**add portmapping** [**InterfaceName=**]*InterfaceName* [**proto=**]{**tcp** | **udp**} [**publicip=**]{*IPAddress* | **0.0.0.0**} [**publicport=**]*Integer* [**privateip=**]*IPAddress* [**privateport=**]*Integer*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to add a port mapping. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ proto=]{ tcp| udp}**
Required. Specifies whether the protocol type is set to TCP or UDP.

**[ publicip=]{ *IPAddress*| 0.0.0.0}**
Required. Specifies an external IP address on the public network or 0.0.0.0 to indicate any IP address not specified within the private network address range.

**[ publicport=] *Integer***
Required. Specifies the public protocol port by using a number from 0 to 9999.

**[ privateip=] *IPAddress***
Required. Specifies an IP address within the private network range.

**[ privateport=] *Integer***
Required. Specifies the private protocol port by using a number from 0 to 9999.

**delete addressmapping**
Deletes an address mapping from the NAT address pool for the specified interface.

**Syntax**
**delete addressmapping** [**InterfaceName=**]*InterfaceName* [[**public=**]*IPAddress*]

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to delete an address mapping. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ public=] *IPAddress***
Specifies the IP address to be deleted. If you do not specify an address, all address mappings from the NAT address pool are deleted from the interface.

**delete addressrange**
Deletes an address range from the NAT address pool for the specified interface.

**Syntax**
**delete addressrange** [**InterfaceName=**]*InterfaceName* [**start=**]*IPAddress*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface from which you want to delete an address range. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ start=] *IPAddress***
Required. Specifies the starting IP address of the range you want to delete.

**delete interface**

Removes network address translation (NAT) from the specified interface.

**Syntax**

**delete interface** [**InterfaceName=**]*InterfaceName*

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface for which you want to remove the use of NAT. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**delete portmapping**

Deletes a protocol port mapping from the specified NAT-enabled interface.

**Syntax**

**delete portmapping** [**InterfaceName=**]*InterfaceName* [[**proto=**]{**tcp** | **udp**}] [**publicip=**]{*IPAddress* | **0.0.0.0**}] [[**publicport=**]*Integer*] [[**privateip=**]*IPAddress*] [**privateport=**]*Integer*]

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface for which you want to delete a port mapping. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, **"***Interface Name***"**).

**[ proto=]{ tcp| udp}**

Specifies the protocol type. The **tcp** parameter specifies that the protocol type is Transmission Control Protocol. The **udp** parameter specifies that the protocol type is User Datagram Protocol.

**[ publicip=]{ *IPAddress*| 0.0.0.0}**

Specifies an external IP address on the public network or 0.0.0.0 to indicate any IP address not specified within the private network address range.

**[ publicport=] *Integer***

Specifies the public protocol port by using a number from 0 to 9999.

**[ privateip=] *IPAddress***

Specifies an IP address within the private network range.

**[ privateport=] *Integer***

Specifies the private protocol port by using a number from 0 to 9999.

**set global**

Sets global parameters for NAT.

**Syntax**

**set global** {[[**tcptimeoutmins=**]*Integer*] | [[**udptimeoutmins=**]*Integer*] | [[**LogLevel**=]{**none** | **error** | **warn** | **info**}]}

**Parameters**

**[ tcptimeoutmins=] *Integer***

Specifies, in minutes, the time-out value for TCP mappings.

**[ udptimeoutmins=] *Integer***

Specifies, in minutes, the time-out value for UDP mappings.

**[ LogLevel=]{ none| error| warn| info}**

Specifies which events should be logged. The **none** parameter specifies that no events related to NAT should be logged. The **error** parameter specifies that only errors related to NAT should be logged. The **warn** parameter specifies that only warnings related to NAT should be logged. The **info** parameter specifies that all events related to NAT should be logged.

**set interface**

Configure NAT parameters for the specified interface.

**Syntax**

**set interface** [**InterfaceName=**]*InterfaceName* [**mode=**]{*Full* | *AddressOnly* | *Private*}

**Parameters**

**[ InterfaceName=] *InterfaceName***

Required. Specifies, by name, the interface for which you want to configure parameters. The *InterfaceName* parameter must

match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**[ mode=]{ *Full*| *AddressOnly*| *Private*}**
Required. Specifies whether the interface should be enabled for full, addressonly, or private mode.

**show global**
Displays network address translation (NAT) global configuration.

**Syntax**
**show global**

**Parameters**
none

**show interface**
Displays network address translation (NAT) configuration for the specified interface.

**Syntax**
**show interface** [**InterfaceName=**]*InterfaceName*

**Parameters**
**[ InterfaceName=] *InterfaceName***
Required. Specifies, by name, the interface for which you want to display information. The *InterfaceName* parameter must match the name of the interface as specified in Network Connections. If *InterfaceName* contains spaces, use quotation marks around the text (for example, "*Interface Name*").

**Netsh Routing example**
To enable router discovery for the interface named Local Area Connection, specifying a minimum interval of 7 minutes, a maximum interval of 10 minutes, a life of 30 minutes for router discovery packets, and a zero (0) or no preference level, type the following from the netsh routing prompt:

**add interface "Local Area Connection" enable 7 10 30 0**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh commands for RPC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for RPC**
The Netsh commands for RPC provide a command-line tool that you can use to change, reset, or display either specified or all subnet and interface settings.

*Interface* refers to an IPv4 address that is active on the computer and has a network adapter associated with it. *Subnet* refers to a set of zero or more interfaces that resolve to the same subnet address when applied with the appropriate mask.

You can run the Netsh RPC commands from the command prompt for the **netsh rpc** context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh rpc** before typing commands and parameters as they appear in the syntax below.

For more information about **netsh**, see Netsh overview and Enter a netsh context.

To view the command syntax, click a command:

- add
- delete
- show interfaces
- show settings
- reset

**add**
This command adds specified subnets. Each subnet must be in dotted-decimal format (for example, 192.168.255.255).

**Syntax**
**add** *Subnet1*[*Subnet2*]

**Parameters**
***Subnet1***
Required. Specifies the first subnet in the list of added subnets.

**[ *Subnet2*]**
Specifies the second subnet in the list of added subnets.

**/?**
Displays help at the command prompt.

**Examples**
The following example adds two interfaces with subnet addresses of 192.168.255.255 and 172.16.1.0.

**add 192.168.255.255 172.16.1.0**

**delete**
This command deletes specified subnets. Each subnet must be in dotted-decimal format (for example, 192.168.255.255).

**Syntax**
**delete** *Subnet1*[*Subnet2*]

**Parameters**
***Subnet1***
Required. Specifies the first subnet in the list of deleted subnets.

**[ *Subnet2*]**
Specifies the second subnet in the list of deleted subnets.

**/?**
Displays help at the command prompt.

**Examples**
The following example deletes two interfaces with subnet addresses of 192.168.255.255 and 172.16.1.0.

**delete 192.168.255.255 172.16.1.0**

**show interfaces**
This command displays all interfaces and the state of each (enabled or disabled) on the computer, grouped by subnet.

**Syntax**
**show interfaces**

**Parameters**
**/?**
Displays help at the command prompt.

**show settings**
This command displays the selective binding settings for each subnet. Setting values are **none**, **add list**, or **delete list**. If the selective binding settings are either **add list** or **delete list**, then the associated subnets are also displayed.

**Syntax**
**show settings**

**Parameters**
**/?**
Displays help at the command prompt.

**reset**
This command sets the selective binding settings to **none**, which specifies that RPC listens on all interfaces.

**Syntax**
**reset**

**Parameters**
**/?**
Displays help at the command prompt.

## Note

- To run all of these commands (with the exception of **show settings**), you must either have administrative credentials or be a user with permission to write to the **HKEY_LOCAL_MACHINE** registry key.

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Netsh commands for WINS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Netsh commands for WINS**

The Netsh commands for WINS offer a command-line tool for administering WINS servers that can be used as an equivalent alternative to console-based management. This is useful in the following situations:

- When managing WINS servers in wide area networks (WANs), commands can be used in interactive mode at the Netsh command prompt to better manage slow-speed network links.
- When managing a large number of WINS servers, commands can be used in batch mode to script and automate recurring administrative tasks that need to be performed for all WINS servers.

You can run these commands from the Windows Server 2003 family command prompt or from the command prompt for the Netsh wins context. For these commands to work at the Windows Server 2003 family command prompt, you must type **netsh wins** before typing commands and parameters as they appear in the syntax below. There might be functional differences between Netsh context commands on Windows 2000 and the Windows Server 2003 family.

**Notes**

- Unless otherwise specified, field tags (such as **Name=** and **EndChar=**) are optional. If tags are used, they must be applied to all of the parameters in the command. If tags are omitted, a value must be provided for each of the fields that are supported in this command.
- The terms Persona Non Grata and Persona Grata refer to the Windows Server 2003 family features **Block records for these owners** and **Accept records only for these owners**, respectively.
- For more information about Netsh, see Netsh overview and Enter a netsh context.
- For an example of how to use Netsh commands for WINS in batch files and scripts, see Netsh WINS example.
- For more information about how to use the Netsh commands for WINS, see Use WINS Command-line Tools.

**Netsh WINS**

The following commands are available at the **wins>** prompt, which is rooted within the netsh environment.

To view the command syntax, click a command:

- server
- add
- add name
- add partner
- add pgserver
- add pngserver
- check
- check database

- check name
- check version
- delete
- delete name
- delete owners
- delete partner
- delete pgserver
- delete pngserver
- delete records
- init
- init backup
- init import
- init pull
- init pullrange
- init push
- init replicate
- init restore
- init scavenge
- init search
- reset
- reset statistics
- set
- set autopartnerconfig
- set backuppath
- set burstparam
- set defaultparam
- set logparam
- set migrateflag

- set namerecord
- set periodicdbchecking
- set pgmode
- set pullparam
- set pullpartnerconfig
- set pushparam
- set pushpartnerconfig
- set replicateflag
- set startversion
- show
- show browser
- show database
- show info
- show name
- show partner
- show partnerproperties
- show pullpartnerconfig
- show pushpartnerconfig
- show recbyversion
- show reccount
- show server
- show serverstatistics
- show version
- show versionmap

**server**
Switches to the specified server context. Used without parameters, the local WINS server is assumed as the default.

**Syntax**
**server** [{****_ServerName_ | _IPAddress_}]

**Parameters**

**{ *ServerName*| *IPAddress*}**
Specifies the remote (non-local) WINS server to which to switch the Netsh WINS command-line context. Identifies the server by server name or IP address.

**Examples**
In the first example, this command changes the Netsh context to the local WINS server.

In the second example, this command changes the Netsh context to a remote server named \\WINS-SRV1.

In the third example, this command changes the Netsh context to a remote server with IP address 10.0.0.1.

**server**

**server \\WINS-SRV1**

**server 10.0.0.1**

**Netsh WINS server**
The following commands are available at the **wins server>** prompt, which is rooted within the netsh environment.

