

# Assign a logon script to a user or group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign a logon script to a user or group**

1. Open Computer Management.
2. In the console tree, click **Users**.

   **Where?**

   - System Tools/Local Users and Groups/Users

3. Double-click the user to which you want to assign a logon script.
4. Click the **Profile** tab.
5. In the **Logon script** field, enter the path and name of the logon script you want to assign to that user, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.
- You can store local logon script files in any local or shared folder that the user can access during logon.
- For most members of the Windows server 2003 family, the default location for local logon scripts is the *%systemroot%*\System32\Repl\Imports\Scripts folder, which is shared using the share name **netlogon**. However, Windows Server 2003, Standard Edition, does not create this folder.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Logon scripts overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logon scripts overview**

A system administrator can use logon scripts to assign tasks that will be automatically performed whenever a user logs on to a particular computer system. These scripts can use system environment variables, and can also call other scripts or executable programs. Logon scripts are frequently used to map network drives, start background processes, and initialize user environment variables.

# Understanding logon scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding logon scripts**

A logon script runs automatically whenever a user logs on to a computer running a member of the Windows Server 2003 family of operating systems. The script can contain operating system commands, such as those that make network connections or start programs. Logon scripts can also set environment variables to specify information such as the computer search path and the directory for temporary files. A logon script is usually a batch file (.bat or .cmd file name extension), but any executable program can be used.

Logon scripts are optional. You can use them to configure user working environments by creating network connections and starting programs. Logon scripts are useful when you want to affect the user work environment without managing all aspects of it.

Script files are text files that contain script commands. The Windows Server 2003 family of operating systems supports these types of scripts:

- Batch file commands are stored in text files with the .bat or .cmd file name extension. Batch files automate simple series of tasks that would otherwise be run from a command line. Scripts written using batch file commands are run by the command shell. For more information about the command shell, see Command shell overview.

- Visual Basic Scripting Edition (VBScript) commands are stored in text files with the .vbs file name extension, and JScript commands are stored in text files with the .js file name extension. VBScript and JScript allow the administrator to construct sophisticated scripts. The Windows Script Host can run these scripts from the desktop of the computer, or from a command line. For more information about the Windows Script Host, see Windows Script Host.

After you create a logon script, you can assign it to one or more local users, sites, domains, or organizational units (OUs).

For more information about specific tasks related to assigning scripts, see Logon Scripts How To....

# Logon script assignment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logon script assignment**

On computers running operating systems in the Windows Server 2003 family, you can assign a logon script to a user account. When a user logs on and a path to a logon script is present in the user account, the file is located and run.

You can also assign logon and logoff scripts, and computer startup and shutdown scripts by using the Group Policy snap-in. These scripts apply to the entire scope of users and computers for which a particular Group Policy object applies.

In **Computer Management**, you can use the **User Property** dialog box to assign logon scripts to user accounts by typing the file name (for example, Clerks.bat) in the **Logon script** text box. At logon, the server authenticating the logon locates an assigned logon script. It looks for the specified file following the local logon script path on the server (usually %systemroot%\SYSVOL\sysvol\domain_name\scripts). If a relative path is provided before the file name (for example, Admins\User1.bat), the server looks for the logon script in that subdirectory of the logon script path.

The entry in the **Logon Script** text box specifies only the file name (and, optionally, the relative path) and does not create the actual logon script. You create a logon script with the specified name and place it in the appropriate directory on the appropriate replication export server.

You can place a logon script in a local directory on a user's computer. You would typically use this location, however, when you are administering user accounts that exist on a single computer rather than in a domain. This logon script runs only when a user logs on locally to the computer and does not run when the user logs on to the domain. You must place the logon script using the computer's logon script path or in a subdirectory of that logon script path. The default location for local logon scripts is the %systemroot%\System32\Repl\Imports\Scripts folder. This folder is not created on an new installation of Windows XP. A folder must be created and shared with the name **netlogon**; for step-by-step instructions, see Share a folder or drive. The NTFS permissions of this folder should allow users and server operators only read and execute permissions, and should allow administrators full control. The folder is created and shared automatically on domain controllers, so you should not attempt to create a **netlogon** folder on a domain controller manually.

For more information, see: Logon Scripts How To..., Group Policy overview, and Privileges.

# Logon script replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logon script replication**

A logon script is always downloaded from the server that validates a user's logon request. For users with accounts on Windows Server 2003 family domains that have one or more domain controllers, any one of the domain controllers can authorize a user's logon attempt. In order for logon scripts to always work for users, logon scripts must exist for all user accounts in a domain, on every domain controller in that domain.

Windows Server 2003, Standard Edition, domain controllers and servers use File Replication Service (FRS) to replicate system policy and logon scripts to every domain controller in a domain. When you make a change to a logon script stored in the SYSVOL share of a domain controller, FRS replicates this change to the SYSVOL shares of all other domain controllers in the domain. If the administrator manages scripts for a domain using Active Directory Users and Computers, then the logon scripts are typically located in the %systemroot%\SYSVOL\sysvol*domain_name*\Scripts folder. The system will look for scripts in the **netlogon** share of the domain controller that authenticates the user.

If the administrator uses Group Policy to manage logon scripts on a standalone system, then the user logon scripts are typically located in the %systemroot%\System32\GroupPolicy\User\Scripts\Logon directory.

For specific information on how to configure the logon script path for a user in a domain, see Assign a logon script to a user in the Active Directory.

For background information about replication, see Understanding Sites and Replication and Replication overview.

For instructions about configuring replication, see Configure Replication Between Sites.

# Logon Scripts Environment variables

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Environment variables**
When managing multiple user and group accounts, you may need to make the same change to many accounts. You can use environment variables to replace static names or labels with a dynamic variable. The dynamic variable is replaced by the appropriate environment data when called.

**Changing the system environment variables**
Servers running Windows Server 2003 require certain information to find programs, to allocate memory space for some programs to run, and to control various programs. This information, called the system and user environment variables, can be viewed using the **System Properties** in **Control Panel** on the **Advanced** tab. These environment variables are similar to those that can be set in the MS-DOS operating system, such as PATH and TEMP.

The *system environment variables* are the same regardless who is logged on to the computer. If you are logged on as a member of the Administrators group, you can add new variables or change the values.

The *user environment variables* can be different for each user of a particular computer. They include any environment variables you want to define, or variables defined by your applications, such as the path where application files are located.

After you change any environment variables, the new values are saved in the registry, making them automatically available the next time you start your computer.

If any conflict exists between environment variables, variables are set in this way:

- System environment variables are set first.
- Variables defined in the Autoexec.bat file (except for Path variables) are set next, and override system variables.
- User environment variables defined in **System Properties** are set next, and override both the system and Autoexec.bat variables.
- Path variables defined in the Autoexec.bat file are set last.

Path settings, unlike other environment variables, are cumulative. The full path (what you see when you type **path** at the command prompt) is created by appending the path contained in Autoexec.bat to the paths defined in **System Properties** in **Control Panel**.

**Using system environment variables in user profile paths, home directory paths, and logon scripts**
Any system environment variable on a Windows-based client computer can be used in a user account profile path, logon script path, home directory path, and within a logon script itself. For a list of system environment variables, see Command shell overview

This feature helps to ensure that logon scripts and user profiles run most efficiently on domains that span wide area network (WAN) links, especially if users work at more than one site.

For example, suppose you have two physical sites, one located in Paris, and the other located in London. On every computer running an operating system in the Windows Server 2003 family at the London site, you can set the *servername* system environment variable to the computer name of a backup domain controller in London. On the computers in Paris, you can set *servername* in a similar way, using the computer name of the backup domain controller in Paris. For domain user accounts, you can use %servername% in the logon script paths (for example, \\%servername%\scripts). When a user logs on, the logon script is always loaded from a server at the local site.

For more information, see the Resource Kit.

For more information about constructing scripts, see System Administration Scripting Guide at the Microsoft Windows Resource Kits Web site.

# Windows Script Host

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Script Host**
Windows Script Host creates an environment in which script engines run the commands contained in script files. The Windows Script Host supports several script engines, including JScript and VBScript. Windows Script Host is ideal for non-interactive scripting needs, and it allows you to run scripts from the Windows desktop or from the command prompt.

- For help with specific tasks, see Windows Script Host How To....
- For general background information, see Windows Script Host Concepts.

# Windows Script Host How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Run Windows Script Host
- Run Windows Script Host samples
- Set global properties for all scripts that are run with the Windows-based script host

# Run Windows Script Host

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run Windows Script Host**

Click the task that you want to perform.

- To start a script so that it runs in a Windows environment
- To start a script so that it runs in a command-line environment

**To start a script so that it runs in a Windows environment**

1. Open Command Prompt.
2. Type: **wscript**[*ScriptName*] [**//B**] [**//D**] [**//E:***Engine*] [**//H:CScript** | **//H:WScript**] [**//I**] [**//Job:***Identifier*] [**//Logo** | **//NoLogo**] [**//S**] [**//T:***Number*] [**//X**] [**//?**] [*ScriptArguments*]

**Parameters**

***ScriptName***

Specifies the path and file name of the script file.

**//B**

Specifies batch mode, which does not display alerts, scripting errors, or input prompts.

**//D**

Starts the debugger.

**//E: *Engine***

Specifies the engine that is used to run the script.

**//H:cscript**

Registers Cscript.exe as the default script host for running scripts.

**//H:wscript**

Registers Wscript.exe as the default script host for running scripts. This is the default.

**//I**

Specifies interactive mode, which displays alerts, scripting errors, and input prompts. This is the default and the opposite of **//B**.

**//Job: *Identifier***

Runs the job identified by *Identifier* in a .wsf script file.

**//Logo**

Specifies that the Windows Script Host banner is displayed in the console before the script runs. This is the default and the opposite of **//Nologo**.

**//Nologo**

Specifies that the Windows Script Host banner is not displayed before the script runs.

**//S**

Saves the current command-prompt options for the current user.

**//T: *Number***

Specifies the maximum time the script can run (in seconds). You can specify up to 32,767 seconds. The default is no time limit.

**//X**

Starts the script in the debugger.

**//?**
Displays available command parameters and provides help for using them.

***ScriptArguments***
Specifies the arguments passed to the script. Each script argument must be preceded by a slash (/).

**Remarks**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Each parameter is optional; however, you cannot specify script arguments without specifying a script. If you do not specify a script or any script arguments, Wscript.exe displays the **Windows Script Host Settings** dialog box, which you can use to set global scripting properties for all scripts that Wscript.exe runs on the local computer.
- The **//T** parameter prevents excessive running of scripts by setting a timer. When the time exceeds the specified value, WScript interrupts the script engine and ends the process.
- Windows script files usually have one of the following file name extensions: .wsf, .vbs, .js.
- If you double-click a script file with an extension that has no association, the **Open With** dialog box appears. Select Wscript or Cscript, and then select **Always use this program to open this file type**. This registers Wscript.exe or Cscript as the default script host for files of this file type.
- You can set properties for individual scripts. See Related Topics for more information.
- Windows Script Host can use .wsf script files. Each .wsf file can use multiple scripting engines and perform multiple jobs.

**To start a script so that it runs in a command-line environment**

1. Open Command Prompt.
2. Type: **cscript**[*ScriptName*] [**//B**] [**//D**] [**//E:***Engine*] [**//H:CScript** | **//H:WScript**] [**//I**] [**//Job:***Identifier*] [**//Logo** | **//NoLogo**] [**//S**] [**//T:***Number*] [**//X**] [**//U**] [**//?**] [*ScriptArguments*]

**Parameters**
***ScriptName***
Specifies the path and file name of the script file.

**//B**
Specifies batch mode, which does not display alerts, scripting errors, or input prompts.

**//D**
Starts the debugger.

**//E: *Engine***
Specifies the engine that is used to run the script.

**//H:cscript**
Registers Cscript.exe as the default script host for running scripts.

**//H:wscript**
Registers Wscript.exe as the default script host for running scripts. This is the default.

**//I**
Specifies interactive mode, which displays alerts, scripting errors, and input prompts. This is the default and the opposite of **//B**.

**//Job:** ***Identifier***
Runs the job identified by *Identifier* in a .wsf script file.

**//Logo**
Specifies that the Windows Script Host banner is displayed in the console before the script runs. This is the default and the opposite of **//Nologo**.

**//Nologo**
Specifies that the Windows Script Host banner is not displayed before the script runs.

**//S**
Saves the current command-prompt options for the current user.

**//T:** ***Number***
Specifies the maximum time the script can run (in seconds). You can specify up to 32,767 seconds. The default is no time limit.

**//U**
Specifies Unicode for input and output that is redirected from the console.

**//X**
Starts the script in the debugger.

**//?**
Displays available command parameters and provides help for using them. This is the same as typing Cscript.exe with no parameters and no script.

***ScriptArguments***
Specifies the arguments passed to the script. Each script argument must be preceded by a slash (/).

**Remarks**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Each parameter is optional; however, you cannot specify script arguments without specifying a script. If you do not specify a script or any script arguments, Cscript.exe displays the Cscript.exe syntax and the valid host options.
- The **//T** parameter prevents excessive running of scripts by setting a timer. When the run time exceeds the specified value, CScript interrupts the script engine and ends the process.
- Windows script files usually have one of the following file name extensions: .wsf, .vbs, .js.
- You can set properties for individual scripts. See Related Topics for more information.
- Windows Script Host can use .wsf script files. Each .wsf file can use multiple scripting engines and perform multiple jobs.
- If you double-click a script file with an extension that has no association, the **Open With** dialog box appears. Select Wscript or Cscript, and then select **Always use this program to open this file type**. This registers Wscript.exe or Cscript as the default script host for files of this file type.
- You can set properties for individual scripts. See Related Topics for more information.
- Windows Script Host can use .wsf script files. Each .wsf file can use multiple scripting engines and perform multiple jobs.

**Formatting legend**

| Format | Meaning |
|---|---|

| | |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Run Windows Script Host samples

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To run Windows Script Host samples**

1. Open the Command Prompt.

2. Type the following:

   **cscript***samples folder******script name*

   Where:

   *samples folder* is the path to the folder into which you downloaded the samples.

   *script name* is the name of the sample script you want to run, including the file name extension (for example, .js or .vbs).

   For example, if you saved the samples to C:\Samples, and you wanted to run the Network.vbs sample, you would type:

   **cscript c:\sample\network.vbs**

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- You must download the Windows Script Host sample files from the **Microsoft Windows Script Technologies** home page at the Microsoft Web site (http://www.microsoft.com/) before you can run them.

- You can also double-click the sample script file to run a script using the Wscript.exe script host.

Run Windows Script Host

# Set global properties for all scripts that are run with the Windows-based script host

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set global properties for all scripts that are run with the Windows-based script host**

1. Click **Start**, and then click **Run**.
2. In the **Open** box, type *wscript*, and then click **OK**. The **Windows Script Host Settings** dialog box appears.
3. Select the **Stop script after specified number of seconds** check box.
4. In the **seconds** box, enter the time limit you want to place on all scripts.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- With one setting, you can set properties for all scripts that are run with the Windows-based script host. Every script that is run with this host automatically uses these settings.

# Set properties of individual scripts that are run with the Windows-based script host

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set properties for individual scripts that are run with the Windows-based script host**

1. Open Windows Explorer. Browse to the folder with the script whose properties you want to set, and right-click it.
2. Select **Properties**, and then click the **Script** tab.
3. Select the **Stop script after specified number of seconds** check box.
4. In the **seconds** box, enter the time limit you want to place on this script.

### Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- These settings override global settings.
- After clicking **OK**, a command file is created that binds the property settings to the script. It has the file name extension .wsh. You can use this command file as an alternate script file to run the script.

For more information, see the Windows Script Technologies Web site at the Microsoft Web site (http://www.microsoft.com/).

# Windows Script Host Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about the Windows Script Host:

- Windows Script Host overview
- Windows Script Host object model

# Windows Script Host overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Script Host overview**

You can use Windows Script Host to run scripts by clicking a script file on the Windows desktop or by typing the name of a script file at the command prompt. Similar to Microsoft Internet Explorer, Windows Script Host serves as a controller of ActiveX scripting engines. Unlike Internet Explorer, Windows Script Host has very low memory requirements and is ideal for both interactive and non-interactive scripting, such as logon scripting and administrative scripting.

There are two versions of the Windows Script Host: a Windows-based version (Wscript.exe), which provides a property sheet for setting script properties, and a command-prompt-based version (Cscript.exe), which provides command-line switches for setting script properties. You can run either of these by typing Wscript.exe or Cscript.exe at the command prompt.

Previously, the only native scripting language supported by the Windows operating system was that of batch files. Although batch language is fast and small, its features are limited compared to VBScript and JScript. For example, the ability to control program flow was not built into the batch language. Today, the Windows Script Host architecture allows you to take advantage of these powerful scripting languages, although support is still provided for batch files.

This version of WSH adds several areas of new functionality:

- **Improved argument handling.** Handling and documenting command-line arguments is now simpler. For more information, see **What's New in WSH 5.6** at the Microsoft Web site (http://www.microsoft.com/)

- **Remote scripting.** You can load a script onto several remote computer systems which you can then run at the same time.

- **A running process is an object.** You can sink events, access standard I/O streams, and share environment variables with other processes.

- **Flexible working directory.** You can determine and modify the path of the current working directory of the active process.

- **Improved script security.** The new script security model makes it safer to distribute and run scripts. For more information, see Windows Script (http://www.microsoft.com/), Microsoft Windows Resource Kits Web site (http://www.microsoft.com/)., and Security and Windows Script Host (http://www.microsoft.com/).

# Windows Script Host object model

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Script Host object model**

The Windows Script Host (WSH) environment includes a built-in library, WScript, and four COM (Component Object Model)-based libraries: WshShell, WshNetwork, WshController and the Scripting Runtime Library. Together, WScript, WshShell, WshNetwork and WshController are referred to as the WSH Objects. Your scripts access the functionality of these libraries through the WSH Object Model.

Scripts use object models to access features of COM-based libraries. In COM-based libraries an object model documents the features of the library. Scripts call an object's methods and manipulate an object's properties to utilize the features required to accomplish a task.

For more information about the Windows Script Host object model, see the Windows Script Host Object Model page at the Microsoft Web site.

For general information about Windows scripting, see the Windows Script Technologies Web site at the Microsoft Web site, and Microsoft Windows Resource Kits Web site.

# Scripting Tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Scripting tools**
This section covers:

- Using batch files
- Netsh
- Logon Scripts
- Windows Management Instrumentation Command-line

For information about Microsoft® Visual Basic® Scripting Edition (VBScript), see "VBScript Primer" at the Microsoft Windows Resource Kits Web site.

For more information about creating scripts, see "Creating Enterprise Scripts" at the Microsoft Windows Resource Kits Web site. For more information about managing scripts, see "Managing Enterprise Scripts" at the Microsoft Windows Resource Kits Web site.

# Using batch files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using batch files**

With batch files, which are also called batch programs or scripts, you can simplify routine or repetitive tasks. A batch file is an unformatted text file that contains one or more commands and has a .bat or .cmd file name extension. When you type the file name at the command prompt, Cmd.exe runs the commands sequentially as they appear in the file.

You can include any command in a batch file. Certain commands, such as **for**, **goto**, and **if**, enable you to do conditional processing of the commands in the batch file. For example, the **if** command carries out a command based on the results of a condition. Other commands allow you to control input and output and call other batch files.

The standard error codes that most applications return are 0 if no error occurred and 1 (or higher value) if an error occurred. To determine the meaning of specific error codes, refer to your application help documentation.

For more information about batch file operations, see the following topics:

- Using batch parameters
- Using filters
- Using command redirection operators

For more information about commands that you can use in batch files, click a command:

- Call
- Choice
- Echo
- Endlocal
- For
- Goto
- If
- Pause
- Rem
- Setlocal
- Shift

# Netsh

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh**

This section provides information about Netsh commands and their use:

- Netsh overview
- Security information for Netsh commands
- Enter a netsh context
- Netsh DHCP example
- Netsh WINS example
- Netsh Commands

# Netsh overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh overview**

**Netsh** is a command-line scripting utility that allows you to, either locally or remotely, display or modify the network configuration of a computer that is currently running. **Netsh** also provides a scripting feature that allows you to run a group of commands in batch mode against a specified computer. **Netsh** can also save a configuration script in a text file for archival purposes or to help you configure other servers.

**Netsh contexts**

**Netsh** interacts with other operating system components using dynamic-link library (DLL) files. Each Netsh helper DLL provides an extensive set of features called a context, which is a group of commands specific to a networking component. These contexts extend the functionality of **netsh** by providing configuration and monitoring support for one or more services, utilities, or protocols. For example, Dhcpmon.dll provides **netsh** the context and set of commands necessary to configure and manage DHCP servers.

To run a **netsh** command, you must start **netsh** from the Cmd.exe prompt and change to the context that contains the command you want to use. The contexts that are available to you depend on which networking components you have installed. For example, if you type **dhcp** at the Netsh command prompt, you change to the DHCP context, but if you do not have DHCP installed the following message appears:

```
The following command was not found: dhcp.
```

For more information about Netsh contexts, see the following topics:

- Netsh commands for AAAA
- Netsh commands for DHCP
- Netsh diagnostic (diag) commands
- Netsh commands for Interface IP
- Netsh commands for Interface IPv6
- Netsh commands for Interface Portproxy
- Netsh commands for Internet Protocol security
- Netsh commands for Network Bridge
- Netsh commands for remote access (ras)
- Netsh commands for Routing
- Netsh commands for RPC
- Netsh commands for WINS

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Using multiple contexts**
A context can exist within a context. For example, within the Routing context, you can change to the IP and IPX subcontexts.

To display a list of commands and subcontexts that you can use within a context, at the **netsh** prompt, type the context name, and then type either **/?** or **help**. For example, to display a list of subcontexts and commands that you can use in the Routing context, at the **netsh** prompt (that is, netsh>), type either of the following:

**routing /?**

**routing help**

To perform tasks in another context without changing from your current context, type the context path of the command you want to use at the **netsh** prompt. For example, to add the Local Area Connection interface in the IGMP context without changing to the IGMP context, at the **netsh** prompt, type:

**routing ip igmp add interface "Local Area Connection" startupqueryinterval=21**

**Running Netsh commands from the Cmd.exe command prompt**
When you run **netsh** from the Cmd.exe command prompt, it uses the following syntax. To run these commands on a remote Windows 2000 Server, you must first use Remote Desktop Connection to connect to a Windows 2000 Server that is running Terminal Services. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

The following describes the netsh command:

**netsh**
Netsh is a command-line scripting utility that allows you to, either locally or remotely, display or modify the network configuration of a currently running computer. Used without parameters, **netsh** opens the Netsh.exe command prompt (that is, netsh>).

**Syntax**
**netsh**[**-a***AliasFile*] [**-c***Context*] [**-r***RemoteComputer*] [{*NetshCommand* | **-f***ScriptFile*}]

**Parameters**
**-a**
Returns you to the **netsh** prompt after running *AliasFile*.

***AliasFile***
Specifies the name of the text file that contains one or more **netsh** commands.

**-c**
Changes to the specified **netsh** context.

***Context***
Specifies the **netsh** context. The following table lists the available **netsh** contexts.

| Context | Description |
|---|---|
| Netsh commands for AAAA | Shows and sets the configuration of the authentication, authorization, accounting, and auditing (AAAA) database used by the Internet Authentication Service (IAS) and the Routing and Remote Access service. |
| Netsh commands for DHCP | Administers DHCP servers and provides an equivalent alternative to console-based management. |
| Netsh diagnostic (diag) commands | Administers and troubleshoots operating system and network service parameters. |
| Netsh commands for Interface IP | Configures the TCP/IP protocol (including addresses, default gateways, DNS servers, and WINS servers) and displays configuration and statistical information. |

| | |
|---|---|
| Netsh commands for Interface IPv6 | Queries and configures IPv6 interfaces, address, caches, and routes. |
| Netsh commands for Interface Portproxy | Administers servers that act as proxies between IPv4 and IPv6 networks and applications. |
| Netsh commands for Interface IPv6 | Provides an equivalent alternative to the console-based management and diagnostic capabilities provided by the IP Security Policy Management and IP Security Monitor snap-ins available in the Microsoft Management Console (MMC). By using the Netsh commands for IPSec, you can configure and view static or dynamic IPSec main mode settings, quick mode settings, rules, and configuration parameters. |
| Netsh commands for Network Bridge | Enables or disables Layer 3 compatibility mode and shows configuration information for the Network Bridge adapters. |
| Netsh commands for remote access (ras) | Administers remote access servers. |
| Netsh commands for Routing | Administers Routing servers. |
| Netsh commands for RPC | Changes, resets or displays selective system binding settings |
| Netsh commands for WINS | Administers WINS servers. |

**-r**
Configures a remote computer.

***RemoteComputer***
Specifies the remote computer to configure.

***NetshCommand***
Specifies the **netsh** command that you want to run.

**-f**
Exits Netsh.exe after running the script.

***ScriptFile***
Specifies the script that you want to run.

**/?**
Displays help at the command prompt.

**Remarks**

- If you specify **-r** followed by another command, **netsh** executes the command on the remote computer and then returns

to the Cmd.exe command prompt. If you specify **-r** without another command, **netsh** opens in remote mode. The process is similar to using **set machine** at the Netsh command prompt. When you use **-r**, you set the target computer for the current instance of **netsh** only. After you exit and reenter **netsh**, the target computer is reset as the local computer. You can run **netsh** commands on a remote computer by specifying a computer name stored in WINS, a UNC name, an Internet name to be resolved by the DNS server, or an IP address.

**Running Netsh commands from the Netsh.exe command prompt**

**Netsh** uses the following standard commands in all contexts that you can run from a Netsh.exe command prompt (that is, netsh>). To run these Netsh commands on a remote Windows 2000 Server, you must first use Remote Desktop Connection to connect to a Windows 2000 Server that is running Terminal server. There might be functional differences between Netsh context commands on Windows 2000 and members of the Windows Server 2003 family.

To view the command syntax, click a command:

- ..
- abort
- add helper
- alias
- bye
- commit
- delete helper
- dump
- exec
- exit
- help
- offline
- online
- popd
- pushd
- quit
- set file
- set machine
- set mode
- show
- unalias

**..**
Moves to the context that is one level up.

**Syntax**
**..**

**Parameters**
**/?**
Displays help at the command prompt.

**abort**
Discards any changes made in offline mode. **Abort** has no effect in online mode.

**Syntax**
**abort**

**Parameters**
**/?**
Displays help at the command prompt.

**add helper**
Installs the helper DLL in **netsh**.

**Syntax**
**add helper** *DLLName*

**Parameters**
***DLLName***
Required. Specifies the name of the helper DLL that you want to install.

**/?**
Displays help at the command prompt.

**alias**
Adds an alias that consists of a user-defined character string, which **netsh** treats as equivalent to another character string. Used without parameters, **alias** displays all available aliases.

**Syntax**
**alias**[*AliasName*] [*String1* [*String2* ...]]

**Parameters**
**alias[ *AliasName*]**
Displays the specified alias.

**alias[ *AliasName*][ *String1*[ *String2*...]]**
Sets *AliasName* to the specified strings.

**/?**
Displays help at the command prompt.

**Examples**
The following **netsh** sample script sets two **netsh** aliases, Shaddr and Shp, and then leaves the Netsh command prompt in the Interface IP context:

```
alias shaddr show interface ip addr
alias shp show helpers
interface ip
```

If you type **shaddr** at the Netsh command prompt, Netsh.exe interprets this as the command **show interface ip addr**. If you type **shp** at the Netsh command prompt, Netsh.exe interprets this as the command **show helpers**.

**bye**
Exits Netsh.exe.

**Syntax**
**bye**

**Parameters**
**/?**

Displays help at the command prompt.

**commit**
Commits any changes made in the offline mode to the router. **Commit** has no effect in online mode.

**Syntax**
**commit**

**Parameters**
**/?**
Displays help at the command prompt.

**delete helper**
Removes the helper DLL from **netsh**.

**Syntax**
**delete helper** *DLLName*

**Parameters**
***DLLName***
Required. Specifies the name of the helper DLL that you want to uninstall.

**/?**
Displays help at the command prompt.

**dump**
Creates a script that contains the current configuration. If you save this script to a file, you can use the file to restore configuration settings that have been changed. Used without parameters, **dump** displays all of the **netsh** context configurations.

**Syntax**
**dump** [*FileName*]

**Parameters**
**[ *FileName*]**
Specifies the name of the file to which you want to redirect output.

**/?**
Displays help at the command prompt.

**exec**
Loads a script file and runs commands from it.

**Syntax**
**exec** *ScriptFile*

**Parameters**
***ScriptFile***
Required. Specifies the name of the script that you want to load and run.

**Remarks**

- The *ScriptFile* can run on one or more computers.

**exit**
Exits Netsh.exe.

**Syntax**
**exit**

**Parameters**
**/?**
Displays help at the command prompt.

**help**
Displays help.

**Syntax**

{**/?** | **?** | **help** | **h**}

**Parameters**
**none**

**offline**
Sets the current mode to offline.

**Syntax**
**offline**

**Parameters**
**/?**
Displays help at the command prompt.

**Remarks**

- Changes that you make in this mode are saved, but you need to run the **commit** or **online** command to set the changes in the router.
- When you switch from offline mode to online mode, changes that you made in offline mode are reflected in the configuration that is currently running.
- Changes that you make in online mode are immediately reflected in the configuration that is currently running.

**online**
Sets the current mode to online.

**Syntax**
**online**

**Parameters**
**/?**
Displays help at the command prompt.

**Remarks**

- Changes that you make in online mode are immediately reflected in the configuration that is currently running.
- When you switch from offline mode to online mode, changes that you made in offline mode are reflected in the configuration that is currently running.

**popd**
Restores a context from the stack.

**Syntax**
**popd**

**Parameters**
**/?**
Displays help at the command prompt.

**Remarks**

- Used in conjunction with **pushd**, **popd** enables you to change the context, run the command in the new context, and then resume the prior context.

**Examples**
The following sample script changes a context from the root context to the **interface ip** context, adds a static IP route, and then returns to the root context:

`netsh>` **pushd**

`netsh>` **interface ip**

```
netsh interface ip> set address local static 10.0.0.9 255.0.0.0 10.0.0.1 1

netsh interface ip> popd

netsh>
```

**pushd**
Saves the current context on a first-in-last-out (FILO) stack.

**Syntax**
**pushd**

**Parameters**
**/?**
Displays help at the command prompt.

**Remarks**

- Used in conjunction with **popd**, **pushd** enables you to change the context, run the command in the new context, and then resume the prior context.

**quit**
Exits Netsh.exe.

**Syntax**
**quit**

**Parameters**
**/?**
Displays help at the command prompt.

**set file**
Copies the Command Prompt window output to a file.

**Syntax**
**set file** {**open***FileName* | **append***FileName* | **close**}

**Parameters**
**open *FileName***
Sends the Command Prompt window output to the specified file.

**append *FileName***
Appends the Command Prompt window output to the specified existing file.

**close**
Stops sending output and closes a file.

**/?**
Displays help at the command prompt.

**Remarks**

- If the specified *FileName* does not currently exist, **netsh** creates a new file with that name. If the specified *FileName* does currently exist, **netsh** overwrites the existing data.

**Examples**
To create a new log file called Session.log and copy all succeeding **netsh** input and output to Session.log, type:

**set file open c:\session.log**

**set machine**
Sets the current computer on which to perform configuration tasks. Used without parameters, **set machine** sets the local computer.

**Syntax**
**set machine** [[*ComputerName*=]*String*]

**Parameters**

***ComputerName***
Specifies the name of the computer on which to perform configuration tasks.

***String***
Specifies the location of the remote computer.

**/?**
Displays help at the command prompt.

**Remarks**

- You can run commands on multiple computers from a single script. You can use **set machine** in a script to specify a destination computer (for example, Computer A), and then run the commands that follow **set machine** on this computer (that is, Computer A). You can then use **set machine** to specify another destination computer (for example, Computer B), and then run commands on this computer (that is, Computer B).

**set mode**
Sets the current mode to online or offline.

**Syntax**
**set mode** {**online** | **offline**}

**Parameters**
**online**
Sets the current mode to online.

**offline**
Sets the current mode to offline.

**/?**
Displays help at the command prompt.

**show**
Displays alias, helper, and mode information.

**Syntax**
**show** {**alias** | **helper** | **mode**}

**Parameters**
**alias**
Lists all defined aliases.

**helper**
Lists all top-level helpers.

**mode**
Displays the current mode.

**/?**
Displays help at the command prompt.

**unalias**
Deletes the specified alias.

**Syntax**
**unalias** *AliasName*

**Parameters**
***AliasName***
Required. Specifies the name of the alias.

**/?**
Displays help at the command prompt.

**Formatting legend**

| Format | Meaning |
|---|---|

| | |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Security information for Netsh commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for Netsh commands**

Netsh commands are available for some of the networking technologies, and the security issues for each technology are distinct. You can use the links provided to review security issues, considerations, and best practices for each . In addition, you can review the recommendations in Best practices for security.

| Technology | Context name | Reference |
|---|---|---|
| Dynamic Host Configuration Protocol (DHCP) | **netsh dhcp** | Security information for DHCP |
| Internet Authentication Service (IAS) | **netsh aaaa** | Security information for IAS |
| Internet Protocol security (IPSec) | **netsh ipsec** | Security issues with IP |
| Internet Protocol version 6 (IPv6) | **netsh interface ipv6** and **netsh interface portproxy** | Security information for IPv6 |
| Remote Access | **netsh ras** | Security information for remote access; Security issues for VPN |
| Routing | **netsh routing** | Security information for routing; Security issues for VPN |
| Transmission Control Protocol/Internet Protocol (TCP/IP) | **netsh interface ip** and **netsh bridge** | Internet Protocol Security (IPSec); IPSec Best practices |
| Windows Internet Name Service (WINS) | **netsh wins** | Security information for WINS |

# Enter a netsh context

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enter a netsh context**

1. Open Command Prompt.
2. At the command prompt, type:

   **netsh**

3. Type one of the following:

| To enter this context | Type |
|---|---|
| AAAA | **aaaa** |
| DHCP | **dhcp** |
| Network Diagnostics (diag) | **diag** |
| Interface | **interface** |
| Interface IP | **interface ip** |
| Interface IPv6 | **interface ipv6** |
| Interface Portproxy | **interface portproxy** |
| Internet Protocol security | **ipsec** |
| Network Bridge | **bridge** |
| Remote Access | **ras** |
| Routing | **routing** |
| RPC Helper | **rpc** |
| WINS | **wins** |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- To enter a context, you can type only enough letters in the context name to allow **netsh** to identify the context. For example, to enter the WINS context from the **netsh** prompt (that is, netsh>), you can type **w**, and then press ENTER.
- Most of the contexts listed above have one or more subcontexts. For more information, see Related Topics.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**

# Netsh DHCP example

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh DHCP example**

You can use Netsh commands for Dynamic Host Configuration Protocol (DHCP) in batch files and other scripts to automate tasks. The following example batch file demonstrates how to use Netsh commands for DHCP to perform a variety of related tasks.

In the circumstance of this example procedure, DHCP-01 is a DHCP server with the IP address 192.168.0.2. The procedure adds a new scope to DHCP-01 with the name MyScope, IP address 192.168.10.0, subnet mask 255.255.255.0, and comment NewScope. It then configures the scope with an address range (192.168.10.1 through 192.168.10.254), an exclusion range (192.168.10.1 through 192.168.10.25), and router IP addresses (DHCP option 003). The scope is then set to an active state.

For more information, see Setting Up Scopes, Setting Up Options, and DHCP options.

For more information and a complete list of Netsh commands for DHCP, see Netsh commands for DHCP.

In the following example procedure, lines that contain comments are preceded by "rem," for remark. Netsh ignores comments.

```
rem one DHCP server:
rem (DHCP-01) 192.168.0.2

rem 1. Connect to (DHCP-01), and add the scope MyScope with IP address 192.168.10.0,
rem 1.1  subnet mask 255.255.255.0, and the comment NewScope.
netsh dhcp server 192.168.0.2 add scope 192.168.10.0 255.255.255.0 MyScope NewScope

rem 2. Connect to (DHCP-01 MyScope), and add IP address range 192.168.10.1 to
192.168.10.254 for distribution
rem 2.1  and the default ClientType of DHCP.
netsh dhcp server 192.168.0.2 scope 192.168.10.0 add iprange 192.168.10.1
192.168.10.254

rem 3. Connect to (DHCP-01 MyScope), and add IP exclusion range 192.168.10.1 to
192.168.10.25
rem 3.1  and the default ClientType of DHCP.
netsh dhcp server 192.168.0.2 scope 192.168.10.0 add excluderange 192.168.10.1
192.168.10.25

rem 4. Connect to (DHCP-01 MyScope), and set the value of option code 003
rem 4.1   to list two router IP addresses (10.1.1.1, 10.1.1.2).
netsh dhcp server 192.168.0.2 scope 192.168.10.0 set optionvalue 003 IPADDRESS 10.1.1.1
10.1.1.2

rem 5.  Connect to (DHCP-01 MyScope), and set the scope state to active.
netsh dhcp server 192.168.0.2 scope 192.168.10.0 set state 1

rem 6. End example batch file.
```

The following table lists the **netsh dhcp** commands that are used in this example procedure.

| Command | Description |
|---|---|
| **server** | Shifts the current DHCP command-line context to the server that is specified by either its name or IP address. |
| **add scope** | Adds a new scope to the specified DHCP server. |
| **scope** | Switches the command context to the DHCP scope that is specified by its IP address. |
| **add iprange** | Adds a range of IP addresses to the current scope. |

| | |
|---|---|
| **add excluderange** | Adds a range of excluded addresses to the current scope. |
| **set optionvalue** | Sets an option value for the current scope. |
| **set state** | Sets or resets the state of the current scope to either an active or inactive state. |

# Netsh WINS example

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh WINS example**

You can use Netsh commands for Windows Internet Name Service (WINS) in batch files and other scripts to automate tasks. The following example batch file demonstrates how to use Netsh commands for WINS to perform a variety of related tasks.

In this example procedure, WINS-A is a WINS server with the IP address 192.168.125.30 and WINS-B is a WINS server with the IP address 192.168.0.189. The procedure adds a dynamic name record with IP address 192.168.0.205, MY_RECORD [04h], to WINS-A, sets WINS-B as a push/pull replication partner of WINS-A, connects to WINS-B, and then sets WINS-A as a push/pull replication partner of WINS-B. Next the procedure initiates a push replication from WINS-A to WINS-B, and then connects to WINS-B to verify that the new record, MY_RECORD, was replicated successfully.

For more information, see WINS Replication, NetBIOS names reference, and Configure Replication.

For a complete list of Netsh commands for WINS, see Netsh commands for WINS.

In the following example procedure, lines that contain comments are preceded by "rem," for remark. Netsh ignores comments.

```
rem two WINS servers:
rem (WINS-A) 192.168.125.30
rem (WINS-B) 192.168.0.189

rem 1. Connect to (WINS-A), and add the dynamic name MY_RECORD [04h] to the (WINS-A)
database.
netsh wins server 192.168.125.30 add name Name=MY_RECORD EndChar=04 IP={192.168.0.205}

rem 2. Connect to (WINS-A), and set (WINS-B) as a push/pull replication partner of
(WINS-A).
netsh wins server 192.168.125.30 add partner Server=192.168.0.189 Type=2

rem 3. Connect to (WINS-B), and set (WINS-A) as a push/pull replication partner of
(WINS-B).
netsh wins server 192.168.0.189 add partner Server=192.168.125.30 Type=2

rem 4. Connect back to (WINS-A), and initiate a push replication to (WINS-B).
netsh wins server 192.168.125.30 init push Server=192.168.0.189 PropReq=0

rem 5. Connect to (WINS-B), and check that the record MY_RECORD [04h] was replicated
successfully.
netsh wins server 192.168.0.189 show name Name=MY_RECORD EndChar=04

rem 6. End example batch file.
```

The following table lists the **netsh wins** commands that are used in this example procedure.

| Command | Description |
|---|---|
| **server** | Shifts the current WINS command-line context to the server specified by either its name or IP address. |
| **add name** | Registers a name to the server. |
| **add partner** | Adds a replication partner to the server. |
| **init push** | Initiates and sends a push trigger to a WINS server. |
| **show name** | Displays detailed information for a particular record in the WINS server database. |

# Netsh Commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands**

This section provides a comprehensive netsh command reference, including syntax, parameters, and examples.

- Netsh commands for AAAA
- Netsh commands for DHCP
- Netsh diagnostic (diag) commands
- Netsh commands for Interface IP
- Netsh commands for Interface IPv6
- Netsh commands for Interface Portproxy
- Netsh commands for Internet Protocol security
- Netsh commands for Network Bridge
- Netsh commands for remote access (ras)
- Netsh commands for Routing
- Netsh commands for RPC
- Netsh commands for WINS

**Notes**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Netsh commands for AAAA

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for AAAA**

You can use commands in the Netsh AAAA context to show and set the configuration of the authentication, authorization, accounting, and auditing (AAAA) database used by the Internet Authentication Service (IAS) and the Routing and Remote Access service. The AAAA database is also known as the IAS database (Ias.mdb). The primary use of commands in the Netsh AAAA context is to:

- Export the configuration of one IAS server, including registry keys and the IAS database (ias.mdb), as a Netsh script using either the **dump** command or one of the **show** commands.
- Import the configuration to another IAS server using the **netsh exec** command, and a Netsh script that contains the **set config** command.

You can run these commands from the Windows Server 2003 family command prompt or from the command prompt for the Netsh AAAA context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh aaaa** before typing commands and parameters as they appear in the syntax below. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

For more information on Netsh, see Netsh overview and Enter a netsh context.

**Netsh AAAA command reference**

- dump
- set config
- show clients
- show config
- show connection_request_policies
- show logging
- show remote_access_policies
- show server_settings
- show version

**dump**

Displays the configuration of the IAS database file (Ias.mdb) as a Netsh command script.

**Syntax**

**dump**

**Remarks**

- The **dump** command displays the Netsh command script that you can use to duplicate the configuration of the server running IAS or the Routing and Remote Access service on which the command is executed. The Netsh command script contains the configuration of the IAS server, including the registry keys and database file (Ias.mdb), in a compressed text format as a large data block. This large data block is used by the **set config** command within the script to import the configuration of a saved data block into an existing IAS database on the same or another computer using the **netsh exec** command. To save the Netsh command script to a file, type: **netsh aaaa show config >***Path\File.txt*
- The **dump** command is not supported on computers running Windows 2000 server.

**set config**

Configures the IAS server and IAS database (Ias.mdb) with the registry keys and database imported from the specified data block.

**Syntax**

**set config** [**type**={**server_settings** | **clients** | **connection_request_policies** | **logging** | **remote_access_policies**] **blob=***DataBlock*}

**Parameters**

**blob= *DataBlock***

Required. Specifies the file that contains the configuration of the IAS server, including registry keys and IAS database (Ias.mdb), in a compressed text format as output by the **dump** or **show** commands.

**type=**
Specifies the kind of data that you want to import from the *DataBlock* to the local server configuration.

**server_settings**
Specifies that the server configuration settings are imported from the *DataBlock* to the local server. The imported settings include server Description, system event log settings, registry keys, and ports that are used specifically for the IAS service.

**clients**
Specifies that the settings for **RADIUS clients**, as viewed in the IAS console, are imported to the local server from *DataBlock*.

**connection_request_policies**
Specifies that the IAS settings for **Connection Request Processing**, including **Connection Request Policies** and **Remote RADIUS server Groups**, are imported to the local server from *DataBlock*.

**logging**
Specifies that the IAS settings for **Remote Access Logging** are imported to the local server from *DataBlock*.

**remote_access_policies**
Specifies that the IAS settings for **Remote Access Policies** are imported to the local server from *DataBlock*.

**Remarks**

- Running the **set config** command manually is not supported. This command is used only within a Netsh command script that is created by using the **dump** or **show** commands.
- To view the version of the IAS database on which the Netsh script is being run, use the **show version** command. Scripts older than those created with Windows Server 2003, Standard Edition; Windows Server 2003, Enterprise Edition; and Windows Server 2003, Datacenter Edition are supported.
- The configuration of IAS servers running on products in the Windows 2000 server family can be imported into products in the Windows Server 2003 family with **set config**. The reverse, however, is not possible.

**show clients**
Displays the RADIUS client list for the local IAS server.

**Syntax**
**show clients**

**Remarks**

- This command dumps the RADIUS client list of the IAS server on which the command is executed. In the IAS console, this client list is displayed in **RADIUS Clients**.
- The Netsh command script contains the local server settings, including registry keys and the IAS database (Ias.mdb), as a large data block in a compressed text format. To import the configuration into an existing IAS server on either the same or another computer, you can use the **netsh exec** command. To save the Netsh command script to a file, type **netsh aaaa show clients >***Path\File.txt* at a command prompt.
- This command is not available on computers running Windows 2000 Server.