To view the command syntax, click a command:

**add**
**add name**
Adds a name record to the database on the specified WINS server.

**Syntax**
**add name** [**Name=**]*ComputerName* [[**EndChar=**]*16thCharInHex*] [[**Scope=**]*ScopeName*] [[**RecType=**]{**0** | **1**}] [[**Group=**]{**0** | **1** | **2** | **3** | **4**}] [[**Node=**]{**0** | **1** | **3**}] [**IP=**]**{***IPAddress1*[**,***IPAddress2*,*IPAddress3*... ]**}**

**Parameters**
**[ Name=] *ComputerName***
Required. Specifies the name to add and register in the WINS server database.

**[ EndChar=] *16thCharInHex***
Indicates the 16th character of the name in hexadecimal. If unspecified, record types are added based on the value of **Group=**. For more information, see Remarks.

**[ Scope=] *ScopeName***
Specifies the name of the NetBIOS scope.

**[ RecType=]{ 0| 1}**
Indicates the record type: **0**-Static (default), **1**-Dynamic.

**[ Group=]{ 0| 1| 2| 3| 4}**
Indicates the group type: **0**-Unique (default), **1**-Group, **2**-Internet **3**-Multihomed, **4**-Domain Name.

**[ Node=]{ 0| 1| 3}**
Indicates the NetBIOS node type: **0**-B Node, **1**-P Node (default), **3**-H Node.

**[ IP=] {*IPAddress1*[ ,*IPAddress2*,*IPAddress3*...] }**
Required. Specifies the IP address of the name record to add. If the computer is multihomed, more than one IP address can be specified. Use braces ({}) to enclose one or more IP addresses, and separate multiple IP addresses with commas.

**Remarks**

- If **EndChar=** and **Group=** are both used, **EndChar=** overrides **Group=**.
- When **EndChar=** is not specified, the following record types are added to the WINS database based on the value of **Group=**:

| Group parameter value | Record type added |
|---|---|
| Unique group (0) | 03h, 20h, 00h |
| Normal group (1) | 1eh |

| | |
|---|---|
| Special group/Internet (2) | 20h |
| Multihomed group (3) | 03h, 20h, 00h |
| Special group/domain (4) | 1ch |

**Examples**
In the first example, this command adds a default NetBIOS record set of the 00h, 03h, and 20h records for a computer named HOSTA with a mapped IP address of 10.0.0.1.

In the second example, this command adds a 20h record for HOSTB, a multihomed computer with IP addresses 10.0.0.2 and 10.0.0.3, on SUBNETA, with a static record type and P-Node configuration.

**add name Name=HOSTA IP={10.0.0.1}**

**add name HOSTB 20 SUBNETA 0 3 1{10.0.0.2,10.0.0.3}**

**add partner**
Adds a replication partner to the list of replication partners on the specified WINS server.

**Syntax**
**add partner** [**Server=**]*IPAddress* [[**NetBIOS=**]*ServerNetBIOSName*] [[**Type=**]{**0** | **1** | **2**}]

**Parameters**
**[ Server=] *IPAddress***
Required. Specifies the replication partner to add to the WINS server. Identifies the partner server by IP address.

**[ NetBIOS=] *ServerNetBIOSName***
Specifies the replication partner to add to the WINS server. Identifies the partner server by NetBIOS name.

**[ Type=]{ 0| 1| 2}**
Indicates the type of partner to add: **0**-Pull, **1**-Push, **2**-Both (default).

**Remarks**

- If the IP address does not resolve, the NetBIOS name parameter is used to create the partner record. Otherwise, the NetBIOS parameter is not used.

**Examples**
In the following example, this command adds a push/pull replication partner with an IP address of 10.2.2.2 to the current WINS server.

**add partner 10.2.2.2**

**add pgserver**
Adds a list of Persona Grata servers to the specified WINS server.

**Syntax**
**add pgserver** [**Servers=**]**{***ListOfServerIPAddresses***}**

**Parameters**
**[ Servers=] {*ListOfServerIPAddresses*}**
Required. Specifies the Persona Grata server or servers to add. Identifies each server by its IP address, enclosed by braces ({}). If you provide a list, IP addresses must be separated by commas and enclosed by braces ({}).

**Remarks**

- This command adds the new server or servers after checking for duplicates. The Persona Grata (PG) list is used to specify owners (other WINS servers) whose records are to be accepted during replication.

**Examples**
In the following example, this command adds the WINS servers 10.2.2.2 and 10.2.2.3 to the Persona Grata list for the current WINS server.

**add pgserver {10.2.2.2,10.2.2.3}**

**add pngserver**
Adds a list of Persona Non Grata servers to the specified WINS server.

**Syntax**
**add pngserver** [**Servers=**]**{***ListOfServerIPAddresses***}**

**Parameters**
**[ Servers=] {*ListOfServerIPAddresses*}**
Required. Specifies the Persona Non Grata server or servers to add. Identifies each server by its IP address, enclosed by braces ({}). If a you provide a list, IP addresses must be separated by commas and enclosed by braces ({}).

**Remarks**

- This command adds the new server or servers after checking for duplicates. The Persona Non Grata (PNG) list is used to specify owners (other WINS servers) whose records are to be blocked during replication.

**Examples**
In the following example, this command adds the WINS servers 10.2.2.2 and 10.2.2.3 to the Persona Non Grata list for the current WINS server.

**add pngserver {10.2.2.2,10.2.2.3}**

**check**
**check database**
Checks the consistency of the WINS database. Used without parameters, a consistency check is performed on all replicas whose verification interval has expired. The consistency check is not be performed immediately if overload conditions exist, but occurs after the configured verification interval period has passed.

**Syntax**
**check database** [[**All=**]{**1** | **0**}] [[**Force=**]{**1** | **0**}]

**Parameters**
**[ All=]{ 1| 0}**
Indicates whether to perform a consistency check on all replicas or to perform a consistency check on the replicas whose verification interval has expired: **1**-All, **0**-Otherwise (default).

**[ Force=]{ 1| 0}**
Indicates whether to override the WINS consistency check under overload conditions: **1**-Override, **0**-Otherwise (default).

**Remarks**

- It is a network and resource intensive operation to check all replicas for consistency.

- Overload condition occurs when the consistency check command is repeated within a duration of one hour.

**Examples**
In the following example, this command does a consistency check for all replicas. If overload conditions exist, the consistency check is performed after the configured verification interval has passed.

**check database 1**

**check name**
Checks a list of name records against a specified set of WINS servers.

**Syntax**
**check name** {**NameFile=***FileName* | **NameList={***NamesList***}**} {**ServerFile=***FileName* | **ServerList={***ListOfServerIPAddresses***}**} [**InclPartner=**{**Y** | **y**}]

**Parameters**
**{ NameFile=*FileName*| NameList={*NamesList*}}**
Required. Specifies the file that contains the list of names to check or specifies a list of names to check. If you provide a list, names must be separated by commas and enclosed by braces ({}).

**{ ServerFile=*FileName*| ServerList={*ListOfServerIPAddresses*}}**
Required. Specifies the file with the list of server IP addresses or specifies a list of the server IP addresses to check. If you provide a list, IP addresses must be separated by commas and enclosed by braces ({}).

**InclPartner={ Y| y}**
Specifies that all partners will be included in the list of servers. Partners are not included by default.

**Remarks**

- Tags are required for this command. Whenever inconsistencies are found, repair is attempted.
- The format for *Name* in both *NameFile* and *NameList* is *Name*16thchar*, where *Name* is the record name and 16thchar is the 16th character for the record.
- In the file, name entries are separated by commas or carriage returns/line feeds.

**Examples**
In the first example, this command checks WINS data against the Names.txt and Servers.txt files, assuming those files to be located in the specified path location (the root of drive D).

In the second example, this command checks the names Name1 with 16th character 03, 00 and 20h respectively against the servers with IP addresses 10.2.2.2 and 10.2.2.3.

**check name NameFile=D:\Names.txt ServerFile=D:\Servers.txt**

**check name NameList={Name1*03,Name1*00,Name1*20} ServerList={10.2.2.2,10.2.2.3}**

**check version**
Checks the consistency of version ID numbers for WINS record owners in the WINS database.

**Syntax**
**check version** [**Server=**]*IPAddress* [[**File=**]*FileName*]

**Parameters**
**[ Server=] *IPAddress***
Required. Specifies the IP address of the start WINS server.

**[ File=] *FileName***
Specifies the file in which to store the index to IP address table. If omitted, **check version** creates the file Wins.rec in the current directory and stores the index to IP address table there.

**Remarks**

- If you provide an invalid file name, *FileName* is set to Wins.rec in the current directory.
- You might need to increase the width of the command window to make it wide enough to view the table correctly.

**Examples**
In the following example, this command verifies the version number consistency of the records for a WINS server with the IP address 10.2.2.2 at its replication partners.

**check version 10.2.2.2**

**delete**
**delete name**
Deletes a registered name from the WINS server database.

**Syntax**
**delete name** [**Name=**]*RegisteredName* [**EndChar=**]*16thCharInHex* [[**Scope=**]*ScopeName*]

**Parameters**
**[ Name=] *RegisteredName***
Required. Specifies the registered name to be deleted.

**[ EndChar=] *16thCharInHex***
Required. Indicates the 16th character of the name of the record to be deleted in hexadecimal.

**[ Scope=] *ScopeName***
Specifies the NetBIOS scope identifier for the record to be deleted.

**Examples**
In the following example, this command deletes the messenger (03h) records with the record name HOSTA from the WINS database.

**delete name Name=HOSTA EndChar=03**

**delete owners**
Deletes or tombstones a list of owners and their records from the database on the specified WINS server.

**Syntax**
**delete owners** [**Servers=**]**{***ListOfServerIPAddresses***}**[[**Op=**]{**0** | **1**}]

**Parameters**
**[ Servers=] {*ListOfServerIPAddresses*}**
Required. Specifies a list of the owner servers with records to delete. Identifies the servers by IP addresses that must be separated by commas and enclosed by braces ({}).

**[ Op=]{ 0| 1}**
Indicates your option: **0**-Tombstone (default), **1**-Delete.

**Examples**
In the following example, this command deletes all records owned by the WINS server with the IP address 10.0.0.1.

**delete owners Servers={10.0.0.1} Op=1**

**delete partner**
Deletes either all replication partners or a specified replication partner from the list of replication partners on the specified WINS server. When used without parameters, all replication partners are deleted from both the pull and the push partner lists without a confirmation prompt.

**Syntax**
**delete partner** [[**Server=**]*IPAddress*] [[**Type=**]{**0** | **1** | **2**}] [[**Confirm=**]{**Y** | **y**}]

**Parameters**
**[ Server=] *IPAddress***
Specifies the partner to delete. Identifies the partner by IP address.

**[ Type=]{ 0| 1| 2}**
Indicates the type of partner list to delete: **0**-Pull, **1**-Push, **2**-Both (default).

**[ Confirm=]{ Y| y}**
Initiates and completes the operation without prompting for confirmation.

**Examples**
In the following example, this command deletes a push/pull type partner with an IP address of 10.0.0.1 from the current WINS server without prompting for confirmation.

**delete partner Server=10.0.0.1 Type=2 Confirm=Y**

**delete pgserver**
Deletes all Persona Grata servers or specific Persona Grata servers from the list of Persona Grata servers on the specified WINS server.

**Syntax**
**delete pgserver** [**Servers=**]**{***ListOfServerIPAddresses***}**

**Parameters**
**[ Servers=] {*ListOfServerIPAddresses*}**
Required. Specifies a list of Persona Grata servers to delete. Identifies Persona Grata servers by IP addresses separated by commas and enclosed by braces ({}).

**Remarks**

- The Persona Grata (PG) list specifies owners (other WINS servers) whose records are to be accepted during replication. If you use an empty set of braces ({}), **delete pgserver** deletes all of the servers on the PG server list.

**Examples**
In the following example, this command deletes the WINS servers 10.2.2.2 and 10.2.2.3 from the Persona Grata list for this

WINS server.

**delete pgserver Servers={10.2.2.2,10.2.2.3}**

**delete pngserver**
Deletes all Persona Non Grata servers or specific Persona Non Grata servers from the list of Persona Non Grata servers on the specified WINS server.

**Syntax**
**delete pngserver** [**Servers=**]**{***ListOfServerIPAddresses***}**

**Parameters**
**[ Servers=] {*ListOfServerIPAddresses*}**
Required. Specifies a list of Persona Non Grata servers to delete. Identifies Persona Non Grata servers by IP addresses separated by commas and enclosed by braces ({}).

**Remarks**

- The Persona Non Grata (PNG) list specifies owners (other WINS servers) whose records are to be blocked during replication. If you use an empty set of braces ({}), **delete pngserver** deletes all of the servers on the PNG server list.

**Examples**
In the following example, this command deletes the WINS servers 10.2.2.2 and 10.2.2.3 from the Persona Non Grata list for this WINS server.

**delete pngserver Servers={10.2.2.2,10.2.2.3}**

**delete records**
Deletes all records or a set of records from the current WINS server or marks records as tombstoned.

**Syntax**
**delete records** [**MinVer=**]**{***High***,***Low***}** [**MaxVer=**]**{***High***,***Low***}** [[**Op=**]{**0** | **1**}]

**Parameters**
**[ MinVer=] {*High*,*Low*}**
Required. Specifies the minimum high and the minimum low record versions from which to begin deletion. High and low values are separated by a comma and enclosed by braces ({}).

**[ MaxVer=] {*High*,*Low*}**
Required. Specifies the maximum high and maximum low record versions at which to end deletion. High and low values are separated by a comma and enclosed by braces ({}).

**[ Op=]{ 0| 1}**
Indicates your option: **0**-Delete (default), **1**-Tombstone.

**Remarks**

- If you set both **MinVer=** and **MaxVer=** to {0,0}, **delete records** deletes all records.

**Examples**
In the first example, this command marks all records on the WINS server as tombstoned.

In the second example, this command deletes all records between and including 2de2d and 2de3f.

**delete records MinVer={0,0} MaxVer={0,0} Op=1**

**delete records MinVer={0,2de2d} MaxVer={0,2de3f}**

**init**
**init backup**
Initiates backup of the WINS database to a specified directory. Used without parameters, this command provides a full backup to the default backup path that is currently set.

**Syntax**
**init backup** [[**Dir=**]*BackupDir*] [[**Type=**]{**0** | **1**}]

**Parameters**

**[ Dir=] *BackupDir***
Specifies the directory in which backups are stored. If unspecified, the default backup path that is currently set is used.

**[ Type=]{ 0| 1}**
Indicates the type of backup: **0**-Full backup (default), **1**-Incremental backup.

**Remarks**

- WINS backup can only be used for a local backup on the same server. Backup of remote WINS servers is not supported.
- Backup files will automatically be created under the wins_bak subdirectory of the **Dir=** directory.

**Examples**
In the following example, this command initiates a full backup of the WINS database on the local WINS server to the folder C:\WINSfiles\wins_bak. WINS will create the wins_bak subdirectory.

**init backup Dir=C:\WINSfiles Type=0**

**init import**
Initiates the import of static mappings from an Lmhosts file.

**Syntax**
**init import** [**File=**]*ImportFile*

**Parameters**
**[ File=] *ImportFile***
Required. Specifies the Lmhosts-formatted text file used for importing static mappings into the WINS database.

**Examples**
In the following example, this command imports the static mappings of the Fixedip.sam file, located at the C:\WINSfiles path, as new static mappings in the local WINS database.

**init import File=C:\WINSfiles\Fixedip.sam**

**init pull**
Initiates and sends a pull trigger to another WINS server.

**Syntax**
**init pull** [**Server=**]{*PullServerName* | *IPAddress*}

**Parameters**
**[ Server=]{ *PullServerName*| *IPAddress*}**
Required. Specifies the WINS server to which to send a pull trigger. Identifies the server by server name or IP address.

**Remarks**

- If you provide a server name that cannot be resolved to an IP address, the operation fails.

**Examples**
In the following example, this command initiates and sends a pull trigger to WINS server 10.2.2.2.

**init pull Server=10.2.2.2**

**init pullrange**
Initiates and pulls a range of records from another WINS server.

**Syntax**
**init pullrange** [**Owner=**]*OwnerServerIP* [**Server=**]*PullServerIP* [**MaxVer=**]**{***High*,*Low***}** [**MinVer=**]**{***High*,*Low***}**

**Parameters**
**[ Owner=] *OwnerServerIP***
Required. Specifies the WINS server with records to be pulled. Identifies the server by IP address.

**[ Server=] *PullServerIP***
Required. Specifies the WINS server that pulls the range of records. Identifies the server by IP address.

**[ MaxVer=] {*High*,*Low*}**

Required. Specifies the maximum high and the maximum low version number of the records to be pulled. High and low values are separated by a comma and enclosed by braces ({}).

**[ MinVer=] {*High*,*Low*}**
Required. Specifies the minimum high and the minimum low version number of the records to be pulled. High and low values are separated by a comma and enclosed by braces ({}).

**Remarks**

- If you set both **MaxVer=** and **MinVer=** to {0,0}, **init pullrange** pulls the entire range of records.

**Examples**
In the following example, this command initiates and sends a pull trigger to WINS server 10.2.2.3 for all records owned by WINS server 10.2.2.2.

**init pullrange Owner=10.2.2.2 Server=10.2.2.3 MaxVer={0,0} MinVer={0,0}**

**init push**
Initiates and sends a push trigger to another WINS server.

**Syntax**
**init push** [**Server=**]{****_PushServerName_ | _IPAddress_} [[**PropReq=**]{**0** | **1**}]

**Parameters**
**[ Server=]{ *PushServerName*| *IPAddress*}**
Required. Specifies the WINS server to which to send a push trigger. Identifies the server by name or IP address.

**[ PropReq=]{ 0| 1}**
Indicates your propagation request: **0**-Push to the specified server only (default), **1**-Have server propagate the push trigger to all of its partners.

**Remarks**

- If you provide a server name that cannot be resolved to an IP address, the operation fails.

**Examples**
In the following example, this command initiates and sends a push trigger to WINS server 10.2.2.2 and has it propagate the trigger to all of its replication partners.

**init push Server=10.2.2.2 PropReq=1**

**init replicate**
Initiates and forces an immediate replication of the database with replication partners.

**Syntax**
**init replicate**

**Parameters**
none

**Remarks**

- This command initiates push/pull replication with all replication partners for this server.

**init restore**
Initiates the restoration of the WINS database from a directory and file at the specified WINS server.

**Syntax**
**init restore** [**Dir=**]*RestoreDir*

**Parameters**
**[ Dir=] *RestoreDir***
Required. Specifies the directory from which to restore files.

**Remarks**

- WINS backups can only be restored locally on the same server. You cannot restore the WINS database from a remote

WINS backups can only be restored locally on the same server. You cannot restore the WINS database from a remote computer.

- **Dir=** should contain a subdirectory wins_bak, which will contain the database file, but this subdirectory should not be included in the **Dir=** parameter.

**Examples**

In the following example, this command restores the WINS database from the backup database file location of C:\WINSfiles.

**init restore Dir=C:\WINSfiles**

**init scavenge**

Initiates the scavenging of the WINS database for the specified WINS server.

**Syntax**

**init scavenge**

**Parameters**

none

**Remarks**

- This command removes outdated information from the WINS database.

**init search**

Initiates a search for the specified record name in the WINS database.

**Syntax**

**init search** [**Name=**]*RecordName* [[**EndChar=**]*EndCharacter*] [[**Case=**]{**0** | **1**}] [[**File=**]*FileName*]

**Parameters**

**[ Name=] *RecordName***

Required. Specifies the name of the record for which to search.

**[ EndChar=] *EndCharacter***

Indicates the 16th character of the NetBIOS name record. If unspecified, the search returns all records that match the string that you entered as a value for **Name=**. For more information, see Remarks.

**[ Case=]{ 0| 1}**

Indicates name case preference: **0**-Ignore name case (default), **1**-Use name case.

**[ File=] *FileName***

Specifies the file in which to store ASCII plain text output. If unspecified, output is displayed in the command prompt window.

**Remarks**

- If you do not supply a value for **EndChar=**, the search returns all records that match the string that is entered as a value for **Name=**. For example, if the database contains a record named MYPC-1, a search that uses MYPC as the value of the name parameter returns all records starting with this name pattern, regardless of record type:

| Record Name | Record Type |
|---|---|
| MYPC-1 | [00h]Workstation |
| MYPC-1 | [01h]Other |
| MYPC-1 | [03h]Messenger |

If you specify a value for **EndChar=**, only records that match the record name and record type are returned. For example, if the value for **Name=** is MYPC and the value for EndChar is 00, the following search results return:

| Record Name | Record Type |
|---|---|
| MYPC-1 | [00h]Workstation |

**Examples**
In the following example, this command searches for records named dc1 with an end character of 1c, ignores name case, and outputs the information to the names.txt file located in C:\WINSfiles.

**init search Name=dc1 EndChar=1c Case=0 File=C:\WINSfiles \names.txt**

**reset**
**reset statistics**
Resets the statistics for the local WINS server.

**Syntax**
**reset statistics**

**Parameters**
none

**set**
**set autopartnerconfig**
Sets the automatic replication partner configuration information for the server. Used without parameters, automatic partner configuration is reset (disabled).