**show config**
Displays the configuration of the IAS database file (Ias.mdb) as a Netsh command script.

**Syntax**
**show config**

**Remarks**

- The **show config** command is equivalent to the **dump** command.
- The **show config** command displays the Netsh command script that you can use to duplicate the configuration of the server running IAS or the Routing and Remote Access service on which the command is run. The Netsh command script contains the configuration of the IAS server, including registry keys and the IAS database (Ias.mdb), as a large data block in a compressed text format. To import the configuration into an existing IAS server on either the same or another computer, you can use the **netsh exec** command. To save the Netsh command script to a file, type **netsh aaaa show config >***Path\File.txt* at a command prompt.
- This command is not available on computers running Windows 2000 Server.

**show connection_request_policies**
Displays the Connection Request Processing policies configuration of the IAS server in script format.

**Syntax**
**show connection_request_policies**

**Remarks**

- This command displays Connection Request Policies for the IAS server on which the command is run. In the IAS console, these policies are displayed in **Connection Request Processing** and include **Connection Request Policies** and **Remote RADIUS server Groups**.

- The Netsh command script contains the local server settings as a large data block in a compressed text format. To import the configuration into an existing IAS server on either the same or another computer, you can use the **netsh exec** command. To save the Netsh command script to a file, type **netsh aaaa show connection_request_policies >***Path**File.txt* at a command prompt.

- This command is not available on computers running Windows 2000 Server.

**show logging**
Displays the logging configuration for the local IAS server.

**Syntax**
**show logging**

**Remarks**

- This command displays the Remote Access Logging configuration for the IAS server on which the command is run. In the IAS console, this information is displayed in **Remote Access Logging**.

- The Netsh command script contains the local server settings as a large data block in a compressed text format. To import the configuration into an existing IAS server on either the same or another computer, you can use the **netsh exec** command. To save the Netsh command script to a file, type **netsh aaaa show logging >***Path**File.txt* at a command prompt.

- This command is not available on computers running Windows 2000 Server.

**show remote_access_policies**
Displays all objects within the remote access policy.

**Syntax**
**show remote_access_policies**

**Remarks**

- This command displays the Remote Access Policies for the IAS server on which the command is run. In the IAS console, this information is displayed in **Remote Access Policies**.

- The Netsh command script contains the local server settings as a large data block in a compressed text format. To import the configuration into an existing IAS server on either the same or another computer, you can use the **netsh exec** command. To save the Netsh command script to a file, type **netsh aaaa show remote_access_policies >***Path**File.txt* at a command prompt.

- This command is not available on computers running Windows 2000 Server.

- The following registry keys and values are displayed:

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RasMan\PPP\ControlProtocols\BuiltIn\DefaultDomain\REG_SZ**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Policy\Allow LM Authentication\REG_DWORD**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Policy\Default User Identity\REG_SZ**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Policy\User Identity Attribute\REG_DWORD**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Policy\Override User-Name\REG_DWORD**

**show server_settings**
Displays the configuration of the local IAS server as a Netsh command script.

**Syntax**
**show server_settings**

**Remarks**

- This command displays the configuration of server settings for the IAS server on which the command is run. These settings include:

  - Server description

  - Settings for accounting and authorization events in the system event log

  - Ports used by the service

- Registry keys and their values

In the IAS console, this information is displayed in server **Properties**.

- The Netsh command script contains the local server settings as a large data block in a compressed text format. This large data block is used within the script by the **netsh exec** command to import the configuration of a saved data block into an existing IAS server on the same or another computer. To save the Netsh command script to a file, type **netsh aaaa show server_settings >***Path\File.txt* at a command prompt.

- This command is not available on computers running Windows 2000 Server.

- The following registry keys and values are displayed:

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\IAS\Parameters\Allow SNMP Set\REG_DWORD**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout\MaxDenials\REG_DWORD**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\RemoteAccess\Parameters\AccountLockout\ResetTime\REG_DWORD**

  **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\IAS\Parameters\Ping User-Name\REG_SZ**

**show version**
Displays the version of the IAS database.

**Syntax**
**show version**

**Examples**
To display the Netsh command script that shows the IAS database in its current state, type:

**show config**

To display the version of the IAS database running on a server, type:

**show version**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh commands for DHCP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for DHCP**
The Netsh commands for DHCP offer a command-line tool that helps with the administration of DHCP servers and provides an equivalent alternative to console-based management. This can be useful in the following situations:

- When managing DHCP servers in wide area networks (WANs), commands can be used in interactive mode at the Netsh command prompt to better manage across slow-speed network links.
- When managing a large number of DHCP servers, commands can be used in batch mode at the Netsh command prompt to help script and automate recurring administrative tasks that need to be performed for all DHCP servers.

You can run these commands from the Windows Server 2003 family command prompt or from the command prompt for the Netsh DHCP context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh dhcp** before typing commands and parameters as they appear in the syntax below. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

For more information about how to use the Netsh commands that are provided for DHCP, see Use DHCP Command-line Tools.

For an example of how to use Netsh commands for DHCP in batch files and scripts, see Netsh DHCP example.

For more information about Netsh commands, see The Netsh Command-Line Utility.

For more information about **netsh**, see Netsh overview and Enter a netsh context.

- Netsh DHCP
- Netsh DHCP server
- Netsh DHCP server scope
- Netsh DHCP server mscope

**Netsh DHCP**
The following commands are available at the **dhcp>** prompt, which is rooted within the **netsh** environment.

To view the command syntax, click a command:

- add server
- delete server
- server
- show server

**add server**
Adds a DHCP server to the list of authorized servers in Active Directory.

**Syntax**
**add server** *ServerDNS ServerIP*

**Parameters**
***ServerDNS***
Required. Specifies the DHCP server to add. Identifies the server by DNS domain name.

***ServerIP***
Required. Specifies the DHCP server to add. Identifies the server by IP address.

**Examples**
In the following example, this command adds a server with the DNS name dhcpsrv1.example.microsoft.com and IP address 10.2.2.2 to the list of authorized servers in Active Directory.

**add server dhcpsrv1.example.microsoft.com 10.2.2.2**

**delete server**
Deletes a DHCP server from the list of authorized servers in Active Directory.

**Syntax**
**delete server** *ServerDNS ServerIP*

**Parameters**
***ServerDNS***
Required. Specifies the DHCP server to delete. Identifies the server by DNS domain name.

***ServerIP***
Required. Specifies the DHCP server to delete. Identifies the server by IP address.

**Examples**
In the following example, this command deletes the server with the DNS name dhcpsrv1.example.microsoft.com and IP address 10.2.2.2 from the list of authorized servers in Active Directory.

**delete server dhcpsrv1.example.microsoft.com 10.2.2.2**

**server**
Shifts the current Netsh DHCP command-line context to a different DHCP server. Used without parameters, **server** shifts the current command-line context to the local computer.

**Syntax**
**server** [{*****ServerNetBIOSName* | *****ServerFQDN* | *ServerIP*}]

**Parameters**
**{ *ServerNetBIOSName*| *ServerFQDN*| *ServerIP*}**
Specifies the DHCP server to which you want to shift the current command-line context. Identifies the server by NetBIOS name, fully qualified domain name (FQDN), or IP address.

**Examples**
In the first example, this command changes the Netsh DHCP command-line context to the DHCP server with the NetBIOS name \\DHCP-SRV1.

In the second example, this command changes the Netsh DHCP command-line context to the DHCP server with IP address 10.0.0.1.

In the third example, this command changes the Netsh DHCP command-line context to the DHCP server with the FQDN \\example.microsoft.com.

**server \\DHCP-SRV1**

**server 10.0.0.1**

**server \\example.microsoft.com**

**show server**
Displays a list of authorized servers in Active Directory.

**Syntax**
**show server**

**Parameters**
none

**Netsh DHCP server**
The following commands are available at the **dhcp server>** prompt, which is rooted within the **netsh** environment.

To view the command syntax, click a command:

- add class
- add mscope
- add optiondef
- add scope
- delete class
- delete dnscredentials
- delete mscope
- delete optiondef
- delete optionvalue
- delete scope
- delete superscope
- dump
- export
- import
- initiate auth
- mscope
- scope
- set auditlog
- set databasebackupinterval
- set databasebackuppath
- set databasecleanupinterval
- set databaseloggingflag
- set databasename
- set databasepath
- set databaserestoreflag
- set detectconflictretry
- set dnsconfig
- set dnscredentials

- set optionvalue
- set server
- set userclass
- set vendorclass
- show all
- show auditlog
- show bindings
- show class
- show detectconflictretry
- show dnsconfig
- show dnscredentials
- show mibinfo
- show mscope
- show optiondef
- show optionvalue
- show scope
- show server
- show dbproperties
- show serverstatus
- show userclass
- show vendorclass
- show version

**add class**
Adds a class to the specified DHCP server.

**Syntax**
add class *ClassName* [*ClassComment*] [*Data*] [[**IsVendor=**]{**0** | **1**}] [[**IsBinary=**]{**B** | **b**}]

**Parameters**
***ClassName***
Required. Specifies the name of the class to create.

***ClassComment***
Specifies the comment to associate with the class.

***Data***
Specifies class data in ASCII or binary format depending on the **IsBinary** parameter. If unspecified, it is assumed that the format of the data is ASCII.

**[ IsVendor=]{0 | 1}**
Indicates whether the class to add is a user class or a vendor class: **0**-User class (default), **1**-Vendor class.

**[ IsBinary=]{B | b}**
Indicates if the class data is in binary format. If unspecified, it is assumed that the format of the data is ASCII.

**Examples**
In the first example, this command creates a vendor class named MyClass, with the comment TestClass, and the class data TestDataForMyClass in ASCII format.

In the second example, this command creates a user class named MyUserClass with binary data of 4345335532 (ASCII-CE3U2).

The third example is an alternate command syntax for the second example.

**add class MyClass TestClass TestDataForMyClass 1**

**add class MyUserClass TestClass1 4345335532 B**

**add class MyUserClass TestClass1 4345335532 0 b**

**add mscope**
Adds a multicast scope to the specified DHCP server.

**Syntax**
**add mscope** *MscopeName* [*MscopeComment*] [*TTL*]

**Parameters**
***MscopeName***
Required. Specifies the name of the multicast scope to add.

***MscopeComment***
Specifies a description of the current multicast scope.

***TTL***
Specifies the Time-To-Live value for the multicast scope. The valid range for this field is 1 to 255, with a default of 32.

**Examples**
In the following example, this command creates a multicast scope with the name My MultiCast Scope, a comment of MyTestMulticastScope, and a multicast TTL value of 40.

**add mscope "My MultiCast Scope" MyTestMulticastScope 40**

**add optiondef**
Adds a new option type definition to the specified DHCP server.

**Syntax**
**add optiondef** *OptCode OptName*{**BYTE** | **WORD** | **DWORD** | **STRING** | **IPADDRESS**} [[**IsArray=**]{**0** | **1**}] [**vendor=***VendorClass*] [**comment=***OptComment*] [*DefValue*]

**Parameters**
***OptCode***
Required. Specifies the option type to define. Identifies the option type with a unique option code. For the value of the code, choose a number between 0 and 255.

***OptName***
Required. Specifies the name of the option type.

**{BYTE | WORD | DWORD | STRING| IPADDRESS}**
Required. Indicates the data type of the option.

**[IsArray=]{0 | 1}**
Indicates whether the data type is arrayed or non-arrayed: **0**-Unary or non-arrayed (default), **1**-Arrayed.

**vendor= *VendorClass***

Specifies the vendor class for the option. If unspecified, the default vendor class, the DHCP standard options class, is used.

**comment=** ***OptComment***
Specifies a comment to add to the new option type definition. If unspecified, the default value is NULL.

***DefValue***
Specifies a default value to use for this option type, if one is not specified otherwise.

**Remarks**

- **IsArray** must be **0** for STRING type options.

**Examples**
In the first example, this command defines a new option type named ExtensionsPath with code 18, a STRING data type, and joins it to the DHCP standard options class, assigning it a default value of c:\Temp.

In the second and third examples, this command defines a new option type named TestOption with code 231 and an IPADDRESS data type. In the second example, the option is defined to provide only a single IP address. IsArray and *DefValue* are not necessary because defaults are assumed. In the third example, *DefValue*, and IsArray are required to create an array containing the IP address values 10.1.1.1, 10.1.1.2, and 10.1.1.3.

**add optiondef 18 ExtensionsPath STRING 0 c:\Temp**

**add optiondef 231 TestOption IPADDRESS**

**add optiondef 231 TestOption IPADDRESS 1 vendor=MyVendorClass 10.1.1.1 10.1.1.2 10.1.1.3**

**add scope**
Adds a scope to the specified DHCP server.

**Syntax**
**add scope** *ScopeAddress SubnetMask ScopeName*[*ScopeComment*]

**Parameters**
***ScopeAddress***
Required. Specifies the scope to add. Identifies the scope by IP network number.

***SubnetMask***
Required. Specifies the subnet mask for the scope to add.

***ScopeName***
Required. Specifies an identifying name for the scope.

***ScopeComment***
Specifies a comment for the scope.

**Examples**
In the following example, this command adds a scope for the DHCP server with scope address 10.2.2.0, subnet mask 255.255.255.0, a scope name of MyScope, and a scope comment of MyComment.

**add scope 10.2.2.0 255.255.255.0 MyScope MyComment**

**delete class**
Deletes a class from the specified DHCP server.

**Syntax**
delete class *Name*

**Parameters**
***Name***
Required. Specifies the user or vendor class to delete.

**Examples**
In the following example, this command deletes the class named MyClass.

**delete class MyClass**

**delete dnscredentials**

Deletes the credentials used for all DNS dynamic updates.

**Syntax**

**delete dnscredentials dhcpforceflag**

**Parameters**

none

**delete mscope**

Deletes a multicast scope from the specified DHCP server.

**Syntax**

**delete mscope** *MscopeName*

**Parameters**

***MscopeName***

Required. Specifies the multicast scope to delete. *MscopeName* is case-sensitive.

**Examples**

In the following example, this command deletes the multicast scope MyMulticastScope from the currently specified DHCP server.

**delete mscope MyMulticastScope**

**delete optiondef**

Deletes a defined option type from the specified DHCP server.

**Syntax**

**delete optiondef** *OptCode* [[**vendor=**]*VendorName*]

**Parameters**

***OptCode***

Required. Specifies the unique identifier for the option type to delete.

**vendor= *VendorName***

Specifies the vendor class name with which the option type is associated. If unspecified, the option type definition is deleted from the non-vendor specific DHCP standard options class.

**Examples**

In the following example, this command deletes an option type with code 18 from the DHCP standard options class.

**delete optiondef 18**

**delete optionvalue**

Deletes the current value of the specified option type for the specified DHCP server.

**Syntax**

**delete optionvalue** *OptCode*[[**vendor=**]*VendorClass*] [[**user=**]*UserClass*]

**Parameters**

***OptCode***

Required. Specifies the unique identifier of the global server option with a value to delete.

**vendor= *VendorClass***

Specifies the vendor class name with which the option is associated. If the tag is not included, the global *VendorName* that was set by **set vendorclass** is assumed. If the tag is used, but no value is specified, then no vendor class is used. This parameter is available only for computers running Windows 2000 Server.

**user= *UserClass***

Specifies the user class name with which the option is associated. If the tag is not included, the global *UserName* that was set by **set userclass** is assumed. If the tag is used, but no value is specified, then no user class is used. This parameter is available only for computers running Windows 2000 Server.

**Examples**

In the following example, this command deletes the current value of the option type with code 18.

**delete optionvalue 18**

**delete scope**

Deletes a scope from the specified DHCP server.

**Syntax**
**delete scope** *ScopeAddress* {**DHCPNOFORCE** | **DHCPFULLFORCE**}

**Parameters**
***ScopeAddress***
Required. Specifies the address of the scope to delete.

**{DHCPNOFORCE | DHCPFULLFORCE}**
Required. Indicates the force with which the scope will be deleted: **DHCPNOFORCE**-Deletes the scope if there are no active clients in the scope, **DHCPFULLFORCE**-Deletes the scope even if there are active clients in the scope.

**Examples**
In the following example, this command forces the deletion of the scope 10.2.2.0 from the DHCP server and ignores all warnings.

**delete scope 10.2.2.0 dhcpfullforce**

**delete superscope**
Deletes a superscope from the specified DHCP server.

**Syntax**
**delete superscope** *SuperscopeName*

**Parameters**
***SuperscopeName***
Required. Specifies the name of the superscope to delete.

**Remarks**

- You can set the superscope from the scope context with the **set superscope** command.
- The superscope name is case-sensitive.

**Examples**
In the following example, this command deletes the superscope named My Superscope from the specified DHCP server.

**delete superscope "My Superscope"**

**dump**
Dumps the configuration of the local DHCP server to the command prompt window when run within the netsh environment.

**Syntax**
**dump**

When run at the command prompt or in a batch file, output can be saved in a text file. Used without parameters, this command dumps the configuration of the local server to the command prompt window.

**Syntax**
**netsh dhcp server [ *IPAddress* ] dump >**[*PathAndFileName*]

**Parameters**
***IPAddress***
Specifies the IP address of the DHCP server for which the configuration is output.

***PathAndFileName***
Specifies both the location where the file is saved, and the name of the destination file to which to dump DHCP server configuration. If unspecified, the DHCP server configuration is dumped to the command prompt window.

**Remarks**

- This command dumps the DHCP configuration as text output within the command prompt window. You can copy or redirect this output to a file to view it in a text editor. After file output is obtained, you can use the **exec** command to configure another DHCP server with the same configuration.
- Before performing the **dump** command at the source server, reconcile all scopes and fix any reported inconsistencies.

- The following command dumps the current configuration for the local DHCP server (the source) to a text file named Dhcpcfg.dmp. This file can be copied to another (destination) DHCP server and used to recreate the source configuration on it. You can recreate the configuration with the following command:

  **dump > dhcpcfg.dmp**

- Before you use the **exec** command to execute a dump file at the destination server, complete the following steps:

  1. Close the DHCP console at the destination server. Do not reopen the console until after you have run the **exec** command.

  2. Delete all default option definitions and any user and vendor classes at the destination server.

- These examples demonstrate how to use the **delete optiondef** and **del class** Netsh commands to delete all default option definitions and any user and vendor classes. You can run these commands at the **dhcp server>** prompt, from within the **netsh** environment.

  - **delete optiondef 76**

  - **del class "Default BOOTP Class"**

  - **del class "Microsoft Windows 98 Options"**

- On the destination server, the **exec** command is used to load and execute the saved configuration:

  **netsh exec dhcpcfg.dmp**

- After you use the **exec** command to load the dump file, you must reconcile all scopes. Use **net stop dhcpserver** to stop the DHCP Server service and **net start dhcpserver** to restart it. Once the service is restarted, DHCP database changes take effect.

**Examples**

The first command, which is run within the netsh environment, dumps the configuration of the local DHCP server to the command prompt window.

The second command, which is run at the command prompt, dumps the configuration of a DHCP server with IP address 192.168.0.1 to a text file named Dhcpcfg.dmp at the location C:\Dhcp\ on the local computer.

The third command, which is run at the command prompt, dumps the configuration of a DHCP server with IP address 192.168.0.1 to a text file named Dhcpcfg.dmp on a shared network folder named \\Backup\Dhcp\.

**dump**

**netsh dhcp server 192.168.0.1 dump > C:\Dhcp\Dhcpcfg.dmp**

**netsh dhcp server 192.168.0.1 dump > \\Backup\Dhcp\Dhcpcfg.dmp**

**export**

Exports the DHCP service configuration to a file.

**Syntax**

**export** [*Path*]*FileName* {**all** | *ScopeList*}

**Parameters**

**[*Path*] *FileName***

Required. Specifies, by name, the file where the DHCP configuration will be stored. If the path, the file name, or both contain spaces, quotation marks must be used.

**{all | *ScopeList*}**

Required. Specifies which scopes you want to export. The parameter **all** exports all scopes. The parameter *ScopeList* exports the scopes that correspond to the IP addresses you list. Each IP address in the list must be separated by spaces.

**Remarks**

- This command works only on the local server.
- While the **export** command runs, the DHCP service is stopped and does not respond to DHCP clients seeking new leases or lease renewals.
- If the DHCP service has a large number of scopes or a large number of client address leases, this command can take a long time to run.

**Examples**
In the first example, this command exports the complete DHCP service configuration to the file c:\Temp\Dhcpdb.

In the second example, this command exports the DHCP configuration for scopes 10.0.0.0 and 192.168.0.0 to the file c:\Temp\Dhcpdb.

In the third example, this command exports the complete DHCP service configuration to the file c:\My Folder\Dhcp Configuration. Note that both the path and file name contain spaces, so quotation marks are used.

**export c:\Temp\Dhcpdb all**

**export c:\Temp\Dhcpdb 10.0.0.0 192.168.0.0**

**export "c:\My Folder\Dhcp Configuration" all**

**import**
Imports a DHCP service configuration from a file to the local service.

**Syntax**
**import** [*Path*]*FileName* {**all** | *ScopeList*]

**Parameters**
**[*Path*] *FileName***
Required. Specifies, by name, the file from which the DHCP configuration will be imported. If the path, the file name, or both contain spaces, quotation marks must be used.

**{all | *ScopeList*}**
Required. Specifies which scopes you want to import. The parameter **all** imports all scopes represented in the file you specify. The parameter *ScopeList* imports the scopes that correspond to the IP addresses you list. Each IP address in the list must be separated by spaces.

**Remarks**

- This command works only on the local server.
- While the **import** command runs, the DHCP service is stopped and does not respond to DHCP clients seeking new leases or lease renewals.
- If the DHCP service has a large number of scopes or a large number of client address leases, this command can take a long time to run.

**Examples**
In the first example, this command imports the complete DHCP service configuration from the file c:\Temp\Dhcpdb.

In the second example, this command imports the DHCP configuration for scopes 10.0.0.0 and 192.168.0.0 from the file c:\Temp\Dhcpdb

In the third example, this command imports the complete DHCP service configuration from the file c:\My Folder\Dhcp Configuration. Note that both the path and file name contain spaces, so quotation marks are used.

**import c:\Temp\Dhcpdb all**

**import c:\Temp\Dhcpdb 10.0.0.0 192.168.0.0**

**import "c:\My Folder\Dhcp Configuration" all**

**initiate auth**
Initiates authorization of the specified DHCP server in Active Directory.

**Syntax**
**initiate auth**

**Parameters**
none

**mscope**
Switches the command context to a DHCP multicast scope.

**Syntax**
**mscope** *MscopeName*

**Parameters**
***MscopeName***
Required. Specifies the name of the multicast scope to which to switch the command context.

**Remarks**

- This command enables you to use any of the available DHCP multicast scope-level commands on the specified DHCP multicast scope. Subsequent operations will be performed on this multicast scope at the specified server.
- The name of the multicast scope is case-sensitive.

**Examples**
In the following example, this command switches the command context to a multicast scope named My Multicast Scope.

**mscope "My Multicast Scope"**

**scope**
Switches the command context to a DHCP scope.

**Syntax**
**scope** *ScopeIPAddress*

**Parameters**
***ScopeIPAddress***
Required. Specifies the scope to which to switch the command context. Identifies the scope by network or subnet IP address.

**Remarks**

- This command enables you to use any of the available DHCP scope-level commands on the specified DHCP scope. Subsequent operations will be performed on this scope at the specified server.

**Examples**
In the following example, this command switches the command context to the scope with IP address 10.0.0.0.

**scope 10.0.0.0**

**set auditlog**
Sets the audit log path parameters for the specified DHCP server.

**Syntax**
**set auditlog** *NewAuditPath*

**Parameters**
***NewAuditPath***
Required. Specifies a local folder for the DHCP server to use when storing audit log files. A valid folder path is required, and the folder must be local to the DHCP server where the path is defined.

**Remarks**

- In order for this change to take effect, you need to stop and restart the DHCP service after you run this command.

**Examples**
In the following example, this command sets the DHCP server to store audit log files in the directory c:\logpath.

**set auditlog c:\logpath**

**set databasebackupinterval**
Sets the backup interval for the specified DHCP server.

**Syntax**
**set databasebackupinterval** *NewInterval*

**Parameters**
***NewInterval***
Required. Specifies the backup interval in minutes.

**Examples**
In the following example, this command sets the database backup interval for the specified DHCP server to 1,440 minutes (24 hours).

**set databasebackupinterval 1440**

**set databasebackuppath**
Sets the database backup path for the specified DHCP server.

**Syntax**
**set databasebackuppath** *NewBackupPath*

**Parameters**
***NewBackupPath***
Required. Specifies a local folder for the DHCP server to use when storing audit log files. A valid folder path is required, and the folder must be local to the DHCP server where the path is defined.

**Examples**
In the following example, this command sets the database backup path to c:\windows\dhcp\backup.

**set databasebackuppath c:\windows\dhcp\backup**

**set databasecleanupinterval**
Sets the database cleanup interval of the specified DHCP server.

**Syntax**
**set databasecleanupinterval** *NewInterval*

**Parameters**
***NewInterval***
Required. Specifies the database cleanup interval, in minutes.

**Examples**
In the following example, this command sets the database cleanup interval to 10,080 minutes (every seven days).

**set databasecleanupinterval 10080**

**set databaseloggingflag**
Sets or resets the database logging flag for the specified DHCP server. Used without parameters, this command resets the database logging flag.

**Syntax**
**set databaseloggingflag** [{**0** | **1**}]

**Parameters**
**{0 | 1}**
Indicates the database logging flag setting: **0**-Resets the flag (default), **1**-Sets the flag.

**Examples**
In the following example, this command resets the database logging flag for the currently specified DHCP server.

**set databaseloggingflag 0**

**set databasename**
Sets the name of the DHCP server database file for the specified DHCP server.

**Syntax**
**set databasename** *NewFileName*

**Parameters**
***NewFileName***
Required. Specifies a new name for the DHCP server database file.

**Remarks**

- In order for this change to take effect, you need to stop and restart the DHCP Server service.

**Examples**
In the following example, this command sets the DHCP server database file name to newdatabase.mdb.

**set databasename newdatabase.mdb**

**set databasepath**
Sets the path of the DHCP server database file for the specified DHCP server.

**Syntax**
**set databasepath** *NewPath*

**Parameters**
***NewPath***
Required. Specifies the path of the DHCP database file.

**Remarks**

- In order for this change to take effect, you need to stop and restart the DHCP Server service.

**Examples**
In the following example, this command sets the path of the DHCP server database file to c:\windows\dhcp.

**set databasepath c:\windows\dhcp**

**set databaserestoreflag**
Sets or resets the database restore flag for the specified DHCP server. Used without parameters, this command resets the database restore flag.

**Syntax**
**set databaserestoreflag** [{**0** | **1**}]

**Parameters**
**{0 | 1}**
Indicates the setting of the database restore flag: **0**-Resets the flag (default), **1**-Sets the flag.

**Examples**
In the following example, this command sets the database restore flag for the currently specified DHCP server.

**set databaserestoreflag 1**

**set detectconflictretry**
Sets the number of conflict detection attempts for the specified DHCP server.

**Syntax**
**set detectconflictretry** *RetryNumber*

**Parameters**
***RetryNumber***
Required. Specifies the number of conflict detection attempts that the DHCP server will make before it leases a scope IP address to a client.

**Remarks**

- The maximum value for *RetryNumber* is five. All values greater than five will default down to five.

**Examples**
In the following example, this command sets the DHCP server to make four attempts to detect if a there is a conflict for a scope IP address before the DHCP server uses this scope IP address in a new address lease.

**set detectconflictretry 4**

**set dnsconfig**
Sets the DNS dynamic update configuration for the specified DHCP server.

**Syntax**
**set dnsconfig** [**Enable=**]{**0** | **1**} [[**Update=**]{**0** | **1**}] [[**Lookup=**]{**0** | **1**}] [[**NonDyn=**]{**0** | **1**}]

**Parameters**
**[Enable=]{0 | 1}**
Required. Indicates whether to enable or disable the dynamic updates of DNS client information: **0**-Disables dynamic updates of DNS client information, **1**-Enables dynamic updates of DNS client information.

**[Update=]{0 | 1}**
Indicates the type of update lookups: **0**-Updates according to client request, **1**-Updates forward and reverse name lookups.

**[Lookup=]{0 | 1}**
Indicates whether to enable or disable forward lookups for clients when leases expire: **0**-Disables forward lookups, **1**-Enables forward lookups.

**[NonDyn=]{0 | 1}**
Indicates whether to update DNS information for clients that do not support dynamic updates: **0**-Disables updates for clients that do not support dynamic updates, **1**-Enables these updates.

**Remarks**

- This command is only supported for DHCP servers running Windows 2000 Server and members of the Windows Server™ 2003 family.
- The configured Preferred DNS server, in the TCP/IP properties of the DHCP server, will be updated with DHCP client records when dynamic updates are enabled. If the Preferred DNS server is not available on the network, the Alternate DNS server will be updated.

**Examples**
In the following example, this command enables the dynamic update of DNS information by the DHCP server and configures updates to always be made for both forward and reverse lookups. This example also disables the option to perform forward lookups when leases expire and enables updates for non-dynamic clients.

**set dnsconfig 1 1 0 1**

**set dnscredentials**
Sets DNS dynamic update credentials for the specified DHCP server.

**Syntax**
**set dnscredentials** *UserName Domain Password*

**Parameters**
***UserName***
Required. The user name associated with a valid domain account.

***Domain***
Required. The domain in which the user account is located.

***Password***
Required. The password for the user account.

**Examples**
In the first example, this command sets the DNS dynamic update credentials to the values specified.

In the second example, this command sets the value of *UserName* to User1 and the value of *Domain* to Domain1, but the password is not specified. Instead an asterisk (*) is used. When an asterisk (*) is used in place of a valid password, the user is

prompted for a password. Without the correct password for the specified *UserName*, the credentials cannot be changed.

**set dnscredentials User1 Domain1 Password1**

**set dnscredentials User1 Domain1 ***

#### set optionvalue

Sets a DHCP server option value that will be applied for all scopes defined at the specified DHCP server.

**Syntax**

**set optionvalue** *OptCode* {**BYTE** | **WORD** | **DWORD** | **STRING** | **IPADDRESS**} [[**user=**]*UserName*] [[**vendor=**]*VendorName*] [*OptionValue*]

**Parameters**

***OptCode***
Required. Specifies the unique identifier for the option type with the value to set.

**{BYTE | WORD | DWORD | STRING | IPADDRESS}**
Required. Specifies the data type for the option type with the value to set.

**[user=]*UserName***
Sets the applicable user class name to which this command will apply. If unspecified, the default user class is assumed.

**[vendor=]*VendorName***
Sets the applicable vendor class name to which this command will apply. If unspecified, the DHCP standard options class is assumed.

**[*OptionValue*]**
Specifies the new server default value for the option type identified by *OptCode*. The value must be of the associated data type.

**Remarks**

- Vendor and user classes are supported only for DHCP servers running Windows 2000 Server.
- To modify the current defaults for an unspecified class, use either **set userclass** or **set vendorclass** commands.

**Examples**

In the first example, this command sets the value of option code 003 to list two router IP addresses, 10.1.1.1 and 10.1.1.2.

In the second example, this command further qualifies the first example and sets the specified value to apply only for those scope clients that identify themselves as members of the vendor class Vendor1. In order for this example to work, this class must already be defined at the server, with the specified option type defined for its use.

**set optionvalue 003 IPADDRESS 10.1.1.1 10.1.1.2**

**set optionvalue 003 IPADDRESS vendor=Vendor1 10.1.1.1 10.1.1.2**

#### set server

Changes the Netsh command-line context to the specified server. Used without parameters, the local server is assumed.

**Syntax**

**set server**[{*ServerIP* | *****ServerDNS*}]

**Parameters**

**{*ServerIP* | *ServerDNS*}**
Specifies the IP address or the DNS name of the specified DHCP server.

**Remarks**

- When this command is used, and the Netsh command-line context is changed to another server, all subsequent command operations are performed on the specified server. To perform command operations on another server, this command must be executed again, with the IP address or DNS name of the new server provided as the parameter.

**Examples**

In the following example, this command switches the DHCP server command-line context to the server at IP address 10.1.1.1

**set server 10.1.1.1**

**set userclass**
Sets the name for the current user class. Used without parameters, the current user class is reset to the default user class

**Syntax**
**set userclass** [*UserClass*]

**Parameters**
***UserClass***
Specifies the name of the user class for the currently specified DHCP server.

**Remarks**

- This command is available only for use with DHCP servers running Windows 2000 Server.

**Examples**
In the first example, this command sets the user class name to MyUserClass.

In the second example, this command resets the current user class to the default user class.

**set userclass MyUserClass**

**set userclass**

**set vendorclass**
Sets the name for the current vendor class. Used without parameters, the current vendor class is reset to the default class, DHCP standard options.

**Syntax**
**set vendorclass** [*VendorClass*]

**Parameters**
***VendorClass***
Specifies the name of the vendor class for the current server.

**Remarks**

- This command is available only for use with DHCP servers running Windows 2000 Server.

**Examples**
In the first example, this command sets the vendor class name to MyVendorClass.

In the second example, this command resets the current vendor class to the default class, DHCP standard options.

**set vendorclass MyVendorClass**

**set vendorclass**

**show all**
Displays all status and configuration information for the specified DHCP server.

**Syntax**
**show all**

**Parameters**
**none**

**Remarks**

- This command lists all current server status and configuration details, including the stored management information base (MIB) information, for the currently specified DHCP server.

**show auditlog**
Displays all audit log information for the specified DHCP server.

**Syntax**
**show auditlog**

**Parameters**
**none**

**show bindings**
Displays bindings information for the specified DHCP server.

**Syntax**
**show bindings**

**Parameters**
none

**Remarks**

- This command displays bindings information for the current DHCP server, indicating which active network connections that are configured with static IP addresses are enabled or disabled for use in servicing DHCP clients on your network.
- The DHCP service automatically disables network connections that obtain their IP address configuration dynamically from service bindings. This happens by default.

**show class**
Enumerates and displays all class information for the specified DHCP server. This includes both user and vendor class information.

**Syntax**
**show class**

**Parameters**
**none**

**show detectconflictretry**
Displays the configured number of conflict detection attempts for the specified DHCP server.

**Syntax**
**show detectconflictretry**

**Parameters**
**none**

**Remarks**

- This command displays the current number of ping retries that are used to attempt the detection of address conflicts for the scope IP addresses that are distributed by the server.

**show dnsconfig**
Displays the DNS dynamic update configuration for the specified DHCP server.

**Syntax**
**show dnsconfig**

**Parameters**
**none**

**Remarks**

- If DNS configuration has not been enabled or set, you can use the DNS console or the **set dnsconfig** command to configure these settings.

**show dnscredentials**
Displays the current DNS dynamic update credentials.

**Syntax**
**show dnscredentials**

**Parameters**
**none**

**show mibinfo**
Displays management information base (MIB) information for the specified DHCP server.

**Syntax**
**show mibinfo**

**Parameters**
none

**show mscope**
Displays all information about multicast scopes for the specified DHCP server.

**Syntax**
**show mscope**

**Parameters**
**none**

**show optiondef**
Displays all defined and available options types for use at the specified DHCP server. Used without parameters, all options are displayed.

**Syntax**
**show optiondef** [**vendor=***VendorName*]

**Parameters**
**vendor= *VendorName***
Indicates which defined and available option types to display. If unspecified, the default for *VendorName* is the default vendor class that is currently set for the DHCP server.

**Remarks**

- The default vendor class can be reset with the **set vendorclass** command.
- *VendorName* is applicable only for DHCP servers running Windows 2000 Server.

**Examples**
In the first example, this command displays all defined option types for the current vendor class.

In the second example, this command displays the defined option types that are available for use with the specified class Vendor1.

**show optiondef**

**show optiondef vendor=Vendor1**

**show optionvalue**
Displays all of the available option values that are currently set for the specified DHCP server. Used without parameters, all option values are displayed, including those that are used for both user and vendor classes.

**Syntax**
**show optionvalue**[{**user=***UserName* | **vendor=***VendorName*}]

**Parameters**
**user= *UserName***
Specifies the default values that are set for the option types that are available for use with the currently set user class.

**vendor=** ***VendorName***

Specifies the default values that are set for the option types that are available for use with the currently set vendor class.

**Remarks**

- **User=** *UserName* and **vendor=***VendorName* are only available for use with DHCP servers running Windows 2000 Server.

- If you provide values for *UserName* or *VendorName*, the respective tags (**user=** or **vendor=**) are required. If the tags are not included, the default that is assumed is the current user class, previously set with the **set userclass** command.

**Examples**

In the following example, this command displays all of the available option types that have values set at the currently specified DHCP server.

**show optionvalue**

**show scope**

Displays information about the scopes for the specified DHCP server.

**Syntax**

**show scope**

**Parameters**

**none**

**show server**

Displays information about the specified DHCP server, including the fully qualified domain name and IP address of the server.

**Syntax**

**show server**

**Parameters**

**none**

**show dbproperties**

Displays information about server database configuration for the specified DHCP server.

**Syntax**

**show dbproperties**

**Parameters**

**none**

**Remarks**

- This command displays the following database configuration information:

    - DatabaseName

    - DatabasePath

    - DatabaseBackupPath

    - DatabaseBackupInterval

    - DatabaseLoggingFlag

    - DatabaseRestoreFlag

    - DatabaseCleanupInterval

**show serverstatus**
Displays status information for the specified DHCP server.

**Syntax**
**show serverstatus**

**Parameters**
**none**

**Remarks**

- This is an example of the type of status information that this command displays:

```
Server Attrib - Server Servicing Clients :TRUE

Server Attrib - Dynamic BootP Support Enabled :TRUE

Server Attrib - DHCP Server Part Of DS :TRUE

Server Attrib - DHCP Server Bindings Aware :TRUE

Server Attrib - Administrative Rights :TRUE
```

**show userclass**
Displays the current user class setting at the specified DHCP server.

**Syntax**
**show userclass**

**Parameters**
**none**

**Remarks**

- This is an example of the type of setting information that this command displays:

```
Current Class Name set for the Server dhcpsrv1.example.microsoft.com is None.
```

**show vendorclass**
Displays the current vendor class setting at the specified DHCP server.

**Syntax**
**show vendorclass**

**Parameters**
**none**

**Remarks**

- This is an example of the type of setting information that this command displays:

```
Current Vendor Name set for the Server dhcpsrv1.example.microsoft.com is None.
```

**show version**
Displays current version information for the specified DHCP server.

**Syntax**
**show version**

**Parameters**

**none**

**Remarks**

- This is an example of the type of version information that this command displays:

```
The version of the DHCP Server 192.168.0.100 is 5.6.
```

**Netsh DHCP server scope**

The following commands are available at the **dhcp server scope>** prompt, which is rooted within the **netsh** environment.

To view the command syntax, click a command:

- add excluderange
- add iprange
- add reservedip
- delete excluderange
- delete iprange
- delete lease
- delete optionvalue
- delete reservedip
- delete reservedoptionvalue
- dump
- initiate reconcile
- set comment
- set name
- set optionvalue
- set reservedoptionvalue
- set scope
- set state
- set superscope
- show clients
- show clientsv5
- show excluderange

- show iprange
- show optionvalue
- show reservedip
- show reservedoptionvalue
- show scope
- show state

**add excluderange**
Adds a range of addresses to exclude from distribution in the current scope.

**Syntax**
**add excluderange** *StartIP EndIP*

**Parameters**
***StartIP***
Required. Specifies the IP address that starts the exclusion range.

***EndIP***
Required. Specifies the IP address that ends the exclusion range.

**Examples**
In the following example, this command excludes the IP addresses in the range 10.2.2.10 to 10.2.2.20 from distribution in the scope.

**add excluderange 10.2.2.10 10.2.2.20**

**add iprange**
Adds a range of IP addresses to the current scope.

**Syntax**
**add iprange** *StartIP EndIP* [{**DHCP** | **BOOTP** | **BOTH**}] [*MaxBootP*]

**Parameters**
***StartIP***
Required. Specifies the IP address that starts the range.

***EndIP***
Required. Specifies the IP address that ends the range.

**{DHCP | BOOTP | BOTH}**
Specifies the type of client to be serviced by this scope and IP range. **DHCP** is the default.

***MaxBootP***
Specifies the maximum number of BOOTP clients.

**Remarks**

- *MaxBootP* is useful only if *ClientType* is set to support BOOTP-type clients for the scope. If an optional command-line option is used, all command-line options (mandatory as well as optional) that come before the optional command that is used are required and must appear in proper sequence.

**Examples**
In the following example, this command adds DHCP clients that are in the IP address range 10.2.2.10 to 10.2.2.20 to the distribution range in the scope.

**add iprange 10.2.2.10 10.2.2.20**

**add reservedip**
Reserves an IP address for use by a specified media access control (MAC) address in the current scope.

**Syntax**

**add reservedip** *ReservedIP MACAddress* [*ClientName*] [*ClientComment*] [{**DHCP** | **BOOTP** | **BOTH**}]

**Parameters**

***ReservedIP***

Required. Specifies the IP address to reserve.

***MACAddress***

Required. Specifies the physical hardware or MAC address to associate with the reserved IP address.

***ClientName***

Specifies a client name to associate with this reserved client entry. If unspecified, a client name is not associated with this reserved client entry.

***ClientComment***

Specifies a client comment to associate with this reserved client entry. If unspecified, a client comment is not associated with this reserved client entry.

**{DHCP | BOOTP | BOTH}**

Specifies the type of clients to associate with this reserved client entry. **DHCP** is the default.

**Remarks**

- If an optional command-line option is used, all command-line options (mandatory as well as optional) that come before the optional command-line option that is used are required and must appear in proper sequence.

**Examples**

In the following example, this command reserves the IP address 10.2.2.32 for use by the DHCP client that identifies its MAC address as 08-00-2b-30-36-9b when it obtains a lease in the current scope.

**add reservedip 10.2.2.32 08002b30369B**

**delete excluderange**

Deletes a range of previously excluded IP addresses from the current scope.

**Syntax**

**delete excluderange** *StartIP EndIP*

**Parameters**

***StartIP***

Required. Specifies the IP address that starts the exclusion range.

***EndIP***

Required. Specifies the IP address that ends the exclusion range.

**Examples**

In the following example, this command deletes the exclusion range that starts with an IP address of 10.2.1.5 and ends with an IP address of 10.2.1.10 from the current scope.

**delete excluderange 10.2.1.5 10.2.1.10**

**delete iprange**

Deletes a range of IP addresses from the current scope.

**Syntax**

**delete iprange** *StartIP EndIP*

**Parameters**

***StartIP***

Required. Specifies the IP address that starts the range to delete.

***EndIP***

Required. Specifies the IP address that ends the range to delete.

**Examples**

In the following example, this command deletes IP addresses in the range 10.2.1.5 to 10.2.1.10 from the current scope.

**delete iprange 10.2.1.5 10.2.1.10**

**delete lease**
Deletes an IP address lease from the current scope.

**Syntax**
**delete lease** [{*LeaseIP* | *****HostName* | **AllBadAddresses** | **AllRasServerAddresses**}]

**Parameters**
***{LeaseIP* | *HostName* | AllBadAddresses | AllRasServerAddresses}**
Required. Specifies the IP address or the host name associated with the leased address. If **AllBadAddresses** is specified, all records marked as BAD_ADDRESS are removed. If **AllRasServerAddresses** is specified, all leases obtained by all Routing and Remote Access Service servers are removed.

**Examples**
In the first example, this command deletes the IP address lease 10.2.1.32 from the current scope.

In the second example, this command deletes all IP address leases marked as BAD_ADDRESS from the current scope.

**delete lease 10.2.1.32**

**delete lease AllBadAddresses**

**delete optionvalue**
Removes or clears the currently set scope option value from the current scope.

**Syntax**
**delete optionvalue** *OptCode*[**user=***UserName*] [**vendor=***VendorName*]

**Parameters**
***OptCode***
Required. Specifies the unique identifier of the option whose value is to delete.

**user= *UserName***
Specifies the user class from which to delete the currently set option value. If the tag is provided, but the value unspecified, the current default user class is assumed.

**vendor= *VendorName***
Specifies the vendor class from which to delete the currently set option value. If the tag is provided, but the value unspecified, the current default vendor class is assumed.

**Remarks**

- Vendor and user classes are only supported for DHCP servers running Windows 2000 Server.
- If you specify a user class, a vendor class, or both, this command deletes the set option value from only the scope clients that are identified as members of the specified class or classes.
- To modify the current defaults for an unspecified class that is used with this command, use either the **set userclass** or **set vendorclass** commands.

**Examples**
In the first example, this command deletes the currently set option value for option code 18 from the current scope.

In the second example, this command deletes the currently set option value for option code 18 from the vendor class MyVendorClass.

**delete optionvalue 18**

**delete optionvalue 18 vendor="MyVendorClass"**

**delete reservedip**
Deletes a reservation for an IP address in the current scope.

**Syntax**
**delete reservedip** *ReservedIP MACAddress*

**Parameters**
***ReservedIP***

Required. Specifies the IP address reservation to delete from the current scope.

***MACAddress***
Required. Specifies the media access control (MAC) or physical hardware address string for which the IP address was reserved.

**Examples**
In the following example, this command removes the IP address reservation 10.2.1.32 for the MAC address 08002B30369B from the current scope.

**delete reservedip 10.2.1.32 08002B30369B**

**delete reservedoptionvalue**
Deletes an option value that is currently assigned to a reserved client in the current scope.

**Syntax**
**delete reservedoptionvalue** *ReservedIP OptCode* [**User=***UserName*] [**vendor=***VendorName*]

**Parameters**
***ReservedIP***
Required. Specifies the IP address of the reserved client.

***OptCode***
Required. Specifies the unique code for the option type that is currently assigned to the reserved client.

**User= *UserName***
Specifies the user class from which to delete the option value. If the tag is provided, but no value is specified, the current default user class is assumed.

**vendor= *VendorName***
Specifies the vendor class from which to delete the option value. If the tag is provided, but no value is specified, the current vendor class is assumed.

**Remarks**

- Vendor and user classes are only supported for DHCP servers running Windows 2000 Server.
- To modify the current defaults for an unspecified class used with this command, use either **set userclass** or **set vendorclass**.

**Examples**
In the following example, this command deletes the currently set option value for the option identified by code 18 for reserved IP address of 10.2.2.32 in the current scope.

**delete reservedoptionvalue 10.2.2.32 18**

**dump**
Dumps the configuration of the current scope to the command prompt window when run within the netsh environment.

**Syntax**
**dump**

When run at the command prompt or in a batch file, output can be saved in a text file. Used without parameters, this command dumps the configuration of the current scope to the command prompt window.

**Syntax**
**netsh dhcp server { *ServerName* | *IPAddress* } scope *ScopeID* dump >**[*PathAndFileName*]

**Parameters**
***ServerName* | *IPAddress***
Specifies the server name or IP address of the DHCP server for which the scope configuration is output.

***ScopeID***
Required. Specifies the IP address of the scope for which the configuration is output.

***PathAndFileName***
Specifies both the location where the file is saved, and the name of the destination file to which to dump the scope

configuration. If unspecified, the scope configuration is dumped to the command prompt window.

**Examples**
The first command, which is run within the netsh environment, dumps the configuration of the current scope to the command prompt window.

The second command, which is run from the command prompt, dumps the configuration of the local server scope 192.168.1.0 to a file named Scopecfg.dmp on the shared network folder \\Backup\Dhcp\.

**dump**

**netsh dhcp server scope 192.168.1.0 dump >** *\\Backup\Dhcp\Scopecfg.dmp*

**initiate reconcile**
Checks and reconciles the current scope. Used without parameters, this command verifies the scopes and check for inconsistencies but does not fix any inconsistencies that it finds in the database.

**Syntax**
**initiate reconcile** [**fix**]

**Parameters**
**[fix]**
Indicates that the command will fix, if possible, any inconsistencies that it finds in the database.

**Examples**
In the first example, this command verifies the scopes and checks for inconsistencies.

In the second example, this command verifies the scopes, checks for inconsistencies, and fixes any inconsistencies that are found.

**initiate reconcile**

**initiate reconcile fix**

**set comment**
Sets the comment for the current scope. Used without parameters, **set comment** deletes the current comment.

**Syntax**
**set comment** [*NewComment*]

**Parameters**
**[*NewComment*]**
Specifies a new or modified comment string for the scope.

**Examples**
In the first example, this command sets a comment string that has no spaces.

In the second example, this command sets a comment string that includes spaces.

**set comment NewCommentNoSpaces**

**set comment "New Comment With Spaces"**

**set name**
Sets the name of the current scope.

**Syntax**
**set name** *NewName*

**Parameters**
***NewName***
Required. Specifies the new name of the scope.

**Examples**
In the first example, this command sets a name that has no spaces.

In the second example, this command sets a name that includes spaces.

**set name NewNameNoSpaces**

**set name "New Name With Spaces"**

#### set optionvalue

Sets an option value for the current scope.

#### Syntax

**set optionvalue** *OptCode*{**BYTE** | **WORD** | **DWORD** | **STRING** | **IPADDRESS**} [**user=***UserName*] [**vendor=***VendorName*] *OptionValue*

#### Parameters

***OptCode***

Required. Specifies the code for the option type whose value is to be set.

**{BYTE | WORD | DWORD | STRING | IPADDRESS}**

Required. Specifies the data type for the option type whose value is to be set.

**user= *UserName***

Specifies the user class. If the tag is provided, but the value is unspecified, the current default user class is assumed.

**vendor= *VendorName***

Specifies the vendor class. If the tag is provided, but the value is unspecified, the current default vendor class is assumed.

***OptionValue***

Required. Specifies the assigned value for the option type that is specified in *OptCode*. If the option type supports an array that contains more than a single numeric or IP address value, provide the additional values, in the order that you prefer them, at the end of the command, with each value separated by a space.

#### Remarks

- Vendor and user classes are only supported for DHCP servers running Windows 2000 Server.
- To modify the current defaults for an unspecified class used with this command, use either **set userclass** or **set vendorclass**.

#### Examples

In the first example, this command sets the value of option code 003 to list two router IP addresses (10.1.1.1, 10.1.1.2).

In the second example, this command sets the value that is specified in the first example to apply only to those scope clients that identify themselves as members of the vendor class Vendor1, a class that was previously defined at the server with this specified option type defined for its use.

**set optionvalue 003 IPADDRESS 10.1.1.1 10.1.1.2**

**set optionvalue 003 IPADDRESS vendor=Vendor1 10.1.1.1 10.1.1.2**

#### set reservedoptionvalue

Sets the value of an option for a reservation IP address in the current scope.

#### Syntax

**set reservedoptionvalue** *ReservedIP OptCode* {**BYTE** | **WORD** | **DWORD** | **STRING** | **IPADDRESS**} [**user=***UserName*] [**vendor=***VendorName*] *OptValue*

#### Parameters

***ReservedIP***

Required. Specifies the reserved IP address for which the option value is to be set.

***OptCode***

Required. Specifies the code for the option type whose value is to be set.

**{BYTE | WORD | DWORD | STRING | IPADDRESS}**

Required. Specifies the data type for the option type whose value is to be set.

**user= *UserName***

Specifies either the current default user class or the class specified as *UserName*. If the tag is provided, but no value is specified, the current default user class is assumed.

**vendor= *VendorName***

Specifies either the current default vendor class or the class specified as *VendorName*. If the tag is provided, but no value is specified, the current default vendor class is assumed.

***OptValue***
Required. Specifies the assigned value for the option type specified in *OptCode*. If the option type supports an array that contains more than a single numeric or IP address value, provide the additional values, in the order that you prefer them, at the end of the command with each value separated by a space.

**Remarks**

- Vendor and user classes are only supported for DHCP servers running Windows 2000 Server.
- To modify the current defaults for an unspecified class used with this command, use either **set userclass** or **set vendorclass**.

**Examples**
In the following example, this command sets the value of the router option (code 003) for the reserved client IP address of 10.1.1.50 in the current scope to set IP addresses of 10.1.1.1 and 10.1.1.2 for its configured routers (default gateways).

**set reservedoptionvalue 10.1.1.50 003 IPADDRESS 10.1.1.1 10.1.1.2**

**set scope**
Sets the scope for use in subsequent operations.

**Syntax**
**set scope** *ScopeAddress*

**Parameters**
***ScopeAddress***
Required. Specifies the IP address of the scope to use in subsequent command operations.

**Examples**
In the following example, this command sets the current scope to 10.2.2.0 for subsequent operations.

**set scope 10.2.2.0**

**set state**
Sets or resets the state of the current scope to either the active or inactive state. Used without parameters, this command activates the scope.

**Syntax**
**set state** [{**0** | **1** | **2** | **3**}]

**Parameters**
**{0 | 1 | 2 | 3}**
Indicates the state of the scope: **0**-Deactivates the scope, **1**-Activates the scope (default), **2**-Deactivates the scope and marks the scope as "Switched," **3**-Activates the scope and marks the scope as "Switched."

**Remarks**

- **2** and **3** are typically used for switched networks or networks where multiple logical networks are hosted on a single physical network.

**Examples**
In the first example, this command activates a scope.

In the second example, this command deactivates a scope.

**set state 1**

**set state 0**

**set superscope**
Sets the superscope to use in subsequent operations.

**Syntax**

**set superscope** *SuperscopeName* {**0** | **1**}

**Parameters**

***SuperscopeName***

Required. Specifies the name of the superscope to include the current scope. The *SuperscopeName* is case-sensitive.

**{0 | 1}**

Required. Indicates whether to set the state of the superscope to active or inactive: **0**-Deactivates the superscope, **1**-Activates the superscope.

**Examples**

In the following example, this command adds the current scope to the superscope MySuperScope and activates the superscope.

**set superscope MySuperScope 1**

**show clients**

Displays all of the available version 4 clients for the current scope. Used without parameters, this command displays the following information for each client: IP address, subnet mask, unique ID, lease expiration, and type.

**Syntax**

**show clients**[{**0** | **1**}]

**Parameters**

**{0 | 1}**

Indicates the detail level of the output: **0**-Shows the following information for each client: IP address, subnet mask, unique ID, lease expiration, and data type (default), **1**-Shows all of the information that **0** provides and also displays the fully qualified domain name of each client.

**Remarks**

- To view the output of this command effectively, increase the width of the command prompt window to at least 95 characters.

**show clientsv5**

Displays all of the available version 5 clients for the current scope. Used without parameters, this command displays the following information for each client: IP address, subnet mask, unique ID, lease expiration, and type.

**Syntax**

**show clientsv5**[{**0** | **1**}]

**Parameters**

**{0 | 1}**

Indicates the detail level of the output: **0**-Shows the following information for each client: IP address, subnet mask, unique ID, lease expires, type (default), **1**-Shows all of the information that **0** provides and also displays the fully qualified domain name of each client.

**Remarks**

- To view the output of this command effectively, increase the width of the command prompt window to at least 95 characters.

**show excluderange**

Displays all of the currently set exclusion ranges of IP addresses for the current scope.

**Syntax**

**show excluderange**

**Parameters**

**none**

**Remarks**

- Use other scope-level commands to add and delete exclusion ranges.

**show iprange**
Displays all of the address ranges that are available for the current scope.

**Syntax**
**show iprange**

**Parameters**
**none**

**show optionvalue**
Displays all of the option values that are set for the current scope. Used without parameters, this command assumes the current default user and vendor classes.

**Syntax**
**show optionvalue**[**user=***UserName*] [**vendor=***VendorName*]

**Parameters**
**user= *UserName***
Specifies that the options that are set for the specified user class will display. If the tag is provided, but no value is specified, the current default user class is assumed.

**vendor= *VendorName***
Specifies that the options that are set for the specified vendor class will display. If the tag is provided, but no value is specified, the current default vendor class is assumed.

**Remarks**

- Vendor and user classes are only supported for DHCP servers running Windows 2000 Server.
- To modify the current defaults for an unspecified class used with this command, use either **set userclass** or **set vendorclass**.

**Examples**
In the following example, this command displays all options and values set for the current scope for the user defined class My User Class.

**show optionvalue user="My User Class"**

**show reservedip**
Displays all of the IP addresses that are currently reserved for the current scope.

**Syntax**
**show reservedip**

**Parameters**
**none**

**show reservedoptionvalue**
Displays all currently set option values for a reserved client IP address in the current scope.

**Syntax**
**show reservedoptionvalue** *ReservedIP*[**user=***UserName*] [**vendor=***VendorName*]

**Parameters**
***ReservedIP***
Required. Specifies the IP address reservation for which currently assigned options are to display.

**user= *UserName***
Specifies that the options that are set for the specified user class will display. If the tag is provided, but no value is specified, the current default user class is assumed.

**vendor= *VendorName***
Specifies that the options that are set for the specified vendor class will display. If the tag is provided, but no value is specified, the current default vendor class is assumed.

**Remarks**

- Vendor and user classes are only supported for DHCP servers running Windows 2000 Server.
- To modify the current defaults for an unspecified class used with this command, use either **set userclass** or **set vendorclass**.

**Examples**
In the following example, this command displays the option values set for the reserved IP address 10.2.2.100 in the current scope.

**show reservedoptionvalue 10.2.2.100**

**show scope**
Displays information for the current scope.

**Syntax**
**show scope**

**Parameters**
**none**

**show state**
Displays the state of the current scope, indicating whether it is active or inactive.

**Syntax**
**show state**

**Parameters**
**none**

**Netsh DHCP server mscope**
The following commands can run from the **dhcp server mscope>** prompt, which is rooted within the **netsh** environment.

To view the command syntax, click a command:

- add excluderange
- add iprange
- delete excluderange
- delete iprange
- dump
- initiate reconcile
- set comment
- set lease
- set mscope
- set name
- set state
- set ttl

- show clients
- show excluderange
- show iprange
- show lease
- show mibinfo
- show mscope
- show state
- show ttl

**add excluderange**
Adds a range of excluded addresses to the current multicast scope.

**Syntax**
**add excluderange** *StartIP EndIP*

**Parameters**
***StartIP***
Required. Specifies the IP address that starts the exclusion range.

***EndIP***
Required. Specifies the IP address that ends the exclusion range.

**Remarks**

- The exclusion range must be a subset of the overall scope address range.

**Examples**
In the following example, this command adds an exclusion range that starts with 224.2.2.10 and ends with 224.2.2.20 to the distribution range of the current multicast scope.

**add excluderange 224.2.2.10 224.2.2.20**

**add iprange**
Adds a range of IP addresses to the current multicast scope.

**Syntax**
**add iprange** *StartIP EndIP*

**Parameters**
***StartIP***
Required. Specifies the IP address that starts the range.

***EndIP***
Required. Specifies the IP address that ends the range.

**Remarks**

- The range must be within the valid range of multicast IP addresses (from 224.0.0.0 to 239.255.255.255).

**Examples**
In the following example, this command adds the IP address range 224.2.2.10 to 224.2.2.20 to the distribution range in the multicast scope.

**add iprange 224.2.2.10 224.2.2.20**

**delete excluderange**

Deletes an exclusion range of previously excluded IP addresses in the current multicast scope.

**Syntax**
**delete excluderange** *StartIP EndIP*

**Parameters**
***StartIP***
Required. Specifies the IP address that starts the exclusion range.

***EndIP***
Required. Specifies the IP address that ends the exclusion range.

**Examples**
In the following example, this command removes a multicast scope exclusion with a range of IP addresses that starts at 224.2.2.10 and ends with 224.2.2.20 for the multicast scope.

**delete excluderange 224.2.2.10 224.2.2.20**

**delete iprange**
Deletes a range of IP addresses from the current multicast scope.

**Syntax**
**delete iprange** *StartIP EndIP*

**Parameters**
***StartIP***
Required. Specifies the IP address that starts the range to delete.

***EndIP***
Required. Specifies the IP address that ends the range to delete.

**Examples**
In the following example, this command deletes the IP address range 224.2.2.10 to 224.2.2.20 from the overall range of the full multicast scope.

**delete iprange 224.2.2.10 224.2.2.20**

**dump**
Dumps the configuration of the current multicast scope to the command prompt window when run within the netsh environment.

**Syntax**
**dump**

When run at the command prompt or in a batch file, output can be saved in a text file. Used without parameters, this command dumps the configuration of the current multicast scope to the command prompt window.

**Syntax**
**netsh dhcp server [** ***ServerName*** **|** ***IPAddress*** **] mscope** ***MscopeID*** **dump >**[*PathAndFileName*]

**Parameters**
***ServerName | IPAddress***
Specifies the server name or IP address of the DHCP server for which the scope configuration is output.

***MscopeID***
Required. Specifies the name of the multicast scope for which the configuration is output.

***PathAndFileName***
Specifies both the location where the file is saved, and the name of the destination file to which to dump the multicast scope configuration. If unspecified, scope configuration is dumped to the command prompt window.

**Examples**
The first command, which is run within the netsh environment, dumps the configuration of the current multicast scope to the command prompt window.

The second command, which is run from the command prompt, dumps the configuration of the local server multicast scope TestMscope to the file Mscopecfg.dmp on the shared network folder \\Backup\Dhcp\.

**dump**

**netsh dhcp server mscope TestMscope dump >** *\\Backup\Dhcp\Mscopecfg.dmp*

#### initiate reconcile

Checks and reconciles the current multicast scope.

**Syntax**

**initiate reconcile**

**Parameters**

**none**

**Remarks**

- This command checks the integrity of the current multicast scope by comparing the current contents of the server database with a mirrored copy of the same information in the Windows registry. If inconsistencies are detected in the database, they are repaired based on the information that is duplicated in the registry. Repair is always attempted for any inconsistency that is found.

#### set comment

Sets the comment for the current multicast scope.

**Syntax**

**set comment** *NewComment*

**Parameters**

***NewComment***

Required. Specifies the new or revised comment for the multicast scope

**Examples**

In the first example, this command modifies the multicast scope comment with a new comment that contains no spaces.

In the second example, this command modifies the multicast scope comment with a new comment that contains spaces.

**set comment NewCommentNoSpaces**

**set comment "New Comment With Spaces"**

#### set lease

Sets the lease duration for the multicast scope IP addresses.

**Syntax**

**set lease** *Time*

**Parameters**

***Time***

Required. Specifies the lease duration for clients of the multicast scope. Specifying **-1** sets the duration of the IP address lease to an unlimited or infinite time.

**Examples**

In the following example, this command sets the lease duration for the clients of the current multicast scope to 691200 seconds (eight days).

**set lease 691200**

#### set mscope

Sets the multicast scope to use in subsequent operations.

**Syntax**

**set mscope** *NewName*

**Parameters**

***NewName***

Required. Specifies the name of the multicast scope to which the command context is changed. *NewName* is case-sensitive.

**Remarks**

- This command changes the context of the **netsh dhcp server mscope>** prompt from one multicast scope to another.

- This command does not rename the current multicast scope. To change the name of the current multicast scope, use the command **set name**.

**Examples**
In the first example, this command changes the command context to a multicast scope named MyMulticastScope. Note that the multicast scope name contains no spaces.

In the second example, this command changes the command context to a multicast scope named My Multicast Scope. Note that the multicast scope name contains spaces.

**set mscope MyMulticastScope**

**set mscope "My Multicast Scope"**

**set name**
Changes the name of the current multicast scope.

**Syntax**
**set name** *NewName*

**Parameters**
***NewName***
Required. Specifies a new name for the current multicast scope.

**Examples**
In the first example, this command sets a new name that contains no spaces for the current multicast scope.

In the second example, this command sets a new name that contains spaces for the current multicast scope.

**set name NewNameNoSpaces**

**set name "New Name With Spaces"**

**set state**
Sets or resets the state of the current multicast scope to either an active or inactive state.

**Syntax**
**set state** {**0** | **1**}

**Parameters**
**{0 | 1}**
Required. Sets the state of the current multicast scope: **0**-Deactivates the current multicast scope, **1**-Activates the current multicast scope .

**Examples**
In the first example, this command activates the current multicast scope.

In the second example, this command deactivates the current multicast scope.

**set state 1**

**set state 0**

**set ttl**
Sets the Time-To-Live (TTL) value for the current multicast scope.

**Syntax**
**set ttl** *TTL*

**Parameters**
***TTL***
Required. Specifies the Time-to-Live (TTL) value. The valid range for this value is a number from 1 to 255.

**Examples**
In the following example, this command sets the TTL value for the current multicast scope to 32.

**set ttl 32**

**show clients**
Displays all available clients for the current multicast scope.

**Syntax**
**show clients**

**Parameters**
**none**

**Remarks**

- To view the output of this command effectively, increase the width of the command prompt window to at least 95 characters.

**show excluderange**
Displays all currently excluded ranges of IP addresses for the current multicast scope.

**Syntax**
**show excluderange**

**Parameters**
**none**

**Remarks**

- If no exclusion ranges have been previously defined for the scope, this command outputs an empty list.

**show iprange**
Displays all available IP address ranges for the current multicast scope.

**Syntax**
**show iprange**

**Parameters**
**none**

**show lease**
Displays the current lease duration settings for the current multicast scope.

**Syntax**
**show lease**

**Parameters**
**none**

**show mibinfo**
Displays management information base (MIB) information for the current multicast scope.

**Syntax**
**show mibinfo**

**Parameters**
**none**

**show mscope**
Displays information for the current multicast scope.

**Syntax**
**show mscope**

**Parameters**
**none**

**show state**
Displays the state of the current multicast scope.

**Syntax**
**show state**

**Parameters**
**none**

**show ttl**
Displays the Time-To-Live (TTL) value for the current multicast scope.

**Syntax**
**show ttl**

**Parameters**
**none**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh diagnostic (diag) commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh diagnostic (diag) commands**
You can use the Netsh Network Diagnostics commands, or diag context, to administer and troubleshoot operating system and network service parameters from the command line. The command prompt for the Netsh diagnostic context is **netsh diag>**.

The following commands are available at the command prompt for the context (as distinguished from the Windows Server 2003 family command prompt). The Netsh Diag context is new to the Windows Server 2003 family. You cannot run Netsh Diag commands on a Windows 2000 Server.

You can run these commands from the Windows Server 2003 family command prompt or from the command prompt for the Netsh diagnostic context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh diag** before typing commands and parameters as they appear in the syntax below. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

For more information about **netsh**, see Netsh overview and Enter a netsh context.

To view the command syntax, click a command:

- connect ieproxy
- connect iphost
- connect mail
- connect news
- dump
- gui
- ping
- ping adapter
- ping dhcp
- ping dns
- ping gateway
- ping ieproxy
- ping ip
- ping iphost
- ping loopback
- ping mail
- ping news
- ping wins

- show adapter
- show all
- show client
- show computer
- show dhcp
- show dns
- show gateway
- show ieproxy
- show ip
- show mail
- show modem
- show news
- show os
- show test
- show version
- show wins

**connect ieproxy**
Establishes, verifies, and then drops a TCP/IP connection with the proxy server specified in Internet Explorer.

**Syntax**
**connect ieproxy**

**Parameters**
none

**Remarks**

- If no proxy server is specified in Internet Explorer, the command generates output similar to the following:

```
Internet Explorer Proxy (Not Configured)
    Not Configured
```

- If you have specified in Internet Explorer a proxy server named corpproxy with a port of 80, the command generates output similar to the following:

```
Internet Explorer Proxy (corpproxy)
    IEProxyPort = 80
    IEProxy = corpproxy
    Server appears to be running on port(s) [80]
```

**connect iphost**
Establishes, verifies, and then drops a TCP/IP connection to a specified host through a specified port.

**Syntax**
**connect iphost** *Host Port*

**Parameters**
***Host***
Specifies the IP address, NetBIOS name, or fully qualified domain name of the host to which you want to connect.

***Port***
Specifies the port through which you want to connect.

**Examples**
To connect to the host named microsoft.com through port 28, type:

**connect iphost microsoft.com 28**

**connect mail**
Establishes, verifies, and then drops a TCP/IP connection with the node specified as the mail server in the default Outlook Express profile of the current user.

**Syntax**
**connect mail**

**Parameters**
none

**connect news**
Establishes, verifies, and then drops a TCP/IP connection with the node specified as the news server in the default Outlook Express profile of the current user.

**Syntax**
**connect news**

**Parameters**
none

**dump**
Creates a script that contains the current configuration.

**Syntax**
**dump**

**Parameters**
none

**Remarks**

- If you save this script to a file, you can use it to restore altered configuration settings.

**gui**
Starts the network diagnostics tool in Help and Support Center.

**Syntax**
**gui**

**Parameters**
none

**ping**
Verifies connectivity with a specified remote host.

**Syntax**
**ping** *Host*

**Parameters**
***Host***
Specifies the IP address, NetBIOS name, or fully qualified domain name of the host with which you want to verify

connectivity.

**ping adapter**
Verifies connectivity with computers and other devices (for example, routers) identified in the TCP/IP properties of the specified network adapter or adapters. Used without parameters, the **ping adapter** command verifies connectivity through all installed adapters.

**Syntax**
**ping adapter** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}]

**Parameters**
***{ IndexNumber | FullAdapterName| PartialAdapterName}***
Specifies the adapter or adapters for which you want to verify connectivity. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**Remarks**

- This command verifies connectivity with all computers and other devices configured in the TCP/IP properties for each network adapter you specify. For example, if you have a network adapter whose TCP/IP properties are configured with IP addresses for a preferred DNS server, a default gateway, and a DHCP server, **ping adapter** verifies connectivity with each of these devices.

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.

- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To verify connectivity with all computers and other devices configured in the TCP/IP properties for each network adapter, type:

**ping adapter**

To verify connectivity with all computers and other devices configured in the TCP/IP properties for each network adapter with an index number of 2, type:

**ping adapter 2**

To verify connectivity with all computers and other devices configured in the TCP/IP properties for each network adapter with "net" at the beginning of its name, type:

**ping adapter net***

**ping dhcp**
Verifies connectivity with the Dynamic Host Configuration Protocol (DHCP) servers configured in the TCP/IP properties for the specified adapter or adapters. Used without parameters, the **ping dhcp** command verifies connectivity with DHCP servers through all installed adapters.

**Syntax**
**ping dhcp** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}]

**Parameters**
***{IndexNumber| FullAdapterName| PartialAdapterName}***
Specifies the adapter or adapters for which you want to verify connectivity. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To verify connectivity with the DHCP server configured in the TCP/IP properties for each network adapter, type:

**ping dhcp**

To verify connectivity with the DHCP server configured in the TCP/IP properties for the network adapter with an index number of 2, type:

**ping dhcp 2**

To verify connectivity with the DHCP server configured in the TCP/IP properties for each network adapter with "net" at the beginning of its name, type:

**ping dhcp net***

**ping dns**
Verifies connectivity with the Domain Name System (DNS) servers configured in the TCP/IP properties for the specified adapter or adapters. Used without parameters, the **ping dns** command verifies connectivity with DNS servers through all installed adapters.

**Syntax**
**ping dns** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}]

**Parameters**
**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to verify connectivity. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To verify connectivity with the DNS server configured in the TCP/IP properties for each network adapter, type:

**ping dns**

To verify connectivity with the DNS server configured in the TCP/IP properties for the network adapter with an index number of 2, type:

**ping dns 2**

To verify connectivity with the DNS server configured in the TCP/IP properties for each network adapter with "net" at the beginning of its name, type:

**ping dns net***

**ping gateway**
Verifies connectivity with the default gateway servers configured in the TCP/IP properties for the specified adapter or adapters. Used without parameters, the **ping gateway** command verifies connectivity through all installed adapters.

**Syntax**

**ping gateway** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}]

**Parameters**

***{ IndexNumber| FullAdapterName| PartialAdapterName}***

Specifies the adapter or adapters for which you want to verify connectivity. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**

To verify connectivity with the gateway server configured in the TCP/IP properties for each network adapter, type:

**ping gateway**

To verify connectivity with the gateway server configured in the TCP/IP properties for the network adapter with an index number of 2, type:

**ping gateway 2**

To verify connectivity with the gateway server configured in the TCP/IP properties for each network adapter with "net" at the beginning of its name:

**ping gateway net***

**ping ieproxy**

Verifies connectivity with the Web server proxy for Internet Explorer.

**Syntax**

**ping ieproxy**

**Parameters**

none

**ping ip**

Verifies connectivity with all IP addresses for the specified adapter or adapters. Used without parameters, the **ping ip** command verifies connectivity through all installed adapters.

**Syntax**

**ping ip** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}]

**Parameters**

***{ IndexNumber| FullAdapterName| PartialAdapterName}***

Specifies the adapter or adapters for which you want to verify connectivity. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.

- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To verify connectivity with each network adapter, type:

**ping ip**

To verify connectivity with the network adapter with an index number of 2, type:

**ping ip 2**

To verify connectivity with each network adapter with "net" at the beginning of its name, type:

**ping ip net***

**ping iphost**
Verifies connectivity with a remote or local host.

**Syntax**
**ping iphost** *Node*

**Parameters**
***Node***
Specifies a host by its IP address, its NetBIOS name, or its fully qualified domain name.

**Examples**
To verify connectivity with the local host (at the loopback address of 127.0.0.1), type:

**ping iphost 127.0.0.1**

To verify connectivity with the host microsoft.com, type:

**ping iphost microsoft.com**

**ping loopback**
Verifies connectivity with the local host loopback address (127.0.0.1).

**Syntax**
**ping loopback**

**Parameters**
none

**ping mail**
Verifies connectivity with the mail server configured in the default Outlook Express profile of the current user.

**Syntax**
**ping mail**

**Parameters**
none

**ping news**
Verifies connectivity with the mail server configured in the default Outlook Express profile of the current user.

**Syntax**
**ping news**

**Parameters**
none

**ping wins**
Verifies connectivity with the preferred and alternate Windows Internet Name Service (WINS) servers for the specified network adapter or adapters. Used without parameters, **ping wins** verifies connectivity through all installed adapters.

**Syntax**
**ping wins** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}]

**Parameters**

**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to verify connectivity. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To verify connectivity with the WINS servers whose IP addresses are configured in the TCP/IP properties of each installed adapter, type:

**ping wins**

To verify connectivity with the WINS servers whose IP addresses are configured in the TCP/IP properties of each installed adapter with an index number number of 2, type:

**ping wins 2**

**show adapter**
Shows information about the specified logical adapter or adapters. Used without parameters, the **show adapter** command shows information about all adapters defined for this server.

**Syntax**
**show adapter** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**
**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to show information. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- This command lists each adapter by index number in square brackets followed by the name of the adapter as it is registered. Typical output from this command follows:

  Network Adapters

  1. [00000001] 3Com 3C920 Integrated Fast Ethernet Controller (3C905C-TX Compatible)
  2. [00000002] RAS Async Adapter
  3. [00000003] WAN Miniport (L2TP)
  4. [00000004] WAN Miniport (PPTP)

5. [00000005] WAN Miniport (PPPOE)

6. [00000006] Direct Parallel

7. [00000007] WAN Miniport (IP)

8. [00000008] WAN Miniport (Network Monitor)

**Examples**
To display the logical adapters defined on the computer, type:

**show adapter**

**show all**
Lists all network objects defined for the local server. Used without parameters, the **show all** command lists overview configuration information for the following hardware and software components: Default Outlook Express Mail, Default Outlook Express News, Internet Explorer Web Proxy, Loopback, Computer System, Operating System, Version, Modems, Network Adapters, and Network Clients.

**Syntax**
**show all** [{**/v** | **/p**}]

**Parameters**
**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- The output from this command can be lengthy and includes configuration information for mail, news, and proxy servers. It lists information for the TCP/IP loopback address and details about the computer, the operating system, and all network adapters and clients.

**show client**
Lists all network clients defined for the specified adapter or adapters. Used without parameters, **show client** lists clients for all installed adapters.

**Syntax**
**show client** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**
**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to list clients. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.

- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**

To list all network clients defined for all network adapters in the host, type:

**show client**

To list all fields with non-null values for all network clients defined for adapter number 2, type:

**show client 2 /p**

**show computer**
Lists Windows Management Interface (WMI) details for the server. Used without parameters, the **show computer** command lists the NetBIOS name of the local computer.

**Syntax**
**show computer** [{**/v** | **/p**}]

**Parameters**
**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Examples**
To list all non-null WMI interface parameters for the server:

**show computer /p**

**show dhcp**
Lists all DHCP servers defined for the specified adapter. Used without parameters, the **show dhcp** command lists the servers defined for all installed adapters.

**Syntax**
**show dhcp** {*IndexNumber* | *FullAdapterName* | *PartialAdapterName*} [{**/v** | **/p**}]

**Parameters**
***{ IndexNumber| FullAdapterName| PartialAdapterName}***
Specifies the adapter or adapters for which you want to list servers. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To list details of all DHCP servers defined for all network adapters, type:

**show dhcp /v**

To list details of any DHCP servers defined for network adapter 2, type:

**show dhcp 2**

**show dns**
Lists all DNS servers defined for a specified adapter. Used without parameters, the **show dns** command lists servers defined for all installed adapters.

**Syntax**

**show dns** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**

**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**

Specifies the adapter or adapters for which you want to list servers. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**

Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**

To list all non-null details of all DNS servers defined for all network adapters, type:

**show dns /p**

To list any DNS servers defined for network adapter 2, type:

**show dns 2**

**show gateway**

Lists all Internet gateways defined for the specified adapter or adapters. Used without parameters, the **show gateway** command lists gateways defined for all installed adapters.

**Syntax**

**show gateway** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**

**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**

Specifies the adapter or adapters for which you want to list gateways. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**

Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**

To list all available details about all Internet gateways defined for all adapters, type:

**show gateway /v**

To list all non-null values available for any gateways defined for network adapter 3, type:

**show gateway 3 /p**

**show ieproxy**
Lists Internet Explorer proxy servers defined for the specified adapter or adapters. Used without parameters, **show ieproxy** lists the servers for all installed adapters.

**Syntax**
**show ieproxy** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**
**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to list servers. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, you must type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, you must type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, you must type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To list all Internet Explorer proxy servers defined for all network adapters in the server, type:

**show ieproxy**

**show ip**
Shows information about the specified adapter or adapters for which TCP/IP is enabled. Used without parameters, the **show ip** command shows information for all installed adapters.

**Syntax**
**show ip** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**
**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to show information. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.

**Examples**
To list the index number, name, and TCP/IP address for all adapters for which TCP/IP is enabled, type:

**show ip**

**show mail**
Shows the Outlook Express mail server specified for the local computer. Used without parameters, the **show mail** command lists overview configuration information for Default Outlook Express Mail.

**Syntax**
**show mail** [{**/v** | **/p**}]

**Parameters**
**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Examples**
To display the mail server configured for the local computer, type:

**show mail**

**show modem**
Lists details about the specified modem device or devices configured on the local computer. Used without parameters, **show modem** lists details about all modem devices.

**Syntax**
**show modem** [{*IndexNumber* | *FullModemName* | *PartialModemName*}] [{**/v** | **/p**}]

**Parameters**
***{ IndexNumber| FullModemName| PartialModemName}***
Specifies the modem device or devices for which you want to list details. The *IndexNumber* parameter specifies the device by its index number. The *FullModemName* parameter specifies the device by its name as registered in the operating system. The *PartialModemName* specifies the device or devices whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Examples**
To show all details, even those with null values, about all modem devices configured on the local computer, type:

**show modem /v**

To show the name and index number of all modem devices configured on the local computer with "dialup" at the beginning of their names, type:

**show modem dialup***

**show news**
Displays configuration information for the news server defined for the local computer. Used without parameters, the **show news** command lists overview configuration information for Default Outlook Express News.

**Syntax**
**show news** [{**/v** | **/p**}]

**Parameters**
**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Examples**
To display the name and the TCP/IP address of the news server, type:

**show news**

**show os**
Displays information about the operating system running on the local computer.

**Syntax**
**show os** [**/v**]

**Parameters**
**/v**
Specifies that fields with a null value should appear.

**Remarks**

- Information shown by this command is collected by the WMI provider win32_operatingsystem.

**show test**
Shows all network objects defined for the local computer and verifies connectivity with each object using the **ping** command. Used without parameters, the **show test** command lists overview configuration information for the following hardware and software components: Default Outlook Express Mail, Default Outlook Express News, Internet Explorer Web Proxy, Loopback, Computer System, Operating System, Version, Modems, Network Adapters, and Network Clients. In addition, connectivity is verified with the Loopback adapter and all IP addresses configured as a client option in the TCP/IP properties of each network adapter.

**Syntax**
**show test** [{**/v** | **/p**}]

**Parameters**
**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- The output of this command can be lengthy and might require a few minutes to complete. The output includes configuration information for mail, news, and proxy servers as well as the results of attempts to verify connectivity to those servers using the **ping** command. This command lists information for and verifies connectivity with the TCP/IP loopback address. This command lists details about the computer and the operating system as well as all network adapters and clients. Connectivity is verified with network adapters and clients using the **ping** command, and the results are displayed.

**Examples**
To show all information available to the Netsh diagnostic context, type:

**show test /v**

**show version**
Shows the version of the operating system and, optionally, the version of Windows Management Infrastructure (WMI). Used without parameters, the **show version** command lists the version number of the operating system installed on the local computer.

**Syntax**
**show version** [{**/v** | **/p**}]

**Parameters**
**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- The first line of output for this command shows the version of the operating system. The second line shows the version of WMI. Typical output for this command follows:

```
Version (5.1.2416)
    Version = 5.1.2416
    BuildVersion = 2416.0000
```

**Examples**
To show the version of the operating system and WMI, including fields with a null value, type:

**show version /v**

**show wins**
Lists WINS servers for the specified adapter or adapters. Used without parameters, the **show wins** command lists servers for all installed adapters.

**Syntax**
**show wins** [{*IndexNumber* | *FullAdapterName* | *PartialAdapterName*}] [{**/v** | **/p**}]

**Parameters**
**{ *IndexNumber*| *FullAdapterName*| *PartialAdapterName*}**
Specifies the adapter or adapters for which you want to list servers. The *IndexNumber* parameter specifies the adapter by its index number. The *FullAdapterName* parameter specifies the adapter by its name as registered in the operating system. The *PartialAdapterName* parameter specifies the adapter or adapters whose names contain the sequence of characters specified in the parameter. If the sequence of characters must appear at the beginning of the name, type an asterisk at the end of the parameter. If the sequence of characters must appear at the end of the name, type an asterisk at the beginning of the parameter. If the sequence of characters can appear anywhere in the name, type an asterisk at the beginning of the parameter and at the end of the parameter.

**{ /v| /p}**
Specifies whether fields with a null value should appear. The **/v** parameter specifies that the fields should appear. The **/p** parameter specifies that the fields should not appear.

**Remarks**

- You can use the **show adapter** command to display the index numbers and the full names of all logical adapters defined on the computer.
- If you specify an adapter by its index number, you do not need to type the leading zeroes.
- Typical output for this command is as follows:

```
WINS Servers
    2. [00000002] 3Com 3C920 Integrated Fast Ethernet Controller (3C905C-TX
Compatible)
    WINSPrimaryServer = 172.16.44.17
    WINSSecondaryServer = 172.16.32.22
```

**Examples**
To list the WINS servers defined for all adapters on the server, type:

**show wins**

To list the WINS servers specified for the adapter with index number 2, type:

**show wins 2**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |

| | |
|---|---|
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh commands for Interface IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for Interface IP**
You can use commands in the Netsh Interface IP context to configure the TCP/IP protocol (including addresses, default gateways, DNS servers, and WINS servers) and to display configuration and statistical information.

You can run these commands from the Windows Server 2003 family command prompt or from the command prompt for the Netsh interface IP context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh interface ip** before typing commands and parameters as they appear in the syntax below. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

For more information on Netsh, see Netsh overview and Enter a netsh context.

To view the command syntax, click a command:

- set address
- add address
- delete address
- show address
- set dns
- add dns
- delete dns
- show dns
- set wins
- add wins
- delete wins
- show wins
- show icmp
- show interface
- show ipaddress
- show ipnet
- show ipstats
- show joins
- show tcpconn

- show tcpstats
- show udpconn
- show udpstats
- show config
- show offload
- delete arpcache
- dump

**set address**
Configures an IP address and a default gateway on a specified interface.

**Syntax**
**set address** [**name=**]*InterfaceName* [**source=**]{**dhcp** | **static** [**addr=**]*IPAddress*[**mask=**]*SubnetMask* [**gateway=**]{**none** | *DefaultGateway* [[**gwmetric=**]*GatewayMetric*]}}

**Parameters**
**[ name =] *InterfaceName***
Required. Specifies the name of the interface for which you want to configure address and gateway information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ source=]{ dhcp| static[ addr=] *IPAddress*[ mask=] *SubnetMask*[ gateway=]{ none| *DefaultGateway*[[ gwmetric=] *GatewayMetric*]}}**
Required. Specifies whether the IP address to configure originates from a Dynamic Host Configuration Protocol (DHCP) server or is static. If the address is static, *IPAddress* specifies the address to configure, and *SubnetMask* specifies the subnet mask for the IP address being configured. If the address is static, you must also specify whether you want to leave the current default gateway (if any) in place or configure one for the address. If you configure a default gateway, *DefaultGateway* specifies the IP address of the default gateway to be configured, and *GatewayMetric* specifies the metric for the default gateway to be configured.

**/?**
Displays help at the command prompt.

**Remarks**

- You can use this command to switch an interface between DHCP configuration and static configuration. If the interface is configured statically, the DNS and WINS server addresses for this interface must also be statically configured.
- Omitting the *DefaultGateway* parameter does not clear gateway configuration but preserves whatever was previously configured.

**add address**
Adds an IP address and a default gateway on a specified interface configured with a static IP address.

**Syntax**
**add address** [**name=**]*InterfaceName* [**addr=**]*IPAddress* [**mask=**]*SubnetMask*[[**gateway=**] *DefaultGateway* [**gwmetric=**]*GatewayMetric*]

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to add address and gateway information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ addr=] *IPAddress*[ mask=] *SubnetMask***
Required. Specifies the IP address to add and the subnet mask for that IP address.

**[ gateway=] *DefaultGateway*[ gwmetric=] *GatewayMetric***
Specifies the IP address of the default gateway to add and the metric for that default gateway.

**/?**
Displays help at the command prompt.

**delete address**
Deletes an IP address or a default gateway on a statically configured interface.

**Syntax**
**delete address** [**name=**]*InterfaceName* [**addr=**] *IPAddress* [[**gateway=**]{*DefaultGateway* | **all**}]

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to delete address and gateway information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *IPAddress***
Required. Specifies the IP address to delete.

**[ gateway=]{ *DefaultGateway*| all}**
Specifies whether to delete one default gateway or all default gateways. If only one default gateway should be deleted, *DefaultGateway* specifies the IP address of the default gateway to be deleted.

**/?**
Displays help at the command prompt.

**Remarks**

- This command will not delete the last IP address on the interface.

**show address**
Displays information about static IP addresses and default gateways on a specified interface. Used without parameters, **show address** displays address information for all interfaces.

**Syntax**
**show address** [[**name=**]*InterfaceName*]

**Parameters**
**[ name=] *InterfaceName***
Specifies the name of the interface for which you want to display address information. The *InterfaceName* must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**/?**
Displays help at the command prompt.

**Remarks**

- For interfaces configured using DHCP, use the **ipconfig** command to display the assigned IP addresses, lease parameters, and other DHCP information.

**set dns**
Configures a DNS server address for a specified interface.

**Syntax**
**set dns** [**name=**]*InterfaceName* [**source=**]{**dhcp** | **static** }[**addr=**]{*IP Address* | **none**} [**register=**]{**none** | **primary** | **both**}

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to set DNS information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ source=]{ dhcp| static }**

Required. Specifies whether the IP address of the DNS server is configured by DHCP or is static.

**[ addr=]{ *IP Address*| none }**
If the IP address is static, *IP Address* specifies the IP address of the DNS server to configure, and **none** specifies that the DNS configuration should be removed.

**[ register=]{ none| primary| both }**
**None** specifies whether to disable Dynamic DNS resolution. **Primary** registers the computer name under the primary DNS suffix only. **Both** registers the computer name under both the primary DNS suffix as well as under the connection-specific suffix.

**/?**
Displays help at the command prompt.

**Remarks**

- If the interface is already statically configured, the **static** parameter replaces the existing list of DNS server addresses with the one specified in the command.

- Only if the [source] is **static** is the [addr] option available for configuring a static list of DNS server IP addresses for the specified interface.

**Examples**
**set dns name="Local Area Connection" source=dhcp**

**set dns "Local Area Connection" static 10.0.0.1 primary**

**add dns**
Adds a DNS server to a list of DNS servers for a specified interface.

**Syntax**
**add dns** [**name=**]*InterfaceName* [**addr=**] *DNSAddress* [[**index=**]*DNSIndex*]

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to add DNS information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *DNSAddress***
Required. Specifies the IP address of the DNS server to add.

**[ index=] *DNSIndex***
Specifies the position of the added DNS server in the list of DNS servers for the interface.

**/?**
Displays help at the command prompt.

**Remarks**

- A lower number for the *DNSIndex* parameter corresponds to a higher preference. If no index is specified, then the server is added with the lowest preference.

**delete dns**
Deletes a DNS server or all DNS servers from a list of DNS servers for a specified interface or for all interfaces.

**Syntax**
**delete dns** [**name=**]*InterfaceName* [**addr=**]{*DNSAddress* | **all**}

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to delete DNS information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=]{ *DNSAddress*| all}**
Required. Specifies whether to delete the address of one DNS server or all servers for all interfaces. If only one DNS server should be deleted, *DNSAddress* specifies the IP address of the DNS server to delete.

**/?**
Displays help at the command prompt.

**show dns**
Displays the DNS configuration of a specified interface. Used without parameters, **show dns** displays the DNS configurations of all interfaces.

**Syntax**
**show dns** [[**name=**]*InterfaceName*]

**Parameters**
**[ name=] *InterfaceName***
Specifies the name of the interface whose DNS configuration you want to display. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**/?**
Displays help at the command prompt.

**set wins**
Sets WINS server configuration to either DHCP or static mode for a specified interface.

**Syntax**
**set wins** [**name=**]*InterfaceName* [**source=**]{**dhcp** | **static** [**addr=**]{*WINSAddress* | **none** }}

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to set WINS information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ source=]{ dhcp| static[ addr=]{ *WINSAddress*| none}}**
Required. Specifies whether the IP address of the WINS server to configure should be assigned by DHCP or is static. If the IP address is static, *WINSAddress* specifies the IP address of the WINS server to configure, and **none** specifies that the WINS configuration should be removed.