**Syntax**
**set autopartnerconfig** [[**State=**]{**0** | **1**}] [[**Interval=**]*Value*] [[**TTL=**]*Value*]

**Parameters**
**[ State=]{ 0| 1}**
Indicates the automatic replication partner configuration information setting: **0**-Reset (default), **1**-Set.

**[ Interval=] *Value***
Specifies the multicast interval value, in seconds.

**[ TTL=] *Value***
Specifies the Time-To-Live value for multicast datagrams between partner WINS servers. The TTL value must be within the range of 1 to 32.

**Examples**
In the following example, this command sets the automatic configuration information for this WINS server for a multicast interval of 3,600 seconds and a Time to Live (TTL) value of 20.

**set autopartnerconfig State=0 Interval=3600 TTL=20**

**set backuppath**
Sets the backup parameters for the specified WINS server.

**Syntax**
**set backuppath** [**Dir=**]*NewPath* [[**Shutdown=**]{**0** | **1**}]

**Parameters**
**[ Dir=] *NewPath***
Required. Specifies the backup path for the server database. If unspecified, the default path is C:\.

**[ Shutdown=]{ 0| 1}**
Indicates the setting for backup during shutdown: **0**-Disable backup of the WINS database during shutdown (default), **1**-Enable backup of the WINS database during shutdown.

**Examples**
In the following example, this command sets the WINS server to automatically back up the WINS database to C:\WINSfiles each time that the server is shut down.

**set backuppath Dir=C:\WINSfiles Shutdown=1**

**set burstparam**
Sets burst handling parameters for the specified WINS server.

**Syntax**
**set burstparam** [**State=**]{**0** | **1**} [[**Value=**]*QueueSize*]

**Parameters**
**[ State=]{ 0| 1}**

Required. Indicates the setting for burst handling: **0**-Reset or disable burst handling for the WINS server, **1**-Set or enable burst handling for the WINS server.

**[ Value=] *QueueSize***
Specifies the value of the burst queue size. The queue size must be within the range of 50 to 5,000.

**Examples**
In the following example, this command sets the size of the burst queue to permit 1,000 client registration and renewal requests before the WINS server uses burst handling.

**set burstparam State=1 Value=1000**

**set defaultparam**
Sets the default parameters for WINS server configuration.

**Syntax**
**set defaultparam**

**Parameters**
none

**Remarks**

- This command sets all the configuration parameters for the WINS server to their default values. It is recommended that you run this command after WINS service installation to configure the server with default parameter settings.

**set logparam**
Sets or resets database and detailed event logging parameters. Used without parameters, the current values are maintained.

**Syntax**
**set logparam** [[**DBChange=**]{**0** | **1**}] [[**Event=**]{**0** | **1**}]

**Parameters**
**[ DBChange=]{ 0| 1}**
Indicates whether you want to log database changes: **1**-Enable logging of database changes to JET log files (default), **0**-Reset this option.

**[ Event=]{ 0| 1}**
Indicates the detail of events: **1**-Log detailed events to the system event log , **0**-Reset this option (default).

**Remarks**

- The WINS database engine can log the database changes to separate files. Because this option improves the performance of database operations, it is turned on by default.

- The WINS server can log detailed event information in the system event log. Because this option is resource-intensive, it is turned off by default.

**Examples**
In the following example, this command sets logging parameters for this WINS server to enable the logging of database changes to JET files and to log detailed events to the system event log.

**set logparam Event=1**

**set migrateflag**
Sets the migration flag for the specified WINS server.

**Syntax**
**set migrateflag** [**State=**]{**0** | **1**}

**Parameters**
**[ State=]{ 0| 1}**
Required. Indicates the setting of the migrate flag: **0**-Disable (migrate off), **1**-Enable (migrate on)

**Remarks**

- The migrate flag determines if unique static mappings can be overwritten by dynamic records.

**Examples**
In the following example, this command sets the migrate flag to permit the overwriting of unique static mappings by dynamic records for the specified WINS server.

**set migrateflag State=1**

**set namerecord**
Sets the intervals that are used to determine when WINS name records are renewed, deleted, and verified at the specified WINS server. Used without parameters, current values are maintained.

**Syntax**
**set namerecord** [[**Renew=**]*Value*] [[**Extinction=**]*Value*] [[**ExTimeout=**]*Value*] [[**Verification=**]*Value*]

**Parameters**
**[ Renew=] *Value***
Specifies the interval renewal rate, in seconds.

**[ Extinction=] *Value***
Specifies the extinction interval, in seconds.

**[ ExTimeout=] *Value***
Specifies the extinction time-out, in seconds.

**[ Verification=] *Value***
Specifies the verification interval, in seconds.

**Remarks**

- All parameters are optional. For parameters not used, previously set or default values are maintained.

**Examples**
In the following example, this command sets each of the values for name records on this WINS server.

**set namerecord Renew=3600 Extinction=7200 ExTimeout=86400 Verification=2073600**

**set periodicdbchecking**
Sets the periodic database consistency checking parameters for the specified WINS server. Used without parameters, current values are maintained.

**Syntax**
**set periodicdbchecking** [[**State=**]{**0** | **1**}] [[**MaxRec=**]*Value*] [[**CheckAgainst=**]{**0** | **1**}] [[**CheckEvery=**]*Value*] [[**Start=**]*Value*]

**Parameters**
**[ State=]{ 0| 1}**
Required. Indicates whether to check the state of the WINS database: **0**-Disable, **1**-Enable(default). If you set the value of this parameter to 0, all checks are disabled regardless of the values of other parameters.

**[ MaxRec=] *Value***
Specifies the maximum number of records that are checked each period. If unspecified, the default is 30,000.

**[ CheckAgainst=]{ 0| 1}**
Indicates the server to check against: **0**-Owner server (default), **1**-Randomly selected server.

**[ CheckEvery=] *Value***
Specifies how often the WINS database should be checked for consistency, in hours. If unspecified, the default is 24 hours.

**[ Start=] *Value***
Specifies the time, in seconds, at which to start the consistency check.

**Remarks**

- In order to set periodic consistency check intervals, it is recommended that you specify values for the **CheckEvery** and **Start** parameters. In order to adjust existing periodic consistency check settings, specify values only for **State** and the parameter or parameters that you want to change. Parameters for which you do not supply a value remain unchanged.

**Examples**
In the following example, this command checks the WINS database against a random replication partner every hour starting at 3,600 seconds.

**set periodicdbchecking State=1 MaxRec=1000 CheckAgainst=1 CheckEvery=1 Start=3600**

**set pgmode**
Sets the Persona Grata mode or the Persona Non Grata mode.

**Syntax**
**set pgmode** [**Mode=**]{**0** | **1**}

**Parameters**
**[ Mode=]{ 0| 1}**
Required. Specifies which mode to set: **0**-Sets the Persona Non Grata (PNG) mode, **1**-Sets the Persona Grata (PG) mode.

**Remarks**

- Use the **add pgserver** and the **delete pgserver** commands to update the Persona Grata list.

**Examples**
In the following example, this command sets the Persona Grata mode. During replication, WINS will accept only the records that are owned by the servers that are specified in the Persona Grata list.

**set pgmode Mode=1**

**set pullparam**
Sets the default pull partner parameters for the specified WINS server. Used without parameters, previously set or default values are maintained.

**Syntax**
**set pullparam** [[**State=**]{**0** | **1**}] [[**Strtup=**]{**0** | **1**}] [[**Start=**]*Value*] [[**Interval=**]*Value*] [[**Retry=**]*Value*]

**Parameters**
**[ State=]{ 0| 1}**
Required. Indicates whether you want persistent connections to be used with pull partners: **0**-Do not use persistent connections with pull partners, **1**-Use persistent connections with pull partners.

**[ Strtup=]{ 0| 1}**
Indicates whether pull replication should start at startup: **0**-Do not start pull replication at startup (default), **1**-Start pull replication at startup.

**[ Start=] *Value***
Specifies the start time for the pull trigger, in seconds.

**[ Interval=] *Value***
Specifies the replication interval, in seconds.

**[ Retry=] *Value***
Specifies the number of times to retry replication.

**Remarks**

- If you do not specify a value for **Interval=**, only one replication occurs.

- If you do not specify a value for **Start=**, execution of the command starts the pull trigger.

**Examples**
In the following example, this command sets the default pull partner parameters for this WINS server to use a persistent connection with its pull partners, begin replication at startup, start the pull trigger in 23,600 seconds at an interval of 259,200 seconds, and retry replication seven times.

**set pullparam State=1 Strtup=1 Start=23600 Interval=259200 Retry=7**

**set pullpartnerconfig**
Sets the configuration parameters for the specified pull partner.

**Syntax**
**set pullpartnerconfig** [[**State=**]{**0** | **1**}] [**Server=**]*ServerName* [[**Start=**]*Value*] [[**Interval=**]*Value*]

**Parameters**
**[ State=]{ 0| 1}**
Indicates the state of the persistent connection flag: **0**-Disable, **1**-Enable (default).

**[ Server=] *ServerName***
Required. Specifies the pull replication partner by server name or IP address.

**[ Start=] *Value***
Specifies the start time for replication, in seconds.

**[ Interval=] *Value***
Specifies the interval between pull replications, in seconds.

**Remarks**

- If you provide a server name for **Server=** that cannot be resolved to an IP address, the function fails.

**Examples**
In the following example, this command sets the pull partner configuration for the current WINS server for the partner WINS server 10.2.2.2. Pull replication starts in 3,600 seconds and runs every 4,320 seconds.

**set pullpartnerconfig State=1 Server=10.2.2.2 Start=3600 Interval=4320**

**set pushparam**
Sets the default push partner parameters for the specified WINS server.

**Syntax**
**set pushparam** [**State=**]{**0** | **1**} [[**Strtup=**]{**0** | **1**}] [[**AddChange=**]{**0** | **1**}] [[**Update=**]*Value*]

**Parameters**
**[ State=]{ 0| 1}**
Required. Indicates whether you want persistent connections to be used with push partners: **0**-Do not use persistent connections with push partners, **1**-Use persistent connections with push partners.

**[ Strtup=]{ 0| 1}**
Indicates whether you want push replication to start at startup: **0**-Do not start push replication at startup (default), **1**-Start push replication at startup.

**[ AddChange=]{ 0| 1}**
Indicates whether you want replication to be triggered upon address change: **0**-Do not trigger replication upon address change (default), **1**-Trigger replication upon address change.

**[ Update=] *Value***
Specifies the number of changes in version ID that will occur before replication.

**Examples**
In the following example, this command sets the default push partner parameters for this WINS server to use persistent connections with its push partners, start push replication at startup and when addresses change, and push to partners after the version ID has been updated twice for records owned at this WINS server.

**set pushparam State=1 Strtup=1 AddChange=1 Update=2**

**set pushpartnerconfig**
Sets the configuration parameters for the specified push partner.

**Syntax**
**set pushpartnerconfig** [[**State=**]{**0** | **1**}] [**Server=**]*****ServerName* [**Update=**]*Value*

**Parameters**
**[ State=]{ 0| 1}**
Indicates the state of the persistent connection flag: **0**-Disable, **1**-Enable (default).

**[ Server=] *ServerName***
Required. Specifies the push partner server for which you want to set configuration parameters. Identifies the server by server name or IP address.

**[ Update=] *Value***
Required. Specifies the threshold for updates.

**Remarks**

- If you provide a name in the server parameter cannot be resolved to an IP address, the function fails.

**Examples**
In the following example, this command sets the push partner configuration for the current WINS server for a partner WINS server with IP address 10.2.2.2 and sets two as the limit of changes in version ID allowed before push partners are informed about them.

**set pushpartnerconfig State=1 Server=10.2.2.2 Update=2**

**set replicateflag**
Sets the replication flag for the specified WINS server.

**Syntax**
**set replicateflag** [**State=**]{**0** | **1**}

**Parameters**
**[ State=]{ 0| 1}**
Required. Indicates the setting of the replication flag: **0**-Disable (replication flag off), **1**-Enable (replication flag on).

**Examples**
In the following example, this command enables the replication flag for this server.

**set replicateflag State=1**

**set startversion**
Sets the value of the beginning (start) version ID number for the database.

**Syntax**
**set startversion** [**Version=**]**{***High***,***Low***}**

**Parameters**
**[ Version=] {*High*,*Low*}**
Required. Specifies the start version ID number for the WINS database. High and low values are separated by a comma and enclosed by braces ({}).

**Examples**
In the following example, this command sets the beginning version ID number for the WINS database to 0.

**set startversion Version={0,0}**

**show**
**show browser**
Displays all active domain master browser [1Bh] records for the specified WINS server.

**Syntax**
**show browser**

**Parameters**
none

**show database**
Displays the database and records for a partial or complete list of specified owner servers.

**Syntax**
**show database** [**Servers=**]**{***IPAddresses***}** [[**RecType=**]{**0** | **1** | **2**}] [[**Count=**]*Count*] [[**Start=**]{**0** | **1**}] [[**EndChar=**]*16thCharInHex*] [[**File=**]*FileName*]

**Parameters**
**[ Servers=] {*IPAddresses*}**

Required. Specifies a list of the owner servers whose records are to be displayed. Identifies owner servers by IP addresses, which must be separated by commas and enclosed in braces ({}).

**[ RecType=]{ 0| 1| 2}**
Indicates the type of record: **0**-Both (default), **1**-Static, **2**-Dynamic.

**[ Count=]** ***Count***
Specifies the number of records that you want to display. If unspecified, all records that match the query parameters are be returned.

**[ Start=]{ 0| 1}**
Indicates where to start sorting the display: **0**-Start from the beginning of the database (default), **1**-Start from the end of the database.

**[ EndChar=]** ***16thCharInHex***
Indicates the 16th character of the records, in hexadecimal. This number filters the records that are retrieved from the database. If unspecified, all record types are returned.

**[ File=]** ***FileName***
Specifies the file in which formatted output is stored. If unspecified, output is displayed in the command prompt window.

**Remarks**

- If you specify an empty set ({}) for **Servers=**, **show database** records are displayed for all owner servers.

**Examples**
In the following example, this command outputs the first 1000 dynamic records in the WINS database for the server 10.2.2.2 to the text file output.txt.

**show database Servers={10.2.2.2} RecType=2 Count=1000 Start=0 Endchar=0 File=C:\WINSfiles\output.txt**

**show info**
Displays configuration information for the specified WINS server.

**Syntax**
**show info**

**Parameters**
none

**Remarks**

- If set, this command displays the following WINS configuration information for the current server:
    - Backup path
    - Name record setting
    - Periodic database consistency checking
    - Burst handling
    - Logging parameters
    - Start version count

**show name**
Queries and displays detailed information for a specified record in the current WINS server database.

**Syntax**
**show name** [**Name=**]*RecordName* [**EndChar=**]*16thCharInHex* [[**Scope=**]*ScopeName*]

**Parameters**
**[ Name=]** ***RecordName***

Required. Specifies the record for which to query.

**[ EndChar=]** ***16thCharInHex***
Required for all queries except unique type records. Indicates the 16th character in hexadecimal.

**[ Scope=]** ***ScopeName*****]**
Specifies the NetBIOS scope, if used.

**Examples**
In the following example, this command shows currently stored information for name record HOSTA, of File Server type, [20h] that exists in the WINS database on the specified WINS server.

**show name Name=HOSTA EndChar=20**

**show partner**
Displays all pull partners, push partners, or pull and push partners for the specified WINS server. When used without parameters, this command displays all push partners, pull partners, and push/pull partners for the specified WINS server.

**Syntax**
**show partner** [[**Type=**]{**0** | **1** | **2** | **3**}]

**Parameters**
**[ Type=]{ 0| 1| 2| 3}**
Indicates the type of partner to display: **0**-All (default), **1**-Pull, **2**-Push, **3**-Both push and pull.

**Examples**
In the following example, this command displays the server name, IP address, and replication type of each replication partner for this WINS server.

**show partner**

**show partnerproperties**
Displays default partner configuration information for the specified WINS server.

**Syntax**
**show partnerproperties**

**Parameters**
none

**Remarks**

- This command displays the auto partner configuration and default push/pull parameters for the current WINS server.

**show pullpartnerconfig**
Displays configuration information for a pull partner.

**Syntax**
**show pullpartnerconfig** [**Server=**]{*Name* | *IPAddress*}

**Parameters**
**[ Server=]{ *Name*| *IPAddress*}**
Required. Specifies the pull partner for which you want to display configuration information. Identifies the partner by name or IP address.

**Remarks**

- If you provide a name that cannot be resolved to an IP address, the function fails.

**Examples**
In the following example, this command displays the pull partner configuration information for WINS server 10.2.2.2.

**show pullpartnerconfig Server=10.2.2.2**

**show pushpartnerconfig**
Displays configuration information for a push partner.

**Syntax**

**show pushpartnerconfig** [**Server=**]{*Name* | *IPAddress*}

**Parameters**

**[ Server=]{ *Name*| *IPAddress}***

Required. Specifies the push partner for which you want to display configuration information. Identifies the push partner by name or IP address.

**Remarks**

- If you provide a name that cannot be resolved to an IP address, the function fails.

**Examples**

In the following example, this command displays the push partner configuration information for WINS server 10.2.2.2.

**show pushpartnerconfig Server=10.2.2.2**

**show recbyversion**

Displays a set of records for an owner, specified as a range of version IDs, and sorts the records by version.

**Syntax**

**show recbyversion** [**Server=**]*IPAddress* [**MaxVer=**]**{***High*,*Low***}** [**MinVer=**]**{***High*,*Low***}** [[**Name=**]*RecordName*] [[**EndChar=**]*16thChar*] [**Case=**]{**0** | **1**}

**Parameters**

**[ Server=] *IPAddress***

Required. Specifies the owner server for which you want to display a set of records. Identifies the server by IP address.

**[ MaxVer=] {*High*,*Low*}**

Required. Specifies the range of records to return by the maximum high and the maximum low version number. High and low values are separated by a comma and enclosed by braces ({}).

**[ MinVer=] {*High*,*Low*}**

Required. Specifies the range of records to return by minimum high and the minimum low version number. High and low values are separated by a comma and enclosed by braces ({}).

**[ Name=] *RecordName***

Specifies the records for which to look.

**[ EndChar=] *16thChar***

Indicates the character for which to look, in hexadecimal.

**[ Case=]{ 0| 1}**

Indicates whether to create a case-sensitive comparison: **0**-Ignore case (default), **1**-Create a case-sensitive comparison.

**Remarks**

- If **Name=** is not specified, **EndChar=** and **Case=** are ignored.
- If you set both **MinVer=** and **MaxVer=** to {0,0}, **show recbyversion** displays the entire range of records.

**Examples**

In the following example, this command displays the total number of records (by record version) owned by WINS server 10.2.2.2.

**show recbyversion Server=10.2.2.2 MaxVer={0,0} MinVer={0,0} Name=dc1 EndChar=1c Case=0**

**show reccount**

Displays the number of records owned by a specific WINS server.

**Syntax**

**show reccount** [**Server=**]*IPAddress* [**MaxVer=**]**{***High*,*Low***}** [**MinVer=**]**{***High*,*Low***}**

**Parameters**

**[ Server=] *IPAddress***

Required. Specifies the owner server for which you want to display the number of records. Identifies the server by IP address.

**[ MaxVer=] {*High*,*Low*}**
Required. Specifies the maximum high and the maximum low version of records to show. High and low values are separated by a comma and enclosed by braces ({}).

**[ MinVer=] {*High*,*Low*}**
Required. Specifies the minimum high and the minimum low version of records to show. High and low values are separated by a comma and enclosed by braces ({}).

**Remarks**

- If you set both **MinVer=** and **MaxVer=** to {0,0}, **show reccount** counts the entire range of records.

**Examples**
In the following example, this command shows the total record count for WINS server 10.2.2.2.

**show reccount Server=10.2.2.2 MaxVer={0,0} MinVer={0,0}**

**show server**
Displays information for the specified WINS server.

**Syntax**
**show server**

**Parameters**
none

**Remarks**

- This command displays the name and IP address of the specified WINS server.

**show serverstatistics**
Displays statistics for the specified WINS server.

**Syntax**
**show statistics**

**Parameters**
none

**show version**
Displays the current maximum version counter value for the specified WINS server.

**Syntax**
**show version**

**Parameters**
none

**show versionmap**
Displays the owner ID to maximum version number mappings table for the specified WINS server.

**Syntax**
**show versionmap**

**Parameters**
none

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |

| | |
|---|---|
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Software Deployment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Software deployment**
This section covers:

- Group Policy
- Windows Update
- Automatic Updates
- Licensing
- Windows Installer
- Remote Installation Services
- Remote Administration
- Terminal Services

# Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy**

You can use Group Policy to manage features included with the Microsoft® Windows Server 2003 family, such as Group Policy Software Installation, Administrative Templates, Folder Redirection, Remote Installation Services, Security Settings, Scripts (Startup/Shutdown and Logon/Logoff) and Internet Explorer Maintenance.

To use Group Policy without the Group Policy Management Console (GPMC), see Group Policy (pre-GPMC).

To use Group Policy with the Group Policy Management Console, see Group Policy Management.

Microsoft makes available new procedures, and new and updated tools online. For the latest information about Group Policy and tools that you can use to manage Group Policy, see Group Policy at the Microsoft Web site.

# Windows Update

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Update**
Windows Update is the online extension of Windows. Use Windows Update to download items such as security fixes, critical updates, the latest Help files, drivers, and Internet products. New content is added to the site regularly, so you can always get the most recent updates and fixes to protect your computer and keep it running smoothly. For more information, see Windows Update at the Microsoft Web site. Also, see Using Windows Update.