**/?**
Displays help at the command prompt.

**Remarks**

- If the interface is already statically configured, the **static** parameter replaces the existing WINS server address list with the one specified in the **set wins** command.

**add wins**
Adds a WINS server to a list of WINS servers for a specified interface.

**Syntax**
**add wins** [**name=**]*InterfaceName* [**addr=**] *WINSAddress* [[**index=**]*WINSIndex*]

**Parameters**
**[ name=] *InterfaceName***
Required. Specifies the name of the interface for which you want to add WINS information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *WINSAddress***
Required. Specifies the IP address of the WINS server to add.

**[ index=] *WINSIndex***
Specifies the position of the added WINS server in the WINS server list for that interface.

**/?**

Displays help at the command prompt.

**Remarks**

- A lower number for the *WINSIndex* parameter corresponds to a higher preference. If no index is specified, then the server is added with the lowest preference.

**delete wins**

Deletes a WINS server or servers from a list of WINS servers for a specified interface or all interfaces.

**Syntax**

**delete wins** [**name=**]*InterfaceName* [**addr=**]{*WINSAddress* | **all**}

**Parameters**

**[ name=] *InterfaceName***

Required. Specifies the name of the interface for which you want to delete a WINS server or servers. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=]{ *WINSAddress*| all}**

Required. Specifies whether to delete only one server for an interface or all servers for all interfaces. If only one server should be deleted, *WINSAddress* specifies the IP address of the WINS server to delete.

**/?**

Displays help at the command prompt.

**show wins**

Displays the WINS configuration for a specified interface. Used without parameters, **show wins** displays the WINS configuration for all interfaces.

**Syntax**

**show wins** [[**name=**]*InterfaceName*]

**Parameters**

**[ name=] *InterfaceName***

Specifies the name of the interface whose WINS information you want to display. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**/?**

Displays help at the command prompt.

**show icmp**

Displays ICMP statistics. Used without parameters, **show icmp** displays the statistics only once.

**Syntax**

**show icmp** [[**rr=**]*RefreshRate*]

**Parameters**

**[ rr=] *RefreshRate***

Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**

Displays help at the command prompt.

**show interface**

Displays statistics for a specified interface. Used without parameters, **show interface** displays statistics for all interfaces only once.

**Syntax**

**show interface** [[**index=**]*InterfaceIndex*] [[**rr=**]*RefreshRate*]

**Parameters**

**[ index=] *InterfaceIndex***

Specifies the interface index, an integer that identifies the interface.

**[ rr=] *RefreshRate***

Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**Remarks**

- To obtain the interface index for an interface, review the output of the **show interface** command used without parameters.

**show ipaddress**
Displays information for a specified IP address. Used without parameters, **show ipaddress** displays information for all IP addresses on all interfaces once.

**Syntax**
**show ipaddress** [[**index=**]*IPAddress*] [[**rr=**]*RefreshRate*]

**Parameters**
**[ index=] *IPAddress***
Specifies an IP address of an interface.

**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**Remarks**

- To obtain the IP addresses of all interfaces, review the display of the **show ipaddress** command used without parameters.

**show ipnet**
Displays the contents of the Address Resolution Protocol (ARP) cache, which contains the hardware addresses of resolved next-hop IP addresses. Used without parameters, **show ipnet** displays the information once.

**Syntax**
**show ipnet** [[**rr=**]*RefreshRate*]

**Parameters**
**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**show ipstats**
Displays IP statistics. Used without parameters, **show ipstats** displays the statistics once.

**Syntax**
**show ipstats** [[**rr=**]*RefreshRate*]

**Parameters**
**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**show joins**
Displays IP multicast groups that have been joined for the specified IP address. Used without parameters, **show joins** displays information for all IP addresses.

**Syntax**
**show joins** [[**index=**]*IPAddress*]

**Parameters**

**[ index=] *IPAddress***
Specifies an IP address of an interface.

**/?**
Displays help at the command prompt.

**Remarks**

- To obtain the IP addresses for all interfaces, review the display of the **show ipaddress** command used without parameters.

**show tcpconn**
Displays information on a specified TCP connection. Used without parameters, **show tcpconn** displays information for all TCP connections once.

**Syntax**
**show tcpconn** [[**index=**]{*LocalIPAddress* | *LocalPort* | *RemoteIPAddress* | *RemotePort*}] [[**rr=**]*RefreshRate*]

**Parameters**
**[ index=]{ *LocalIPAddress*| *LocalPort*| *RemoteIPAddress*| *RemotePort*}**
Specifies the connection about which to display information. The *LocalIPAddress* parameter specifies an IP address of an interface. The *LocalPort* parameter specifies a TCP port for a local process. The *RemoteIPAddress* parameter specifies an IP address of a remote host. The *RemotePort* parameter specifies a TCP port for a remote process.

**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the information).

**/?**
Displays help at the command prompt.

**show tcpstats**
Displays TCP statistics. Used without parameters, **show tcpstats** displays the statistics once.

**Syntax**
**show tcpstats** [[**rr=**]*RefreshRate*]

**Parameters**
**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**show udpconn**
Displays information about the UDP ports used for each IP address. Used without parameters, **show udpconn** displays UDP port information for all IP addresses once.

**Syntax**
**show udpconn** [[**index=**]{*LocalIPAddress* | *LocalPort*}] [[**rr=**]*RefreshRate*]

**Parameters**
**[ index=]{ *LocalIPAddress*| *LocalPort*}**
Specifies the connection about which to display information. The *LocalIPAddress* parameter specifies an IP address of an interface. The *LocalPort* parameter specifies a UDP port for a local process.

**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**show udpstats**
Displays UDP statistics. Used without parameters, **show udpstats** displays the statistics once.

**Syntax**
**show udpstats** [[**rr=**]*RefreshRate*]

**Parameters**

**[ rr=] *RefreshRate***
Specifies the refresh rate (the number of seconds between refreshing the display of the statistics).

**/?**
Displays help at the command prompt.

**show config**
Displays IP address and other configuration information for a specified interface. Used without parameters, **show config** displays configuration information for all interfaces.

**Syntax**
**show config** [[**name=**]*InterfaceName*]

**Parameters**
**[ name=] *InterfaceName***
Specifies the name of the interface for which you want to display configuration information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**/?**
Displays help at the command prompt.

**show offload**
Displays the tasks that can be performed by the network adapter for the specified interface corresponding to installed network hardware. Used without parameters, **show offload** displays offload information for all interfaces corresponding to installed network hardware.

**Syntax**
**show offload** [[**name=**]*InterfaceName* ]

**Parameters**
**[ name=] *InterfaceName***
Specifies the name of the interface for which you want to display offload information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**/?**
Displays help at the command prompt.

**delete arpcache**
Removes the entries in the Address Resolution Protocol (ARP) cache for a specified interface. Used without parameters, **delete arpcache** removes the entries in the ARP caches of all interfaces.

**Syntax**
**delete arpcache** [[**name=**]*InterfaceName*]

**Parameters**
**[ name=] *InterfaceName***
Specifies the name of the interface for which you want to remove the ARP cache entries. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**/?**
Displays help at the command prompt.

**dump**
Displays the current configuration as a series of Netsh Interface IP commands.

**Syntax**
**dump**

**Parameters**
none

**Remarks**

- To create a configuration script file, redirect the output of this command to a file.

**Netsh Interface IP example**

The following command configures the interface named **Local Area Connection** with the static IP address 10.0.5.99, the subnet mask of 255.255.255.0, and a default gateway of 10.0.5.1:

```
set address name="Local Area Connection" source=static addr=10.0.5.99 mask=255.255.255.0 gateway=10.0.5.1
gwmetric=1
```

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh commands for Interface IPv6

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for Interface IPv6**
The Netsh commands for Interface IPv6 provide a command-line tool that you can use to query and configure IPv6 interfaces, address, caches, and routes.

In addition, the Interface IPv6 context of **netsh** has a subcontext for 6to4. You can use the commands in the **netsh interface IPv6 6to4** context to configure or display the configuration of the 6to4 service on either a 6to4 host or a 6to4 router.

You can run these commands from the Windows Server™ 2003 family command prompt or from the command prompt for the **netsh interface IPv6** context. For these commands to work at the Windows Server™ 2003 family command prompt, you must type **netsh interface ipv6** before typing commands and parameters as they appear in the syntax below. There might be functional differences between **netsh** context commands on Windows 2000 and the Windows Server™ 2003 family.

To view help for a command at the command prompt, type *CommandName***/?**, where *CommandName* is the name of the command.

For more information about **netsh**, see Netsh overview and Enter a netsh context.

To view the command syntax, click a command:

- 6to4
- add 6over4tunnel
- add address
- add dns
- add prefixpolicy
- add route
- add v6v4tunnel
- delete address
- delete destinationcache
- delete dns
- delete interface
- delete neighbors
- delete prefixpolicy
- delete route
- dump
- install
- isatap

- renew
- reset
- set address
- set global
- set interface
- set mobility
- set prefixpolicy
- set privacy
- set route
- set state
- show address
- show bindingcacheentries
- show destinationcache
- show dns
- show global
- show interface
- show joins
- show mobility
- show neighbors
- show prefixpolicy
- show privacy
- show routes
- show siteprefixes
- uninstall

**6to4**
Specifies that the **6to4** context of **netsh interface IPv6 6to4** is used.

**Syntax**
**6to4**

**add 6over4tunnel**
Creates a 6over4 interface using the specified IPv4 address.

**Syntax**

**add 6over4tunnel** [[**interface=**]*String*] [**localaddress=**]*IPv4Address* [[**store=**]{**active** | **persistent**}]

**Parameters**

**[[ interface=] *String*]**
Specifies an interface name or index.

**[ localaddress=] *IPv4Address***
Required. Specifies the IPv4 address that is encapsulated.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**

This example command creates a 6over4 interface using the IPv4 address 10.1.1.1 on the interface named "Private."

**add 6over4tunnel "Private" 10.1.1.1**

**add address**

Adds an IPv6 address to a specified interface. Time values can be expressed in days (d), hours (h), minutes (m), and seconds (s). For example, 2d represents two days.

**Syntax**

**add address** [[**interface=**]*String*] [**address=**]*IPv6Address* [[**type=**]{**unicast** | **anycast**}] [[**validlifetime=**]{*Integer* | **infinite**}] [[**preferredlifetime=**]{*Integer* | **infinite**}] [[**store=**]{**active** | **persistent**}]

**Parameters**

**[[ interface=] *String*]**
Specifies an interface name or index.

**[ address=] *IPv6Address***
Required. Specifies the IPv6 address to add.

**[[ type=]{ unicast| anycast}]**
Specifies whether a unicast address (**unicast**) or an anycast address (**anycast**) is added. The default selection is **unicast**.

**[[ validlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the address is valid. The default value is **infinite**.

**[[ preferredlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the address is preferred. The default value is **infinite**.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**

This example command adds the IPv6 address FE80::2 to the interface named "Private."

**add address "Private" FE80::2**

**add dns**

Adds a new DNS server IP address to the statically-configured list of DNS servers for the specified interface.

**Syntax**

**add dns** [**interface=**]*String* [**address=**]*IPAddress* [[**index=**]*Integer*]

**Parameters**

**[ interface=] *String***
Required. Specifies, by name, which interface will have a DNS server IP address added to its list of DNS server IP addresses.

**[ address=] *IPAddress***
Required. Specifies the IPv6 address of the DNS server to add to the list.

**[[ index=] *Integer*]**
Specifies the position on the statically-configured list in which to place the DNS server IP address specified in **address**. By default, the DNS server IP address is added to the end of the list.

**Remarks**
If an index is specified, the DNS server is placed in that position in the list.

**Examples**
In the first example command, a DNS server with the IPv6 address FEC0:0:0:FFFF::1 is added to the list of DNS server IP addresses for the interface named "Local Area Connection." In the second example, a DNS server with the IPv6 address FEC0:0:0:FFFF::2 is added at index 2 as the second server on the list of servers for the interface named "Local Area Connection".

**add dns "Local Area Connection" FEC0:0:0:FFFF::1**

**add dns "Local Area Connection" FEC0:0:0:FFFF::2 index=2**

**add prefixpolicy**
Adds a source and destination address selection policy for a specified prefix.

**Syntax**
**add prefixpolicy** [**prefix=**]*IPv6Address***/***Integer* [**precedence=**]*Integer* [**label=**]*Integer* [[**store=**]{**active** | **persistent**}]

**Parameters**
**[ prefix=] *IPv6Address/Integer***
Required. Specifies the prefix for which to add a policy in the policy table. *Integer* specifies the prefix length.

**[ precedence=] *Integer***
Required. Specifies the precedence value used for sorting destination addresses in the policy table.

**[ label=] *Integer***
Required. Specifies the label value that allows for policies that require a specific source address prefix for use with a destination address prefix.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command adds a prefix policy for prefix ::/96, with a precedence value of 3 and a label value of 4.

**add prefixpolicy ::/96 3 4**

**add route**
Adds a route for a specified prefix. Time values can be expressed in days (d), hours (h), minutes (m), and seconds (s). For example, 2d represents two days.

**Syntax**
**add route** [**prefix=**]*IPv6Address***/***Integer* [[**interface=**]*String*] [[**nexthop=**]*IPv6Address*] [[**siteprefixlength=**]*Integer*] [[**metric=**]*Integer*] [[**publish=**]{**no** | **yes** | **immortal**}] [[**validlifetime=**]{*Integer* | **infinite**}] [[**preferredlifetime=**]{*Integer* | **infinite**}] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[ prefix=] *IPv6Address/Integer***
Required. Specifies the prefix for which to add a route. *Integer* specifies the prefix length.

**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ nexthop=] *IPv6Address*]**
Specifies the gateway address, if the prefix is not on-link.

**[[ siteprefixlength=] *Integer*]**
Specifies the prefix length for the entire site, if the prefix is not on-link.

**[[ metric=] *Integer*]**
Specifies the route metric.

**[[ publish=]{ no| yes| immortal}]**
Specifies whether routes are advertised (**yes**), advertised with an infinite lifetime (**immortal**), or not advertised (**no**) in Route Advertisements. The default selection is **no**.

**[[ validlifetime=]{ *Integer*| infinite}]**

Specifies the lifetime over which the route is valid. The default value is **infinite**.

**[[ preferredlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the route is preferred. The default value is **infinite**.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command adds a route on the interface named "Internet" with a prefix of 3FFE:: and a prefix length of 16 bits (3FFE::/16). The **nexthop** value is FE80::1.

**add route 3FFE::/16 "Internet" FE80::1**

**add v6v4tunnel**
Creates an IPv6-in-IPv4 tunnel.

**Syntax**
**add v6v4tunnel** [[**interface=**]*String*] [**localaddress=**]*IPv4Address* [**remoteaddress=**]*IPv4Address* [[**neighbordiscovery=**]{**enabled** | **disabled**}] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**[ localaddress=] *IPv4Address***
Required. Specifies the IPv4 address of the local tunnel endpoint.

**[ remoteaddress=] *IPv4Address***
Required. Specifies the IPv4 address of the remote tunnel endpoint.

**[[ neighbordiscovery=]{ enabled| disabled}]**
Specifies whether Neighbor Discovery is enabled (**enabled**) or disabled (**disabled**) on the interface. The default selection is **disabled**.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command creates an IPv6-in-IPv4 tunnel between the local address 10.0.0.1 and the remote address 192.168.1.1 on the interface "Private."

**add v6v4tunnel "Private" 10.0.0.1 192.168.1.1**

**delete address**
**Syntax**
**delete address** [[**interface=**]*String*] [**address=**]*IPv6Address* [[**store=**]{**active** | **persistent**}]

Modifies an IPv6 address on a specified interface.

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**[ address=] *IPv6Address***
Required. Specifies the IPv6 address to delete.

**[[ store=]{ active| persistent}]**
Specifies whether the deletion lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command deletes the address FE80::2 from the interface named "Private".

**delete address "Private" FE80::2**

**delete destinationcache**

Clears the destination cache. If an interface is specified, clears the cache only on that interface. If an address is also specified, deletes only that destination cache entry.

**Syntax**

**delete destinationcache** [[**interface=**]*String*] [[**address=**]*IPv6Address*]

**Parameters**

**[[ interface=] *String*]**

Specifies an interface name or index.

**[[ address=] *IPv6Address*]**

Specifies the address of the destination.

**Remarks**

When no parameters are specified, all entries in the destination caches for all interfaces are deleted.

**Examples**

This example command deletes the destination cache for the interface named "Private."

**delete destinationcache "Private"**

**delete dns**

Deletes statically configured DNS server IPv6 addresses for a specific interface.

**Syntax**

**delete dns** [**interface=**]*String* [[**address=**]{*IPv6Address* | **all**}]

**Parameters**

**[ interface=] *String***

Required. Specifies the interface, by name, for which you want to remove a DNS server from the list of DNS servers.

**[[ address=]{ *IPv6Address*| all}]**

Specifies the DNS server IPv6 address to delete. If **all** is specified, all DNS server IPv6 addresses on the list for the interface are deleted.

**Examples**

In the first example command, the DNS server IPv6 address FEC0:0:0:FFFF::1 is deleted from the list of addresses for the connection named "Local Area Connection." In the second example command, all DNS server IPv6 addresses are deleted for the connection named "Local Area Connection."

**delete dns "Local Area Connection" FEC0:0:0:FFFF::1**

**delete dns "Local Area Connection" all**

**delete interface**

Deletes a specified interface from the IPv6 stack.

**Syntax**

**delete interface** [[**interface=**]*String*] [[**store=**]{**active** | **persistent**}]

**Parameters**

**[[ interface=] *String*]**

Specifies an interface name or index.

**[[ store=]{ active| persistent}]**

Specifies whether the deletion lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**

This example command deletes the interface named "Private."

**delete interface "Private"**

**delete neighbors**

Specifies that all entries in the neighbor cache are deleted. If an interface is specified, clears the cache only on that interface. If an address is also specified, deletes only that neighbor cache entry.

**Syntax**

**delete neighbors** [[**interface=**]*String*] [[**address=**]*IPv6Address*]

**Parameters**

**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ address=] *IPv6Address*]**
Specifies the address of the neighbor.

**Examples**

This example command removes all entries from the neighbor cache on the interface named "Private."

**delete neighbors "Private"**

**delete prefixpolicy**

Deletes the source and destination address selection policy for a specified prefix.

**Syntax**

**delete prefixpolicy** [**prefix=**]*IPv6Address***/***Integer* [[**store=**]{**active** | **persistent**}]

**Parameters**

**[ prefix=] *IPv6Address/Integer***
Required. Specifies the prefix (*IPv6Address*) and prefix length (*Integer*) to delete from the policy table.

**[[ store=]{ active| persistent}]**
Specifies whether the deletion lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**

This example command deletes the prefix ::/96 from the policy table.

**delete prefixpolicy ::/96**

**delete route**

Deletes an IPv6 route.

**Syntax**

**delete route** [**prefix=**]*IPv6Address***/***Integer* [[**interface=**]*String*] [[**nexthop=**]*IPv6Address*] [[**store=**]{**active** | **persistent**}]

**Parameters**

**[ prefix=] *IPv6Address/Integer***
Required. Specifies the prefix of the route to delete.

**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ nexthop=] *IPv6Address*]**
Specifies the gateway address, if the prefix is not on-link.

**[[ store=]{ active| persistent}]**
Specifies whether the deletion lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**

This example command deletes the route with the prefix 3FFE::/16 and the gateway FE80::1 from the interface named "Internet."

**delete route 3FFE::/16 "Internet" FE80::1**

**dump**

Dumps the network adapter IPv6 configuration to the command prompt window when run within the netsh context. When used in a batch file or script, output can be saved in a text file.

**Syntax**

**netsh interface ipv6 dump > [ *PathAndFileName* ]**

**Parameters**

**[ *PathAndFileName*]**
Specifies both the location where to the file is saved and the name of the destination file to which the configuration is saved.

**Remarks**

- After file output is obtained, you can use the **netsh exec** command to either configure another computer with the same IPv6 configuration or to restore the original configuration on the same computer.

- All IPv6 configuration information is saved with the dump command. For example, if an ISATAP or a 6to4 configuration is defined on an interface, the **dump** command saves these settings in the text file.

**Examples**
In the first example, the command is run manually at the **netsh interface ipv6** context of a command prompt. The IPv6 configuration is displayed in the command prompt window, and can be copied and pasted into a text file. In the second example, the **dump** command is run in a batch file, and the configuration is saved to a text file named Ipv6_conf.txt at the location C:\Temp.

**dump**

**netsh interface ipv6 dump > C:\temp\ipv6_conf.txt**

**install**
Installs IPv6.

**Syntax**
**install**

**isatap**
Specifies that the **isatap** context of **netsh interface IPv6 isatap** is used.

**Syntax**
**isatap**

**Remarks**

- Intrasite Automatic Tunnel Addressing Protocol (ISATAP) is used for communication between IPv6 and IPv4 nodes within an IPv4 site. It is described in the Internet draft titled "Intra-Site Automatic Tunnel Addressing Protocol (ISATAP)" (draft-ietf-ngtrans-isatap-*00*.txt). For more information, see IPv6 traffic between nodes on different subnets of an IPv4 internetwork.

**renew**
Restarts IPv6 interfaces.

**Syntax**
**renew** [[**interface=**]*String*]

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**Examples**
**renew "Private"**

**reset**
Resets the IPv6 configuration state.

**Syntax**
**reset**

**set address**
Modifies an IPv6 address on a specified interface. Time values can be expressed in days (d), hours (h), minutes (m), and seconds (s). For example, 2d represents two days.

**Syntax**
**set address** [[**interface=**]*String*] [**address=**]*IPv6Address* [[**type=**]{**unicast** | **anycast**}] [[**validlifetime=**]{*Integer* | **infinite**}] [[**preferredlifetime=**]{*Integer* | **infinite**}] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**[ address=] *IPv6Address***
Required. Specifies the IPv6 address to modify.

**[[ type=]{ unicast| anycast}]**
Specifies whether the address is marked as a unicast address (**unicast**) or as an anycast address (**anycast**). The default selection is **unicast**.

**[[ validlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the address is valid. The default value is **infinite**.

**[[ preferredlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the address is preferred. The default value is **infinite**.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command sets the address FE80::2 on the interface named "Private" as an anycast address.

**set address "Private" FE80::2 anycast**

**set global**
Modifies global configuration parameters.

**Syntax**
**set global** [[**defaultcurhoplimit=**]*Integer*] [**neighborcachelimit=**]*Integer* [[**routecachelimit=**]*Integer*] [[**reassemblylimit=**]*Integer*] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ defaultcurhoplimit=] *Integer*]**
Specifies the default hop limit of packets sent.

**[ neighborcachelimit=] *Integer***
Required. Specifies the maximum number of neighbor cache entries.

**[[ routecachelimit=] *Integer*]**
Specifies the maximum number of route cache entries.

**[[ reassemblylimit=] *Integer*]**
Specifies the maximum size of the reassembly buffer.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command sets global parameters for all IPv6-enabled interfaces on the computer. The default hop limit is set to 32, the maximum number of neighbor cache entries is set to 100, and the maximum number of route cache entries is 100,000.

**set global 32 100 100000**

**set interface**
Modifies interface configuration parameters.

**Syntax**
**set interface** [[**interface=**]*String*] [[**forwarding=**]{**enabled** | **disabled**}] [[**advertise=**]{**enabled** | **disabled**}] [[**mtu=**]*Integer*] [[**siteid=**]*Integer*] [[**metric=**]*Integer*] [[**firewall=**]{**enabled** | **disabled**}] [[**siteprefixlength=**]*Integer*] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ forwarding=]{ enabled| disabled}]**
Specifies whether packets arriving on this interface can be forwarded to other interfaces. The default selection is **disabled**.

**[[ advertise=]{ enabled| disabled}]**

Specifies whether Router Advertisements are sent on this interface. The default selection is **disabled**.

**[[ mtu=]** ***Integer*****]**
Specifies the MTU of this interface. The default MTU is the natural MTU of the link.

**[[ siteid=]** ***Integer*****]**
Specifies the site scope zone identifier.

**[[ metric=]** ***Integer*****]**
Specifies the interface metric, which is added to route metrics for all routes over the interface.

**[[ firewall=]{ enabled| disabled}]**
Specifies whether to operate in firewall mode.

**[[ siteprefixlength=]** ***Integer*****]**
Specifies the default length of the global prefix for the entire site.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command sets the interface with the name "Private," with a siteid of 2 and a metric of 2. All other parameter values are left at the default values.

**set interface "Private" siteid=2 metric=2**

**set mobility**
Modifies mobility configuration parameters.

**Syntax**
**set mobility** [[**security=**]{**enabled** | **disabled**}] [[**bindingcachelimit=**]*Integer*] [[**correspondentnode=**]**enabled** | **disabled**] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ security=]{ enabled| disabled}]**
Specifies whether binding updates must be secured.

**[[ bindingcachelimit=]** ***Integer*****]**
Specifies the maximum number of binding cache entries.

**[[ correspondentnode=] enabled| disabled]**
Specifies whether Correspondent Node functionality is set to **enabled** or the default of **disabled**.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
**set mobility security=disabled bindingcachelimit=1000 corr=enabled**

**set prefixpolicy**
Modifies a source and destination address selection policy for a specified prefix.

**Syntax**
**set prefixpolicy** [**prefix=**]*IPv6Address***/***Integer* [**precedence=**]*Integer* [**label=**]*Integer* [[**store=**]{**active** | **persistent**}]

**Parameters**
**[ prefix=]** ***IPv6Address/Integer***
Required. Specifies the prefix for which to add a policy in the policy table. *Integer* specifies the prefix length.

**[ precedence=]** ***Integer***
Required. Specifies the precedence value used for sorting destination addresses in the policy table.

**[ label=]** ***Integer***
Required. Specifies the label value that allows for policies that require a specific source address prefix for use with a destination address prefix.

**[[ store=]{ active| persistent}]**

Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

#### Examples

This example command sets a policy in the policy table for the prefix ::/96, with a precedence value of 3 and a label value of 4.

**set prefixpolicy ::/96 3 4**

### set privacy

Modifies parameters related to temporary address generation. If **randomtime=** is specified, **maxrandomtime=** is not used. Time values can be expressed in days (d), hours (h), minutes (m), and seconds (s). For example, 2d represents two days.

#### Syntax

**set privacy** [[**state=**]{**enabled** | **disabled**}] [[**maxdadattempts=**]*Integer*] [[**maxvalidlifetime=**]*Integer*] [[**maxpreferredlifetime=**]*Integer*] [[**regeneratetime=**]*Integer*] [[**maxrandomtime=**]*Integer*] [[**randomtime=**]*Integer*] [[**store=**]{**active** | **persistent**}]

#### Parameters

**[[ state=]{ enabled| disabled}]**
Specifies whether temporary addresses are enabled.

**[[ maxdadattempts=] *Integer*]**
Specifies the number of duplicate address detection attempts made. The default value is 5.

**[[ maxvalidlifetime=] *Integer*]**
Specifies the maximum lifetime over which a temporary address is valid. The default value is 7d (seven days).

**[[ maxpreferredlifetime=] *Integer*]**
Specifies the maximum lifetime over which an anonymous is preferred. The default value is 1d (one day).

**[[ regeneratetime=] *Integer*]**
Specifies the duration of time that elapses when a new address is generated prior to deprecating a temporary address. The default value is 5s (five seconds).

**[[ maxrandomtime=] *Integer*]**
Specifies the upper limit to use when computing a random delay at boot. The default value is 10m (ten minutes).

**[[ randomtime=] *Integer*]**
Specifies a time value to use, instead of a value generated at boot.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

### set route

Modifies route parameters. Time values can be expressed in days (d), hours (h), minutes (m), and seconds (s). For example, 2d represents two days.

#### Syntax

**set route** [**prefix=**]*IPv6Address***/***Integer* [[**interface=**]*String*] [[**nexthop=**]*IPv6Address*] [[**siteprefixlength=**]*Integer*] [[**metric=**]*Integer*] [**publish=**]{**no** | **yes** | **immortal**}] [[**validlifetime=**]{*Integer* | **infinite**}] [[**preferredlifetime=**]{*Integer* | **infinite**}] [[**store=**]{**active** | **persistent**}]

#### Parameters

**[ prefix=] *IPv6Address/Integer***
Required. Specifies the prefix (*IPv6Address*) and prefix length (*Integer*) of the route to modify.

**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ nexthop=] *IPv6Address*]**
Specifies the gateway address, if the prefix is not on-link.

**[[ siteprefixlength=] *Integer*]**
Specifies the prefix length for the entire site, if the prefix is not on-link.

**[[ metric=] *Integer*]**
Specifies the route metric.

**[[ publish=]{ no| yes| immortal}]**
Specifies whether routes are advertised (**yes**), advertised with an infinite lifetime (**immortal**), or not advertised (**no**) in Route Advertisements. The default selection is **no**.

**[[ validlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the route is valid. The default value is **infinite**.

**[[ preferredlifetime=]{ *Integer*| infinite}]**
Specifies the lifetime over which the route is preferred. The default value is **infinite**.

**[[ store=]{ active| persistent}]**
Specifies whether the change lasts only until the next boot (**active**) or is persistent (**persistent**). The default selection is **persistent**.

**Examples**
This example command sets a route on the interface named "Internet." The route prefix is 3FFE::, and has a length of 16 bits. The gateway address, defined by the **nexthop=** parameter, is FE80::1.

**set route 3FFE::/16 "Internet" FE80::1**

**set state**
Enables or disables IPv4 compatibility. The default value for all parameters is disabled.

**Syntax**
**set state** [[**6over4=**]{**enabled** | **disabled** | **default**}] [[**v4compat=**]{**enabled** | **disabled** | **default**}]

**Parameters**
**[[6over4=]{enabled| disabled| default}]**
Specifies whether 6over4 interfaces are created. To both disable and delete 6over4 compatible interfaces, specify **default**. To disable 6over4 compatible interfaces without deleting them, specify **disabled**.

**[[ v4compat=]{ enabled| disabled| default}]**
Specifies whether IPv4 compatible interfaces are created. To both disable and delete IPv4 compatible interfaces, specify **default**. To disable IPv4 compatible interfaces without deleting them, specify **disabled**.

**Examples**
In the first example command, IPv4-compatible addresses are disabled, and any previously existing interfaces are deleted. In the second example command, IPv4-compatible addresses are enabled

**set state default**

**set state 6over4=disabled v4compat=enabled**

**show address**
Displays all IPv6 addresses, or all addresses on a specified interface.

**Syntax**
**show address** [[**interface=**]*String*] [[**level=**]{**normal** | **verbose**}] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ level=]{ normal| verbose}]**
Specifies whether one line per interface is displayed (**normal**) or additional information is displayed for each interface (**verbose**). When no interface is specified, the default selection is **normal**. When an interface is specified, the default selection is **verbose**.

**[[ store=]{ active| persistent}]**
Specifies whether active (**active**) or persistent (**persistent**) addresses are displayed. The default selection is **active**.

**show bindingcacheentries**
Displays all binding cache entries.

**Syntax**
**show bindingcacheentries**

**show destinationcache**
Displays destination cache entries. If an interface is specified, displays the cache only on that interface. If an address is also

specified, displays only that destination cache entry.

**Syntax**

**show destinationcache** [[**interface=**]*String*] [[**address=**]*IPv6Address*]

**Parameters**

**[[ interface=] *String*]**

Specifies an interface name or index.

**[[ address=] *IPv6Address*]**

Specifies the address of the destination.

**show dns**

Displays the DNS server configuration for a specific interface or interfaces.

**Syntax**

**show dns** [[**interface=**]*String*]

**Parameters**

**[[ interface=] *String*]**

Specifies the interface, by name, for which you want to display configured DNS server IPv6 addresses. If no interface is specified, servers for all interfaces are displayed.

**Examples**

In this example command, DNS server IPv6 addresses configured on the "Local Area Connection" interface are displayed.

**show dns "Local Area Connection"**

**show global**

Displays global configuration parameters.

**Syntax**

**show global** [[**store=**]{**active** | **persistent**}]

**Parameters**

**[[ store=]{ active| persistent}]**

Specifies whether active (**active**) or persistent (**persistent**) information is displayed. The default selection is **active**.

**show interface**

Displays information about all interfaces, or about a specified interface.

**Syntax**

**show interface** [[**interface=**]*String*] [[**level=**]{**normal** | **verbose**}] [[**store=**]{**active** | **persistent**}]

**Parameters**

**[[ interface=] *String*]**

Specifies an interface name or index.

**[[ level=]{ normal| verbose}]**

Specifies whether one line per interface is displayed (**normal**) or additional information is displayed for each interface (**verbose**). When no interface is specified, the default selection is **normal**. When an interface is specified, the default selection is **verbose**.

**[[ store=]{ active| persistent}]**

Specifies whether active (**active**) or persistent (**persistent**) interfaces are displayed. The default selection is **active**.

**show joins**

Displays all IPv6 multicast addresses, or all multicast addresses on a specified interface.

**Syntax**

**show joins** [[**interface=**]*String*] [[**level=**]{**normal** | **verbose**}]

**Parameters**

**[[ interface=] *String*]**

Specifies an interface name or index.

**[[ level=]{ normal| verbose}]**

Specifies whether one line per interface is displayed (**normal**) or additional information is displayed for each interface (**verbose**). When no interface is specified, the default selection is **normal**. When an interface is specified, the default

selection is **verbose**.

**show mobility**
Displays mobility configuration parameters.

**Syntax**
**show mobility** [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ store=]{ active| persistent}]**
Specifies whether active (**active**) or persistent (**persistent**) information is displayed. The default selection is **active**.

**show neighbors**
Displays neighbor cache entries. If an interface is specified, displays only the cache on that interface. If an address is also specified, displays only that neighbor cache entry.

**Syntax**
show neighbors [[**interface=**]*String*] [[**address=**]*IPv6Address*]

**Parameters**
**[[ interface=] *String*]**
Specifies an interface name or index.

**[[ address=] *IPv6Address*]**
Specifies the address of the neighbor.

**show prefixpolicy**
Displays prefix policy table entries used in source and destination address selection.

**Syntax**
**show prefixpolicy** [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ store=]{ active| persistent}]**
Specifies whether active (**active**) or persistent (**persistent**) information is displayed. The default selection is **active**.

**show privacy**
Displays privacy configuration parameters.

**Syntax**
**show privacy** [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ store=]{ active| persistent}]**
Specifies whether active (**active**) or persistent (**persistent**) information is displayed. The default selection is **active**.

**show routes**
Displays route table entries.

**Syntax**
**show routes** [[**level=**]{**normal** | **verbose**}] [[**store=**]{**active** | **persistent**}]

**Parameters**
**[[ level=]{ normal| verbose}]**
Specifies whether only normal routes (**normal**) or routes used for loopback (**verbose**) are displayed. The default selection is **normal**.

**[[ store=]{ active| persistent}]**
Specifies whether active (**active**) or persistent (**persistent**) routes are displayed. The default selection is **active**.

**show siteprefixes**
Displays the site prefix table.

**Syntax**
**show siteprefixes**

**uninstall**
Uninstalls IPv6.

**Syntax**

**uninstall**

**Netsh interface IPv6 6to4**

You can use the following commands in the **netsh interface IPv6 6to4** context to display the configuration of or configure the 6to4 service on either a 6to4 host or a 6to4 router. For more information about using the 6to4 service, see IPv6 traffic between nodes in different sites across the Internet (6to4).

For more information about Netsh, see Netsh overview.

- set interface
- show interface
- set relay
- show relay
- set routing
- show routing
- set state
- show state
- reset

**set interface**

Configures the 6to4 service on an interface.

**Syntax**

**set interface** [**name=**] *InterfaceName* [[**routing=**] {**enabled** | **disabled** | **default**}]

**Parameters**

**[ name=] *InterfaceName***

Required. Specifies the name of the interface for which you want to set 6to4 service configuration. *InterfaceName* must match the name of the interface specified in Network Connections. If *InterfaceName* contains any spaces, it must be enclosed in quotes.

**[[ routing=] { enabled| disabled| default}]**

Specifies whether the forwarding of 6to4 packets received on the interface is enabled, disabled, or set to its default value.

**Remarks**

- This command enables, disables, or sets to default the routing behavior of the 6to4 service on a specified interface.

The default setting for the **routing=** parameter is **enabled**, which enables routing on private interfaces if Internet Connection Sharing (ICS) is used.

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**show interface**

Displays the 6to4 service routing configuration on all interfaces, or on a specified interface.

**Syntax**

**show interface** [[**name=**] *InterfaceName*]

**Parameters**

**[[ name=] *InterfaceName*]**

Specifies the name of the interface for which you want to display the 6to4 service configuration. *InterfaceName* must match the name of the interface specified in Network Connections. If *InterfaceName* contains any spaces, it must be enclosed in quotes.

**Remarks**

- If an interface name is not specified, the 6to4 configuration for all interfaces is displayed.

**set relay**

Configures the name of the 6to4 relay router for the 6to4 service. Additionally, specifies how often the name is resolved and the state of the relay component for the 6to4 service.

**Syntax**

**set relay** [[**name=**] {*RelayDNSName* | **default**}] [[**state=**] {**enabled** | **disabled** | **automatic** | **default**}] [[**interval=**] {*ResInterval* | **default**}]

**Parameters**

**[[ name=] { *RelayDNSName*| default}]**

Specifies either the fully qualified domain name (FQDN) of a 6to4 relay router on the IPv4 Internet (*RelayDNSName*), or sets the relay name to its default value of 6to4.ipv6.microsoft.com (**default**).

**[[ state=] { enabled| disabled| automatic| default}]**

Specifies whether the state of the relay component for the 6to4 service is enabled, disabled, automatically enabled if a public IPv4 address is configured, or set to its default value.

**[[ interval=] { *ResInterval*| default}]**

Specifies how often the name of the relay router is resolved in minutes (*ResInterval*) or sets the resolution interval to its default value of 1440 minutes (**default**).

**Remarks**

- The 6to4 relay router is a router that provides an access point between the IPv4 Internet and the 6bone (the native IPv6 portion of the Internet). In order to access 6bone resources from a 6to4 router, the 6to4 router encapsulates 6to4 traffic with an IPv4 header and sends it to the IPv4 address of the 6to4 relay router. The 6to4 relay router removes the IPv4 header and forwards the traffic to the 6bone. For return traffic, the 6to4 relay router encapsulates IPv6 traffic and sends it to the 6to4 router at the 6to4 host's site.

- The default name of the 6to4 relay router is 6to4.ipv6.microsoft.com.

- The default state is **automatic**, which enables the forwarding of native IPv6 traffic to a relay router when a public IPv4 address is assigned to any interface.

- The default resolution interval is 1440 minutes (once each day).

**show relay**

Displays the relay router configuration for the 6to4 service.

**Syntax**

**show relay**

**set routing**

Sets both the state of routing and the inclusion of site-local address prefixes in Router Advertisements that are sent by the 6to4 router.

**Syntax**

**set routing** [[**routing=**] {**enabled** | **disabled** | **automatic** | **default**}] [[**sitelocals=**] {**enabled** | **disabled** | **default**}]

**Parameters**

**[[ routing=] { enabled| disabled| automatic| default}]**

Specifies whether the state of routing on a 6to4 router is enabled, disabled, automatically enabled if Internet Connection Sharing (ICS) is enabled, or set to its default value.

**[[ sitelocals=] { enabled| disabled| default}]**
Specifies whether the advertising of site-local address prefixes, in addition to 6to4 address prefixes, is enabled, disabled, or set to its default value.

**Remarks**

- The default setting for the **routing=** parameter is **automatic**, which enables routing on private interfaces when ICS is used.
- The default setting for the **sitelocals=** parameter is **enabled**, which enables the advertising of site-local prefixes when site-local addresses are configured on private interfaces.

### Note

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**show routing**
Displays the routing configuration of the 6to4 service.

**Syntax**
**show routing**

**set state**
Configures the state of the 6to4 service.

**Syntax**
**set state** [[**state=**] {**enabled** | **disabled** | **default**}] [[**undoonstop=**] {**enabled** | **disabled** | **default**}] [[**6over4=**] {**enabled** | **disabled** | **default**}]

**Parameters**
**[[ state=] { enabled| disabled| default}]**
Specifies whether the state of the 6to4 service is enabled, disabled, or set to its default value.

**[[ undoonstop=] { enabled| disabled| default}]**
Specifies whether the reversal of all automatic configuration that has been performed by the 6to4 service occurs when the service stops is enabled, disabled, or set to its default value.

**Remarks**

- The default setting for the **state=** parameter is **enabled**, which enables the 6to4 service.
- The default setting for the **undoonstop=** parameter is **enabled**, which reverses all automatic configuration performed by the 6to4 service when the service is stopped.

**show state**
Displays the state of the 6to4 service.

**Syntax**
**show state**

**reset**
Resets the 6to4 service.

**Syntax**
**reset**

**Netsh interface ipv6 isatap**
Intra-Site Automatic Tunnel Addressing Protocol (ISATAP) is an address assignment and tunneling mechanism for communication between IPv6/IPv4 nodes within an IPv4 site. It is described in the Internet draft titled "Intra-Site Automatic Tunnel Addressing Protocol (ISATAP)" (draft-ietf-ngtrans-isatap-*00*.txt). You can use the following commands to configure the ISATAP router.

- set router
- show router

**set router**
Specifies the Intra-Site Automatic Tunneling Address Protocol (ISATAP) router information, including router name, state, and resolution interval.

**Syntax**
**set router** [[**name=**]{*String* | **default**}] [[**state=**]{**Enabled** | **Disabled** | **Default**}] [[**interval**]=*Integer*]

**Parameters**
**[[ name=]{ *String*| default}]**
Specifies whether the router is named with a string. If **default** is specified, the system reverts to using the default name.

**[[ state=]{ Enabled| Disabled| Default}]**
Specifies whether the ISATAP router relays packets between subnets.

**[[ interval]= *Integer*]**
Specifies the router resolution interval, in minutes. The default interval is 1440 (24 hours).

**Examples**
The following example command sets the router name to isatap, enables the router, and sets the resolution interval to 120 minutes:

**set router isatap enabled 120**

**show router**
Displays configuration information for the ISATAP router.

**Syntax**
**show router**

**Remarks**
This command displays the router name, the relay state, and the resolution interval.

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh commands for Interface Portproxy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for Interface Portproxy**
The Netsh Interface Portproxy commands provide a command-line tool for use in administering servers that act as proxies between IPv4 and IPv6 networks and applications. You can use these commands to establish proxy service in the following ways:

- IPv4-configured computer and application messages sent to other IPv4-configured computers and applications.
- IPv4-configured computer and application messages sent to IPv6-configured computers and applications.
- IPv6-configured computer and application messages sent to IPv4-configured computers and applications.
- IPv6-configured computer and application messages sent to other IPv6-configured computers and applications.

When writing batch files or scripts using these commands, each command must be preceded by **netsh interface portproxy**. For example, when using the **delete v4tov6** command to specify that the portproxy server delete an IPv4 port and address from the list of IPv4 addresses for which the server listens, the batch file or script must use the following syntax:

**netsh interface portproxy delete v4tov6 listenport=** {*Integer* | *ServiceName*} [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

You can run these commands from the Windows Server 2003 family command prompt or from the command prompt for the Netsh interface portproxy context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh interface portproxy** before typing commands and parameters as they appear in the syntax below. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

For more information about **Netsh**, see Netsh overview and Enter a netsh context.

#### add v4tov4

Specifies that the portproxy server listen for messages sent to a specific port and IPv4 address, and maps a port and IPv4 address to which to send the messages received after establishing a separate TCP connection.

#### Syntax

**add v4tov4 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv4Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

#### Parameters

**listenport**

Required. Specifies the IPv4 port, by port number or service name, on which to listen.

**connectaddress**

Specifies the IPv4 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**

Specifies the IPv4 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**

Specifies the IPv4 address for which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**

Specifies the protocol to use. Currently, only Transmission Control Protocol (TCP) is supported.

**/?**

Displays help at the command prompt.

#### add v4tov6

Specifies that the portproxy server listen for messages sent to a specific port and IPv4 address, and maps a port and IPv6 address to which to send the messages received after establishing a separate TCP connection.

#### Syntax

**add v4tov6 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv6Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

#### Parameters

**listenport**

Required. Specifies the IPv4 port, by port number or service name, on which to listen.

**connectaddress**

Specifies the IPv6 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**

Specifies the IPv6 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**

Specifies the IPv4 address on which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

#### add v6tov4

Specifies that the portproxy server listen for messages sent to a specific port and IPv6 address, and maps a port and IPv4 address to which to send the messages received after establishing a separate TCP connection.

##### Syntax

**add v6tov4 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv4Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv6Address*| *HostName*}] [[**protocol=**]**tcp**]

##### Parameters

**listenport**
Required. Specifies the IPv6 port, by port number or service name, on which to listen.

**connectaddress**
Specifies the IPv4 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**
Specifies the IPv4 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**
Specifies the IPv6 address on which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

#### add v6tov6

Specifies that the portproxy server listen for messages sent to a specific port and IPv6 address, and maps a port and IPv6 address to which to send the messages received after establishing a separate TCP connection.

##### Syntax

**add v6tov6 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv6Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv6Address*| *HostName*}] [[**protocol=**]**tcp**]

##### Parameters

**listenport**
Required. Specifies the IPv6 port, by port number or service name, on which to listen.

**connectaddress**
Specifies the IPv6 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**
Specifies the IPv6 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**
Specifies the IPv6 address on which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

#### delete v4tov4

Specifies that the portproxy server delete an IPv4 address from the list of IPv4 ports and addresses for which the server listens.

##### Syntax

**delete v4tov4 listenport=** {*Integer* | *ServiceName*} [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

##### Parameters

**listenport**

Required. Specifies the IPv4 port to delete.

**listenaddress**

Specifies the IPv4 address to delete. If an address is not specified, the default is the local computer.

**protocol**

Specifies the protocol to use. Currently only TCP is supported.

**/?**

Displays help at the command prompt.

#### delete v4tov6

Specifies that the portproxy server delete an IPv4 port and address from the list of IPv4 addresses for which the server listens.

##### Syntax

**delete v4tov6 listenport=** {*Integer* | *ServiceName*} [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

##### Parameters

**listenport**

Required. Specifies the IPv4 port to delete.

**listenaddress**

Specifies the IPv4 address to delete. If an address is not specified, the default is the local computer.

**protocol**

Specifies the protocol to use. Currently only TCP is supported.

**/?**

Displays help at the command prompt.

#### delete v6tov4

Specifies that the portproxy server delete an IPv6 port and address from the list of IPv6 addresses for which the server listens.

##### Syntax

**delete v6tov4 listenport=** {*Integer* | *ServiceName*} [[**listenaddress=**] {*IPv6Address*| *HostName*}] [[**protocol=**]**tcp**]

##### Parameters

**listenport**

Required. Specifies the IPv6 port to delete.

**listenaddress**

Specifies the IPv6 address to delete. If an address is not specified, the default is the local computer.

**protocol**

Specifies the protocol to use. Currently only TCP is supported.

**/?**

Displays help at the command prompt.

#### delete v6tov6

Specifies that the portproxy server delete an IPv6 address from the list of IPv6 addresses for which the server listens.

##### Syntax

**delete v6tov6 listenport=** {*Integer* | *ServiceName*} [[**listenaddress=**] {*IPv6Address*| *HostName*}] [[**protocol=**]**tcp**]

##### Parameters

**listenport**

Required. Specifies the IPv6 port to delete.

**listenaddress**

Specifies the IPv6 address to delete. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

#### reset
Resets the IPv6 configuration state.

#### Syntax
**reset**

#### set v4tov4
Modifies the parameter values of an existing entry on the portproxy server created with the **add v4tov4** command, or adds a new entry to the list that maps port/address pairs.

#### Syntax
**set v4tov4 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv4Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

#### Parameters
**listenport**
Required. Specifies the IPv4 port, by port number or service name, on which to listen.

**connectaddress**
Specifies the IPv4 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**
Specifies the IPv4 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**
Specifies the IPv4 address for which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently, only Transmission Control Protocol (TCP) is supported.

**/?**
Displays help at the command prompt.

#### Remarks

- You can change any parameter values for an existing portproxy server entry. If values are not supplied, no changes are made.

#### set v4tov6
Modifies the parameter values of an existing entry on the portproxy server created with the **add v4tov6** command, or adds a new entry to the list that maps port/address pairs.

#### Syntax
**set v4tov6 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv6Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv4Address*| *HostName*}] [[**protocol=**]**tcp**]

#### Parameters
**listenport**
Required. Specifies the IPv4 port, by port number or service name, on which to listen.

**connectaddress**
Specifies the IPv6 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**
Specifies the IPv6 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**
Specifies the IPv4 address on which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

**Remarks**

- You can change any parameter values for an existing portproxy server entry. If values are not supplied, no changes are made.

**set v6tov4**
Modifies the parameter values of an existing entry on the portproxy server created with the **add v6tov4** command, or adds a new entry to the list that maps port/address pairs.

**Syntax**
**set v6tov4 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv4Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv6Address*| *HostName*}] [[**protocol=**]**tcp**]

**Parameters**
**listenport**
Required. Specifies the IPv6 port, by port number or service name, on which to listen.

**connectaddress**
Specifies the IPv4 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**
Specifies the IPv4 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**
Specifies the IPv6 address on which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

**Remarks**

- You can change any parameter values for an existing portproxy server entry. If values are not supplied, no changes are made.

**set v6tov6**
Modifies the parameter values of an existing entry on the portproxy server created with the **add v6tov6** command, or adds a new entry to the list that maps port/address pairs.

**Syntax**
**set v6tov6 listenport=** {*Integer* | *ServiceName*} [[**connectaddress=**] {*IPv6Address* | *HostName*}] [[**connectport=**] {*Integer* | *ServiceName*}] [[**listenaddress=**] {*IPv6Address*| *HostName*}] [[**protocol=**]**tcp**]

**Parameters**
**listenport**
Required. Specifies the IPv6 port, by port number or service name, on which to listen.

**connectaddress**
Specifies the IPv6 address to which to connect. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If an address is not specified, the default is the local computer.

**connectport**
Specifies the IPv6 port, by port number or service name, to which to connect. If **connectport** is not specified, the default is the value of **listenport** on the local computer.

**listenaddress**
Specifies the IPv6 address on which to listen. Acceptable values are IP address, computer NetBIOS name, or computer DNS name. If you do not specify an address, the default is the local computer.

**protocol**
Specifies the protocol to use. Currently only TCP is supported.

**/?**
Displays help at the command prompt.

**Remarks**

- You can change any parameter values for an existing portproxy server entry. If values are not supplied, no changes are made.

**show all**
Displays all portproxy parameters, including port/address pairs for v4tov4, v4tov6, v6tov4, and v6tov6.

**Syntax**
**show all**

**show v4tov4**
Displays v4tov4 portproxy parameters.

**Syntax**
**show v4tov4**

**show v4tov6**
Displays v4tov6 portproxy parameters.

**Syntax**
**show v4tov6**

**show v6tov4**
Displays v6tov4 portproxy parameters.

**Syntax**
**show v6tov4**

**show v6tov6**
Displays v6tov6 portproxy parameters.

**Syntax**
**show v6tov6**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

Understanding IPv6

Command shell overview

# Netsh commands for Internet Protocol security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for Internet Protocol security (IPSec)**
The Netsh commands for Internet Protocol security (IPSec) provide an equivalent alternative to the console-based management and diagnostic capabilities provided by the IP Security Policy Management and IP Security Monitor snap-ins available in the Microsoft Management Console (MMC). By using the Netsh commands for IPSec, you can configure and view static or dynamic IPSec main mode settings, quick mode settings, rules, and configuration parameters.

Administering IPSec from the command line is especially useful when you want to:

- Script IPSec configuration.
- Extend the security and manageability of IPSec by configuring the following features, which are not available in the IP Security Policy Management snap-in: IPSec diagnostics, default traffic exemptions, strong certificate revocation list (CRL) checking, IKE (Oakley) logging, logging intervals, computer startup security, and computer startup traffic exemptions.

You can run these commands from the Windows Server™ 2003 family command prompt or from the command prompt for the **netsh ipsec** context. For these commands to work at the Windows Server™ 2003 family command prompt, you must type **netsh ipsec** before typing commands and parameters as they appear in the syntax below.

**Netsh ipsec static mode commands**
You can use the **netsh ipsec static** commands to perform the same management and monitoring tasks that you can perform by using the IP Security Policy Management and IP Security Monitor consoles. By using these commands, you can create, modify, and assign IPSec policies without immediately affecting the configuration of the active IPSec policy.

**Netsh ipsec dynamic mode commands**
You can use the **netsh ipsec dynamic** commands to display the active state of IPSec and to immediately affect the configuration of the active IPsec policy. These commands directly configure the security policy database (SPD). Changes that you make to an IPSec policy while using these commands take effect only while the IPSec service is running. If the IPSec service is stopped, the dynamic policy settings are discarded. Although most of these commands take effect immediately, several configuration commands still require you to restart the IPSec service or restart the computer before they take effect. For more information about these commands, see the syntax descriptions for the **netsh ipsec dynamic set config** commands.

### Caution

- Because the IPSec Policy Agent does not interpret the **netsh ipsec dynamic** commands, you must be knowledgeable in the application of IKE main mode and quick mode policies to use these commands effectively. Exercise caution when using these commands, because it is possible to create invalid IPSec policy configurations without warning.

### Notes

- The Netsh commands for IPSec can only be used to configure IPSec policies on computers running members of the Windows Server™ 2003 family.

  To use the command line to configure IPSec policies on computers running Windows XP, use Ipseccmd.exe, which is provided on the Windows XPCD, in the \Support\Tools folder. To use the command line to configure IPSec policies on computers running Windows 2000, use Ipsecpol.exe, which is provided with the *Windows 2000 Server Resource Kit*.
- For more information about **netsh**, see Netsh overview and Enter a netsh context.
- For more information about Netsh commands, see The Netsh Command-Line Utility.

**Netsh ipsec**
The following commands are available at the **ipsec**> prompt, which is rooted within the netsh environment.

**Note**

- Although the **dump** command is available at the **ipsec**> prompt, it is not functional.

To view the command syntax, click a command:

- static
- dynamic

**static**
Switches to the static context.

**Syntax**
**static**

**Parameters**
none

**dynamic**
Switches to the dynamic context.

**Syntax**
**dynamic**

**Parameters**
none

**Netsh ipsec static**
The following commands are available at the **ipsec static**> prompt, which is rooted within the netsh environment.

To view the command syntax, click a command:

- add filter
- add filteraction
- add filterlist
- add policy
- add rule
- delete all
- delete filter
- delete filteraction
- delete filterlist
- delete policy
- delete rule
- exportpolicy
- importpolicy
- restorepolicyexamples

- set defaultrule
- set filteraction
- set filterlist
- set policy
- set rule
- set store
- show all
- show filteraction
- show filterlist
- show gpoassignedpolicy
- show policy
- show rule

**add filter**
Adds a filter to the specified filter list.

**Syntax**
**add filter filterlist= srcaddr= dstaddr=** [**description=**][**protocol=**][**mirrored=**] [**srcmask=**][**dstmask=**][**srcport=**] [**dstport=**]

**Parameters**
**filterlist=** ***String***
Required. Specifies the name of the filter list to which the filter is added. Each filter defines a set of inbound or outbound network traffic to be secured.

**srcaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**
Required. Specifies the source IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**dstaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**
Required. Specifies the destination IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ description=*String*]**
Provides information about the IP filter.

**[ protocol={ ANY| ICMP| TCP| UDP| RAW|** ***Integer*** **}]**
Specifies the IP protocol if, in addition to addressing information, you want to filter a specific IP protocol. The default value is **ANY**, meaning all protocols are used for the filter.

**[ mirrored={ yes| no}]**
Specifies whether to create a mirrored filter. Use **yes** to create two filters based on the filter settings--one for traffic to the destination and one for traffic from the destination. The default value is **yes**.

**[ srcmask={** ***Mask*****|** ***Prefix*****}]**
Specifies the source address subnet mask or the prefix of the packets to be filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={** ***Mask*****|** ***Prefix*****}**

Specifies the destination address subnet mask or the prefix value of the packets to be filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ srcport=*Port*]**
Specifies the source port number of the packets to be filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent from any port are filtered. The default is any.

**[ dstport=*Port*]**
Specifies the destination port number of the packets to be filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent to any port are filtered. The default is any.

**Remarks**

- If a filter list does not exist, it is created.
- Do not create a filter list with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec filter lists (for example, **delete filterlist all**).
- To filter any packets sent from or to the computer, you can use **srcaddr=Me** or **dstaddr=Me**.
- To filter packets sent from or to any computer, you can use **srcaddr=Any** or **dstaddr=Any**.
- All string parameters are case-sensitive.

**add filteraction**
Creates a filter action with the specified quick mode security methods.

**Syntax**
**add filteraction name=** [**description=**][**qmpfs=**][**inpass=**] [**soft=**][**action=**][**qmsecmethods=**]

**Parameters**
**name= *String***
Required. Specifies the name of the filter action to be created.

**[ description=*String*]**
Provides information about the filter action.

**[ qmpfs={ yes| no}]**
Specifies whether to enable session key perfect forward secrecy (PFS). If **yes** is specified, new master key material is renegotiated each time a new session key is required. The default value is **no**.

**[ inpass={ yes| no}]**
Specifies whether to allow an incoming packet that matches the configured filter list to be unsecured, but require IPSec-secured communication when replying. The default value is **no**.

**[ soft={ yes| no}]**
Specifies whether to fall back to unsecured communication with other computers that do not support IPSec, or when IPSec negotiations with an IPSec-capable computer fail. The default value is **no**.

**[ action={ permit| block| negotiate}]**
Specifies whether to permit traffic without negotiating IP security. If **permit** is specified, traffic is transmitted or received without negotiating or applying IP security. If **block** is specified, traffic is blocked. If **negotiate** is specified, IP security is used with the specified list of security methods. The default value is **negotiate**.

**[ qmsecmethods="*Neg1Neg2*"]**
Specifies one or more security methods, separated by spaces and defined by the following format:

{**ESP** [*ConfAlg*,*AuthAlg*]**:***k/s* | **AH** [*HashAlg*]**:***k/s* | **AH** [*HashAlg*+**ESP***ConfAlg*,*AuthAlg*]**:***k/s*}]

Where:

***ConfAlg***
Specifies the encryption algorithm. *ConfigAlg* can be **DES** (Data Encryption Standard), **3DES**, or **none**.

***AuthAlg***

Specifies the integrity algorithm. *AuthAlg* can be **MD5** (Message Digest 5), **SHA1** (Secure Hash Algorithm 1), or **none**.

***HashAlg***
Specifies the hash function. *HashAlg* can be **MD5** (Message Digest 5) or **SHA1**.

***k***
Specifies the session key lifetime in kilobytes. After the specified number of kilobytes of data is transferred, a new session key for the quick mode SA is generated. The default value is 100000 kilobytes.

***s***
Specifies the session key lifetime in seconds. The default value is 3600 seconds.

**Remarks**

- Do not create a filter action with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec filter actions (for example, **delete filteraction all**).
- If **action=permit** or **action=block** are specified, and **qmsecmethods** parameters are specified, the **qmsecmethods** parameters are not used. In addition, if **qmpfs=yes**, **inpass=yes**, or **soft=yes** are specified, those parameters are also not used.
- Session key regeneration will start based on whichever interval, seconds or kilobytes, is reached first. If you do not configure new intervals, the default intervals are used.
- If you do not specify **qmsecmethods=** (quick mode security methods), the following default values are used:
    - ESP [3DES, SHA1]:100000k/3600s
    - ESP [3DES, MD5]:100000k/3600s
- The preference order of each quick mode security method is determined by the order in which it was specified in the command.
- All string parameters are case-sensitive.

**add filterlist**
Creates an empty filter list with the specified name.

**Syntax**
**add filterlist name=** [**description=**]

**Parameters**
**name=** ***String***
Required. Specifies the name of the filter list to be created.

**[ description=*String*]**
Provides information about the filter list.

**Remarks**

- Do not create a filter list with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec filter lists (for example, **delete filterlist all**).
- All string parameters are case-sensitive.

**add policy**
Creates an IPSec policy with the specified name.

**Syntax**
**add policy name=** [**description=**][**mmpfs=**][**qmpermm=**] [**mmlifetime=**][**activatedefaultrule=**][**pollinginterval=**] [**assign=**][**mmsecmethods=**]

**Parameters**

**name= *String***
Required. Specifies the name of the IPSec policy to be created.

**[ description=*String*]**
Provides information about the IPSec policy.

**[ mmpfs={ yes| no}]**
Specifies whether to enable master key perfect forward secrecy (PFS). If **yes** is specified, main mode security SAs are reauthenticated and new master key keying material is negotiated each time session key material for a quick mode SA is required. The default value is **no**.

**[ qmpermm=*Integer*]**
Specifies the number of times that master keying material can be used to derive the session key. The default value is 0, meaning an unlimited number of quick mode SAs can be derived from the main mode SA.

**[ mmlifetime=*Integer*]**
Specifies the number of minutes after which a new master key will be generated. The default value is 480 minutes.

**[ activatedefaultrule={ yes| no}]**
Specifies whether to activate the default response rule for this IPSec policy. The default value is **yes**.

**[ pollinginterval=*Integer*]**
Specifies how often IPSec polls for changes to this policy. The default value is 180 minutes.

**[ assign={ yes| no}]**
Specifies whether to assign this IPSec policy (only one IPSec policy can be assigned) The default value is **no**.

**[ mmsecmethods="*SecMeth1SecMeth2*"]**
Specifies one or more key exchange security methods, separated by spaces and defined by the following format: *ConfAlg-HashAlg-GroupNumb*, where:

***ConfAlg***
Specifies the encryption algorithm. *ConfAlg* can be **DES** (Data Encryption Standard) or **3DES**.

***HashAlg***
Specifies the hash function. *HashAlg* can be **MD5** (Message Digest 5) or **SHA1** (Secure Hash Algorithm 1).

***GroupNum***
Specifies the Diffie-Hellman group to be used for the base keying material. *GroupNumb* can be: **1** (low, protects with 768 bits of keying material), **2** (medium, protects with 1024 bits), and **3** (high, protects with 2048 bits).

**Remarks**

- Do not create a policy with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec policies (for example, **delete policy all**).
- Because only one IPSec policy can be assigned, if a policy is currently assigned and you assign a new policy, the currently assigned policy is automatically unassigned.
- If **set store=domain** is specified (when the IPSec policy is stored in Active Directory), **assign** has no effect. To assign a policy to a Group Policy object, you must first create a policy by using the **add policy** command, and then use the **set store** command.
- If **mmpfs=yes** is specified (master key PFS is enabled), by default **qmperm** is set to 1 and not configurable, because each new session will cause the master key keying material to be renegotiated.
- If you do not specify **mmsecmethods=** (key exchange security methods), the following default values are used:
    - 3DES-SHA1-2
    - 3DES-MD5-2
    - 3DES-SHA1-3

- IPSec peers must have at least one common key exchange security method (one that uses the same settings) or negotiations will fail.

- If the number of quick mode negotiations will exceed the value set for the number of quick mode negotiations per main mode negotiation during the main mode lifetime, a new main mode negotiation occurs.

- All string parameters are case-sensitive.

**add rule**

Creates a rule that links the specified IPSec policy, filter list, and filter action with the specified authentication methods.

**Syntax**

**add rule name= policy= filterlist= filteraction=**[**tunnel=**][**conntype=**] [**activate=**][**description=**][**kerberos=**][**psk=**] [**rootca=**]

**Parameters**

**name=** ***String***

Required. Specifies the name of the IPSec rule to be created.

**policy=** ***String***

Required. Specifies the name of the IPSec policy that contains this rule.

**filterlist=** ***String***

Required. Specifies the name of the IP filter list for this rule.

**filteraction=** ***String***

Required. Specifies the name of the filter action for this rule.

**[ tunnel={** ***IPAddress*****|** ***DNSName*****}]**

Specifies the IP address or DNS name of the tunnel endpoint for tunnel mode. By default, this option is not specified and transport mode is used.

**[ conntype={ lan| dialup| all}]**

Specifies whether the rule applies only to remote access or dial-up connections or to local area network (LAN) connections, or to all connections. The default value is **all**.

**[ activate={ yes | no}]**

Specifies whether to activate this rule for the specified IPSec policy. The default value is **yes**.

**[ description=*String*]**

Provides information about the rule.

**[ kerberos={ yes | no}]**

Specifies whether to use the Kerberos V5 protocol as an authentication method.

**[ psk=*String*]**

Specifies the string of characters to use for the preshared key, if a preshared key is used as an authentication method.

**[ rootca="*String*certmap:{ yes| no} excludecaname:{ yes| no} "]**

Specifies certificate authentication options, where:

***String***

Specifies the distinguished name of the certificate, if a certificate is used as an authentication method.

**certmap:{ yes| no}**

Specifies whether to enable certificate-to-account mapping. You can enable certificate-to-account mapping to verify that the certificate is being used by a trusted computer.

**excludecaname:{ yes| no}**

Specifies whether to exclude from the certificate request the list of trusted root CA names from which a certificate is accepted.

**Remarks**

- Do not create a rule with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec rules (for example, **delete rule all**).

- You can only use Kerberos V5 authentication or certificate-to-account mapping for computers that are members of an Active Directory domain.

- Although you can use only one preshared key for authentication, you can use multiple certificates by specifying the **rootca** parameter once, for each certificate you want to use.

- All certificate authentication parameters must be contained within quotation marks. Embedded quotation marks must be replaced by a backslash followed by an apostrophe (\').

- All string parameters are case-sensitive.

- The preference order of each authentication method is determined by the order in which it was specified in the command.

- If no authentication methods are specified, dynamic defaults are used. By default, IPSec policies use Kerberos V5 authentication. If the computer has a computer certificate, any root CA to which the computer certificate chains is also used for authentication.

- If **excludecaname:yes** is specified, the list of trusted root CAs is not sent as part of the certificate request, which prevents the potential disclosure of sensitive information about the trust relationships of a computer. To enhance security for computers connected to the Internet, specify this option.

- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext.

- IPSec peers must have at least one common authentication method or communication will fail.

**delete all**
Deletes all IPSec policies, filter lists, and filter actions.

**Syntax**
**delete all**

**Parameters**
None.

**delete filter**
Deletes a filter from a filter list that matches the specified parameters.

**Syntax**
**delete filter filterlist= srcaddr= dstaddr=**[**protocol=**] [**srcmask=**][**dstmask=**][**srcport=**] [**dstport=**][**mirrored=**]

**Parameters**
**filterlist=** ***String***
Required. Specifies the name of the filter list to which the filter was added.

**srcaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**
Required. Specifies the source IP address, DNS name, or server type for the IP traffic being matched. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**dstaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**
Required. Specifies the destination IP address, DNS name, or server type for the IP traffic being matched. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ protocol={ ANY| ICMP| TCP| UDP| RAW|** ***Integer*** **}]**
Specifies the IP protocol if, in addition to addressing information, a specific IP protocol is filtered. A value of **ANY** matches filters with a protocol setting of **any**.

**[ srcmask={** ***Mask*****|** ***Prefix*****}]**

Specifies the source address subnet mask or the prefix of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={ *Mask*| *Prefix*}]**
Specifies the destination address subnet mask or the prefix value of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ srcport=*Port*]**
Specifies the source port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. A value of **0** matches filters with a source port setting of **any**.

**[ dstport=*Port*]**
Specifies the destination port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. A value of **0** matches filters with a destination port setting of **any**.

**[ mirrored={ yes| no}]**
Specifies whether a mirrored filter was created.

**Remarks**

- This command only deletes a filter that matches the exact parameters specified.
- If no optional parameters are specified, all filters that match the specified (required) parameters are deleted.
- To delete a filter that filtered any packets sent from or to the computer, you can use **srcaddr=Me** or **dstaddr=Me**.
- To delete a filter that filtered packets sent from or to any computer, you can use **srcaddr=Any** or **dstaddr=Any**.
- All string parameters are case-sensitive.

**delete filteraction**
Deletes the specified filter action, or all filter actions.

**Syntax**
**delete filteraction name=** | **all**

**Parameters**
**name= *String*| all**
Required. Specifies the name of the filter action to delete. Or, if **all** is specified, all filter actions are deleted.

**Remarks**

- All string parameters are case-sensitive.

**delete filterlist**
Deletes the specified filter list, or all filter lists.

**Syntax**
**delete filterlist name=** | **all**

**Parameters**
**name= *String*| all**
Required. Specifies the name of the filter list to delete. Or, if **all** is specified, all filter lists are deleted.

**Remarks**

- All string parameters are case-sensitive.

**delete policy**
Deletes the specified IPSec policy and all associated rules, or all IPSec policies.

**Syntax**
**delete policy name=** | **all**

**Parameters**

**name= *String*| all**

Required. Specifies the name of the IPSec policy to delete. Or, if **all** is specified, all IPSec policies are deleted.

**Remarks**

- All string parameters are case-sensitive.

**delete rule**

Deletes a specified rule, or all rules from the specified IPSec policy.

**Syntax**

**delete rule name= | ID= | allpolicy=**

**Parameters**

**name= *String*| ID=*Integer*| all**

Required. Specifies the rule to delete. If either the rule name or the rule ID (the number identifying the position of the rule in the policy rule list) is specified, the corresponding rule is deleted. If **all** is specified, all rules are deleted.

**policy= *String***

Required. Specifies the name of the policy from which one or more rules are deleted.

**Remarks**

- The default response rule cannot be deleted.
- After a rule is deleted, all IDs for the remaining rules change accordingly.
- All string parameters are case-sensitive.

**exportpolicy**

Exports all IPSec policy information to the specified file.

**Syntax**

**exportpolicy file=**

**Parameters**

**file= *String***

Required. Specifies the name of the file into which the IPSec policy information is exported.

**Remarks**

- By default, when an IPSec policy is imported into a file, the .ipsec extension added to the file name.
- To enhance interoperablity in a mixed environment with computers running Windows 2000, limit the name of the file to which you want the policy information saved to 60 characters.
- All string parameters are case-sensitive.

**importpolicy**

Imports all IPSec policy information from the specified IPSec file.

**Syntax**

**importpolicy file=**

**Parameters**

**file= *String***

Required. Specifies the name of the file from which the IPSec policy information is imported.

**Remarks**

- All string parameters are case-sensitive.

**restorepolicyexamples**
Restores the default IPSec policies.

**Syntax**
**restorepolicyexamples release=**

**Parameters**
**release={ win2K| Win2003}**
Required. Specifies the version of the default IPSec policies being restored. If **win2K** is specified, the default IPSec policies that were provided with Windows 2000 are restored. If **Win2003** is specified, the default IPSec policies that were provided with the Windows Server™ 2003 family are restored.

**Remarks**

- Restoring default IPSec policies will overwrite any changes to the original default policies, filter lists, and filter actions, even when the names of these configuration items have been changed. If you have modified these items and you do not want the modifications to be overwritten, do not restore the default policies.

- You can only restore default IPSec policies for computer-based IPSec policies. You cannot restore the default IPSec policies for IPSec policies in Active Directory.

**set defaultrule**
Modifies the default response rule for the specified policy.

**Syntax**
**set defaultrule policy=**[**qmpfs=**][**activate=**] [**qmsecmethods=**][**kerberos=**][**psk=**][**rootca=**]

**Parameters**
**policy=** ***String***
Required. Specifies the name of the IPSec policy for which the default response rule is to be modified.

**[ qmpfs={ yes| no}]**
Specifies whether to enable session key perfect forward secrecy (PFS). If **yes** is specified, new master key material is renegotiated each time a new session key is required. The default value is **no**.

**[ activate={ yes | no}]**
Specifies whether to activate this rule for the specified IPSec policy. The default value is **yes**.

**[ qmsecmethods="*Neg1Neg2*"]**
Specifies one or more security methods, separated by spaces and defined by the following format:

{**ESP** [*ConfAlg*,*AuthAlg*]:*k*/*s* | **AH** [*HashAlg*]:*k*/*s* | **AH** [*HashAlg*+**ESP***ConfAlg*,*AuthAlg*]:*k*/*s*}]

Where:

***ConfAlg***
Specifies the encryption algorithm. *ConfigAlg* can be **DES** (Data Encryption Standard), **3DES**, or **none**.

***AuthAlg***
Specifies the integrity algorithm. *AuthAlg* can be **MD5** (Message Digest 5), **SHA1** (Secure Hash Algorithm 1), or **none**.

***HashAlg***
Specifies the hash function. *HashAlg* can be **MD5** (Message Digest 5) or **SHA1**.

***k***
Specifies the session key lifetime in kilobytes. After the specified number of kilobytes of data is transferred, a new session key for the quick mode SA is generated. The default value is 100,000 kilobytes.

***s***
Specifies the session key lifetime in seconds. The default value is 3600 seconds.

**[ kerberos={ yes | no}]**
Specifies whether to use the Kerberos V5 protocol as an authentication method.

**[ psk=*String*]**
Specifies the string of characters to use for the preshared key, if a preshared key is used as an authentication method.

**[ rootca="*String*certmap:{ yes| no} excludecaname:{ yes| no} "]**
Specifies certificate authentication options, where:

***String***
Specifies the distinguished name of the certificate, if a certificate is used as an authentication method.

**certmap:{ yes| no}**
Specifies whether to enable certificate-to-account mapping. You can enable certificate-to-account mapping to verify that the certificate is being used by a trusted computer.

**excludecaname:{ yes| no}**
Specifies whether to exclude from the certificate request the list of trusted root CA names from which a certificate is accepted.

**Remarks**

- You can only use Kerberos V5 authentication or certificate-to-account mapping for computers that are members of an Active Directory domain.
- Although you can use only one preshared key for authentication, you can use multiple certificates by specifying the **rootca** parameter once, for each certificate you want to use.
- All certificate authentication parameters must be contained within quotation marks. Embedded quotation marks must be replaced by a backslash followed by an apostrophe (\').
- All string parameters are case-sensitive.
- The preference order of each authentication method is determined by the order in which it was specified in the command.
- If no authentication methods are specified, dynamic defaults are used. By default, IPSec policies use Kerberos V5 authentication. If the computer has a computer certificate, any root CA to which the computer certificate chains is also used for authentication.
- If **excludecaname:yes** is specified, the list of trusted root CAs is not sent as part of the certificate request, which prevents the potential disclosure of sensitive information about the trust relationships of a computer. To enhance security for computers connected to the Internet, specify this option.
- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext.
- IPSec peers must have at least one common authentication method or communication will fail.
- Modifying authentication methods will overwrite all previous authentication methods, even if the previous authentication methods were different. For example, if **kerberos=yes** and **psk=yes** were previously specified, and then you specify **kerberos=no**, the **psk=yes** parameter will also be overwritten, and preshared key authentication will no longer be used.
- *ConfAlg* and *AuthAlg* cannot both be set to **none**.

**set filteraction**
Modifies a filter action.

**Syntax**
**set filteraction name=** | **guid=**[**newname=**] [**description=**][**qmpfs=**][**inpass=**] [**soft=**][**action=**][**qmsecmethods=**]

**Parameters**
**name= *String*| guid= *guid***
Required. Specifies the name or global unique identifier (GUID) of the filter action to modify.

**[ newname=*String*]**
Specifies the new name of the filter action.

**[ description=*String*]**
Provides information about the filter action.

**[ qmpfs={ yes| no}]**
Specifies whether to enable session key perfect forward secrecy (PFS). If **yes** is specified, new master key material is renegotiated each time a new session key is required.

**[ inpass={ yes| no}]**
Specifies whether to allow an incoming packet that matches the configured filter list to be unsecured, but require IPSec-secured communication when replying.

**[ soft={ yes| no}]**
Specifies whether to fall back to unsecured communications with other computers that do not support IPSec, or when IPSec negotiations with an IPSec-capable computer fail.

**[ action={ permit| block| negotiate}]**
Specifies whether to permit traffic without negotiating IP security. If **permit** is specified, traffic is transmitted or received without negotiating or applying IP security. If **block** is specified, traffic is blocked. If **negotiate** is specified, IP security is used, with the specified list of security methods.

**[ qmsecmethods="*Neg1Neg2*"]**
Specifies one or more security methods, separated by spaces and defined by the following format:

{**ESP** [*ConfAlg*,*AuthAlg*]**:***k/s* | **AH** [*HashAlg*]**:***k/s* | **AH** [*HashAlg*+**ESP***ConfAlg*,*AuthAlg*]**:***k/s*}]

Where:

***ConfAlg***
Specifies the encryption algorithm. *ConfigAlg* can be **DES** (Data Encryption Standard), **3DES**, or **none**.

***AuthAlg***
Specifies the integrity algorithm. *AuthAlg* can be **MD5** (Message Digest 5), **SHA1** (Secure Hash Algorithm 1), or **none**.

***HashAlg***
Specifies the hash function. *HashAlg* can be **MD5** (Message Digest 5) or **SHA1** (Secure Hash Algorithm 1).

***k***
Specifies the session key lifetime in kilobytes. After the specified number of kilobytes of data is transferred, a new session key for the quick mode SA is generated. The default value is 100000 kilobytes.

***s***
Specifies the session key lifetime in seconds. The default value is 3600 seconds.

**Remarks**

- If you specify a new name for the filter action, do not use the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec filter actions (for example, **delete filteraction all**).
- If **action=permit** or **action=block** are specified, do not set **qmpfs=yes**, **inpass=yes**, or **soft=yes**.
- Session key regeneration will start based on whichever interval, seconds or kilobytes, is reached first. If you do not configure new intervals, the default intervals are used.
- If **qmsecmethods=** (quick mode security methods) were not previously specified for this filter action, the following default values are used:
    - ESP [3DES, SHA1]:100000s/3600k
    - ESP [3DES, MD5]:100000s/3600k
- The preference order of each quick mode security method is determined by the order in which it was specified in the command.
- All string parameters are case-sensitive.

**set filterlist**
Modifies a filter list.

**Syntax**
**set filterlist name=** [**newname=**] [**description=**]

**Parameters**
**name= *String***
Required. Specifies the name of the filter list to modify.

**[ newname=*String*]**
Specifies the new name of the filter list.

**[ description=*String*]**
Provides information about the filter list.

**Remarks**

- If you specify a new name for the filter list, do not use the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec filter lists (for example, **delete filterlist all**).

- All string parameters are case-sensitive.

**set policy**
Modifies an IPSec policy.

**Syntax**
**set policy name= newname=** [**description=**][**mmpfs=**][**qmpermm=**] [**mmlifetime=**][**activatedefaultrule=**] [**pollinginterval=**][**assign=**][**gponame=**][**mmsecmethods=**]

**Parameters**
**name= *String*| guid=*guid***
Required. Specifies the name or GUID of the IPSec policy to modify.

**newname= *String***
Required. Specifies the new name of the IPSec policy.

**[ description=*String*]**
Provides information about the IPSec policy.

**[ mmpfs={ yes| no}]**
Specifies whether to enable master key perfect forward secrecy (PFS). If **yes** is specified, main mode security SAs are reauthenticated and new master key keying material is negotiated each time session key material for a quick mode SA is required.

**[ qmpermm=*Integer*]**
Specifies the number of times that master keying material can be used to derive the session key.

**[ mmlifetime=*Integer*]**
Specifies the number of minutes after which a new master key will be generated.

**[ activatedefaultrule={ yes| no}]**
Specifies whether to activate the default response rule for this IPSec policy.

**[ pollinginterval=*Integer*]**
Specifies how often IPSec polls for changes to this policy. The default value is 180 minutes.

**[ assign={ yes| no}]**
Specifies whether to assign this IPSec policy.

**[ gponame=*String*]**
Specifies the name of the Group Policy object to which the IPSec policy is assigned. This parameter is only applicable if you are configuring policy for a computer that is an Active Directory domain member.

**[ mmsecmethods="*SecMeth1SecMeth2*"]**

Specifies one or more key exchange security methods, separated by spaces and defined by the following format: *ConfAlg-HashAlg-GroupNumb*, where:

***ConfAlg***
Specifies the encryption algorithm. *ConfAlg* can be **DES** (Data Encryption Standard) or **3DES**.

***HashAlg***
Specifies the hash function. *HashAlg* can be **MD5** (Message Digest 5) or **SHA1** (Secure Hash Algorithm 1).

***GroupNum***
Specifies the Diffie-Hellman group to be used for the base keying material. *GroupNumb* can be: **1** (low, protects with 768 bits of keying material), **2** (medium, protects with 1024 bits), and **3** (high, protects with 2048 bits).

**Remarks**

- If you specify a new name for the policy, do not use the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec policies (for example, **delete policy all**).
- If **set store=domain** is specified (when the IPSec policy is stored in Active Directory), **assign** will have no effect.
- If **mmpfs=yes** is specified (master key PFS is enabled), by default **qmperm** is set to 1 and not configurable, because each new session will cause the master key keying material to be renegotiated.
- IPSec peers must have at least one common key exchange security method (one that uses the same settings) or negotiations will fail.
- You can only specify a Group Policy object name if **set store=domain**.
- All string parameters are case-sensitive.

**set rule**
Modifies a rule in an IPSec policy.

**Syntax**
**set rule name=** | **ID=policy=** [**newname=**][**description=**][**filterlist=**] [**filteraction=**] [**tunnel=**][**conntype=**] [**activate=**] [**kerberos=**][**psk=**][**rootca=**]

**Parameters**
**name=** ***String*** | **ID=*Integer***
Required. Specifies the name or ID (the number identifying the position of the rule in the policy rule list) of the rule to modify.

**policy=** ***String***
Required. Specifies the name of the IPSec policy that contains this rule.

**[ newname=*String*]**
Specifies the new name of the rule.

**[ description=*String*]**
Provides information about the rule.

**[ filterlist=*String*]**
Specifies the name of the IP filter list for this rule.

**[ filteraction=*String*]**
Specifies the name of the filter action for this rule.

**[ tunnel={ *IPAddress*| *DNSName*}]**
Specifies the IP address or DNS name of the tunnel endpoint for tunnel mode.

**[ conntype={ lan| dialup| all}]**
Specifies whether the rule applies only to remote access or dial-up connections or to local area network (LAN) connections, or to all connections.

**[ activate={ yes | no}]**
Specifies whether to activate this rule for the specified IPSec policy.

**[ kerberos={ yes | no}]**
Specifies whether to use the Kerberos V5 protocol as an authentication method.

**[ psk=*String*]**
Specifies the string of characters to use for the preshared key, if a preshared key is used as an authentication method.

**[ rootca="*String*certmap:{ yes| no} excludecaname:{ yes| no} "]**
Specifies certificate authentication options, where:

***String***
Specifies the distinguished name of the certificate, if a certificate is used as an authentication method.

**certmap:{ yes| no}**
Specifies whether to enable certificate-to-account mapping. You can enable certificate-to-account mapping to verify that the certificate is being used by a trusted computer.

**excludecaname:{ yes| no}**
Specifies whether to exclude from the certificate request the list of trusted root CA names from which a certificate is accepted.

**Remarks**

- You can only use Kerberos V5 authentication or certificate-to-account mapping for computers that are members of an Active Directory domain.
- Although you can use only one preshared key for authentication, you can use multiple certificates by specifying the **rootca** parameter once, for each certificate you want to use.
- All certificate authentication parameters must be contained within quotation marks. Embedded quotation marks must be replaced by a backslash followed by an apostrophe (\').
- All string parameters are case-sensitive.
- The preference order of each authentication method is determined by the order in which it was specified in the command.
- If no authentication methods are specified, dynamic defaults are used. By default, IPSec policies use Kerberos V5 authentication. If the computer has a computer certificate, any root CA to which the computer certificate chains is also used for authentication.
- If **excludecaname:yes** is specified, the list of trusted root CAs is not sent as part of the certificate request, which prevents the potential disclosure of sensitive information about the trust relationships of a computer. To enhance security for computers connected to the Internet, specify this option.
- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext.
- IPSec peers must have at least one common authentication method or communication will fail.
- Modifying authentication methods will overwrite all previous authentication methods, even if the previous authentication methods were different. For example, if **kerberos=yes** and **psk=yes** were previously specified, and then you specify **kerberos=no**, the **psk=yes** parameter will also be overwritten, and preshared key authentication will no longer be used.

**set store**
Sets the current IPSec policy storage location.

**Syntax**
**set store location=** [**domain=**]

**Parameters**

**location={ local| persistent| domain}**

Required. Specifies the storage location for the IPSec policy.

**[ domain=]**

Specifies the name of the domain where the IPSec policy is stored, if the policy is stored in Active Directory (when **location=domain** is specified).

**Remarks**

- The **set store** command only works from within the netsh environment, that is:
    - If you run this command from the command prompt for the **netsh ipsec** context).
    - If you run a batch file by using the **netsh.exe** command.
- The persistent store contains IPSec policies that can be assigned to secure this computer at start up, before the local policy or domain-based policy is applied. A persistent IPSec policy provides security in the event of a failure because it remains in effect whether the local policy or domain-based policy is applied or not (for example, an IPSec policy might not be applied if it is corrupted). For enhanced security, it is recommended that you create and assign a persistent policy.
- The local store contains IPSec policies that can be assigned to secure this computer. If a domain policy is available, the domain policy is applied instead of the local policy.
- The domain store contains IPSec policies that can be assigned to secure groups of computers in a domain.
- It is recommended that the persistent policy be the most restrictive of all policies. Domain policies and local policies should complement persistent policies.
- Use the **set machine** command to configure a remote computer.
- All string parameters are case-sensitive.

**show all**

Displays configuration information for all IPSec policies, rules, filter lists, and filter actions.

**Syntax**

**show all** [**format=**] [**wide=**]

**Parameters**

**[ format={ list| table}]**

Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ wide={ yes | no}]**

Specifies whether to allow the display of IPSec configuration information to exceed the screen width of 80 characters. The default value is **no**, meaning that the display of configuration information is limited to the screen width.

**Remarks**

- Because the **show all** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show all** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

2. Then type:

   **ipsec static show all**

3. To stop sending output and close the file, type:

   **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **netsh ipsec static show all >***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show filteraction**
Displays configuration information for one or more filter actions.

**Syntax**
**show filteraction name=** | **rule=** | **all** [**level=**][**format=**] [**wide=**]

**Parameters**
**name=** ***String*| rule=*String*| all**
Required. Specifies one or more filter actions for which configuration information is to be displayed. If **name** is specified, the filter action with the specified name is displayed. If **rule** is specified, all filter actions associated with the specified rule are displayed. If **all** is specified, all filter actions are displayed.

**[ level={ verbose| normal}]**
Specifies the level of information to display. If **verbose** is specified, information about the security methods, policy storage location, and whether session key perfect forward secrecy (PFS) is enabled is displayed, in addition to basic filter action information. The default value is **normal**.

**[ format={ list| table}]**
Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ wide={ yes | no}]**
Specifies whether to allow the display of IPSec configuration information to exceed the screen width of 80 characters. The default value is **no**, meaning that the display of configuration information is limited to the screen width.

**Remarks**

- All string parameters are case-sensitive.

- Because the **show filteraction** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show filteraction** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

**set file open** *FileName*.txt

2. Then type:

   **ipsec static show filteraction***Name* | *Rule* | **all** [**level=verbose** | **normal**]

3. To stop sending output and close the file, type:

   **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **netsh ipsec static show filteraction***Name* | *Rule* | **all** [**level=verbose** | **normal**] >*FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show filterlist**

Displays configuration information for one or more filter lists.

**Syntax**

**show filterlist name=** | **rule=** | **all** [**level=**][**format=**][**resolvedns=**] [**wide=**]

**Parameters**

**name=** ***String*| rule=*String*| all**

Required. Specifies one or more filter lists to display. If **name** is specified, the filter list with the specified name is displayed. If **rule** is specified, all filter lists associated with the specified rule are displayed. If **all** is specified, all filter lists are displayed.

**[ level={ verbose| normal}]**

Specifies the level of information to display. If **verbose** is specified, the source, destination, and type of IP traffic defined by each filter are displayed, in addition to basic filter list information. The default value is **normal**.

**[ format={ list| table}]**

Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ resolvedns={ yes | no}]**

Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations. If **yes** is specified, **level** must also be set to **verbose**, or the DNS names are not displayed. The default value is **no**.

**[ wide={ yes | no}]**

Specifies whether to allow the display of IPSec configuration information to exceed the screen width of 80 characters. The default value is **no**, meaning that the display of configuration information is limited to the screen width.

**Remarks**

- All string parameters are case-sensitive.

- Because the **show filterlist** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show all** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

1. At the netsh prompt, type:

   **set file open** *FileName*.txt

2. Then type:

   **ipsec static show filterlist***Name* | *rule* | **all** [**level=verbose** | **normal**][**resolvedns=yes** | **no**

3. To stop sending output and close the file, type:

   **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **netsh ipsec static show filterlist***Name* | *rule* | **all** [**level=verbose** | **normal**][**resolvedns=yes** | **no** >*FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show gpoassignedpolicy**
Displays configuration information for the active IPSec policy assigned to the specified Group Policy object.

**Syntax**
**show gpoassignedpolicy** [**name=** ]

**Parameters**
**[ name=*String*]**
Specifies the name of the Group Policy object to which the active IPSec policy is assigned. If no name is specified, the local IPSec policy is displayed.

**Remarks**

- You can only specify a Group Policy object name if **set store=domain**.

- All string parameters are case-sensitive.

  To save output in a text file for the **show gpossignedpolicy** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec static show gpoassignedpolicy** [*Name*]

  3. To stop sending output and close the file, type:

     **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **netsh ipsec static show gpoassignedpolicy** [*Name*] >*FileName*.txt

**show policy**

Displays configuration information for the specified IPSec policy, or for all IPSec policies.

**Syntax**

**show policy name=** | **all** [**level=**] [**format=**] [**wide=**]

**Parameters**

**name=** ***String*****| all**

Required. Specifies the name of the IPSec policy to display or, if **all** is specified, that all IPSec policies are displayed.