With Windows Update Catalog, you can select updates that you plan to deploy later, which means you can control how and when the updates are deployed. For more information, see Windows Update Catalog at the Microsoft Web site.

With Automatic Updates, which is built into Windows XP and products in the Windows Server 2003 family, the operating system can automatically download and install critical updates from the Windows Update site. For more information, see Automatic Updates.

With Microsoft Windows Update Services, you can deploy a limited version of the Windows Update site inside your firewall. You can control how and when updates are deployed, and deliver updates to users through your intranet rather than having updates occur directly from the Internet. For more information about Windows Update Services, see Evaluate Windows Update Services Now at the Microsoft Web site.

**Note**

- You must be logged on as an administrator or as a member of the Administrators group to update system files, including Help files.

# Automatic Updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Automatic Updates**
Windows can keep your computer up-to-date automatically with the latest updates and enhancements. You do not need to search for critical updates and information because Windows delivers them directly to your computer. Windows recognizes when you are online and uses your Internet connection to search for downloads from the Windows Update Web site. An icon appears in the notification area each time new updates are available.

**Difference between Windows Update and Automatic Updates**
Windows Update and Automatic Updates are two separate components designed to work together to keep Windows secure. Windows Update is Microsoft-owned Web site from which Windows users can download critical and non-critical software. Automatic Updates enables you to automatically interact with the Windows Update Web site to obtain the critical software updates. These items include security fixes, critical updates, and critical drivers. You have full control over the level of this interaction. For example, you could choose to automatically download and install updates as they become available, or simply be notified when new updates become available.

- For tips about using Automatic Updates, see Best practices for Automatic Updates.
- For help with specific tasks, see Automatic Updates How to....
- For general background information, see Automatic Updates Concepts.

# Best practices for Automatic Updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for Automatic Updates**

**Use a schedule to keep Windows automatically updated**
Scheduled updates keep your operating system up-to-date, and minimize the time you need to spend logged onto your computer as a member of the Administrators group. By minimizing the time you spend logged onto your computer as a member of the Administrators group, you keep your computer more secure.

# Turn on Automatic Updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Turn on Automatic Updates**

You must be logged on as a computer administrator to complete this procedure.

1. Open **System**, and then click the **Automatic Updates** tab.

   – or –

   If you are running Windows 2000, click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Automatic Updates**.

2. Click **Automatic (recommended)**.

3. Under **Automatically download recommended updates for my computer and install them**, select the day and time you want Windows to install updates.

## Notes

- To open System, click **Start**, click **Control Panel**, click **Performance and Maintenance**, and then click **System**.

- Automatic Updates provides high-priority updates, which include security and other critical updates that can help protect your computer. It's a good idea to visit the Windows Update Web site (http://www.microsoft.com/) on a regular basis to get optional updates, such as recommended software and hardware updates, that can help improve your computer's performance.

# Schedule automatic updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Schedule automatic updates**

You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

1. Open **System**, and then click the **Automatic Updates** tab.

   – or –

   If you are running Windows 2000, click **Start**, point to **Settings**, click Control Panel, and then double-click **Automatic Updates**.

2. Click **Automatic (recommended)**.

3. Under **Automatically download recommended updates for my computer and install them**, set the time and day you want Windows to install updates, and then click **Apply**.

**Notes**

- To open System, click **Start**, click **Control Panel**, click **Performance and Maintenance**, and then click **System**.

- Scheduled updates are automatically installed at the scheduled time, regardless of who is logged on to the computer. If you choose to be notified before updates can be installed, you must be logged on as an administrator to get notifications and to install updates.

- Some updates require you to restart your computer before they can take effect. Windows will notify any user who is logged on to the computer before restarting; however, only members of the local Administrators group can stop the computer from restarting. Make sure you save your work before restarting your computer and remind other users to save their work, especially before scheduled installation times.

# Change how updates are downloaded and installed

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Change how updates are downloaded and installed**
You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

1. Open System, and then click the **Automatic Updates** tab.

   – or–

   If you are running Windows 2000, click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Automatic Updates**.

2. Select a setting, and then click **Apply**.

You can select from the following options:

- Automatic (recommended)
- Download updates for me, but let me choose when to install them
- Notify me but don't automatically download or install updates
- Turn off Automatic Updates

**Automatic (recommended)**
When you are connected to the Internet, Windows finds and downloads updates in the background—you are not notified or interrupted during this process and the updates do not interfere with other downloads. If you do not change the default schedule, updates that have been downloaded to your computer will be installed at 3 A.M.

If your computer is turned off during a scheduled update, Windows will install the updates the next time you start your computer. If you need to help complete the installation process, Windows will notify you. For example, you might need to accept an End User License Agreement (EULA) before some updates can be installed. If you need to restart your computer for an update to take effect, Windows will notify you but will also restart your computer at the scheduled time.

**Download updates for me, but let me choose when to install them**
With this option, updates will be downloaded to your computer and Windows will alert you that they are ready to be installed. To receive alerts, you must be a member of the Administrators group for your computer. When you are connected to the Internet, Windows finds and downloads updates in the background—you are not notified or interrupted during this process and the updates do not interfere with other downloads.

After downloading is complete, the **Windows Update** icon appears in the notification area and an alert pops up, letting you know that the updates are ready to be installed. To review and install available updates, click the icon or the alert. You can install all or some of the available updates.

**Notify me but don't automatically download or install updates**
To manually download and install updates, you must be a member of the Administrators group for your computer. Windows checks for important updates and notifies you if any are available but they are not delivered or installed on your computer until you choose to do so. When Windows finds updates for your computer, the **Windows Update** icon appears in the notification area and an alert pops up, letting you know that updates are ready to be downloaded. After you click the icon or the alert, you can select some or all of the updates to download.

Windows then downloads the updates in the background—you aren't notified or interrupted during this process and the updates do not interfere with other downloads. When downloading is complete, the **Windows Update** icon appears in the notification area again, this time to let you know that the updates are ready to be installed. You can choose to install all or some of the available updates.

**Turn off Automatic Updates**
You will never be notified when important updates are available for your computer, and you will never be asked to download or install them. This means that your computer can be vulnerable to security threats and harmful viruses that can damage your computer or your files. Viruses can also spread over the Internet to other people with whom you exchange e-mail, share files, or work with on a network.

New viruses and security threats are continually developed by attackers, so helping protect your computer is an ongoing process. If you don't turn on Automatic Updates, we recommend that you regularly install updates from the Windows Update Web site (http://www.microsoft.com/).

### Notes

- To open System, click **Start**, click **Control Panel**, click **Performance and Maintenance**, and then click **System**.

- Only users with administrator privileges may add or remove programs, including Windows updates. It is strongly recommended that you log out of the computer administrator account when you are not performing tasks that require administrator privileges. If you are logged on as an administrator when your computer is the target of a virus or malicious user, the attack can cause extensive damage. For example, it might be able to reformat your hard drive, delete all your files, or create a new administrator account so the attacker can take over your computer. For more information about user accounts and why you should not run your computer as an administrator, see Help and Support.

# Download updates that apply to your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Download updates that apply to your computer**
Based on your Automatic Updates settings, Windows can notify you when updates that apply to your computer are ready to download. You can review each update and choose whether to download it. To help protect your computer, we recommend that you download and install all updates that apply to your computer as soon as they are available.

1. When you are notified that new updates are ready to be downloaded, click the **Windows Update** icon that appears in the notification area.

2. By default, all updates are selected to be downloaded. If you do not want Windows to download an update, clear the check box beside it.

3. Click **Download**.

### Notes

- If you are using the **Automatic (recommended)** setting, Windows automatically downloads important updates as soon as they are available. You are not notified or interrupted during the process.

- Windows Update software might automatically be updated prior to applying any other updates.

# Review and install downloaded updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Review and install downloaded updates**

1. When the **Windows Update** icon appears in the notification area, or when you are notified that updates are ready to install, click the icon.

2. To install all available updates, click **Express install (Recommended)**, or, to choose which downloads to install, click **Custom install (Advanced)**. By default, all updates are selected to be installed. If you do not want Windows to download an update, clear the check box next to it.

Windows notifies you when the updates are installed. Windows will also notify you if you need to accept an End User License Agreement (EULA) or restart your computer to complete the installation process.

### Notes

- Windows might prompt you to restart your computer after installing certain updates. Please restart your computer when prompted; otherwise, your computer might not work properly.

- If you are using the **Automatic (recommended)** setting, Windows automatically installs important updates on the schedule that you selected. You are not notified or interrupted during the process unless you need to accept an End User License Agreement (EULA) or restart your computer.

- Windows Update software might automatically be updated prior to applying any other updates.

# View a list of updates installed on your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**View a list of updates installed on your computer**

1. Open **Add or Remove Programs**.
2. On the top right, select the **Show updates** check box. All installed updates appear at the top of your program list.

**Notes**

- To open Add or Remove Programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove Programs**.
- You can also view your installation history at the Windows Update Web site (http://www.microsoft.com/).

# Check if there are new updates for your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Check if there are new updates for your computer**
If you turned on Automatic Updates, Windows automatically checks for important updates for your computer. These updates can include critical updates, security updates, and service packs. Windows notifies you about (or automatically installs) important updates, based on your Automatic Updates settings.

It is also a good idea to routinely check the Windows Update Web site to see if other types of updates, such as driver updates, are available. You must be logged on as a computer administrator to complete this procedure. You must also be connected to the Internet.

1. Go to the Windows Update Web site (http://www.microsoft.com/).

2. Click **Express Install**.

If updates are found, we recommend that you first install all high-priority updates, and then install all other updates such as software and hardware updates.

### Notes

- Some updates require you to accept an End User License Agreement (EULA) before you can install them. If you decline, these updates are not installed. If you change your mind, you can install them later by visiting the Windows Update Web site (http://www.microsoft.com/).

- Some updates require you to restart your computer before the updates can take effect. Windows will notify any user who is logged on to the computer before restarting; however, only members of the local Administrators group can delay the restart. Make sure you save your work before restarting your computer and remind other users to save their work, especially before scheduled installation times.

# Stop Windows from notifying you about updates that you have already decided not to download or install (hide updates)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Stop Windows from notifying you about updates that you have already decided not to download or install (hide updates)**
You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure. You must also be connected to the Internet.

1. When the **Windows Update** icon appears in the notification area, or when you are notified that updates are ready to download, click the icon.

2. Review the recommended updates. If you do not want to download an item, clear the check box next to it.

3. Click **Download**. (If you cleared all the check boxes, click **Close**.)

4. In the confirmation dialog box, select the **Don't notify me about this update again** check box, and then click **OK**.

### Note

- Hiding an update means that Windows will no longer try to download it when checking for updates that apply to your computer. If you change your mind and want to download a hidden update later, go to the Windows Update Web site (http://www.microsoft.com/), click **Custom Install**, and then click **Restore hidden updates**.