**[ level={ verbose| normal}]**

Specifies the level of information to display. If **verbose** is specified, the security methods and authentication method are displayed, in addition to information about filter actions and rules. The default value is **normal**.

**[ format={ list| table}]**

Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ wide={ yes | no}]**

Specifies whether to allow the display of IPSec configuration information to exceed the screen width of 80 characters. The default value is **no**, meaning that the display of configuration information is limited to the screen width.

**Remarks**

- All string parameters are case-sensitive.

- Because the **show policy** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show policy** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec static show policy***Name* | **all** >*FileName*.txt

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec static show policy***Name* | **all** >*FileName***.txt**

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

- Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

- Use Task Manager to end the **Netsh** program.

**show rule**

Displays configuration information for a rule for a specified policy, or for all rules for a specified policy.

**Syntax**

**show rule name=** | **ID=** | **all** | **defaultpolicy=** [**type=**][**level=**][**format=**] [**wide=**]

**Parameters**

**name={ *String*| ID=*Integer*| all| default}**

Required. Specifies one or more rules to display. If either the rule name or the rule ID (the number identifying the position of the rule in the policy rule list) is specified, the corresponding rule is displayed. If **all** is specified, all rules for the specified policy are displayed. If **default** is specified, the default response rule is displayed.

**policy= *String***

Required. Specifies the name of the policy for which the specified rule, or all rules, are displayed.

**[ type={ transport| tunnel}]**

Specifies whether to display all transport rules or all tunnel rules. The default value is to display all rules.

**[ level={ verbose| normal}]**

Specifies the level of information to display. If **verbose** is specified, information about associated filter actions is displayed, in addition to basic information about the rule. The default value is **normal**.

**[ format={ list| table}]**

Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ wide={ yes | no}]**

Specifies whether to allow the display of IPSec configuration information to exceed the screen width of 80 characters. The default value is **no**, meaning that the display of configuration information is limited to the screen width.

**Remarks**

- If you use the **type** parameter, you must also use the **all** parameter (you must specify **show rule all**).

- All string parameters are case-sensitive.

- Because the **show rule** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show rule** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec static show rule***Name* | *ID* | **all** | **default***Policy* [**level=verbose** | **normal**]

  3. To stop sending output and close the file, type:

     **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **netsh ipsec static show rule***Name* | *ID* | **all** | **default***Policy* [**level=verbose** | **normal**] >*FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**Netsh ipsec dynamic**

The following commands are available at the **ipsec dynamic** > prompt, which is rooted within the netsh environment.

To view the command syntax, click a command:

- add mmpolicy
- add qmpolicy
- add rule
- delete all
- delete mmpolicy
- delete qmpolicy
- delete rule
- set config
- set mmpolicy
- set qmpolicy
- set rule
- show all
- show config
- show mmfilter
- show mmpolicy
- show mmsas
- show qmfilter
- show qmpolicy
- show qmsas
- show rule

- show stats

**add mmpolicy**
Creates an IPSec main mode policy with the specified name and adds it to the security policy database (SPD).

**Syntax**
**add mmpolicy name=** [**qmpermm=**] [**mmlifetime=**][**softsaexpirationtime=**][**mmsecmethods=**]

**Parameters**
**name=** ***String***
Required. Specifies the name of the IPSec policy to be created.

**[ qmpermm=*Integer*]**
Specifies the number of times that master keying material can be used to derive the session key. The default value is 0, The default value is 0, meaning an unlimited number of quick mode SAs can be derived from the main mode SA.

**[ mmlifetime=*Integer*]**
Specifies the number of minutes after which a new master key is generated. The default value is 480 minutes.

**[ softsaexpirationtime=*Integer*]**
Specifies the number of minutes after which an unprotected security association expires. The default value is 480 minutes.

**[ mmsecmethods="*SecMeth1SecMeth2*"]**
Specifies one or more key exchange security methods, separated by spaces and defined by the following format: *ConfAlg-HashAlg-GroupNumb*, where:

***ConfAlg***
Specifies the encryption algorithm. *ConfAlg* can be **DES** or **3DES**.

***HashAlg***
Specifies the hash function. *HashAlg* can be **MD5** or **SHA1**.

***GroupNum***
Specifies the Diffie-Hellman group to be used for the base keying material. *GroupNumb* can be: **1** (low, protects with 768 bits of keying material), **2** (medium, protects with 1024 bits), and **3** (high, protects with 2048 bits).

**Remarks**

- Do not create a main mode policy with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec main mode policies (for example, **delete mmpolicy all**).
- If the number of quick mode negotiations will exceed the value set for the number of quick mode negotiations per main mode negotiation during the main mode lifetime, a new main mode negotiation occurs.
- If you do not specify **mmsecmethods=** (key exchange security methods), the following default values are used:
    - 3DES-SHA1-2
    - 3DES-MD5-2
    - 3DES-SHA1-3
- IPSec peers must have at least one common key exchange security method (one that uses the same settings) or negotiations will fail.
- All string parameters are case-sensitive.

**add qmpolicy**
Creates an IPSec quick mode policy with the specified name and adds it to the SPD.

**Syntax**

**add qmpolicy name=** [**soft=**][**pfsgroup=**][**qmsecmethods=**]

**Parameters**

**name=** ***String***

Required. Specifies the name of the IPSec quick mode policy to be created.

**[ soft={ yes| no}]**

Specifies whether to fall back to unsecured communications with other computers that do not support IPSec, or when IPSec negotiations with an IPSec-capable computer fail. The default value is **no**.

**[ pfsgroup={ grp1| grp2| grp3| grpmm| nopfs}]**

Specifies the Diffie-Hellman group to use for session key PFS. If **grp1** is specified, Group 1 (low) is used. If **grp2** is specified, Group 2 (medium) is used. If **grp3** is specified, Group 2048 (high) is used. If **grpmm** is specified, the group value is taken from the current main mode settings. The default value is **nopfs**, meaning session key PFS is disabled.

**[ qmsecmethods="*Neg1Neg2*"]**

Specifies one or more security methods, separated by spaces and defined by the following format:

{**ESP** [*ConfAlg*,*AuthAlg*]**:***k/s* | **AH** [*HashAlg*]**:***k/s* | **AH** [*HashAlg*+**ESP***ConfAlg*,*AuthAlg*]**:***k/s*}]

Where:

***ConfAlg***

Specifies the encryption algorithm. *ConfigAlg* can be **DES** (Data Encryption Standard), **3DES**, or **none**.

***AuthAlg***

Specifies the integrity algorithm. *AuthAlg* can be **MD5** (Message Digest 5), **SHA1** (Secure Hash Algorithm 1), or **none**.

***HashAlg***

Specifies the hash function. *HashAlg* can be **MD5** (Message Digest 5) or **SHA1** (Secure Hash Algorithm 1).

***k***

Specifies the session key lifetime in kilobytes. After the specified number of kilobytes of data is transferred, a new session key for the quick mode SA is generated. The default value is 100000 kilobytes.

***s***

Specifies the session key lifetime in seconds. The default value is 3600 seconds.

**Remarks**

- Do not create a quick mode policy with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec quick mode policies (for example, **delete qmpolicy all**).
- If you do not specify **qmsecmethods=** (quick mode security methods), the following default values are used:
    - ESP [3DES, SHA1]100000k/3600s
    - ESP [3DES, MD5]100000k/3600s
- *ConfAlg* and *AuthAlg* cannot both be set to **none**.
- IPSec peers must have the same **pfsgroup** enabled (that is, both peers must use the same Diffie-Hellman group for session key PFS), or communication will fail.
- For enhanced security, do not use Diffie-Hellman Group 1. For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP.
- All string parameters are case-sensitive.

**add rule**

Creates an IPSec rule with the specified main mode policy and quick mode policy and adds it to the SPD.

**Syntax**

**add rule srcaddr= dstaddr= mmpolicy=**[**qmpolicy=**][**protocol=**][**srcport=**][**dstport=**][**mirrored=**][**conntype=**] [**actioninbound=**][**actionoutbound=**][**srcmask=**][**dstmask=**][**tunneldstaddress=**][**kerberos=**][**psk=**][**rootca=**]

**Parameters**

**srcaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}**
Required. Specifies the source IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**dstaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}**
Required. Specifies the destination IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**mmpolicy= *String***
Required. Specifies the name of the main mode policy.

**[ qmpolicy=] *String***
Specifies the name of the quick mode policy. Required if **actioninbound=negotiate** or **actionoutbound=negotiate** are specified.

**[ protocol={ ANY| ICMP| TCP| UDP| RAW| *Integer* }]**
Specifies the IP protocol if, in addition to address information, you want to filter a specific IP protocol. The default value is **ANY**, meaning all protocols are used for the filter.

**[ srcport=*Port*]**
Specifies the source port number of the packets to be filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent from any port are filtered. The default is any.

**[ dstport=*Port*]**
Specifies the destination port number of the packets to be filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent to any port are filtered. The default is any.

**[ mirrored={ yes| no}]**
Specifies whether to create a mirrored filter. Use **yes** to create two filters based on the filter settings, one for traffic to the destination and one for traffic from the destination. The default value is **yes**.

**[ conntype={ lan| dialup| all}]**
Specifies whether the rule applies only to remote access or dial-up connections or to local area network (LAN) connections, or to all connections. The default value is **all**.

**[ actioninbound={ permit| block| negotiate}]**
Specifies the action that IPSec is required to take for inbound traffic. If **permit** is specified, traffic is received without negotiating or applying IP security. If **block** is specified, traffic is blocked. If **negotiate** is specified, IP security is used, with the list of security methods specified in the main mode and quick mode policies. The default value is **negotiate**.

**[ actionoutbound={ permit| block| negotiate}]**
Specifies the action that IPSec is required to take for outbound traffic. If **permit** is specified, traffic is sent without negotiating or applying IP security. If **block** is specified, traffic is blocked. If **negotiate** is specified, IP security is used, with the list of security methods specified in the main mode and quick mode policies. The default value is **negotiate**.

**[ srcmask={ *Mask*| *Prefix*}]**
Specifies the source address subnet mask or the prefix of the packets to be filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={ *Mask*| *Prefix*}]**
Specifies the destination address subnet mask or the prefix value of the packets to be filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ tunneldstaddress={ *IPAddress*| *DNSName*}]**
Specifies whether the traffic is tunneled and, if it is, the IP address or DNS name of the tunnel destination (the computer or gateway on the other side of the tunnel).

**[ kerberos={ yes | no}]**
Specifies whether to use the Kerberos V5 protocol as an authentication method.

**[ psk=*String*]**
Specifies the string of characters to use for the preshared key, if a preshared key is used as an authentication method.

**[ rootca="*String*certmap:{ yes| no} excludecaname:{ yes| no} "]**

Specifies certificate authentication options, where:

***String***

Specifies the distinguished name of the certificate, if a certificate is used as an authentication method.

**certmap:{ yes| no}**

Specifies whether to enable certificate-to-account mapping. You can enable certificate-to-account mapping to verify that the certificate is being used by a trusted computer.

**excludecaname:{ yes| no}**

Specifies whether to exclude from the certificate request the list of trusted root CA names from which a certificate is accepted.

**Remarks**

- Do not create a rule with the name **all**. Doing this creates a conflict with the **netsh ipsec** option to select all IPSec rules (for example, **delete rule all**).
- If the filter action for both inbound and outbound traffic (**actioninbound** and **actionoutbound**) are set to **Permit** or **Block**, a quick mode filter is not required.
- If a tunnel rule is specified, **mirror** should be set to **no** (by default, **mirror** is set to **yes**). For IPSec tunnels, you must create two rules--one rule describes the traffic to be sent through the tunnel (outbound traffic) and the other describes the traffic to be received through the tunnel (inbound). Next, create two rules that use the inbound and outbound filter lists in your policy.
- To filter any packets sent from or to the computer, you can use **srcaddr=Me** or **dstaddr=Me**.
- To filter packets sent from or to any computer, you can use **srcaddr=Any** or **dstaddr=Any**.
- You can only use Kerberos V5 authentication or certificate-to-account mapping for computers that are members of an Active Directory domain.
- Although you can use only one preshared key for authentication, you can use multiple certificates by specifying the **rootca** parameter once, for each certificate you want to use.
- All certificate authentication parameters must be contained within quotation marks. Embedded quotation marks must be replaced by a backslash followed by an apostrophe (\').
- All string parameters are case-sensitive.
- The preference order of each authentication method is determined by the order in which it was specified in the command.
- If no authentication methods are specified, dynamic defaults are used. By default, IPSec policies use Kerberos V5 authentication. If the computer has a computer certificate, any root CA to which the computer certificate chains is also used for authentication.
- If **excludecaname:yes** is specified, the list of trusted root CAs is not sent as part of the certificate request, which prevents the potential disclosure of sensitive information about the trust relationships of a computer. To enhance security for computers connected to the Internet, specify this option.
- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext.
- IPSec peers must have at least one common authentication method or communication will fail.

**delete all**

Deletes all IPSec policies, filters, and authentication methods, if possible, from the SPD.

**Syntax**

**delete all**

**Parameters**

None.

**delete mmpolicy**

Deletes the specified IPSec main mode policy, or all IPSec main mode policies, from the SPD.

**Syntax**

**delete mmpolicy name=** | **all**

**Parameters**

**name=** ***String*****| all**

Required. Specifies the name of the IPSec main mode policy to delete. Or, if **all** is specified, all IPSec main mode policies are deleted.

**Remarks**

- If a rule is associated with the main mode policy, you must delete the rule before you can delete the policy.
- All string parameters are case-sensitive.

**delete qmpolicy**

Deletes the specified IPSec quick mode policy, or all IPSec quick mode policies, from the SPD.

**Syntax**

**delete qmpolicy** [**name=**] | [**all**]

**Parameters**

**name=** ***String*****| all**

Required. Specifies the name of the IPSec quick mode policy to delete. Or, if **all** is specified, all IPSec quick mode policies are deleted.

**Remarks**

- If a rule is associated with the quick mode policy, you must delete the rule before you can delete the policy.
- All string parameters are case-sensitive.

**delete rule**

Deletes an IPSec rule from the SPD.

**Syntax**

**delete rule srcaddr= dstaddr= protocol= srcport= dstport= mirrored= conntype=**[**srcmask=**][**dstmask=**] [**tunneldstaddress=**]

**Parameters**

**srcaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**

Required. Specifies the source IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**dstaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**

Required. Specifies the destination IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**protocol={ ANY| ICMP| TCP| UDP| RAW|** ***Integer*** **}**

Required. Specifies the IP protocol used for the filter.

**srcport=** ***Port***

Required. Specifies the source port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. A value of **0** matches filters set to a source port of **0** or **any**.

**dstport=** ***Port***

Required. Specifies the destination port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. A value of **0** matches filters set to a destination port of **0** or **any**.

**mirrored={ yes| no}**
Required. Specifies whether the rule was created with mirrored filters.

**conntype={ lan| dialup| all}**
Required. Specifies whether the rule to be deleted applies only to remote access or dial-up connections or to local area network (LAN) connections, or to all connections.

**[ srcmask={ *Mask*| *Prefix*}]**
Specifies the source address subnet mask or the prefix of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={ *Mask*| *Prefix*}]**
Specifies the destination address subnet mask or the prefix value of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ tunneldstaddress={ *IPAddress*| *DNSName*}]**
Specifies whether the traffic is tunneled and, if it is, the IP address or DNS name of the tunnel destination (the computer or gateway on the other side of the tunnel).

**Remarks**

- To filter any packets sent from or to the computer, you can use **srcaddr=Me** or **dstaddr=Me**.
- To filter packets sent from or to any computer, you can use **srcaddr=Any** or **dstaddr=Any**.

**set config**
Creates or modifies the following IPSec settings: IPSec diagnostics, default traffic exemptions, strong certificate revocation list (CRL) checking, IKE (Oakley) logging, logging intervals, computer startup security, and computer startup traffic exemptions.

**Syntax**
**set config** [**property=**] [**value=**]

**Parameters**
**[ property=]{ ipsecdiagnostics value=| ipsecexempt value=| ipseclogginterval value=| ikelogging value=| strongcrlcheck value=| bootmode value=| bootexemptions value=}**
Required. Specifies the name of the IPSec setting to be created or modified and a value for the setting,

where:

**ipsecdiagnostics value={ 0| 1| 2| 3| 4| 5| 6| 7}**
Specifies whether to enable IPSec diagnostic logging and, if so, which level of logging to provide. The default value is **0**, meaning that logging is disabled. If you change the value for this setting, you must restart the computer for the new value to take effect.

You can specify other values as follows, to enable different levels of logging:

- When **1** is specified, bad SPI packets (the total number of packets for which the Security Parameters Index or SPI was incorrect), IKE negotiation failures, IPSec processing failures, packets received with invalid packet syntax, and other errors are recorded in the System log. Unauthenticated hashes (with the exception of the "Clear text received when should have been secured" event) are logged as well.
- When **2** is specified, inbound per-packet drop events are recorded in the System log.
- When **3** is specified, level 1 and level 2 logging are performed. In addition, unexpected clear text events (packets that are sent or received in plaintext) are also recorded.
- When **4** is specified, outbound per-packet drop events are recorded in the System log.
- When **5** is specified, level 1 and level 4 logging are performed.

- When **6** is specified, level 2 and level 4 logging are performed.
- When **7** specified, all levels of logging are performed.

**ipsecexempt value={ 0| 1| 2| 3}**
Specifies whether to modify the default IPSec traffic exemption (traffic that is not matched against IPSec filters but is still permitted). The default value is **3**, meaning that only IKE traffic is exempted from IPSec filtering. If you change the value for this setting, you must restart the computer for the new value to take effect.

You can specify other values as follows:

- If **0** is specified, multicast, broadcast, RSVP, Kerberos, and IKE traffic is exempted from IPSec filtering.
- If **1** is specified, Kerberos and RSVP traffic is not exempted from IPSec filtering (multicast, broadcast, and IKE traffic is exempted).
- If **2** is specified, multicast and broadcast traffic is not exempted from IPSec filtering (RSVP, Kerberos, and IKE traffic is exempted).

**ipseclogginterval value={ *Integer*}**
Specifies the interval, in seconds, after which IPSec event logs are sent to the System log. For *Integer*, valid values range from **60** through **86400**. The default value is **3600**. If you change the value for this setting, you must restart the computer for the new value to take effect.

**ikelogging value={ 0| 1}**
Specifies whether to enable IKE (Oakley) logging, to generate details about the SA establishment process. The default value is **0**, meaning that IKE logging is disabled.

**strongcrlcheck value={ 0| 1| 2}**
Specifies the level of CRL checking to use. If **0** is specified, CRL checking is disabled. If **1** is specified, standard CRL checking is used, and certificate validation fails only if the certificate is determined to be revoked. If **2** is specified, strong CRL checking is used, and certificate validation fails if any CRL check error occurs. The default value is **1**.

**bootmode value={ stateful| block| permit}**
Specifies the action that IPSec is required to take when the computer starts. If **stateful** is specified, only the following traffic is permitted during computer startup: outbound traffic initiated by the computer during startup, inbound traffic that is sent in response to the outbound traffic, and DHCP traffic. If **block** is specified, all inbound and outbound traffic is blocked until a local IPSec policy or a domain-based IPSec policy is applied. If **permit** is specified, all traffic is transmitted and received. The default value is **stateful**. If you use either stateful filtering or if you specify that traffic be blocked during computer startup, you can also use the **bootexemptions** parameter to specify traffic types that you want to exempt from IPSec filtering during computer startup.

If you change the value for this setting, you must restart the computer for the new value to take effect.

**bootexemptions value= *Exemption1Exemption2***
Specifies one or more IPSec traffic exemptions from startup security, separated by spaces and defined by the following format for TCP and UDP traffic: *protocol:srcport:dstport:direction* and the following format for non-TCP/UDP traffic: *protocol:direction*, where:

***protocol* ={ ICMP| TCP| UDP| RAW| *Integer* }**
Specifies the IP protocol type to exempt from IPSec filtering during computer startup.

***srcport* = *Port***
Specifies the source port number of the packets to exempt from IPSec filtering during computer startup. A value of 0 means that any source port is exempted.

***dstport* = *Port***
Specifies the destination port number of the packets to exempt from IPSec filtering during computer startup. A value of 0 means that any destination port is exempted.

***direction* ={ inbound | outbound}**
Specifies the direction of the traffic to exempt from IPSec filtering during computer startup.

**Remarks**

- Use strong CRL checking (set **property=strongcrlcheck value=2**) if the CRL distribution point must be reachable on the network and certificates can only be validated if no CRL check error occurs.

- IPSec can only negotiate security associations for Kerberos traffic if your IPSec policy does not use Kerberos as the authentication method. If Kerberos is required for authentication, you must exempt Kerberos traffic by using the **ipsecexempt** parameter.

- In Windows 2000 and Windows XP, by default, all broadcast, multicast, Internet Key Exchange (IKE), Kerberos, and Resource Reservation Protocol (RSVP) traffic was exempted from IPSec filtering. In the Windows Server™ 2003 family, only IKE traffic is exempted from IPSec filtering by default. All other traffic types are now matched against IPSec filters, and you can configure block or permit filter actions specifically for multicast and broadcast traffic (IPSec does not negotiate security associations for multicast and broadcast traffic).

  As a result of this change in default behavior for IPSec, you should verify the behavior of IPSec policies designed for Windows 2000 or Windows XPand determine whether to configure explicit permit filters to permit specific traffic types. To restore the default behavior of Windows 2000 and Windows XPfor IPSec policies, edit the following registry key: **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\IPSec**. Add a new DWORD value named **NoDefaultExempt** and assign to it a value of **0**. For more information about adding values to registry keys, see Add a value to a registry key entry.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

- Modifying IPSec traffic exemptions from startup security (that is, modifying the **bootexemptions=** parameter) will overwrite all previous exemptions from startup security.

**set mmpolicy**

Modifies an IPSec main mode policy and writes the changes to the SPD.

**Syntax**

**set mmpolicy name=** [**qmperm=**][**mmlifetime=**][**softsaexpirationtime=**][**mmsecmethods=**]

**Parameters**

**name=** ***String***

Required. Specifies the name of the IPSec main mode policy to modify.

**[ qmpermm=*Integer*]**

Specifies the number of times that master keying material is used to derive the session key. A value of 0 means that an unlimited number of quick mode SAs can be derived from the main mode SA.

**[ mmlifetime=*Integer*]**

Specifies the number of minutes after which a new master key is generated.

**[ softsaexpirationtime=*Integer*]**

Specifies the number of minutes after which an unprotected security association expires.

**[ mmsecmethods="*SecMeth1SecMeth2*"]**

Specifies one or more key exchange security methods, separated by spaces and defined by the format *ConfAlg-HashAlg-GroupNumb*, where:

***ConfAlg***

Specifies the encryption algorithm. *ConfAlg* can be **DES** or **3DES**.

***HashAlg***

Specifies the hash function. *HashAlg* can be **MD5** or **SHA1**.

***GroupNum***

Specifies the Diffie-Hellman group to be used for the base keying material. *GroupNumb* can be: **1** (low, protects with 768

bits of keying material), **2** (medium, protects with 1024 bits), and **3** (high, protects with 2048 bits).

**Remarks**

- IPSec peers must have at least one common key exchange security method (one that uses the same settings) or negotiations will fail.
- If the number of quick mode negotiations will exceed the value set for the number of quick mode negotiations per main mode negotiation during the main mode lifetime, a new main mode negotiation occurs.
- All string parameters are case-sensitive.

**set qmpolicy**

Modifies an IPSec quick mode policy and writes the changes to the SPD.

**Syntax**

**set qmpolicy name=** [**soft=**][**pfsgroup=**][**qmsecmethods=**]

**Parameters**

**name=** ***String***

Required. Specifies the name of the IPSec quick mode policy to modify.

**[ soft={ yes| no}]**

Specifies whether to fall back to unsecured communications with other computers that do not support IPSec, or when IPSec negotiations with an IPSec-capable computer fail.

**[ pfsgroup={ grp1| grp2| grp3| grpmm| nopfs}]**

Specifies the Diffie-Hellman group to use for session key PFS. If **grp1** is specified, Group 1 (low) is used. If **grp2** is specified, Group 2 (medium) is used. If **grp3** is specified, Group 2048 (high) is used. If **grpmm** is specified, the group value is taken from the current main mode settings. A value of **nopfs** means that session key PFS is disabled.

**[ qmsecmethods="*Neg1Neg2*"]**

Specifies one or more security methods, separated by spaces and defined by the following format:{**ESP** [*ConfAlg*,*AuthAlg*]**:***k/s* | **AH** [*HashAlg*]**:***k/s* | **AH** [*HashAlg*+**ESP***ConfAlg*,*AuthAlg*]**:***k/s*}]

Where:

***ConfAlg***

Specifies the encryption algorithm. *ConfigAlg* can be **DES** (Data Encryption Standard), **3DES**, or **none**.

***AuthAlg***

Specifies the integrity algorithm. *AuthAlg* can be **MD5** (Message Digest 5), **SHA1** (Secure Hash Algorithm 1), or **none**.

***HashAlg***

Specifies the hash function. *HashAlg* can be **MD5** or **SHA1**.

***k***

Specifies the session key lifetime in kilobytes. After the specified number of kilobytes of data is transferred, a new session key for the quick mode SA is generated. The default value is 100000 kilobytes.

***s***

Specifies the session key lifetime in seconds. The default value is 3600 seconds.

**Remarks**

- The preference order of each quick mode security method is determined by the order in which it was specified in the command.
- IPSec peers must have the same **pfsgroup** enabled (that is, both peers must use the same Diffie-Hellman group for session key PFS), or communication will fail.
- For enhanced security, do not use Diffie-Hellman Group 1. For maximum security, use Group 2048 whenever possible. Use Group 2 when required for interoperability with Windows 2000 and Windows XP.

- All string parameters are case-sensitive.

**set rule**

Modifies an IPSec rule that defines a set of filters and writes the changes to the SPD.

**Syntax**

**set rule srcaddr= dstaddr= protocol= srcport= dstport= mirrored= conntype=** [**srcmask=**][**dstmask=**] [**tunneldstaddress=**][**mmpolicy=**][**qmpolicy=**][**actioninbound=**][**actionoutbound=**][**kerberos=**][**psk=**][**rootca=**]

**Parameters**

**srcaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**

Required. Specifies the source IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**dstaddr={ Me| Any|** ***IPAddress*****|** ***DNSName*****|** ***ServerType*****}**

Required. Specifies the destination IP address, DNS name, or server type for the IP traffic. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**protocol={ ANY| ICMP| TCP| UDP| RAW|** ***Integer*** **}**

Required. Specifies the IP protocol used for the filter.

**srcport=** ***Port***

Required. Specifies the source port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. A value of **0** matches filters set to a source port of **0** or **any**.

**dstport=** ***Port***

Required. Specifies the destination port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. A value of **0** matches filters set to a destination port of **0** or **any**.

**mirrored={ yes| no}**

Required. Specifies whether the rule was created with mirrored filters.

**conntype={ lan| dialup| all}**

Required. Specifies whether the rule applies only to remote access or dial-up connections or to local area network (LAN) connections, or to all connections.

**[ srcmask={** ***Mask*****|** ***Prefix*****}]**

Specifies the source address subnet mask or the prefix of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={** ***Mask*****|** ***Prefix*****}]**

Specifies the destination address subnet mask or the prefix value of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ tunneldstaddress={** ***IPAddress*****|** ***DNSName*****}]**

Specifies whether the traffic is tunneled and, if it is, the IP address or DNS name of the tunnel destination (the computer or gateway on the other side of the tunnel).

**[ mmpolicy=*****String*****]**

Specifies the name of the main mode policy.

**[ qmpolicy=*****String*****]**

Specifies the name of the quick mode policy.

**[ actioninbound={ permit| block| negotiate}]**

Specifies the action that IPSec is required to take for inbound traffic. If **permit** is specified, traffic is received without negotiating or applying IP security. If **block** is specified, traffic is blocked. If **negotiate** is specified, IP security is used, with the list of security methods specified in the main mode and quick mode policies.

**[ actionoutbound={ permit| block| negotiate}]**

Specifies the action that IPSec is required to take for outbound traffic. If **permit** is specified, traffic is sent without negotiating or applying IP security. If **block** is specified, traffic is blocked. If **negotiate** is specified, IP security is used, with the list of security methods specified in the main mode and quick mode policies.

**[ kerberos={ yes | no}]**

Specifies whether to use the Kerberos V5 protocol as an authentication method.

**[ psk=*String*]**
Specifies the string of characters to use for the preshared key, if a preshared key is used as an authentication method.

**[ rootca="*String*certmap:{ yes| no} excludecaname:{ yes| no} "]**
Specifies certificate authentication options, where:

***String***
Specifies the distinguished name of the certificate, if a certificate is used as an authentication method.

**certmap:{ yes| no}**
Specifies whether to enable certificate-to-account mapping. You can enable certificate-to-account mapping to verify that the certificate is being used by a trusted computer.

**excludecaname:{ yes| no}**
Specifies whether to exclude from the certificate request the list of trusted root CA names from which a certificate is accepted.

**Remarks**

- You can modify the following parameters: **mmpolicy=**, **qmpolicy=**, **actioninbound=**, and **actionoutbound=**. All other parameters are used to identify the rule that you want to modify, and therefore they cannot be modified.
- If the filter action for both inbound and outbound traffic (**actioninbound** and **actionoutbound**) are set to **Permit** or **Block**, a quick mode filter is not required.
- If a tunnel rule is specified, **mirror** should be set to **no** (by default, **mirror** is set to **yes**). For IPSec tunnels, you must create two rules: one rule describes the traffic to be sent through the tunnel (outbound traffic) and the other describes the traffic to be received through the tunnel (inbound). Next, create two rules that use the inbound and outbound filter lists in your policy.
- To filter any packets sent from or to the computer, you can use **srcaddr=Me** or **dstaddr=Me**.
- To filter packets sent from or to any computer, you can use **srcaddr=Any** or **dstaddr=Any**.
- You can only use Kerberos V5 authentication or certificate-to-account mapping for computers that are members of an Active Directory domain.
- Although you can use only one preshared key for authentication, you can use multiple certificates by specifying the **rootca** parameter once, for each certificate you want to use.
- All certificate authentication parameters must be contained within quotation marks. Embedded quotation marks must be replaced by a backslash followed by an apostrophe (\').
- All string parameters are case-sensitive.
- The preference order of each authentication method is determined by the order in which it was specified in the command.
- If no authentication methods are specified, dynamic defaults are used. By default, IPSec policies use Kerberos V5 authentication. If the computer has a computer certificate, any root CA to which the computer certificate chains is also used for authentication.
- If **excludecaname:yes** is specified, the list of trusted root CAs is not sent as part of the certificate request, which prevents the potential disclosure of sensitive information about the trust relationships of a computer. To enhance security for computers connected to the Internet, specify this option.
- The use of preshared key authentication is not recommended because it is a relatively weak authentication method. In addition, preshared keys are stored in plaintext.
- IPSec peers must have at least one common authentication method or communication will fail.

- Modifying authentication methods will overwrite all previous authentication methods, even if the previous authentication methods were different. For example, if **kerberos=yes** and **psk=yes** were previously specified, and then you specify **kerberos=no**, the **psk=yes** parameter will also be overwritten, and preshared key authentication will no longer be used.

**show all**
Displays configuration information for all IPSec policies, filters, statistics, and security associations in the SPD.

**Syntax**
**show all** [**resolvedns=**]

**Parameters**
**[ resolvedns={ yes | no}]**
Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations.

**Remarks**

- Because the **show all** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show all** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show all**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show all >***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show config**
Displays values for the following IPSec settings: IPSec diagnostics, default traffic exemptions, strong certificate revocation list (CRL) checking, IKE (Oakley) logging, logging intervals, computer startup security, and computer startup traffic exemptions.

**Syntax**
**show config**

**Parameters**
None.

**Remarks**

- To save output in a text file for the **show config** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show config**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show config >***FileName*.txt

**show mmfilter**

Displays configuration information for the specified IPSec main mode filter, or for all IPSec main mode filters, in the SPD.

**Syntax**

**show mmfilter name=** | **all** [**type=**] **srcaddr=dstadd=** [**srcmask=**][**dstmask=**] [**resolvedns=**]

**Parameters**

**name= *String*| all**
Required. Specifies the name of the IPSec main mode filter to display. Or, if **all** is specified, all IPSec main mode filters are displayed.

**type={ generic| specific}**
Specifies whether to display generic or specific main mode filters. The default value is **generic**.

**[ srcaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the source IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ dstaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the destination IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ srcmask={ *Mask*| *Prefix*}]**
Specifies the source address subnet mask or the prefix of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={ *Mask*| *Prefix*}]**
Specifies the destination address subnet mask or the prefix value of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ resolvedns={ yes | no}]**
Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations. The default value is **no**.

**Remarks**

- All string parameters are case-sensitive.

- Because the **show mmfilter** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show mmfilter** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show mmfilter***Name* | **all**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **ipsec dynamic show mmfilter***Name* | **all >=***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show mmpolicy**

Displays configuration information for the specified IPSec main mode policy, or for all IPSec main mode policies, in the SPD.

**Syntax**

**show mmpolicy name=** | **all**

**Parameters**

**name=** ***String*| all**

Required. Specifies the name of the IPSec main mode policy to display. Or, if **all** is specified, all IPSec main mode policies are displayed.

**Remarks**

- All string parameters are case-sensitive.

- Because the **show mmpolicy** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show mmpolicy** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

2. Then type:

   **ipsec dynamic show mmpolicy***Name* | **all**

3. To stop sending output and close the file, type:

   **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **ipsec dynamic show mmpolicy***Name* | **all >***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show mmsas**

Displays the IPSec main mode security associations for the specified source and destination addresses, or all IPSec main mode security associations, in the SPD.

**Syntax**

**show mmsas** [**all**] [**srcaddr=**][**dstaddr=**][**format=**] [**resolvedns=**]

**Parameters**

**[ all]**
Specifies that all main mode security associations are displayed.

**[ srcaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the source IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ dstaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the destination IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ format={ list| table}]**
Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ resolvedns={ yes | no}]**
Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations. The default value is **no**.

**Remarks**

- If no parameters are specified, all main mode security associations are displayed.

- All string parameters are case-sensitive.

- Because the **show mmsas** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show mmsas** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

1. At the netsh prompt, type:

   **set file open** *FileName*.txt

2. Then type:

   **ipsec dynamic show mmsas**

3. To stop sending output and close the file, type:

   **set file close**

**If you are not in the netsh environment**

- At the command prompt, type:

  **netsh ipsec dynamic show mmsas >***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:
  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.
  - Use Task Manager to end the **Netsh** program.

**show qmfilter**

Displays configuration information for the specified quick mode filter, or for all quick mode filters, in the SPD.

**Syntax**

**show qmfilter name=** | **all** [**type=**] [**srcaddr=**][**dstaddr=**][**srcmask=**][**dstmask=**][**protocol=**][**srcport=**][**dstport=**] [**actioninbound=**][**actionoutbound=**][**resolvedns=**]

**Parameters**

**name=** ***String*| all**
Required. Specifies the name of the IPSec quick mode filter to display, or, if **all** is specified, that all IPSec quick mode filters are displayed.

**[ type={ generic| specific}]**
Specifies whether to display generic or specific quick mode filters. The default value is **generic**.

**[ srcaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the source IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ dstaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the destination IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ srcmask={ *Mask*| *Prefix*}]**
Specifies the source address subnet mask or the prefix of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={ *Mask*| *Prefix*}]**
Specifies the destination address subnet mask or the prefix value of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ protocol={ ANY| ICMP| TCP| UDP| RAW| *Integer* }]**
Specifies the IP protocol if, in addition to addressing information, a specific IP protocol is filtered. The default value is **ANY**, meaning all protocols are used for the filter.

**[ srcport=*Port*]**
Specifies the source port number of the packets being filtered. This option only applies if you are filtering TCP or UDP

packets. If 0 is specified, packets sent from any port are filtered. The default is any.

**[ dstport=*Port*]**
Specifies the destination port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent to any port are filtered. The default is any.

**[ actioninbound={ permit| block| negotiate}]**
Specifies the action that IPSec is required to take for inbound traffic. The default value is **negotiate**.

**[ actionoutbound={ permit| block| negotiate}]**
Specifies the action that IPSec is required to take for outbound traffic. The default value is **negotiate**

**[ resolvedns={ yes | no}]**
Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations. The default value is **no**.

**Remarks**

- All string parameters are case-sensitive.
- Because the **show qmfilter** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show qmfilter** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show qmfilter** *Name* | **all**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show qmfilter** *Name* | **all** >*FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:
  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.
  - Use Task Manager to end the **Netsh** program.

**show qmpolicy**
Displays configuration information for the specified IPSec quick mode policy, or for all IPSec quick mode policies, in the SPD.

**Syntax**
**show qmpolicy name=** | **all**

**Parameters**
**name=** ***String*| all**
Required. Specifies the name of the IPSec quick mode policy to display. Or, if **all** is specified, all IPSec quick mode policies are

displayed.

**Remarks**

- All string parameters are case-sensitive.
- Because the **show qmpolicy** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show qmpolicy** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show qmpolicy***Name* | **all**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show qmpolicy***Name* | **all** >*FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:
  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.
  - Use Task Manager to end the **Netsh** program.

**show qmsas**
Displays the IPSec quick mode security associations for the specified source and destination addresses, or all IPSec quick mode security associations, in the SPD.

**Syntax**
**show qmsas** [**all**][**srcaddr=**][**dstaddr=**][**protocol=**][**format=**][**resolvedns=**]

**Parameters**
**[ all]**
Specifies that all IPSec quick mode security associations are displayed.

**[ srcaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the source IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ dstaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*]**
Specifies the destination IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ protocol={ ANY| ICMP| TCP| UDP| RAW| *Integer* }]**
Specifies the IP protocol if, in addition to addressing information, a specific IP protocol is being used for the security association. The default value is **ANY**, meaning all protocols are used for the security association.

**[ format={ list| table}]**
Specifies whether to display IPSec configuration information in screen or tab-delimited format. The default value is **list**, meaning that output is displayed in screen format.

**[ resolvedns={ yes | no}]**
Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations. The default value is **no**.

**Remarks**

- Because the **show qmsas** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show qmsas** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show qmsas all**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show qmsas all** >*FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.

  - Use Task Manager to end the **Netsh** program.

**show rule**
Displays configuration information for one or more IPSec rules in the SPD.

**Syntax**
**show rule** [**type=**][**srcaddr=**] [**dstaddr=**][**srcmask=**][**dstmask=**] [**protocol=**][**srcport=**][**dstport=**][**actioninbound=**] [**actionoutbound=**][**resolvedns=**]

**Parameters**
**[ type={ transport| tunnel}]**
Specifies whether to display a transport rule or a tunnel rule. The default value is to display all rules.

**[ srcaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the source IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ dstaddr={ Me| Any| *IPAddress*| *DNSName*| *ServerType*}]**
Specifies the destination IP address, DNS name, or server type for the IP traffic being filtered. You can use **WINS**, **DNS**, **DHCP**, or **gateway** for *ServerType*.

**[ srcmask={ *Mask*| *Prefix*}]**
Specifies the source address subnet mask or the prefix of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ dstmask={ *Mask*| *Prefix*}]**
Specifies the destination address subnet mask or the prefix value of the packets being filtered. You can specify a prefix value in the range of 1 through 32. The default value is the mask of 255.255.255.255.

**[ protocol={ ANY| ICMP| TCP| UDP| RAW| *Integer* }]**
Specifies the IP protocol if, in addition to addressing information, a specific IP protocol is used for the rule. The default value is **ANY**, meaning all protocols are used for the rule.

**[ srcport=*Port*]**
Specifies the source port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent from any port are filtered. The default is any.

**[ dstport=*Port*]**
Specifies the destination port number of the packets being filtered. This option only applies if you are filtering TCP or UDP packets. If 0 is specified, packets sent to any port are filtered. The default is any.

**[ actioninbound={ permit| block| negotiate}]**
Specifies the action that IPSec is required to take for inbound traffic. The default value is **negotiate**.

**[ actionoutbound={ permit| block| negotiate}]**
Specifies the action that IPSec is required to take for outbound traffic. The default value is **negotiate**.

**[ resolvedns={ yes | no}]**
Specifies whether to resolve the Domain Name System (DNS) or NETBIOS computer name associated with an IP address when displaying sources or destinations. The default value is **no**.

**Remarks**

- All string parameters are case-sensitive.

- Because the **show rule** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show rule** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show rule**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show rule >***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:

- Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.
- Use Task Manager to end the **Netsh** program.

**show stats**
Displays main mode and quick mode statistics for IPSec.

**Syntax**
**show stats** [**type=**]

**Parameters**
**[ type=all| ike| ipsec]**
Specifies the IPSec statistics to display. If **all** is specified, IPSec main mode and quick mode statistics are displayed. If **ike** is specified, only IPSec main mode statistics are displayed. If **ipsec** is specified, only IPSec quick mode statistics are displayed.

**Remarks**

- Because the **show stats** command can result in lengthy, rapidly scrolling output, consider saving the output in a text file, unless you only need to view limited portions.

  To save output in a text file for the **show stats** command, do either of the following:

  **If you are in the netsh environment (netsh>)**

  1. At the netsh prompt, type:

     **set file open** *FileName*.txt

  2. Then type:

     **ipsec dynamic show stats**

  3. To stop sending output and close the file, type:

     **set file close**

  **If you are not in the netsh environment**

  - At the command prompt, type:

    **netsh ipsec dynamic show stats >***FileName*.txt

- To stop the output of IPSec configuration information, you must exit **Netsh** by doing one of the following:
  - Close the **Netsh** window by clicking the **X** icon in the upper-right corner of the window.
  - Use Task Manager to end the **Netsh** program.

**Formatting legend**

# Netsh commands for Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for Network Bridge**
For adapters that are part of the Network Bridge, you can use commands in the **netsh bridge** context to enable or disable Layer 3 compatibility mode and show configuration information for these adapters.

You can run these commands from the Windows Server 2003 family command prompt or from the **netsh bridge** context. To successfully run these commands at the Windows Server 2003 family command prompt, you must type **netsh bridge** before typing the commands and parameters as they appear in this topic.

For more information about **netsh**, see Netsh overview and Enter a netsh context.

To view the command syntax, click a command:

- show adapter
- set adapter

### Note

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**show adapter**
Displays adapter identification, adapter names, and the state of the Layer 3 compatibility mode of adapters that are part of Network Bridge.

**Syntax**
**show adapter** [[**id=**]*AdapterID*]

**Parameters**
**[[ id=] *AdapterID*]**
Optional. Specifies the information to display for a specific adapter.

***/?***
Displays help at the command prompt.

**Examples**
In the first example, this command lists all of the adapters that are part of Network Bridge, and provides adapter ID numbers, friendly names, and the state of the Layer 3 compatibility mode that corresponds to each adapter.

In the second example, this command lists the adapter ID, friendly name, and the state of the Layer 3 compatibility mode information for adapter 2.

**show adapter**

**show adapter 2**

**set adapter**
This command modifies the configuration of a specified adapter that is part of Network Bridge by setting the state of the adapter to either enable or disable network layer (Layer 3) compatibility mode.

**Syntax**
**set adapter** [**id=**]*AdapterID* [**forcecompatmode=**]{**enable** | **disable**}

**Parameters**
**[ id=] *AdapterID***
Required. Specifies which adapter that is part of Network Bridge to configure.

**[ forcecompatmode=]{ enable| disable}**
Required. Specifies whether Layer 3 mode compatibility is enabled or disabled for the specified adapter.

**/?**
Displays help at the command prompt.

**Remarks**

- This command should only be run if an enabled Network Bridge does not forward network traffic to all network segments. This condition can exist if one or more network adapters (typically wireless) included in the bridge do not support promiscuous mode.

- For more information about determining adapter ID values, see show adapter.

**Examples**
In this example, the command is used to force adapter 2 to run in Layer 3 compatibility mode.

**set adapter 2 forcecompatmode=enable**

## Notes

- The **install** and **uninstall** commands are not supported in the **netsh bridge** context. Network Bridge can only be set up or removed through Network Connections. For more information, see Set up Network Bridge or Remove Network Bridge.

- The **dump** command is not supported in the **netsh bridge** context.

**Formatting legend**

| Format | Meaning |

# Netsh commands for remote access (ras)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for remote access (ras)**
You can administer remote access servers by typing commands at the command prompt for the **Netsh ras** context. By using the **Netsh ras** command prompt, you can administer servers more quickly over slow network connections, and you can create scripts that automate the administration of many servers.

For more information on Netsh, see Netsh overview and Enter a netsh context.