**See Also**
**Concepts**
Automatic Updates: Frequently Asked Questions
Restore hidden updates

# Restore hidden updates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Restore hidden updates**

You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

1. Open System, and then click the **Automatic Updates** tab.

   – or –

   If you are running Windows 2000, click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Automatic Updates**.

2. Click **Restore hidden updates**.

The next time you connect to the Internet, Windows will check for any high-priority updates for your computer, including updates that you previously declined. Windows will either download the updates automatically or notify you that they are available, depending on your Automatic Updates setting.

Alternately, you can restore hidden updates by visiting the Windows Update Web site.

1. Go to the Windows Update Web site (http://www.microsoft.com/).

2. Click **Custom Install**.

3. In the left pane, click **Restore Hidden Updates**, and then select the updates you want to install.

4. Click **Install**.

**Notes**

- To open System, click **Start**, click **Control Panel**, click **Performance and Maintenanc**e, and then click **System**.

- When you restore hidden updates, Windows determines which updates still apply to your computer. If you cannot find a specific hidden update, you might have installed a more recent update that replaced the original.

- Some updates require you to accept an End User License Agreement (EULA) before you can install them. If you decline the agreement, the updates are not installed. If you change your mind, you can install the updates later by visiting the Windows Update Web site (http://www.microsoft.com/).

- Some updates require you to restart your computer before they take effect. Windows will notify any user who is logged on to the computer before restarting; however, only members of the local Administrators group can stop the computer from restarting. Make sure you save your work before restarting your computer and remind other users to save their work, especially before scheduled installation times.

# Uninstall an update

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Uninstall an update**

You must be logged on as an administrator or a member of the Administrators group in order to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

1. Open Add or Remove Programs.
2. On the top right, select the **Show updates** check box. All installed updates appear at the top of your program list.
3. Click the update you want to uninstall, and then click **Remove**.

**Note**

- To open Add or Remove Programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove Programs**.

# Automatic Updates overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automatic Updates overview**

With Automatic Updates, Windows routinely checks for updates that can help protect your computer against the latest viruses and other security threats. These high-priority updates are available through the Windows Update Web site and include security updates, critical updates, or service packs.

When you turn on Automatic Updates, you don't have to search for updates online or worry that critical fixes might be missing. Windows automatically downloads and installs them for you, using a schedule that you determine. If you prefer to download and install updates yourself, you can also set up Automatic Updates to notify you whenever any high-priority updates become available.

Options for setting up Automatic Updates on your computer

# How does Automatic Updates work?

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How does Automatic Updates work?**
When you turn on Automatic Updates, Windows routinely checks the Windows Update Web site for high-priority updates that can help protect your computer from the latest viruses and other security threats. These updates can include security updates, critical updates, and service packs. Depending on the setting you choose, Windows automatically downloads and installs any high-priority updates that your computer needs, or notifies you as these updates become available.

How are updates downloaded?

How are updates installed?

**How are updates downloaded?**
When you connect to the Internet, Windows sends data to the Windows Update Web site about the way your computer is set up so the service can determine which updates your computer needs. Windows does not use your name, address, e-mail address, or any information that can be used to identify you or contact you. For details, see the Windows Update privacy statement.

It makes no difference whether you use a dial-up or broadband connection; important updates are downloaded behind the scenes and do not interfere with other downloads. If you disconnect from the Internet before updates are fully downloaded, nothing is lost. The download process will continue the next time you connect to the Internet.

**How are updates installed?**
You do not have to be connected to the Internet for Windows to install new updates. But updates must be installed, not just downloaded, before they can help protect your computer. If you use the **Automatic (recommended)** setting, new updates are installed at 3 A.M. However, you can change the time or frequency of scheduled updates to best suit your needs.

If your computer is turned off during a scheduled update, updates are installed the next time you start your computer. You can also choose to have Windows notify you when new updates are available, and then install them yourself.

You might be asked to accept an End User License Agreement (EULA) before certain updates can be installed. Other updates might require you to restart your computer before the installation process can be completed. If you are an administrator for your computer, you can delay the restart. Otherwise, Windows notifies you and then restarts your computer for you so the updates can begin to help protect your computer. It is always a good idea to save your work frequently, and to remind other users of your computer to save their work, especially before scheduled installation times.

### Note

- Installing updates before you shut down your computer is another way to keep your computer up to date and more secure. This option is available only in Microsoft Windows XP Service Pack 2 (SP2) and only if important updates have been downloaded but not yet installed. Do not turn off or unplug your computer while updates are installing. Windows will automatically turn off your computer after the updates are installed.

Turn on Automatic Updates

# Why use scheduled updates to help protect your computer?

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Why use scheduled updates to help protect your computer?**

If you have not turned on Automatic Updates, your computer is more vulnerable to viruses and other security threats. When you turn on Automatic Updates, Windows routinely checks the Windows Update Web site for high-priority updates that can help protect your computer against attacks. High-priority updates include security updates, critical updates, and service packs.

Scheduled updates offer:

**Convenience**

You don't have to remember to visit the Windows Update Web site or other online security sites to get updates. And you don't have to choose which updates are most important for protecting your computer—Automatic Updates looks for security updates, critical updates, and service packs, and installs them on the schedule that you set.

**Reliability**

Updates are downloaded behind the scenes whenever you're connected to the Internet. The downloading process doesn't interfere with other downloads or interrupt you while you work. If you disconnect from the Internet before updates are fully downloaded, the download process will continue the next time you connect to the Internet. Don't forget, however, that updates must be installed to take effect. When you schedule updates, Windows automatically installs them for you, unless you choose to be notified and then install them yourself.

**Up-to-date software**

You set the schedule for Windows to install new updates. This means that Windows is routinely checking for and installing any important updates that your computer needs. Even if you choose to be notified and install updates yourself, you still learn about important updates as they are released. By scheduling updates, you can quickly and easily keep your computer up to date—without thinking about it.

# Automatic Updates: Frequently Asked Questions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automatic Updates: Frequently Asked Questions**

Why are updates important?

How does Automatic Updates work?

What if ...?

**Why are updates important?**

- What are updates?
- How can I keep my computer updated?
- Why should I use Automatic Updates?

**What are updates?**

Microsoft offers important updates, which include security and other critical updates, to help protect your computer against new viruses and other security threats that can spread over the Internet or a network. Other updates contain enhancements, such as upgrades and tools that can help your computer run more smoothly. What are all of the different types of Microsoft software updates?

**How can I keep my computer updated?**

**Turn on Automatic Updates**

Get high-priority updates, which include security and other critical updates, automatically delivered to your computer and installed on a schedule that you set. Turn on Automatic Updates and choose a setting by opening System and then clicking the **Automatic Updates** tab. (If you are running Windows 2000, click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Automatic Updates**.)

**Visit the Windows Update Web site (http://www.microsoft.com/)**

Go here on a regular basis to get high priority and optional updates for your computer.

**Why should I use Automatic Updates?**

Turning on Automatic Updates is the easiest way to help protect your computer against new and ongoing attacks. When you turn on Automatic Updates, Windows regularly checks the Windows Update Web site for important updates that your computer might need. These updates can include security updates, critical updates, and service packs. Windows downloads updates behind the scenes when you are online—the updates do not interfere with other downloads and you aren't interrupted while you're working.

Windows automatically installs important updates for you, though in some cases you may be asked to accept an End User License Agreement (EULA) or restart your computer to finish the process. Updates are installed on a schedule that you set, so you don't have to search the Windows Update Web site for new updates or worry that something important might be missing. You can also set up Automatic Updates to notify you when updates are available so you can download and install updates yourself.

**How does Automatic Updates work?**

- How are updates downloaded?
- How are important updates installed?
- Are Automatic Updates the same updates as those that are available from the Windows Update Web site?
- How long will it take to download or install an update?
- Will I need to restart my computer?

- Will I need to accept an End User License Agreement (EULA)?
- How do I know which updates are already installed?
- How can I be sure that updates are safe to install?
- How much does it cost to use Automatic Updates?
- What type of information is sent to Microsoft during the update process?

**How are updates downloaded?**
When you connect to the Internet, Windows sends data about the way your computer is set up to the Windows Update Web site so the service can determine which updates your computer might need. Windows does not send your name, address, e-mail address, or any information that can be used to identify you or contact you. If updates are available, they are downloaded behind the scenes when you are online—they do not interfere with other downloads and you are not interrupted.

If you use a broadband connection, updates can be downloaded at any time, even if you are not actively using the Internet. If you use a dial-up connection, updates can be downloaded only when you are connected to the Internet. If you disconnect from the Internet before updates are fully downloaded, the download process will continue the next time you connect to the Internet.

Remember that updates must be installed before they can help protect your computer. Remember, too, that if you do not use the **Automatic (recommended)** setting, Windows can only remind you about updates if you are logged on as a member of the Administrators group. (Only administrators can add or remove programs, including updates.) To notify you, the **Windows Update** icon appears in the notification area and an alert appears, stating that new updates are ready to be downloaded.

**How are important updates installed?**
How updates are installed depends on the Automatic Update settings you choose. If you use the **Automatic (recommended)** setting, updates are installed at 3 A.M. However, you can change the time or frequency of scheduled updates to best suit your needs. If your computer is turned off during a scheduled update, updates are installed the next time you start your computer.

In some cases, an update will require you to accept an End User License Agreement (EULA). If so, Windows notifies you. If an update requires you to restart your computer before it can be installed, Windows notifies you to restart your computer for security maintenance. Make sure you save your work frequently and remind other users to save their work, especially before scheduled installation times.

Remember that if you do not use the **Automatic (recommended)** setting, Windows can only notify you about updates if you are logged on as a member of the Administrators group. (Only administrators can add or remove programs, including updates.) To notify you, the **Windows Update** icon appears in the notification area and an alert appears, stating that new updates are ready to be installed.

You do not have to be connected to the Internet for updates to be installed.

**Are Automatic Updates the same updates as those that are available from the Windows Update Web site?**
Yes. However, Automatic Updates delivers only the latest important updates that can help protect your computer against viruses and other security threats. These updates can include security updates, critical updates and service packs and should be installed as soon as they are released. You can download and install other types of updates, such as upgrades and tools that help improve the performance of your computer, by visiting the Windows Update Web site (http://www.microsoft.com/) on a regular basis.

**How long will it take to download or install an update?**
It depends on the type of Internet connection you have and the size and number of updates that are being downloaded or installed. You can view the progress of downloads by hovering over the **Windows Update** icon which will appear in the notification area. Remember that updates are downloaded behind the scenes so you are not interrupted. You can view more details about the installation progress by clicking the **Windows Update** icon while updates are being installed. If there are a large number of updates and the download process is expected to take a long time (due to infrequent or slow Internet connections), Windows will also notify you at least once every other day about updates that have successfully finished downloading.