To view the command syntax, click a command:

- help
- show activeservers
- show client
- dump
- show tracing
- set tracing
- show authmode
- set authmode
- add authtype
- delete authtype
- show authtype
- add link
- delete link
- show link
- add multilink
- delete multilink
- show multilink
- add registeredserver
- delete registeredserver
- show registeredserver
- show user

- set user
- Netsh ras diagnostics context commands
- Netsh ras IP context commands
- Netsh ras AppleTalk context commands
- Netsh ras AAAA context commands

**help**
Displays command-line help for commands you can use in the Netsh ras context.

**Syntax**
**help**

**Parameters**
none

**Remarks**

- You can also display command-line help by typing any of the following at the command prompt for the Netsh ras context: **?**, **/?**, or **-?**.

**show_activeservers**
Displays a list of remote access server advertisements.

**Syntax**
**show activeservers**

**Parameters**
none

**show_client**
Lists remote access clients connected to this server.

**Syntax**
**show client**

**Parameters**
none

**dump**
Displays the configuration of the remote access server in script form.

**Syntax**
**dump**

**Parameters**
none

**show_tracing**
Shows whether tracing is enabled for the specified component. Used without parameters, **show tracing** lists all installed components and whether tracing is enabled for each.

**Syntax**
**show tracing** [*Component*]

**Parameters**
***Component***
Specifies the component for which to display information.

**set_tracing**
Enables or disables tracing for the specified component.

**Syntax**

**set tracing** *Component* {**enabled** | **disabled**}

**Parameters**

***Component***

Required. Specifies the component for which you want to enable or disable tracing. Use ***** to specify all components.

**{ enabled| disabled}**

Required. Specifies whether to enable or disable tracing for the specified component.

**Remarks**

- To see a list of all installed components, use the **show tracing** command without parameters.

**Examples**

To set tracing for the PPP component, type:

**set tracing ppp enabled**

**show_authmode**

Shows whether dial-up clients using certain types of devices should be authenticated.

**Syntax**

**show authmode**

**Parameters**

none

**set_authmode**

Specifies whether dial-up clients using certain types of devices should be authenticated.

**Syntax**

**set authmode** {**standard** | **nodcc** | **bypass**}

**Parameters**

**{ standard| nodcc| bypass}**

Required. Specifies whether dial-up clients using certain types of devices should be authenticated. The parameter **standard** specifies that clients using any type of device should be authenticated. The parameter **nodcc** specifies that clients using any type of device except a direct-connect device should be authenticated. The parameter **bypass** specifies that no clients should be authenticated.

**add_authtype**

Adds an authentication type to the list of types through which the remote access server should attempt to negotiate authentication.

**Syntax**

**add authtype** {**pap** | **spap** | **md5chap** | **mschap** | **mschapv2** | **eap**}

**Parameters**

**{ pap| spap| md5chap| mschap| mschapv2| eap}**

Required. Specifies which authentication type to add to the list of types through which the remote access server should attempt to negotiate authentication. The **pap** parameter specifies that the remote access server should use the Password Authentication Protocol (plaintext). The **spap** parameter specifies that the remote access server should use the Shiva Password Authentication Protocol. The **md5chap** parameter specifies that the remote access server should use the Challenge Handshake Authentication Protocol (using the Message Digest 5 hashing scheme to encrypt the response). The **mschap** parameter specifies that the remote access server should use the Microsoft Challenge-Handshake Authentication Protocol. The **mschapv2** parameter specifies that the remote access server should use Version 2 of MSCHAP. The **eap** parameter specifies that the remote access server should use Extensible Authentication Protocol.

**Remarks**

- The remote access server will attempt to negotiate authentication by using protocols in order from the most secure to the least secure. After both the client and the server have agreed on an authentication type, PPP negotiation proceeds according to the appropriate RFCs.

**delete_authtype**

Deletes an authentication type from the list of types through which the remote access server should attempt to negotiate

authentication.

**Syntax**

**delete authtype**{**pap** | **spap** | **md5chap** | **mschap** | **mschapv2** | **eap**}

**Parameters**

**{ pap| spap| md5chap| mschap| mschapv2| eap}**

Required. Specifies which authentication type to delete from the list of types through which the remote access server should attempt to negotiate authentication. The **pap** parameter specifies that the remote access server should not use the Password Authentication Protocol (plaintext). The **spap** parameter specifies that the remote access server should not use the Shiva Password Authentication Protocol. The **md5chap** parameter specifies that the remote access server should not use the Challenge Handshake Authentication Protocol (using the Message Digest 5 hashing scheme to encrypt the response). The **mschap** parameter specifies that the remote access server should not use the Microsoft Challenge-Handshake Authentication Protocol. The **mschapv2** parameter specifies that the remote access server should not use Version 2 of MSCHAP. The **eap** parameter specifies that the remote access server should not use Extensible Authentication Protocol.

**show_authtype**

Lists the authentication type (or types) that the remote access server uses to attempt to negotiate authentication.

**Syntax**

**show authtype**

**Parameters**

none

**add_link**

Adds a link property to the list of link properties PPP should negotiate.

**Syntax**

**add link** {**swc** | **lcp**}

**Parameters**

**{ swc| lcp}**

Required. Specifies which link property to add to the list of link properties PPP should negotiate. The parameter **swc** specifies that software compression (MPPC) should be added. The parameter **lcp** specifies that Link Control Protocol extensions from the PPP suite of protocols should be added.

**delete_link**

Deletes a link property from the list of link properties PPP should negotiate.

**Syntax**

**delete link** {**swc** | **lcp**}

**Parameters**

**{ swc| lcp}**

Required. Specifies which link property to delete from the list of link properties PPP should negotiate. The parameter **swc** specifies that software compression (MPPC) should be deleted. The parameter **lcp** specifies that Link Control Protocol extensions from the PPP suite of protocols should be deleted.

**show link**

Displays the link properties PPP should negotiate.

**Syntax**

**show link**

**Parameters**

none

**add multilink**

Adds a multilink type to the list of multilink types PPP should negotiate.

**Syntax**

**add multilink** {**multi** | **bacp**}

**Parameters**

**{ multi| bacp}**

Required. Specifies which multilink type to add to the list of multilink types PPP should negotiate. The parameter **multi** specifies that multilink PPP sessions should be added. The parameter **bacp** specifies that Bandwidth Allocation Control

Protocol should be added.

**delete multilink**
Deletes a multilink type from the list of multilink types PPP should negotiate.

**Syntax**
**delete multilink** {**multi** | **bacp**}

**Parameters**
**{ multi| bacp}**
Required. Specifies which multilink type to delete from the list of multilink types PPP should negotiate. The parameter **multi** specifies that multilink PPP sessions should be deleted. The parameter **bacp** specifies that Bandwidth Allocation Control Protocol should be deleted.

**show multilink**
Shows the multilink types PPP should negotiate.

**Syntax**
**show multilink**

**Parameters**
none

**add registeredserver**
Registers the specified server as a remote access server in the specified Active Directory domain. Used without parameters, **add registeredserver** registers the computer from which you type the command in its primary domain.

**Syntax**
**add registeredserver** [[**domain=**]*DomainName*] [[**server=**]*ServerName*]

**Parameters**
**[ domain=] *DomainName***
Specifies, by domain name, the domain in which to register the server. If you do not specify a domain, the server is registered in its primary domain.

**[ server=] *ServerName***
Specifies, by DNS name or IP address, the server to register. If you do not specify a server, the computer from which you type the command is registered.

**delete registeredserver**
Deletes the registration of the specified server as a remote access server from the specified Active Directory domain. Used without parameters, **delete registeredserver** deletes the registration of the computer from which you type the command from its primary domain.

**Syntax**
**delete registeredserver** [[**domain=**]*DomainName*] [[**server=**]*ServerName*]

**Parameters**
**[ domain=] *DomainName***
Specifies, by domain name, the domain from which to remove the registration. If you do not specify a domain, the registration is removed from the primary domain of the computer from which you type the command.

**[ server=] *ServerName***
Specifies, by IP address or DNS name, the server whose registration you want to remove. If you do not specify a server, the registration is removed for the computer from which you type the command.

**show registeredserver**
Displays status information about the specified server registered as a remote access server in the specified Active Directory domain. Used without parameters, **show registeredserver** displays information about the computer from which you type the command in its primary domain.

**Syntax**
**show registeredserver** [[**domain=**]*DomainName*] [[**server=**]*ServerName*]

**Parameters**
**[ domain=] *DomainName***
Specifies, by domain name, the domain in which the server about which you want to display information is registered. If you do not specify a domain, information is displayed about the server as it is registered in the primary domain of the computer

from which you type the command.

**[ server=] *ServerName***
Specifies, by IP address or DNS name, the server about which you want to display information. If you do not specify a server, information about the computer from which you typed the command is displayed.

**show user**
Displays the properties of a specified remote access user or users. Used without parameters, **show user** displays the properties of all remote access users.

**Syntax**
**show user** [**name=***UserName*] [[**mode=**] {**permit** | **report**}]

**Parameters**
**name= *UserName***
Specifies, by logon name, the user whose properties you want to display. If you do not specify a user, the properties of all users are displayed.

**mode={ permit| report}**
Specifies whether to show properties for all users or only those whose dial-up permission is set to permit. The **permit** parameter specifies that properties should be displayed only for users whose dial-up permission is permit. The **report** parameter specifies that properties should be displayed for all users.

**setuser**
Sets the properties of the specified remote access user.

**Syntax**
**set user** [**name=**]*UserName* [**dialin**] {**permit** | **deny** | **policy**} [**cbpolicy**] {**none** | **caller** | **admin** [**cbnumber=**]*CallbackNumber*}

**Parameters**
**name= *UserName***
Required. Specifies, by logon name, the user for which you want to set properties.

**[ dialin] { permit| deny| policy}**
Required. Specifies under what circumstances the user should be allowed to connect. The **permit** parameter specifies that the user should always be allowed to connect. The **deny** parameter specifies that the user should never be allowed to connect. The **policy** parameter specifies that remote access policies should determine whether the user is allowed to connect.

**[ cbpolicy] { none| caller| admin[ cbnumber=] *CallbackNumber*}**
Required. Specifies the callback policy for the user. The callback feature saves the user the cost of the phone call used to connect to a remote access server. The **none** parameter specifies that the user should not be called back. The **caller** parameter specifies that the user should be called back at a number specified by the user at connection time. The **admin** parameter specifies that the user should be called back at the number specified by the *CallbackNumber* parameter.

**Remarks**

- For users in a mixed-mode domain, the **policy** parameter and the **deny** parameter are equivalent.

**Examples**
To allow GuestUser to connect and be called back at 4255550110, type:

**set user guestuser permit admin 4255550110**

**Netsh ras diagnostics context commands**
The following commands are specific to the **ras diagnostics** context within the Netsh environment.

To view the command syntax, click a command:

- dump
- show installation
- show logs

- show configuration
- show all
- show cmtracing
- set cmtracing
- show modemtracing
- set modemtracing
- show rastracing
- set rastracing
- show securityeventlog
- set securityeventlog
- show tracefacilities
- set tracefacilities

**dump**
Displays the configuration of Remote Access Diagnostics in script form.

**Syntax**
**dump**

**Parameters**
none

**show installation**
Creates a Remote Access Diagnostic Report that includes only diagnostics results for Information Files, Installation Check, Installed Networking Components, and Registry Check and delivers the report to a location you specify.

**Syntax**
**show installation** [**type=**] {**file** | **email**} [**destination=**] {*FileLocation* | *E-mailAddress*} [[**compression=**] {**enabled** | **disabled**}] [[**hours=**] *NumberOfHours*] [[**verbose=**] {**enabled** | **disabled**}]

**Parameters**
**[ type=] { file| email}**
Required. Specifies whether you want to save the report to a file or you want to send it to an e-mail address.

**[ destination=] { *FileLocation*| *E-mailAddress*}**
Required. Specifies the full path and file name to which the report should be saved or the full e-mail address to which the report should be sent.

**[[ compression=] { enabled| disabled}]**
Specifies whether to compress the report into a .cab file. If you do not specify this parameter, the report is compressed if you send it to an e-mail address but not if you save it to a file.

**[[ hours=] *NumberOfHours*]**
Specifies the number of past hours for which to show activity in the report. This parameter must be an integer between 1 and 24. If you do not specify this parameter, all past information is included.

**[[ verbose=] { enabled| disabled}]**
Specifies the amount of data to include in the report. If you do not specify this parameter, only minimal data is included.

**Remarks**

- The Remote Access Diagnostic Report is saved as an HTML file (.htm).

#### show logs

Creates a Remote Access Diagnostic Report that contains only diagnostics results for Tracing Logs, Modem Logs, Connection Manager Logs, IP Security Log, Remote Access Event Logs, and Security Event Logs and delivers the report to a location you specify.

**Syntax**

**show logs** [**type=**] {**file** | **email**} [**destination=**] {*FileLocation* | *E-mailAddress*} [[**compression=**] {**enabled** | **disabled**}] [[**hours=**] *NumberOfHours*] [[**verbose=**] {**enabled** | **disabled**}]

**Parameters**

**[ type=] { file| email}**
Required. Specifies whether you want to save the report to a file or you want to sent it to an e-mail address.

**[ destination=] { *FileLocation*| *E-mailAddress*}**
Required. Specifies the full path and file name to which the report should be saved or the full e-mail address to which the report should be sent.

**[[ compression=] { enabled| disabled}]**
Specifies whether to compress the report into a .cab file. If you do not specify this parameter, the report is compressed if you send it to an e-mail address but not if you save it to a file.

**[[ hours=] *NumberOfHours*]**
Specifies the number of past hours for which to show activity in the report. This parameter must be an integer between 1 and 24. If you do not specify this parameter, all past information will be included in the report.

**[[ verbose=] { enabled| disabled}]**
Specifies the amount of data to include in the report. If you do not specify this parameter, minimal data is included.

**Remarks**

- The Remote Access Diagnostic Report is saved as an HTML file (.htm).

#### show configuration

Creates a Remote Access Diagnostic Report that includes only diagnostics results for Installed Devices, Process Information, Command-Line Utilities, and Phone Book Files and delivers the report to a location you specify.

**Syntax**

**show configuration** [**type=**] {**file** | **email**} [**destination=**] {*FileLocation* | *E-mailAddress*} [[**compression=**] {**enabled** | **disabled**}] [[**hours=**] *NumberOfHours*] [[**verbose=**] {**enabled** | **disabled**}]

**Parameters**

**[ type=] { file| email}**
Required. Specifies whether the report should be saved to a file or sent to an e-mail address.

**[ destination=] { *FileLocation*| *E-mailAddress*}**
Required. Specifies the full path and file name to which the report should be saved or the full e-mail address to which the report should be sent.

**[[ compression=] { enabled| disabled}]**
Specifies whether to compress the report into a .cab file. If you do not specify this parameter, the report is compressed if you send it to an e-mail address but not if you save it to a file.

**[[ hours=] *NumberOfHours*]**
Specifies the number of past hours for which to show activity in the report. This parameter must be an integer between 1 and 24. If you do not specify this parameter, all past information is included.

**[[ verbose=] { enabled| disabled}]**
Specifies the amount of data to include in the report. If you do not specify this parameter, minimal data is included.

**Remarks**

- The Remote Access Diagnostic Report is saved as an HTML file (.htm).

**show all**
Creates a Remote Access Diagnostic Report for all remote access logs and delivers the report to a location you specify.

**Syntax**
**show all** [**type=**] {**file** | **email**} [**destination=**] {*FileLocation* | *E-mailAddress*} [[**compression=**] {**enabled** | **disabled**}] [[**hours=**] *NumberOfHours*] [[**verbose=**] {**enabled** | **disabled**}]

**Parameters**
**[ type=] { file| email}**
Required. Specifies whether you want to save the report to a file or sent it to an e-mail address.

**[ destination=] { *FileLocation*| *E-mailAddress*}**
Required. Specifies the full path and file name to which the report should be saved or the full e-mail address to which the report should be sent.

**[[ compression=] { enabled| disabled}]**
Specifies whether to compress the report into a .cab file. If you do not specify this parameter, the report is compressed if you send it to an e-mail address but not if you save it to a file.

**[[ hours=] *NumberOfHours*]**
Specifies the number of past hours for which to show activity in the report. This parameter must be an integer between 1 and 24. If you do not specify this parameter, all past information is included.

**[[ verbose=] { enabled| disabled}]**
Specifies the amount of data to include in the report. If you do not specify this parameter, minimal data is included.

**Remarks**

- The Remote Access Diagnostic Report is saved as an HTML file (.htm).
- The Remote Access Diagnostic Report that you create by using the **show all** command contains all diagnostic information available. You can use other commands, such as **show configuration**, to create reports that contain a narrower scope of information.

**show cmtracing**
Shows whether information about Connection Manager connections is being logged.

**Syntax**
**show cmtracing**

**Parameters**
none

**set cmtracing**
Enables or disables logging of information about all Connection Manager connections.

**Syntax**
**set cmtracing** {**enabled** | **disabled**}

**Parameters**
**{ enabled| disabled}**
Required. Specifies whether you want information about Connection Manager connections to be logged. The **enabled** parameter specifies that you want information to be logged. The **disabled** parameter specifies that you do not want information to be logged.

**Remarks**

- Each log file for a Connection Manager connection contains information that is specific to the history of that connection. Each Connection Manager connection generates a unique log file. Depending on the configuration of the connection, the log file might be saved in any of various locations. For more information, see Connection Manager Administration Kit and Troubleshooting process.
- This command will be be overridden for a particular connection if the user enables or disables logging for that connection or if the user installs and uses a Connection Manager profile for which an administrator has enabled or disabled logging.

**show modemtracing**
Shows whether modem tracing is enabled or disabled.

**Syntax**
**show modemtracing**

**Parameters**
none

**set modemtracing**
Enables or disables modem tracing for all modems installed for the local computer.

**Syntax**
**set modemtracing** {**enabled** | **disabled**}

**Parameters**
**{ enabled| disabled}**
Required. Specifies whether you want modem activity for each modem to be logged. The **enabled** parameter specifies that you want activity to be logged. The **disabled** parameter specifies that you do not want activity to be logged.

**Remarks**

- This command enables or disables the logging of modem activity for all modems. If you want to enable or disable modem logging for a specific modem, you should configure the modem in Device Manager.

**show rastracing**
Shows whether all activity for remote access components is traced.

**Syntax**
**show rastracing**

**Parameters**
none

**set rastracing**
Enables or disables tracing and logging of all activity for all remote access components or for a specific remote access component.

**Syntax**
**set rastracing** [**component=**] {*Component* | *} {**enabled** | **disabled**}

**Parameters**
**[ component=] { *Component*| *}**
Required. Specifies whether you want to enable or disable tracing and logging for a component that you specify or for all components. The *Component* parameter specifies the component for which you want to enable or disable tracing and logging.

**{ enabled| disabled}**
Required. Specifies whether you want activity to be traced and logged. The **enabled** parameter specifies that you want activity to be traced and logged. The **disabled** parameter specifies that you do not want activity to be traced and logged.

**Remarks**

- If you enable tracing and logging, a log file named *Component*.txt is created in the %windir%\tracing directory for each component being traced.

**show securityeventlog**
Shows whether security events are being logged.

**Syntax**
**show securityeventlog**

**Parameters**
none

**set securityeventlog**
Enables or disables logging of all security events.

**Syntax**
**set securityeventlog** {**enabled** | **disabled**}

**Parameters**
**{ enabled| disabled}**
Required. Specifies whether you want security events to be logged. The **enabled** parameter specifies that you want security events to be logged. The **disabled** parameter specifies that you do not want security events to be logged.

**show tracefacilities**
Shows whether all activity for all remote access components or for a remote access component that you specify is being traced and logged.

**Syntax**
**show tracefacilities**

**Parameters**
none

**set tracefacilities**
Enables or disables tracing and logging of all activity for all remote access components that are configured on the local computer.

**Syntax**
**set tracefacilities** [**state=**] {**enabled** | **disabled** | **clear**}

**Parameters**
**[ state=] { enabled| disabled| clear}**
Required. Specifies whether you want to enable tracing for all remote access components, to disable tracing, or to clear all logs generated by tracefacilities. The **enabled** parameter specifies that you want to enable tracing. The **disabled** parameter specifies that you want to disable tracing. The **clear** parameter specifies that you want to clear all logs.

**Netsh ras IP context commands**
The following commands are specific to the **ras IP** context within the Netsh environment.

To view the command syntax, click a command:

- dump
- show config
- set negotiation
- set access
- set addassign
- set addrreq
- set broadcastnameresolution
- show broadcastnameresolution
- add range
- delete range
- delete pool

**dump**
Creates a script that contains the IP configuration of a remote access server. If you save this script to a file, you can use it to

restore IP configuration settings.

**Syntax**
**dump**

**Parameters**
none

**show config**
Displays the current IP configuration of the remote access server.

**Syntax**
**show config**

**Parameters**
none

**set negotiation**
Specifies whether the remote access server should allow IP to be configured for any client connections the server accepts.

**Syntax**
**set negotiation** {**allow** | **deny**}

**Parameters**
**{ allow| deny}**
Required. Specifies whether to permit IP over client connections. The **allow** parameter allows IP over client connections. The **deny** parameter prevents IP over client connections.

**set access**
Specifies whether IP network traffic from any client should be forwarded to the network or networks to which the remote access server is connected.

**Syntax**
**set access** {**all** | **serveronly**}

**Parameters**
**{ all| serveronly}**
Required. Specifies whether clients should be able to reach the remote access server and any networks to which it is connected. The **all** parameter allows clients to reach networks through the server. The **serveronly** parameter allows clients to reach only the server.

**set addrassign**
Sets the method by which the remote access server should assign IP addresses to its clients.

**Syntax**
**set addrassign** {**auto** | **pool**}

**Parameters**
**{ auto| pool}**
Required. Specifies whether IP addresses should be assigned by using DHCP or from a pool of addresses held by the remote access server. The **auto** parameter specifies that addresses should be assigned by using DHCP. If no DHCP server is available, a random, private address is assigned. The **pool** parameter specifies that addresses should be assigned from a pool.

**set addrreq**
Specifies whether dial-up clients should be able to request their own IP addresses.

**Syntax**
**set addrreq** {**allow** | **deny**}

**Parameters**
**{ allow| deny}**
Required. Specifies whether clients should be able to request their own IP addresses. The **allow** parameter allows clients to request addresses. The **deny** parameter prevents clients from requesting addresses.

**set broadcastnameresolution**
Enables or disables broadcast name resolution using NetBIOS over TCP/IP.

**Syntax**

**set broadcastnameresolution** {**enabled** | **disabled**}

**Parameters**

**{ enabled| disabled}**

Required. Specifies whether to enable or disable broadcast name resolution using NetBIOS over TCP/IP.

**show broadcastnameresolution**

Displays whether broadcast name resolution using NetBIOS over TCP/IP has been enabled or disabled for the remote access server.

**Syntax**

**show broadcastnameresolution**

**Parameters**

none

**add range**

Adds a range of addresses to the pool of static IP addresses that the remote access server can assign to clients.

**Syntax**

**add range** [**from**=]*StartingIPAddress* [**to**=]*EndingIPAddress*

**Parameters**

**[ from=] *StartingIPAddress*[ to=] *EndingIPAddress***

Required. Specifies the range of IP addresses to add. The *StartingIPAddress* parameter specifies the first IP address in the range. The *EndingIPAddress* parameter specifies the last IP address in the range.

**Examples**

To add the range of IP addresses 10.2.2.10 to 10.2.2.20 to the static pool of IP addresses that the remote access server can assign, type:

**add range from=10.2.2.10 to=10.2.2.20**

**delete range**

Deletes a range of addresses from the pool of static IP addresses that the remote access server can assign to clients.

**Syntax**

**delete range** [**from**=]*StartingIPAddress* [**to**=]*EndingIPAddress*

**Parameters**

**[ from=] *StartingIPAddress*[ to=] *EndingIPAddress***

Required. Specifies the range of IP addresses to delete. The *StartingIPAddress* parameter specifies the first IP address in the range. The *EndingIPAddress* parameter specifies the last IP address in the range.

**Examples**

To delete the range of IP addresses 10.2.2.10 to 10.2.2.20 from the pool of static IP addresses that the remote access server can assign, type:

**delete range from=10.2.2.10 to=10.2.2.20**

**delete pool**

Deletes all addresses from the pool of static IP addresses that the remote access server can assign to clients.

**Syntax**

**delete pool**

**Parameters**

none

**Netsh ras AppleTalk context commands**

The following commands are specific to the **ras AppleTalk** context within the Netsh environment.

This feature is not available on the Itanium-based versions of the Windows operating systems. This content is not available in this preliminary release.

To view the command syntax, click a command:

- dump

- show config
- set negotiation

**dump**
Creates a script that contains the AppleTalk configuration of the remote access server. If you save this script to a file, you can use it to restore AppleTalk configuration settings.

**Syntax**
**dump**

**Parameters**
none

**show config**
Displays the current AppleTalk configuration of the remote access server.

**Syntax**
**show config**

**Parameters**
none

**set negotiation**
Specifies whether the remote access server should allow AppleTalk to be configured for any client connections the server accepts.

**Syntax**
**set negotiation** {**allow** | **deny**}

**Parameters**
**{ allow| deny}**
Required. Specifies whether to allow AppleTalk configuration. The **allow** parameter allows configuration. The **deny** parameter prevents configuration.

**Netsh ras AAAA context commands**
The following commands are specific to the **ras AAAA** context within the Netsh environment.

To view the command syntax, click a command:

- dump
- add acctserv
- delete acctserv
- set acctserv
- show authserv
- add authserv
- delete authserv
- set authserv
- show authserv
- set acco
- show acco

- set authe
- show authe

**dump**
Displays the AAAA configuration of a remote access server in script form.

**Syntax**
**dump**

**Parameters**
none

**add acctserv**
Specifies the IP address or the DNS name of a RADIUS server to use for accounting and specifies accounting options.

**Syntax**
**add acctserv** [**name**=]*ServerID*[[**secret**=]*SharedSecret*] [[**init-score**=]*ServerPriority*] [[**port**=]*Port*] [[**timeout**=]*Seconds*] [[**messages**] {**enabled** | **disabled**}]

**Parameters**
**[ name=] *ServerID***
Required. Specifies, by IP address or DNS name, the RADIUS server.

**[ secret=] *SharedSecret***
Specifies the shared secret.

**[ init-score=] *ServerPriority***
Specifies the initial score (server priority).

**[ port=] *Port***
Specifies the port to which accounting requests should be sent.

**[ timeout=] *Seconds***
Specifies the timeout period, in seconds, during which the RADIUS server can be idle before it should be marked unavailable.

**[ messages] { enabled| disabled}**
Specifies whether to send accounting on/off messages. The **enabled** parameter specifies that messages should be sent. The **disabled** parameter specifies that messages should not be sent.

**delete acctserv**
Deletes a RADIUS accounting server.

**Syntax**
**delete acctserv** [**name**=]*ServerID*

**Parameters**
**[ name=] *ServerID***
Required. Specifies, by DNS name or IP address, which server to delete.

**set acctserv**
Provides the IP address or the DNS name of a RADIUS server to use for accounting.

**Syntax**
**add acctserv** [**name=**]*ServerID* [[**secret=**]*SharedSecret*] [[**init-score=**]*ServerPriority*] [[**port=**]*Port*] [[**timeout=**]*Seconds*] [[**messages**] {**enabled** | **disabled**}]

**Parameters**
**[ name=] *ServerID***
Required. Specifies, by IP address or DNS name, the RADIUS server.

**[ secret=] *SharedSecret***
Specifies the shared secret.

**[ init-score=] *ServerPriority***
Specifies the initial score (server priority).

**[ port=] *Port***
Specifies the port on which to send the authentication requests.

**[ timeout=] *Seconds***
Specifies, in seconds, the amount of time that should elapse before the RADIUS server is marked unavailable.

**[ messages=] { enabled| disabled}**
Specifies whether accounting on/off messages should be sent.

#### show acctserv

Displays detailed information about an accounting server. Used without parameters, **show acctserv** displays information about all configured accounting servers.

#### Syntax

**show acctserv** [[**name**=]*ServerID*]

#### Parameters

**[ name=] *ServerID***
Specifies, by DNS name or IP address, the RADIUS server about which to display information.

#### add authserv

Provides the IP address or the DNS name of a RADIUS server to which authentication requests should be passed.

#### Syntax

**add authserv** [**name**=]*ServerID*[[**secret**=]*SharedSecret*] [[**init-score**=]*ServerPriority*] [[**port**=]*Port*] [[**timeout**=]*Seconds*] [[**signature**] {**enabled** | **disabled**}]

#### Parameters

**[ name=] *ServerID***
Required. Specifies, by IP address or DNS name, the RADIUS server.

**[ secret=] *SharedSecret***
Specifies the shared secret.

**[ init-score=] *ServerPriority***
Specifies the initial score (server priority).

**[ port=] *Port***
Specifies the port to which authentication requests should be sent.

**[ timeout=] *Seconds***
Specifies the timeout period, in seconds, during which the RADIUS server can be idle before it should be marked unavailable.

**[ signature] { enabled| disabled}**
Specifies whether to use digital signatures. The **enabled** parameter specifies that digital signatures should be used. The **disabled** parameter specifies that digital signatures should not be used.

#### delete authserv

Deletes a RADIUS authentication server.

#### Syntax

**delete authserv** [**name**=]*ServerID*

#### Parameters

**[ name=] *ServerID***
Required. Specifies, by DNS name or IP address, which server to delete.

#### set authserv

Provides the IP address or the DNS name of a RADIUS server to which authentication requests should be passed.

#### Syntax

**set authserv** [**name=**]*ServerID* [[**secret=**]*SharedSecret*] [[**init-score=**]*ServerPriority*] [[**port=**]*Port*] [[**timeout=**]*Seconds*] [[**signature**] {**enabled** | **disabled**}]

#### Parameters

**[ name=] *ServerID***
Required. Specifies, by IP address or DNS name, the RADIUS server.

**[ secret=] *SharedSecret***

Specifies the shared secret.

**[ init-score=]** ***ServerPriority***
Specifies the initial score (server priority).

**[ port=]** ***Port***
Specifies the port on which to send the authentication requests.

**[ timeout=]** ***Seconds***
Specifies the amount of time, in seconds, that should elapse before the RADIUS server is marked unavailable.

**[ signature=] { enabled| disabled}**
Specifies whether digital signatures should be used.

**show authserv**
Displays detailed information about an authentication server. Used without parameters, **show authserv** displays information about all configured authentication servers.

**Syntax**
**show authserv** [[**name**=]*ServerID*]

**Parameters**
**[ name=]** ***ServerID***
Specifies, by DNS name or IP address, the RADIUS server about which to display information.

**set acco**
Specifies the accounting provider.

**Syntax**
**set acco** {**windows** | **radius** | **none**}

**Parameters**
**{ windows| radius| none}**
Required. Specifies whether accounting should be performed and by which server. The **windows** parameter specifies that Windows security should perform accounting. The **radius** parameter specifies that a RADIUS server should perform accounting. The **none** parameter specifies that no accounting should be performed.

**show acco**
Displays the accounting provider.

**Syntax**
**show acco**

**Parameters**
none

**set authe**
Specifies the authentication provider.

**Syntax**
**set authe** {**windows** | **radius**}

**Parameters**
**{ windows| radius}**
Required. Specifies which technology should perform authentication. The **windows** parameter specifies that Windows security should perform authentication. The **radius** parameter specifies that a RADIUS server should perform authentication.

**show authe**
Displays the authentication provider.

**Syntax**
**show authe**

**Parameters**
none

**Formatting legend**

| Format | Meaning |
|---|---|

| | |
|---|---|
| Italic | Information that the user must supply |
| Bold | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| Courier font | Code or program output |

# Netsh commands for Routing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for Routing**
You can use the Netsh commands for Routing to administer routing servers from the command line, rather than through the Routing and Remote Access console. Administering servers from the command line is most useful in the following situations:

- You can administer routing servers more quickly from the command line than you can using a console. The ability is especially important if you are using a slow-speed network link, for example, a connection over a wide area network (WAN).
- You can administer routing servers more consistently by incorporating these commands into a script that you can run on many servers.

You can use the following commands at the command prompt for the appropriate Netsh context to administer routing servers. To run these Netsh commands on a remote Windows 2000 Server, you must first use Remote Desktop Connection to connect to a Windows 2000 Server that is running Terminal server. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

For more information on Netsh, see Netsh overview and Enter a netsh context.

**Netsh Routing IP IGMP commands**
The following commands are available for use in the Netsh Routing IP IGMP context.

To view the command syntax, click a command:

- add interface
- install
- delete interface
- uninstall
- set interface
- set global
- show interface
- show global
- show ifstats
- show iftable
- show grouptable
- show rasgrouptable
- show proxygrouptable

**add interface**
Configures IGMP on the specified interface.

**Syntax**

**add interface** [**InterfaceName=**][**InterfaceName=**]*InterfaceName* [[**IgmpPrototype=**]{**igmprtrv1** | **igmprtrv2** | **igmprtrv3** | **igmpproxy**}] [[**IfEnabled=**]{**enable** | **disable**}] [[**RobustVar**=]*Integer*] [[**GenQueryInterval=**]*Integer*] [[**GenQueryRespTime=**]*Integer*] [[**StartUpQueryCount=**]*Integer*] [[**StartUpQueryInterval=**]*Integer*] [[**LastMemQueryCount=**]*Integer*] [[**LastMemQueryInterval=***Integer*] [[**AccNonRtrAlertPkts=**]{**yes** | **no**}]

**Parameters**

**[ InterfaceName=][ InterfaceName=] *InterfaceName***

Required. Specifies the name of the interface on which you want to configure IGMP. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ IgmpPrototype=]{ igmprtrv1| igmprtrv2| igmprtrv3| igmpproxy}**

Specifies the type of protocol to be configured on the interface. The default type is igmprtrv2.

**[ IfEnabled=]{ enable| disable}**

Specifies whether the protocol you are configuring should be enabled or disabled. The default is enabled.

**[ RobustVar=]= *Integer***

Specifies the robustness variable. The value should be greater than zero (0). The default value is 2.

**[ GenQueryInterval=] *Integer***

Specifies the interval, in seconds, at which general queries should be sent on the interface. The default value is 125 seconds.

**[ GenQueryRespTime=] *Integer***

Specifies the maximum response time, in seconds, by which hosts should respond to a general query. The default value is 10 seconds.

**[ StartUpQueryCount=] *Integer***

Specifies the number of general queries that will be sent during startup. The default value is 2.

**[ StartUpQueryInterval=] *Integer***

Specifies the interval, in seconds, between general queries sent during startup. The default value is 31 seconds.

**[ LastMemQueryCount=] *Integer***

Specifies the number of group-specific queries sent when notice of a host leaving the group is received. The default value is 2.

**[ LastMemQueryInterval=] *Integer***

Specifies the interval, in milliseconds, between group-specific queries. The default value is 1000 milliseconds.

**[ AccNonRtrAlertPkts=]{ yes| no}**

Specifies whether to accept IGMP packets that might not have the router alert option set. The default is **yes**.

**Examples**

To modify the default startup query interval to 21 seconds for use with IGMP configuration of the interface named Local Area Connection, type:

**add interface "Local Area Connection" startupqueryinterval=21**

**install**

Installs an IGMP router/proxy and sets global logging. Used without parameters, **install** installs the IGMP router/proxy and specifies that errors related to IGMP are logged but no other IGMP-related events are logged.

**Syntax**

**install** [[**LogLevel**=]{**none** | **error** | **warn** | **info**}]

**Parameters**

**[ LogLevel=]{ none| error| warn| info}**

Specifies which events should be logged. The **none** parameter specifies no events related to IGMP should be logged. The **error** parameter specifies that only errors related to IGMP should be logged. The **warn** parameter specifies that only warnings related to IGMP should be logged. The **info** parameter specifies that all events related to IGMP should be logged.

**delete interface**

Removes an IGMP router or proxy from the specified interface.

**Syntax**

**delete interface** [**InterfaceName=**][**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, an interface from which you want to remove an IGMP router or proxy. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**Examples**

**delete interface "Local Area Connection"**

**uninstall**

Removes IGMP router/proxy from all interfaces.

**Syntax**

**uninstall**

**Parameters**

none

**set interface**

Changes interface configuration parameters.

**Syntax**

**set interface** [**InterfaceName=**]*InterfaceName* [[**IgmpPrototype=**]{**igmprtrv1** | **igmprtrv2** | **igmprtrv3** | **igmpproxy**}] [[**IfEnabled=**]{**enable** | **disable**}] [[**RobustVar=**]*Integer*] [[**GenQueryInterval=**]*Integer*] [[**GenQueryRespTime=**]*Integer*] [[**StartUpQueryCount=**]*Integer*] [[**StartUpQueryInterval=**]*Integer*] [[**LastMemQueryCount=**]*Integer*] [[**LastMemQueryInterval=**]*Integer*] [[**AccNonRtrAlertPkts=**]{**yes** | **no**}]

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies the name of the interface on which you want to configure IGMP. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ IgmpPrototype=]{ igmprtrv1| igmprtrv2| igmprtrv3| igmpproxy}**

Specifies the type of protocol to be configured on the interface. The default type is igmprtrv2.

**[ IfEnabled=]{ enable| disable}**

Specifies whether the protocol you are configuring should be enabled or disabled. The default is enabled.

**[ RobustVar=] *Integer***

Specifies the robustness variable. The value should be greater than zero (0). The default value is 2.

**[ GenQueryInterval=] *Integer***

Specifies the interval, in seconds, at which general queries should be sent on the interface. The default value is 125 seconds.

**[ GenQueryRespTime=] *Integer***

Specifies the maximum response time, in seconds, by which hosts should respond to a general query. The default value is 10 seconds.

**[ StartUpQueryCount=] *Integer***

Specifies the number of general queries that will be sent during startup. The default value is 2.

**[ StartUpQueryInterval=] *Integer***

Specifies the interval, in seconds, between general queries sent during startup. The default value is 31 seconds.

**[ LastMemQueryCount=] *Integer***

Specifies the number of group-specific queries sent when notice of a host leaving the group is received. The default value is 2.

**[ LastMemQueryInterval=] *Integer***

Specifies the interval, in milliseconds, between group-specific queries. The default value is 1,000 milliseconds.

**[ AccNonRtrAlertPkts=]{ yes| no}**

Specifies whether to accept IGMP packets that do not have the router alert option set. The default is to accept those packets.

**Examples**

To modify the default startup query interval to 21 seconds for use with IGMP configuration of an interface named Local Area Connection, type:

**set interface "Local Area Connection" startupqueryinterval=21**

**set global**
Sets IGMP global parameters. Used without parameters, **set global** specifies that warnings are logged but that no other events related to IGMP are logged.

**Syntax**
**set global** [**LogLevel**=]{**none** | **error** | **warn** | **info**}

**Parameters**
**[ LogLevel=]{ none| error| warn| info}**
Required. Specifies which events should be logged. The **none** parameter specifies that no events related to IGMP should be logged. The **error** parameter specifies that only errors related to IGMP should be logged. The **warn** parameter specifies that only warnings related to IGMP should be logged. The **info** parameter specifies that all events related to IGMP should be logged.

**show interface**
Displays the IGMP configuration of the specified interface. Used without parameters, **show interface** displays IGMP configuration information for all interfaces.

**Syntax**
**show interface** [**InterfaceName=**]*InterfaceName*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**show global**
Displays the global IGMP parameters.

**Syntax**
**show global**

**Parameters**
none

**show ifstats**
Displays IGMP statistics for the specified interface. Used without parameters, **show ifstats** shows IGMP statistics once for all interfaces.

**Syntax**
**show ifstats** [[**Index**=]*Integer*] [[**Rr**=]*Integer*]

**Parameters**
**[ Index=] *Integer***
Specifies a number identifying the interface for which you want to display information.

**[ Rr=] *Integer***
Specifies, in seconds, how often you want the information to be refreshed.

**Examples**
To show IGMP statistics every 5 seconds for an interface with an index value of 1001, type:

**show ifstats index=1001 rr=5**

**show iftable**
Shows IGMP host groups for a specified interface. Used without parameters, **show iftable** shows IGMP host groups for all interfaces once.

**Syntax**
**show iftable** [[**Index**=]*Integer*] [[**Rr**=]*Integer*]

**Parameters**
**[ Index=] *Integer***
Specifies, by index number, the interface for which you want to display information.

**[ Rr=] *Integer***

Specifies, in seconds, how often you want the information to be refreshed.

**Examples**
To show IGMP host groups every 5 seconds for an interface with an index value of 1001, type:

**show iftable index=1001 rr=5**

**show grouptable**
Shows the IGMP hosts group table for a multicast group. Used without parameters, **show grouptable** shows the IGMP hosts group tables once for all multicast groups on all interfaces associated with the router.

**Syntax**
**show grouptable** [[**Index**=]*Integer*] [[**Rr**=]*Integer*]

**Parameters**
**[ Index=] *Integer***
Specifies, by IP address, the multicast group for which you want to display information.

**[ Rr=] *Integer***
Specifies, in seconds, how often you want the information to be refreshed.

**Examples**
To display the IGMP hosts group table every 5 seconds for an IGMP multicast group identified by the IP address of 192.168.100.239, type:

**show grouptable index=192.168.100.239 rr=5**

**show rasgrouptable**
Displays the hosts group table for a remote access client interface. Used without parameters, **show rasgrouptable** displays the hosts group tables once for all remote access client interfaces.

**Syntax**
**show rasgrouptable** [[**Index**=]*IPAddress*] [[**Rr**=]*Integer*]

**Parameters**
**[ Index=] *IPAddress***
Specifies, by IP address, the remote access client interface for which you want to display information.

**[ Rr=] *Integer***
Specifies, in seconds, how often you want the information to be refreshed.

**Examples**
To display the hosts group table for a remote access client interface with an IP address of 10.10.1.100 and to refresh the information every five seconds, type:

**show rasgrouptable index=10.10.1.100 rr=5**

**show proxygrouptable**
Displays the IGMP hosts group table for an IGMP proxy interface. Used without parameters, **show proxygrouptable** displays information for all interfaces once.

**Syntax**
**show proxygrouptable** [[**InterfaceName=**]*InterfaceName*] [[**Rr**=]*Integer*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Specifies, by name, the interface for which you want to display information.

**[ Rr=] *Integer***
Specifies, in seconds, how often you want the information to be refreshed.

**Examples**
To display IGMP hosts group tables for all IGMP proxy interfaces and to refresh the information every five seconds, type:

**show proxygrouptable rr=5**

**Netsh Routing IP Routerdiscovery commands**
The following commands are available for use in the Netsh Routing IP Routerdiscovery context.

To view the command syntax, click a command:

- add interface
- set interface
- delete interface
- show interface

**add interface**
Configures router discovery for the specified interface.

**Syntax**
**add interface** [**InterfaceName=**]*InterfaceName* [[**Disc=**]{**enable** | **disable**}] [[**MinInt=**]*Integer*] [[**MaxInt=**]*Integer*] [[**Life=**]*Integer*] [[**Level=**]*Integer*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to configure router discovery. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Disc=]{ enable| disable}**
Specifies whether router discovery should occur on this interface. The **enable** parameter specifies that router discovery should occur, and the **disable** parameter specifies that router discovery should not occur.

**[ MinInt=] *Integer***
Specifies a minimum interval, in minutes, between when router discovery packets are sent.

**[ MaxInt=] *Integer***
Specifies a maximum interval, in minutes, between when router discovery packets are sent.

**[ Life=] *Integer***
Specifies the number of minutes for which a router discovery packet sent from this router or server is valid.

**[ Level=] *Integer***
Specifies a number indicating preference for using this interface as the default gateway. Where multiple interfaces are enabled for router discovery, a higher number used here indicates a higher level of preference.

**Remarks**

- When added, router discovery advertisements are sent at random times bounded by the set minimum and maximum intervals.

**Examples**
To enable router discovery for the Local Area Connection interface, specifying a minimum interval of 7 minutes, a maximum interval of 10 minutes, a life of 30 minutes for router discovery packets, and a zero (0) or no preference level, type:

**add interface "Local Area Connection" enable 7 10 30 0**

**set interface**
Configures router-discovery for an interface.

**Syntax**
**set interface** [**InterfaceName=**]*InterfaceName* [[**Disc=**]{**enable** | **disable**}] [[**MinInt=**]*Integer*] [[**MaxInt=**]*Integer*] [[**Life=**]*Integer*] [[**Level=**]*Integer*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to configure router discovery. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Disc=]{ enable| disable}**
Specifies whether router discovery should occur on this interface. The **enable** parameter specifies that router discovery should occur, and the **disable** parameter specifies that router discovery should not occur.

**[ MinInt=]** ***Integer***
Specifies, in minutes, a minimum interval between when router discovery packets are sent.

**[ MaxInt=]** ***Integer***
Specifies, in minutes, a maximum interval between when router discovery packets are sent.

**[ Life=]** ***Integer***
Specifies, in minutes, how long a router discovery packet sent from this router or server is valid.

**[ Level=]** ***Integer***
Specifies a number indicating preference for using this interface as the default gateway. A higher number used here specifies a higher level of preference.

**Examples**
To enable router discovery for the Local Area Connection interface, specifying a minimum interval of 7 minutes, a maximum interval of 10 minutes, a life of 30 minutes for router discovery packets, and a zero (0) or no preference level, type:

**set interface "Local Area Connection" enable 7 10 30 0**

**delete interface**
Deletes router-discovery configuration.

**Syntax**
**delete interface** [**InterfaceName=**]*InterfaceName*

**Parameters**
**[ InterfaceName=]** ***InterfaceName***
Required. Specifies, by name, the interface for which you want to delete router-discovery configuration. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**Examples**
To delete the router-discovery configuration for an interface named Local Area Connection, type:

**delete interface name="Local Area Connection"**

**show interface**
Displays router-discovery information. Used without parameters, **show interface** displays information for all interfaces.

**Syntax**
**show interface** [[**InterfaceName=**]*InterfaceName*]

**Parameters**
**[ InterfaceName=]** ***InterfaceName***
Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**Examples**
To display router-discovery information for an interface named Local Area Connection, type:

**show interface "Local Area Connection"**

**Netsh Routing IP RIP commands**
The following commands are available for use in the Netsh Routing IP RIP context.

To view the command syntax, click a command:

- add peerfilter
- add acceptfilter
- add announcefilter

- add neighbor
- add interface
- add helper
- delete peerfilter
- delete acceptfilter
- delete announcefilter
- delete neighbor
- delete interface
- delete helper
- set interface
- set flags
- set global
- show interface
- show flags
- show global
- show ifstats
- show ifbinding

**add peerfilter**
Adds a filter for servers that can be accepted as peers.

**Syntax**
**add peerfilter** [**Server**=]*IPAddress*

**Parameters**
**[ Server=] *IPAddress***
Required. Specifies, by IP address, the peer server whose traffic you want to filter.

**add acceptfilter**
Adds an acceptance filter for routes received on an interface.

**Syntax**
**add acceptfilter** [**InterfaceName=**]*InterfaceName* [**Addr=**]*IPAddress1IPAddress2*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, an interface where RIP is available for use. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ Addr=] *IPAddress1IPAddress2***
Required. Specifies an IP address pairing. The first address is for the low IP address, and the second address is for the high IP

address to use in building the filter.

**Examples**

To add an acceptance filter for an interface named Local Area Connection for an IP range of 10.0.0.2 to 10.11.21.154, type:

**add acceptfilter "Local Area Connection" 10.0.0.2 10.11.21.154**

**add announcefilter**

Adds a filter for routes announced on an interface.

**Syntax**

**add announcefilter** [**InterfaceName=**]*InterfaceName* [**Addr=**]*IPAddress1IPAddress2*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies the name of an interface where RIP is available for use. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Addr=] *IPAddress1IPAddress2***

Required. Specifies an IP address pairing. The first address is for the low IP address, and the second address is for the high IP address to use in building the filter.

**Examples**

To add a filter for routes announced on an interface named Local Area Connection for a range of IP addresses from 10.0.0.2 to 10.11.21.154, type:

**add announcefilter Local Area Connection 10.0.0.2 10.11.21.154**

**add neighbor**

Adds a RIP neighbor on an interface.

**Syntax**

**add neighbor** [**InterfaceName=**]*InterfaceName* [**addr=**]*IPAddress*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, an interface where RIP is available for use. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *IPAddress***

Required. Specifies the IP address of the RIP neighbor you want to add.

**Examples**

To add a RIP neighbor located at an IP address of 10.0.0.2 for an interface named Local Area Connection, type:

**add neighbor "Local Area Connection" 10.0.0.2**

**add interface**

Adds RIP to a specified interface.

**Syntax**

**add interface** [**InterfaceName=**]*InterfaceName* [[**Metric=**]*Integer*] [[**UpdateMode=**]{**demand** | **periodic**}] [[**Announce=**]{**none** | **rip1** | **rip1compat** | **rip2**}] [[**Accept=**]{**none** | **rip1** | **rip1compat** | **rip2**}] [[**Expire=**]*Integer*] [[**Remove=**]*Integer*] [[**Update=**]*Integer*] [[**AuthMode=**]{**authnone** | **authsimplepassword**}] [[**Tag=**]*Integer*] [[**Unicast=**]{**also** | **only** | **disable**}] [[**AccFiltMode=**]{**include** | **exclude** | **disable**}] [[**AnnFiltMode=**]{**include** | **exclude** | **disable**}] [[**Password=**]*String*]

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface on which to add RIP. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Metric=] *Integer***

Specifies a metric value for routes based on this interface.

**[ UpdateMode=]{ demand| periodic}**

Specifies when updates will occur. The **demand** parameter specifies that updates should occur on demand. The **periodic** parameter specifies that updates should occur at regular intervals.

**[ Announce=]{ none| rip1| rip1compat| rip2}**
Specifies which routes should be announced. The **none** parameter specifies that all routes should be announced. The **rip1** parameter specifies that only RIP version 1 routes should be announced. The **rip1compat** parameter specifies that announcements should be made in RIP version-compatible mode. The **rip2** parameter specifies that only RIP version 2 routes should be announced.

**[ Accept=]{ none| rip1| rip1compat| rip2}**
Specifies which routes should be accepted. The **none** parameter specifies that all routes should be accepted. The **rip1** parameter specifies that only RIP version 1 routes should be accepted. The **rip1compat** parameter specifies that routes should be accepted in RIP version-compatible mode. The **rip2** parameter specifies that only RIP version 2 routes should be accepted.

**[ Expire=]** ***Integer***
Specifies, in seconds, the route expiration interval.

**[ Remove=]** ***Integer***
Specifies, in seconds, the route removal interval.

**[ Update=]** ***Integer***
Specifies, in seconds, the full update interval.

**[ AuthMode=]{ authnone| authsimplepassword}**
Specifies whether authorization should be required. The **authnone** parameter specifies that no authorization should be required. The **authsimplepassword** parameter specifies that password authorization should be required.

**[ Tag=]** ***Integer***
Specifies the route tag.

**[ Unicast=]{ also| only| disable}**
Specifies the unicast mode. The **also** parameter specifies use also unicast mode. The **only** parameter specifies use only unicast mode. The **disable** parameter specifies that unicast mode should be disabled.

**[ AccFiltMode=]{ include| exclude| disable}**
Specifies whether acceptance filters should be included or disabled. The **include** parameter specifies that acceptance filters should be included. The **exclude** parameter specifies that acceptance filters should not be included. The **disable** parameter specifies that acceptance filters should be disabled.

**[ AnnFiltMode=]{ include| exclude| disable}**
Specifies whether announcement filters should be included or disabled. The **include** parameter specifies that announcement filters should be included. The **exclude** parameter specifies that announcement filters should not be included. The **disable** parameter specifies that announcement filters should be disabled.

**[ Password=]** ***String***
Specifies a plaintext password no longer than 16 characters.

#### add helper
Installs a helper DLL under RIP.

#### Syntax
**add helper** *DLLName*

#### Parameters
***DLLName***
Required. Specifies a DLL that supports this context.

#### delete peerfilter
Deletes a filter for an accepted peer server.

#### Syntax
**delete peerfilter** [**Server**=]*IPAddress*

#### Parameters
**[ Server=]** ***IPAddress***
Required. Specifies, by IP address, the peer server whose traffic you do not want to filter.

**delete acceptfilter**
Deletes an acceptance filter for routes received on a specified interface.

**Syntax**
**delete acceptfilter** [**InterfaceName=**]*InterfaceName* [**Addr=**]*IPAddress1IPAddress2*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, an interface where RIP is available for use. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Addr=] *IPAddress1IPAddress2***
Required. Specifies an IP address pairing. The first address is for the low IP address, and the second address is for the high IP address used in building the filter.

**Examples**
To delete an acceptance filter for the IP ranges of 10.0.0.2 to 10.11.21.154 on an interface named Local Area Connection, type:

**delete acceptfilter "Local Area Connection" 10.0.0.2 10.11.21.154**

**delete announcefilter**
Deletes an announcement filter set for an interface.

**Syntax**
**delete announcefilter** [**InterfaceName=**]*InterfaceName* [**Addr=**]*IPAddress1IPAddress2*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies the name of an interface where RIP is available for use. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Addr=] *IPAddress1IPAddress2***
Required. Specifies an IP address pairing. The first address specifies the low IP address, and the second address specifies the high IP address used in building the filter.

**Examples**
To delete an announcement filter for the IP range 10.0.0.2 to 10.11.21.154 for an interface named Local Area Connection, type:

**delete announcefilter "Local Area Connection" 10.0.0.2 10.11.21.154**

**delete neighbor**
Deletes a RIP neighbor from an interface.

**Syntax**
**delete neighbor** [**InterfaceName=**]*InterfaceNameIPAddress*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, an interface where RIP is available for use. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

***IPAddress***
Required. Specifies, by IP address, the RIP neighbor to delete.

**Examples**
To delete a RIP neighbor located at 10.0.0.2 for an interface named Local Area Connection, type:

**delete neighbor "Local Area Connection" 10.0.0.2**

**delete interface**
Removes RIP from the specified interface.

**Syntax**
**delete interface** [**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, an interface from which you want to remove RIP. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**delete helper**
Removes a specified helper DLL from Netsh.

**Syntax**
**delete helper** *HelperName*

**Parameters**
***HelperName***
Required. Specifies, by file name, the helper DLL to remove.

**set interface**
Configures RIP on a specified interface.

**Syntax**
**set interface** [**InterfaceName=**]*InterfaceName* [[**Metric=**]*Integer*] [[**UpdateMode=**]{**demand** | **periodic**}] [[**Announce=**]{**none** | **rip1** | **rip1compat** | **rip2**}] [[**Accept=**]{**none** | **rip1** | **rip1compat** | **rip2**}] [[**Expire=**]*Integer*] [[**Remove=**]*Integer*] [[**Update=**]*Integer*] [[**AuthMode=**]{**authnone** | **authsimplepassword**}] [[**Tag=**]*Integer*] [[**Unicast=**]{**also** | **only** | **disable**}] [[**AccFiltMode=**]{**include** | **exclude** | **disable**}] [[**AnnFiltMode=**]{**include** | **exclude** | **disable**}] [[**Password=**]*String*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface on which to configure RIP. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ Metric=] *Integer***
Specifies a metric value for routes based on this interface.

**[ UpdateMode=]{ demand| periodic}**
Specifies when updates should occur. The **demand** parameter specifies that updates should occur on demand. The **periodic** parameter specifies that updates should occur at regular intervals.

**[ Announce=]{ none| rip1| rip1compat| rip2}**
Specifies which routes should be announced. The **none** parameter specifies that all routes should be announced. The **rip1** parameter specifies that only RIP version 1 routes should be announced. The **rip1compat** parameter specifies that announcements should be made in RIP version-compatible mode. The **rip2** parameter specifies that only RIP version 2 routes should be announced.

**[ Accept=]{ none| rip1| rip1compat| rip2}**
Specifies which routes should be accepted. The **none** parameter specifies that all routes should be accepted. The **rip1** parameter specifies that only RIP version 1 routes should be accepted. The **rip1compat** parameter specifies that acceptance should occur using RIP version-compatible mode. The **rip2** parameter specifies that only RIP version 2 routes should be accepted.

**[ Expire=] *Integer***
Specifies, in seconds, how much time should elapse before the route expires.

**[ Remove=] *Integer***
Specifies, in seconds, how much time should elapse before the route is removed.

**[ Update=] *Integer***
Specifies, in seconds, how often full updates occur.

**[ AuthMode=]{ authnone| authsimplepassword}**
Specifies whether authorization should be required. The **authnone** parameter specifies that no authorization should be required. The **authsimplepassword** parameter specifies that password authorization should be required.

**[ Tag=] *Integer***
Specifies the route tag.

**[ Unicast=]{ also| only| disable}**
Specifies the unicast mode. The **also** parameter specifies use also unicast mode. The **only** parameter specifies use only

unicast mode. The **disable** parameter specifies that unicast mode should be disabled.

**[ AccFiltMode=]{ include| exclude| disable}**
Specifies whether acceptance filters should be included. The **include** parameter specifies that acceptance filters should be included. The **exclude** parameter specifies that acceptance filters should not be included. The **disable** parameter specifies that acceptance filters should be disabled.

**[ AnnFiltMode=]{ include| exclude| disable}**
Specifies whether announcement filters should be included or disabled. The **include** parameter specifies that announcement filters should be included. The **exclude** parameter specifies that announcement filters should not be included. The **disable** parameter specifies that announcement filters should be disabled.

**[ Password=]** ***String***
Specifies a plaintext password no longer than 16 characters long.

**Examples**
To modify the RIP configuration on the interface named Local Area Connection, specifying a metric value of 2 and that updates should occur on demand, type:

**set interface "Local Area Connection" metric=2 updatemode=periodic**

**set flags**
Sets RIP-related flags for a specified interface.

**Syntax**
**set flags** [**InterfaceName=**]*InterfaceName* [**clear,**][**splithorizon,**][**poisonreverse,**][**triggeredupdates,**][**cleanupupdates**] [**accepthostroutes,**][**acceptdefaultroutes,**][**senddefaultroutes,**][**nosubnetsummary**]

**Parameters**
**[ InterfaceName=]** ***InterfaceName***
Required. Specifies, by name, the interface on which to set flags. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ clear,][ splithorizon,][ poisonreverse,][ triggeredupdates,][ cleanupupdates,][ accepthostroutes,][ acceptdefaultroutes,][ senddefaultroutes,][ nosubnetsummary]**
Specifies policies for RIP-related flags. The **clear** parameter specifies that all set RIP flags should be cleared. The **splithorizon** parameter specifies that RIP for split horizon should be enabled. The **poisonreverse** parameter specifies that RIP for poison reverse should be enabled. The **triggeredupdates** parameter specifies that RIP triggered updates should occur. The **cleanupupdates** parameter specifies that cleanup updates for RIP should occur. The **accepthostroutes** parameter specifies that host routes should be accepted. The **acceptdefaultroutes** parameter specifies that default routes should be accepted. The **senddefaultroutes** parameter specifies that default routes should be sent. The **nosubnetsummary** parameter specifies that subnet summarization should not occur.

**Remarks**

- The last policy parameter should not have a comma after it.

**set global**
Sets global RIP parameters.

**Syntax**
**set global** {[[**loglevel**=]{**none** | **error** | **warn** | **info**}] | [[**mintrig**=]*Integer*] | [[**peermode**=]{**include** | **exclude** | **disable**}]}

**Parameters**
**[ loglevel=]{ none| error| warn| info}**
Specifies which RIP events should be logged. The **none** parameter specifies that no RIP events should be logged. The **error** parameter specifies that only errors related to RIP should be logged. The **warn** parameter specifies that only warnings related to RIP should be logged. The **info** parameter specifies that all events related to RIP should be logged.

**[ mintrig=]** ***Integer***
Specifies, in minutes, the minimum amount of time that should elapse between triggers.

**[ peermode=]{ include| exclude| disable}**
Specifies whether peers should be included and whether peer mode should be disabled. The **include** parameter specifies that peers should be included.The **exclude** parameter specifies that peers should not be included.The **disable** parameter

specifies that peer mode should be disabled.

**show interface**
Shows RIP configuration for the specified interface. Used without parameters, **show interface** displays configuration information for all interfaces.

**Syntax**
**show interface** [[**InterfaceName=**]*InterfaceName*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Specifies, by name, the interface whose information you want to display. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**show flags**
Displays RIP flags set for a specified interface. Used without parameters, **show flags** displays information for all interfaces.

**Syntax**
**show flags** [[**InterfaceName=**]*InterfaceName*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**show global**
Shows RIP global parameters.

**Syntax**
**show global**

**Parameters**
none

**show ifstats**
Displays RIP statistics for a specified interface. Used without parameters, **show ifstats** displays information once for all interfaces.

**Syntax**
**show ifstats** [[**Index**=]*Integer*] [[**Rr**=]*Integer*]

**Parameters**
**[ Index=] *Integer***
Specifies, by index number, the interface for which you want to display information.

**[ Rr=] *Integer***
Specifies, in seconds, how often you want the information to be refreshed.

**Remarks**

- To list the index value for each interface, use the **show interface** command in the Netsh Interface IP context.

**Examples**
To display RIP statistics every 5 seconds for an interface with an index value of 1, type:

**show ifstats index=1 rr=5**

**show ifbinding**
Displays RIP interface IP address binding. Used without parameters, **show ifbinding** displays information once for all interfaces.

**Syntax**
**show ifbinding** [[**Index**=]*Integer*] [[**Rr**=]*Integer*]

**Parameters**
**[ Index=] *Integer***

Specifies, by index number, the interface for which you want to display information.

**[ Rr=] *Integer***
Specifies, in seconds, how often you want the information to be refreshed.

**Remarks**

- To list the index value for each interface, use the **show interface** command in the Netsh Interface IP context.

**Examples**
To display the bindings every 5 seconds for an interface with an index value of 1, type:

**show ifbinding index=1 rr=5**

**Netsh Routing IP DHCP Relay Agent commands**
The following commands are available for use in the Netsh Routing IP DHCP Relay Agent context.

To view the command syntax, click a command:

- add dhcpserver
- add interface
- delete interface
- delete dhcpserver
- set global
- set interface
- show interface
- show global
- show ifconfig
- show ifbinding
- show ifstats

**add dhcpserver**
Adds a DHCP server to the list of DHCP servers whose messages will be forwarded by DHCP Relay Agent.

**Syntax**
**add dhcpserver** *IPAddress*

**Parameters**
***IPAddress***
Required. Specifies, by IP address, the DHCP server you want to add.

**add interface**
Enables DHCP Relay Agent on the specified interface.

**Syntax**
**add interface** [**InterfaceName=**]*InterfaceName*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface on which you want to enable DHCP Relay Agent.

**delete interface**

Disables DHCP Relay Agent on the specified interface.

**Syntax**

**delete interface** [**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface on which you want to disable DHCP Relay Agent. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**delete dhcpserver**

Removes a DHCP server from the list of DHCP servers whose messages will be forwarded by DHCP Relay Agent.

**Syntax**

**delete dhcpserver** *IPAddress*

**Parameters**

***IPAddress***

Required. Specifies, by IP address, the DHCP server to be deleted.

**set global**

Sets global parameters for DHCP Relay Agent configuration.

**Syntax**

**set global** [**LogLevel=**]{**none** | **error** | **warn** | **info**}

**Parameters**

**[ LogLevel=]{ none| error| warn| info}**

Required. Specifies which DHCP Relay Agent events should be logged. The **none** parameter specifies that no events related to DHCP Relay Agent should be logged. The **error** parameter specifies that only errors related to DHCP Relay Agent should be logged. The **warn** parameter specifies that only warnings related to DHCP Relay Agent should be logged. The **info** parameter specifies that all events related to DHCP Relay Agent should be logged.

**set interface**

Updates the DHCP Relay Agent configuration on an interface.

**Syntax**

**set interface** [**InterfaceName=**]*InterfaceName* [**relaymode=**]{**enable** | **disable**} [[**maxhop=**]*Integer*] [[**minsecs=**]*Integer*]

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface on which you want to update the configuration of DHCP Relay Agent. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ relaymode=]{ enable| disable}**

Required. Specifies whether the DHCP Relay Agent is enabled or disabled. The **enable** parameter specifies that DHCP Relay Agent should be enabled for this interface. The **disable** parameter disables DHCP Relay Agent for this interface.

**[ maxhop=] *Integer***

Specifies the number of hops a DHCP packet can make before it should be dropped and should no longer be relayed.

**[ minsecs=] *Integer***

Specifies the minimum number of seconds from boot time that must appear in a DHCP packet before it should be sent to a DHCP server in the list of servers whose messages will be forwarded by DHCP Relay Agent.

**Examples**

To update the DHCP Relay Agent configuration on the interface named Local Area Connection with a maximum hop count of 16 and a value of 4 seconds for the minimum seconds from boot time, type:

**set interface Local Area Connection enable 16 4**

**show interface**

Displays configuration information for DHCP Relay Agent on the specified interface.

**Syntax**

**show interface** [**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**show global**

Displays DHCP Relay Agent global configuration.

**Syntax**

**show global** [[**Rr=**]*Integer*]

**Parameters**

**[ Rr=] *Integer***

Specifies, in seconds, how often you want the information to be refreshed.

**show ifconfig**

Displays DHCP Relay Agent configuration information for the specified interface. Used without parameters, **show ifconfig** displays information once for all interfaces where DHCP Relay Agent is enabled.

**Syntax**

**show ifconfig** [[**Index**=]*Integer*] [[**Rr=**]*Integer*]

**Parameters**

**[ Index=] *Integer***

Specifies, by index value, the interface for which you want to display information.

**[ Rr=] *Integer***

Specifies, in seconds, how often you want the information to be refreshed.

**show ifbinding**

Displays IP address bindings for the specified interface. Used without parameters, **show ifbinding** displays information once for all interfaces where DHCP relay is enabled for use.

**Syntax**

**show ifbinding** [[**Index**=]*Integer*] [[**Rr=**]*Integer*]

**Parameters**

**[ Index=] *Integer***

Specifies, by index value, the interface for which you want to display information.

**[ Rr=] *Integer***

Specifies, in seconds, how often you want the information to be refreshed.

**show ifstats**

Displays DHCP Relay Agent statistics for the specified interface. Used without parameters, **show ifstats** displays information once for all interfaces where DHCP relay is enabled for use.

**Syntax**

**show ifstats** [[**Index**=]*Integer*] [[**Rr=**]*Integer*]

**Parameters**

**[ Index=] *Integer***

Specifies, by index value, the interface for which you want to display information.

**[ Rr=] *Integer***

Specifies, in seconds, how often you want the information to be refreshed.

**Netsh Routing IP OSPF commands**

The following commands are available for use in the Netsh Routing IP OSPF context.

## Notes

- This feature is not available on the Itanium-based versions of the Windows operating systems.
- This content is not available in this preliminary release.

To view the command syntax, click a command:

- add range
- add area
- add virtif
- add neighbor
- add interface
- add routefilter
- add protofilter
- install
- delete range
- delete area
- delete virtif
- delete neighbor
- delete interface
- delete routefilter
- delete protofilter
- uninstall
- set area
- set virtif
- set interface
- set global
- set routefilter
- set protofilter
- show global
- show area
- show virtif
- show interface
- show routefilter

- show protofilter
- show area
- show virtif

**add range**
Adds the IP address and mask pair that define a range of addresses belonging to this area.

**Syntax**
**add range** [**Areaid=**]*IPAddress* [**Range=**]*IPAddressSubnetMask*

**Parameters**
**[ Areaid=] *IPAddress***
Required. Specifies the IP address of the area to which the range is added.

**[ Range=] *IPAddressSubnetMask***
Required. Specifies the IP address and the mask of the range to add.

**Remarks**

- OSPF ranges are used to summarize the routes within the OSPF area.

**add area**
Adds an ID for the area.

**Syntax**
**add area** [**Areaid=**]*IPAddress*

**Parameters**
**[ Areaid=] *IPAddress***
Required. Specifies the IP address of the area to which you want to add the range.

**Remarks**

- The **Areaid** parameter is a 32-bit number expressed in dotted decimal notation that identifies the OSPF area. The area ID does not need to coincide with an IP address or an IP network ID. The area ID of 0.0.0.0 is reserved for the backbone. If the area represents a subnetted network, you can use the IP network number of the subnetted network for the area ID.

**add virtif**
Adds the virtual interface for a router.

**Syntax**
**add virtif** [**transareaid=**]*TransitAreaID* [**virtnbrid=**]*VirtualNeighborID*

**Parameters**
**[ transareaid=] *TransitAreaID***
Required. Specifies the IP address of the transit area used to exchange routing information between the backbone area border router and the area border router of the noncontiguous area.

**[ virtnbrid=] *VirtualNeighborID***
Required. Specifies, by IP address, the router ID of the virtual neighbor to add.

**add neighbor**
Adds an OSPF neighbor to the specified interface.

**Syntax**
**add neighbor** [**InterfaceName=**]*InterfaceName* [**addr**=]*IPAddress* [**nbraddr**=]*IPAddress* [**nbrprio=**]*Priority*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface to which you want to add a neighbor. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *IPAddress***
Required. Specifies the OSPF interface, by IP address.

**[ nbraddr=] *IPAddress***
Required. Specifies the IP address of the neighbor you want to add.

**[ nbrprio=] *Priority***
Required. Specifies the OSPF router priority of the neighbor you want to add.

**add interface**
Configures OSPF on the specified interface.

**Syntax**
**add interface** [**InterfaceName=**]*InterfaceName* [**areaid**=]*IPAddress* [**addr**=]*IPAddress* [**mask**=]*SubnetMask*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface on which you want to add OSPF. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ areaid=] *IPAddress***
Required. Specifies the IP address of the area to which the interface belongs.

**[ addr=] *IPAddress***
Required. Specifies the IP address of the interface to add.

**[ mask=] *SubnetMask***
Required. Specifies the subnet mask of the interface to add.

**add routefilter**
Adds an OSPF route filter.

**Syntax**
**add routefilter** [**Filter=**]*IPAddressSubnetMask*

**Parameters**
**[ Filter=] *IPAddressSubnetMask***
Required. Specifies, by IP address and subnet mask, the route you want to filter.

**add protofilter**
Adds an OSPF protocol filter.

**Syntax**
**add protofilter** [**filter=**]{**autostatic** | **local** | **rip** | **snmp** | **nondod** | **static**}

**Parameters**
**[ filter=]{ autostatic| local| rip| snmp| nondod| static}**
Required. Specifies the protocol filter you want to add. The **autostatic** parameter specifies a RIP autostatic route. The **local** parameter specifies a route added by the network to which the computer is connected. The **rip** parameter specifies that the filter is added using RIP. The **snmp** parameter specifies that the route is added using SNMP. The **nondodm** parameter specifies an RTM route that is present only when a DOD interface is connected. The **static** parameter specifies an RTM route.

**Remarks**

- The **add protofilter** command is used on an OSPF router acting as an Autonomous System Boundary Router. The filters you add filter other route sources by protocol source, such as static routes and RIP, so that they are not redistributed into the OSPF Autonomous System.

**install**
Installs OSPF.

**Syntax**
**install**

**Parameters**
none

**delete range**
Deletes the specified range for the area ID.

**Syntax**
**delete range** [**Areaid=**]*IPAddress* [**Range=**]*IPAddressSubnetMask*

**Parameters**
**[ Areaid=] *IPAddress***
Required. Specifies, by IP address, the area you want to delete.

**[ Range=] *IPAddressSubnetMask***
Required. Specifies the IP address and the subnet mask of the area range you want to delete.

**delete area**
Deletes the specified area.

**Syntax**
**delete area** [**Areaid=**]*IPAddress*

**Parameters**
**[ Areaid=] *IPAddress***
Required. Specifies, by IP address, the area you want to delete.

**Remarks**
The area ID is a 32-bit number expressed in dotted decimal notation that identifies the OSPF area. The area ID does not need to coincide with an IP address or an IP network ID. The area ID of 0.0.0.0 is reserved for the backbone. If the area represents a subnetted network, you can use the IP network number of the subnetted network for the area ID.

**delete virtif**
Deletes the specified virtual interface.

**Syntax**
**delete virtif** [**transareaid=**]*TransitAreaID* [**virtnbrid=**]*VirtualNeighborID*

**Parameters**
**[ transareaid=] *TransitAreaID***
Required. Specifies the IP address of the transit area used to exchange routing information between the backbone area border router and the area border router of the noncontiguous area.

**[ virtnbrid=] *VirtualNeighborID***
Required. Specifies the router ID of the virtual neighbor to delete.

**delete neighbor**
Deletes the specified OSPF neighbor.

**Syntax**
**delete neighbor** [**InterfaceName=**]*InterfaceName* [**addr**=]*IPAddress* [**nbraddr**=]*IPAddress* [**nbrprio=**]*Priority*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface from which you want to delete a neighbor. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *IPAddress***
Required. Specifies, by IP address, the interface from which you want to delete a neighbor.

**[ nbraddr=] *IPAddress***
Required. Specifies the IP address of the neighbor to delete.

**[ nbrprio=] *Priority***
Required. Specifies the OSPF router priority of the neighbor to delete.

**delete interface**
Deletes OSPF from the specified interface.

**Syntax**
**delete interface** [**InterfaceName=**]*InterfaceName* [**addr**=]*IPAddress* [**mask**=]*SubnetMask*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface from which you want to delete OSPF. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ addr=] *IPAddress***

Required. Specifies, by IP address, the interface to delete.

**[ mask=] *SubnetMask***

Required. Specifies, by subnet mask, the interface to delete.

**delete routefilter**

Deletes the specified OSPF route filter.

**Syntax**

**delete routefilter** [**Filter=**]*IPAddressSubnetMask*

**Parameters**

**[ Filter=] *IPAddressSubnetMask***

Required. Specifies the IP address and the subnet mask of the route filter you want to delete.

**delete protofilter**

Deletes the specified OSPF protocol filter.

**Syntax**

**delete protofilter** [**filter=**]{**autostatic** | **local** | **rip** | **snmp** | **nondod** | **static**}

**Parameters**

**[ filter=]{ autostatic| local| rip| snmp| nondod| static}**

Required. Specifies the protocol filter you want to delete. The **autostatic** parameter specifies a RIP autostatic route. The **local** parameter specifies a route added by the network to which the computer is connected. The **rip** parameter specifies that the filter is added using RIP. The **snmp** parameter specifies that the route is added using SNMP. The **nondodm** parameter specifies an RTM route that is present only when a DOD interface is connected. The **static** parameter specifies an RTM route.

**Remarks**

- The **delete protofilter** command is used on an OSPF router acting as an Autonomous System Boundary Router. The filters you add filter other route sources by protocol source, such as static routes and the Routing Information Protocol (RIP), so that they are not redistributed into the OSPF Autonomous System.

**uninstall**

Deletes OSPF.

**Parameters**

none

**set area**

Changes parameters for the specified area.

**Syntax**

**set area** [**areaid=**]*AreaID* [[**auth=**]{**none** | **password**}] [[**stubarea**=]{**yes** | **no**}] [[**metric**=]*StubMetric*] [[**sumadv**=]{**yes** | **no**}]

**Parameters**

**[ areaid=] *AreaID***

Required. Specifies, by IP address, the OSPF area for which you want to change parameters.

**[ auth=]{ none| password}**

Specifies whether passwords are required for the area. If passwords are required for an area, all interfaces that are in the same area and on the same network segment must use the same password, and interfaces that are in the same area but on different network segments can have different passwords. By default, passwords are required and the password is 12345678. Passwords are transmitted in plaintext format, so this option is for identification, not security.

**[ stubarea=]{ yes| no}**

Specifies whether this area is configured as a stub area, which is an OSPF area that does not enumerate external routes. Routes from outside the OSPF Autonomous System (AS) are not flooded into or through stub areas. Routing to AS external destinations in these areas is based only on a summary default route. This reduces the overhead for the routers in the stub

area.

**[ metric=] *StubMetric***
Specifies the cost of the summary default route that the router advertises into the stub area.

**[ sumadv=]{ yes| no}**
Specifies whether to import summary advertisements.

**set virtif**
Configures parameters for the specified virtual interface.

**Syntax**
**set virtif** [**transareaid=**]*TransitAreaID* [**virtnbrid =**] *VirtualNeighborID* [[**transdelay=**]*TransitDelay*] [[**retrans=**]*ReTransmitInterval*] [[**hello=**]*HelloInterval*] [[**dead=**]*DeadInterval*] [[**password=**]*Password*]

**Parameters**
**[ transareaid=] *TransitAreaID***
Required. Specifies the IP address of the transit area.

**[ virtnbrid=] *VirtualNeighborID***
Required. Specifies the router ID of the virtual neighbor.

**[ transdelay=] *TransitDelay***
Specifies the estimated number of seconds it takes to transmit a link state update packet over this interface. If you do not specify this parameter, the estimated delay is set to 1 second.

**[ retrans=] *ReTransmitInterval***
Specifies the number of seconds between link state advertisement retransmissions for adjacencies belonging to this interface. A typical value for a local area network is 5 seconds.

**[ hello=] *HelloInterval***
Specifies, in seconds, the interval between transmissions of hello packets by the router on the interface. This setting must be the same for all routers that are connected to the same network. A typical value for a local area network is 10 seconds.

**[ dead=] *DeadInterval***
Specifies, in seconds, how long a router can fail to respond before a neighboring router should consider this router is malfunctioning. This setting should be an integral multiple of the hello interval (commonly 4). This value must be the same for all OSPF router interfaces that are connected to the same network segment.

**[ password=] *Password***
Specifies the password for this interface, if passwords are required for the area. All interfaces that are in the same area and on the same network must use the same password. By default, passwords are required and the password is 12345678.

**set interface**
Configures OSPF parameters for an interface.

**Syntax**
**set interface** [**interfacename=**]*InterfaceName* [**addr=**]*IPAddress* [**mask=**]*SubnetMask* [[**state=**]{**enable** | **disable**}] [[**areaid=**]*AreaID*] [[**type=**]{**nbma** | **p2p** | **broadcast**}] [[**prio=**]*Priority*] [[**transdelay=**]*TransitDelay*] [[**retrans=**]*ReTransmitInterval*] [[**hello=**]*HelloInterval*] [[**dead=**]*DeadInterval*] [[**poll=**]*PollInterval*] [[**metric=**]*Metric*] [[**password=**]*Password*] [[**mtu=**]*MTUSize*]

**Parameters**
**[ interfacename=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to configure parameters. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ addr=] *IPAddress***
Required. Specifies the IP address of the interface.

**[ mask=] *SubnetMask***
Required. Specifies the subnet mask of the interface.

**[ state=]{ enable| disable}**
Specifies whether the interface is enabled. The **enable** parameter enables the interface. The **disable** parameter disables the interface.

**[ areaid=]** ***AreaID***
Specifies the IP address of the interface area.

**[ type=]{ nbma| p2p| broadcast}**
Specifies the type of OSPF interface for which you want to configure parameters. The **nbma** parameter specifies a non-broadcast multiple access (NBMA) OSPF interface. The **p2p** parameter specifies a point-to-point OSPF interface. The **broadcast** parameter specifies a broadcast OSPF interface.

**[ prio=]** ***Priority***
Specifies the interface priority.

**[ transdelay=]** ***TransitDelay***
Specifies the estimated number of seconds it takes to transmit a link state update packet over this interface. If you do not specify this parameter, the estimated delay is set to 1 second.

**[ retrans=]** ***ReTransmitInterval***
Specifies the number of seconds between link state advertisement retransmissions for adjacencies belonging to this interface. A typical value for a local area network is 5 seconds.

**[ hello=]** ***HelloInterval***
Specifies, in seconds, the interval between transmissions of hello packets by the router on the interface. This setting must be the same for all routers that are connected to the same network. A typical value for a local area network is 10 seconds.

**[ dead=]** ***DeadInterval***
Specifies, in seconds, how long a router can fail to respond before a neighboring router should consider this router to be malfunctional. This setting should be an integral multiple of the hello interval (commonly 4). This value must be the same for all OSPF router interfaces connected to the same network segment.

**[ poll=]** ***PollInterval***
Specifies the number of seconds between OSPF network polls for non-broadcast multiple access (NBMA) interfaces only. You should set the poll interval to be at least twice as long as the dead interval. A typical value for an X.25 network is two minutes.

**[ metric=]** ***Metric***
Specifies the cost of sending a packet out of this interface. The value set here is advertised as the link cost for this interface in the link state advertisement of the router. Faster interfaces usually have lower costs. The maximum setting is 32,767.

**[ password=]** ***Password***
Specifies the password for this interface, if passwords are required for the area. All interfaces that are in the same area and on the same network must use the same password. By default, passwords are required and the password is 12345678.

**[ mtu=]** ***MTUSize***
Specifies, in bytes, the maximum size of IP packets carrying OSPF information that can be sent without fragmentation. The default IP MTU for an Ethernet network is 1,500 bytes.

#### set global
Configures global OSPF parameters.

#### Syntax
**set global** [**routerid=**]*IPAddress* [**asborder=**]{**yes** | **no**} [[**loglevel=**]{**none** | **error** | **warn** | **info**}]

#### Parameters
**[ routerid=]** ***IPAddress***
Required. Specifies, by IP address, the router for which you want to configure parameters.

**[ asborder=]{ yes| no}**
Required. Specifies whether the router acts as an Autonomous System (AS) boundary router.

**[ loglevel=]{ none| error| warn| info}**
Specifies which events should be logged. The **none** parameter specifies that no events related to OSPF should be logged. The **error** parameter specifies that only errors related to OSPF should be logged. The **warn** parameter specifies that only warnings related to OSPF should be logged. The **info** parameter specifies that all events related to OSPF should be logged.

#### set routefilter
Configures the OSPF route filter action.

#### Syntax

**set routefilter** [**action=**]{**drop** | **accept**}

**Parameters**

**[ action=]{ drop| accept}**

Required. Specifies whether the route filter drops or accepts packets. The **drop** parameter specifies that packets should be dropped. The **accept** parameter specifies that packets should be accepted.

**set protofilter**

Configures OSPF protocol filter action.

**Syntax**

**set protofilter** [**action=**]{**drop** | **accept**}

**Parameters**

**[ action=]{ drop| accept}**

Required. Specifies whether the protocol filter accepts or drops packets. The **drop** parameter specifies that packets should be dropped. The **accept** parameter specifies that packets should be accepted.

**show global**

Displays global OSPF parameters.

**Syntax**

**show global**

**Parameters**

none

**show area**

Displays area parameters.

**Syntax**

**show area**

**Parameters**

none

**show virtif**

Displays parameters for all virtual interfaces.

**Syntax**

**show virtif**

**Parameters**

none

**show interface**

Displays OSPF configuration information for the specified interface.

**Syntax**

**show interface** [**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**show routefilter**

Displays information about the OSPF route filter.

**Syntax**

**show routefilter**

**Parameters**

None

**show protofilter**

Displays information about the OSPF protocol filter.

**Syntax**

**show protofilter**

**Parameters**
none

**show area**
Displays information about OSPF areas.

**Syntax**
**show area**

**Parameters**
none

**show virtif**
Displays information about OSPF virtual interfaces.

**Syntax**
**show virtif**

**Parameters**
none

**Netsh Routing IP Autodhcp commands**
The following commands are available for use in the Netsh Routing IP Autodhcp context.

To view the command syntax, click a command:

- add exclusion
- delete exclusion
- install
- set global
- set interface
- show global
- show interface
- uninstall

**add exclusion**
Adds an exclusion to the DHCP allocator scope.

**Syntax**
**add exclusion** *IPAddress*

**Parameters**
***IPAddress***
Required. Specifies an IP address to exclude from the DHCP allocator scope.

**delete exclusion**
Deletes an exclusion from the DHCP allocator scope.

**Syntax**
**delete exclusion** *IPAddress*

**Parameters**
***IPAddress***
Required. Specifies an IP address already excluded from the DHCP allocator scope.

**install**

Installs the routing protocol under IP.

**Syntax**
**install**

**Parameters**
none

**set global**
Configures global parameters for DHCP allocation.

**Syntax**
**set global** {[[**scopenetwork=**]*IPAddress*] | [[**scopemask=**]*SubnetMask*] | [[**leasetime=**]*Minutes*] | [[**loglevel=**]{**none** | **error** | **warn** | **info**}]}

**Parameters**
**[ scopenetwork=] *IPAddress***
Specifies the IP address for the DHCP allocator scope.

**[ scopemask=] *SubnetMask***
Specifies the subnet mask associated with the IP address for the scope.

**[ leasetime=] *Minutes***
Specifies, in minutes, the lease duration time.

**[ LogLevel=]{ none| error| warn| info}**
Specifies which events should be logged. The **none** parameter specifies that no events related to DHCP should be logged. The **error** parameter specifies that only errors related to DHCP should be logged. The **warn** parameter specifies that only warnings related to DHCP should be logged. The **info** parameter specifies that all events related to DHCP should be logged.

**Examples**
To set the IP network for DHCP allocation to 10.10.10.0, with an associated scope subnet mask of 255.255.255.0, a lease time of 11520 minutes (8 days), and logging of information for all related events, type:

**set global 10.10.10.0 255.255.255.0 11520 info**

To adjust only the lease time globally for all scopes on all interfaces to a value of 4320 minutes (3 days), type:

**set global leasetime=4320**

**set interface**
Configures DHCP allocator parameters for the specified interface.

**Syntax**
**set interface** [**InterfaceName=**]*InterfaceName* [**mode=**]{**enable** | **disable**}

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface on which to configure parameters. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ mode=]{ enable| disable}**
Required. Specifies whether DHCP allocation is enabled or disabled for the interface.

**show global**
Displays the DHCP allocator global configuration.

**Syntax**
**show global**

**Parameters**
none

**show interface**
Displays the DHCP allocator configuration for the specified interface.

**Syntax**
**show interface** [**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**uninstall**

Removes the routing protocol under IP.

**Syntax**

**uninstall**

**Parameters**

none

**Netsh Routing IP Dnsproxy commands**

The following commands are available for use in the Netsh Routing IP Dnsproxy context.

To view the command syntax, click a command:

- set global
- install
- set interface
- show global
- show interface
- uninstall

**set global**

Sets global DNS proxy parameters.

**Syntax**

**set global** [**querytimeout=**]*Integer* [[**dnsmode=**]{**enable** | **disable**}] [[**loglevel=**]{**none** | **error** | **warn** | **info**}]

**Parameters**

**[ querytimeout=] *Integer***

Required. Specifies a time-out, in seconds, for proxied DNS queries.

**[ dnsmode=]{ enable| disable}**

Specifies whether DNS proxy operation is enabled or disabled.

**[ loglevel=]{ none| error| warn| info}**

Specifies which events should be logged. The **none** parameter specifies that no events related to DNS proxy should be logged. The **error** parameter specifies that only errors related to DNS proxy should be logged. The **warn** parameter specifies that only warnings related to DNS proxy should be logged. The **info** parameter specifies that all events related to DNS proxy should be logged.

**Examples**

To specify that queries should time out after 10 seconds, to enable DNS proxy operation, and to prevent logging of DNS proxy events, type:

**set global 10 enable none**

**install**

Installs the routing protocol under IP.

**Syntax**

**install**

**Parameters**

none

**set interface**
Configures DNS proxy parameters for an interface.

**Syntax**
**set interface** [**InterfaceName=**]*InterfaceName* [[**mode=**]{**enable** | **disable** | **default**}]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which to configure parameters. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ mode=]{ enable| disable| default}**
Specifies whether DNS proxy is enabled, disabled, or set to use the default for the specified interface. The **enable** parameter specifies that DNS proxy is enabled. The **disable** parameter specifies that DNS proxy is disabled. The **default** parameter specifies that DNS proxy is set according to the default for the interface.

**show global**
Displays the DNS proxy global configuration.

**Syntax**
**show global**

**Parameters**
none

**show interface**
Displays the DNS proxy configuration for the specified interface.

**Syntax**
**show interface** [**InterfaceName=**]*InterfaceName*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**uninstall**
Removes the routing protocol under IP.

**Syntax**
**uninstall**

**Parameters**
none

**Netsh Routing IP NAT commands**
The following commands are available for use in the Netsh Routing IP NAT context.

To view the command syntax, click a command:

- add addressmapping
- add addressrange
- add interface
- add portmapping
- delete addressmapping
- delete addressrange
- delete interface

- delete portmapping
- set global
- set interface
- show global
- show interface

**add addressmapping**
Adds an IP address mapping to the network address translation (NAT) address pool for the specified interface.

**Syntax**
**add addressmapping** [**InterfaceName=**]*InterfaceName* [**public=**]*IPAddress* [**private=**]*IPAddress* [**inboundsessions=**] {**enable** | **disable**}

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface on which you want to use network address translation. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ public=] *IPAddress***
Required. Specifies the IP address used on a public network.

**[ private=] *IPAddress***
Required. Specifies the IP address in the pooled range of addresses available for use on the private network.

**[ inboundsessions=]{ enable| disable}**
Required. Specifies whether inbound sessions are enabled or disabled. The **enable** parameter specifies that inbound sessions are enabled. The **disable** parameter specifies that inbound sessions are disabled.

**Examples**
To map the public IP address 10.11.11.1 to the private IP address 10.10.10.1 and to disable inbound sessions for this NAT table mapping, type:

**add addressmapping Local Area Connection 10.11.11.1 10.10.10.1 disable**

**add addressrange**
Adds an address range to the NAT address pool for the specified interface.

**Syntax**
**add addressrange** [**InterfaceName=**]*InterfaceName* [**start=**]*IPAddress* [**end=**]*IPAddress* [**mask=**]*SubnetMask*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface to whose address pool you want to add an address range.

**[ start=] *IPAddress***
Required. Specifies the starting IP address for the address range.

**[ end=] *IPAddress***
Required. Specifies the ending IP address for the address range.

**[ mask=] *SubnetMask***
Required. Specifies the IP subnet mask associated with the network range bounded by the start and end IP addresses.

**add interface**
Configures NAT on the specified interface.

**Syntax**
**add interface** [**InterfaceName=**]*InterfaceName* [[**mode=**]{**full** | **addressonly** | **private**}]

**Parameters**
**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface on which you want to configure NAT. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ mode=]{ full| addressonly| private}**
Specifies whether the interface uses full, addressonly, or private mode.

**add portmapping**
Adds a protocol port mapping on the NAT interface.

**Syntax**