**Will I need to restart my computer?**
It depends. Some updates cannot be installed or will not take effect until you restart your computer. For those, Windows notifies you to restart your computer for security maintenance. If you are an administrator for your computer, you can delay the restart; otherwise, Windows warns you and then restarts your computer for you. Make sure you save your work and remind other users to save their work, especially before scheduled installation times.

**Will I need to accept an End User License Agreement (EULA)?**
Sometimes. Some updates require you to accept a EULA before the updates can be installed. These updates can not be automatically installed so an alert and the Windows Update icon will appear in the notification area to let you know that updates are ready to be installed. Click the icon to view and accept the EULA for these updates and then install them.

**How do I know which updates are already installed?**
To see a list of updates already installed on your computer, go to the Windows Update Web site (http://www.microsoft.com/). In the left pane, under **Other Options**, click **View installation history**. In Microsoft Windows XP Service Pack 2 (SP2), you can also open **Add or Remove Programs** in Control Panel and select the **Show Updates** check box.

**How can I be sure that updates are safe to install?**
Windows uses Secure Socket Layer (SSL) to encrypt the transfer of system information and updates between your computer and the Windows Update Web site. Each file that you download using Automatic Updates has a digital signature from Microsoft. Digital signatures are designed to ensure the authenticity and integrity of signed files. Automatic Updates will not install files that do not contain the correct digital signature.

**How much does it cost to use Automatic Updates?**
There is no charge to you for this service. Updates from Microsoft are provided at no cost, as part of maintenance and support service for Windows users. Microsoft is committed to helping protect your computing environment, no matter what tasks you perform at your computer. Depending on your Internet connection, standard local and long distance phone charges and Internet service charges might apply.

**What type of information is sent to Microsoft during the update process?**
To provide you with the best possible service, Windows Update collects some system configuration data in order to provide you with updates that apply to your computer. This information includes:

- Computer make and model
- Windows version number
- Internet Explorer version number
- Version numbers of other Microsoft software for which updates might be available
- Plug and Play ID numbers of hardware devices
- Region and Language setting
- Globally Unique Identifier (GUID)
- Product ID and Product Key
- BIOS name, revision number, and revision date

Microsoft is committed to helping protect your privacy. Windows Update does not collect your name, address, e-mail address, or any other form of personally identifiable information. Your Internet Protocol (IP) address is logged when you connect to the Windows Update site, but this address will only be used to generate aggregate statistics. For more details on how the information is protected, see the Windows Update privacy statement. You can always find the privacy statement at the Windows Update Web site (http://www.microsoft.com/).

**What if ...?**

- I'm not an administrator for my computer?
- My Internet connection disconnects before an update is downloaded?
- My Automatic Updates options are grayed out?
- I hid an update but want to install it later?

- I can't hide an update?
- I can't uninstall an update?
- I want to uninstall some of the updates from a security package?
- I've restored my hidden updates but cannot find the one I want?
- I share my computer with other users—do we get the same updates?
- I have a home network—do all computers get the same updates?
- My computer is in hibernate or standby mode during a scheduled update?
- My computer is turned off during a scheduled update?
- I never turn off my computer?

**I'm not an administrator for my computer?**
To help protect your computer, use the **Automatic (recommended)** setting, which checks for new updates and automatically downloads and installs them—regardless of whether you or other users are administrators for your computer.

Only users with administrator privileges may add or remove programs, including Windows updates. If you are not an administrator for your computer, you need to contact someone who is so they can change your Automatic Updates settings to the recommended setting.

It is strongly recommended that you log out of the computer administrator account when you are not performing tasks that require administrator privileges. If you are logged on as an administrator when your computer is the target of a virus or malicious user, the attack can cause extensive damage. For example, it might be able to reformat your hard drive, delete all your files, or create a new administrator account so the attacker can take over your computer. For more information about user accounts and why you should not run your computer as an administrator, see Help and Support.

**My Internet connection disconnects before an update is downloaded?**
If you disconnect from the Internet before updates are fully downloaded, the download process will continue from where it was interrupted the next time you connect to the Internet. If you use a dial-up connection, we recommend that you try to stay connected long enough for Windows to download all applicable updates. You do not need to be connected to the Internet to install updates, just to download them.

**My Automatic Updates options are grayed out?**
If your computer is part of a network, your network administrator might have configured your Automatic Updates options for you. Network administrators often need to implement systemwide changes to help make sure that the network operates smoothly and more securely whenever changes, such as updates, are applied. Your options might also be grayed out if you are not an administrator for your computer. Only administrators can add or remove programs, including updates.

**I hid an update but want to install it later?**
You can install all hidden updates by opening **System**, and, on the **Automatic Updates** tab, **clicking Restore hidden updates**. (If you are running Windows 2000, click **Start**, point to **Settings**, click **Control Panel**, and then double-click **Automatic Updates**.) The next time you connect to the Internet, Windows will check for all applicable updates for your computer, old or new.

To choose which hidden updates you want to install, go to the Windows Update Web site (http://www.microsoft.com/) and click **Custom Install**. In the left pane, under **Other Options**, click **Restore hidden update**s and then select the updates you want to download and install.

**I can't hide an update?**
If your computer is part of a network, a network administrator has determined that the update must be installed for security maintenance. The update will be installed on the schedule that the network administrator sets. In rare cases, Microsoft will issue an update deemed critical to how the Windows Update Web site or Automatic Updates functions. These updates cannot be hidden, so you will always be notified that they are available to be downloaded or installed so you can continue using Automatic Updates.

**I can't uninstall an update?**

Only administrators can add or remove programs, including updates. If you are not an administrator for your computer, you must contact an administrator to manage updates. If your computer is part of a network and you uninstall an update, your network administrator may re-install it as part of systemwide security or maintenance policy. In rare cases, some updates can not be uninstalled.

**I want to uninstall some of the updates from a security package?**
Some security updates can contain multiple updates, which are downloaded and installed as a package. You cannot uninstall some of the updates within a security package; you need to uninstall the entire package.

**I've restored my hidden updates but cannot find the one I want?**
If you visit the Windows Update Web site (http://www.microsoft.com/) but cannot find the update in the **Restore hidden updates** list, the update no longer applies to your computer. Updates no longer apply when another update, such as a critical update, security update, service pack, or other type of update, includes the same solution for your computer and that later update has already been installed.

**I share my computer with other users—do we get the same updates?**
Yes. Updates apply to the computer, not to each user account. If you install an update, the update applies for all users of the computer. Similarly, if you decline or uninstall an update, it will not be available for other users.

**I have a home network—do all computers get the same updates?**
Not necessarily. If you use more than one computer, including laptops, in a home network, each computer must have access to the Internet and you must turn on Automatic Updates for each computer separately. Also, if any computers run different versions of Windows, different updates will apply.

It's a good idea to use the **Automatic (recommended)** setting for all your computers so you can keep Windows up to date and help protect your home network, no matter who uses the computers. Unless you use the **Automatic (recommended)** setting for all computers on your network, or set policies using a domain controller, you need to be sure that updates are downloaded and installed for each computer separately.

**My computer is in hibernate or standby mode during a scheduled update?**
Updates will not be installed at the scheduled time. Instead, updates will be installed the next time you start your computer. This means you need to shut down your computer, not let it hibernate or stand by, and then restart it before the updates can be installed.

If you are an administrator for your computer and you usually hibernate or suspend it, you can install available updates as soon as they become available. The **Windows Update** icon appears in the notification area whenever updates are fully downloaded and ready to install. If you like, you can click the icon and install new updates before the scheduled time.

**My computer is turned off during a scheduled update?**
Any updates that have been downloaded are not installed. Instead, updates are installed the next time you start your computer. If you are an administrator for your computer, the **Windows Update** icon appears in the notification area whenever updates are ready to install. If you like, you can click the icon and install new updates before the scheduled time.

**I never turn off my computer?**
If you use the **Automatic (recommended)** setting, or scheduled updates, Windows will download new updates whenever you are connected to the Internet. Updates are installed at the scheduled time, as long as your computer is turned on. If any updates require you to accept an End User License Agreement (EULA), Windows will notify you and the updates will not be installed until you view and accept the agreement.

Some updates cannot be installed unless your computer is restarted. For these, Windows notifies you that your computer needs to be restarted for security maintenance. If you are an administrator for your computer, you can delay the restart. Otherwise, Windows will warn you and then restart your computer so the updates can begin to help protect your computer.

# Options for setting up Automatic Updates on your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Options for setting up Automatic Updates on your computer**
To choose when and how updates will be delivered to your computer, you have four options:

- Automatic (recommended)
- Download updates for me, but let me choose when to install them
- Notify me but don't automatically download or install updates
- Turn off Automatic Updates

**Automatic (recommended)**
When you are connected to the Internet, Windows finds and downloads updates in the background—you are not notified or interrupted during this process and the updates do not interfere with other downloads. If you do not change the default schedule, updates that have been downloaded to your computer will be installed at 3 A.M.

If your computer is turned off during a scheduled update, Windows will install the updates the next time you start your computer. If you need to help complete the installation process, Windows will notify you. For example, you might need to accept an End User License Agreement (EULA) before some updates can be installed. If you need to restart your computer for an update to take effect, Windows will notify you and will restart your computer at the scheduled time.

**Download updates for me, but let me choose when to install them**
To receive alerts, you must be a member of the Administrators group for your computer. When you are connected to the Internet, Windows finds and downloads updates in the background—you are not notified or interrupted during this process and the updates do not interfere with other downloads.

After downloading is complete, the **Windows Update** icon appears in the notification area and an alert pops up, letting you know that the updates are ready to be installed. To review and install available updates, click the icon or the alert. You can install all or some of the available updates.

**Notify me but don't automatically download or install updates**
To manually download and install updates, you must be a member of the Administrators group for your computer. Windows checks for important updates and notifies you if any are available; updates are not delivered or installed on your computer until you choose to do so. When Windows finds updates for your computer, the **Windows Update** icon appears in the notification area and an alert pops up, letting you know that updates are ready to be downloaded. After you click the icon or the alert, you can select some or all of the updates to download.

Windows downloads the updates in the background—you are not notified or interrupted during this process and the updates do not interfere with other downloads. When downloading is complete, the **Windows Update** icon appears in the notification area again, this time to let you know that the updates are ready to be installed. You can choose to install all or some of the available updates.

**Turn off Automatic Updates**
You will never be notified when important updates are available for your computer, and you will never be asked to download or install them. This means that your computer can be vulnerable to security threats and harmful viruses that can damage your computer or your files. Viruses can also spread over the Internet to other people with whom you exchange e-mail, share files, or work with on a network.

New viruses and security threats are continually developed by attackers, so helping protect your computer is an ongoing process. If you do not turn on Automatic Updates, we recommend that you regularly install updates from the Windows Update Web site (http://www.microsoft.com/).

### Notes

- To open System, click **Start**, click **Control Panel**, click **Performance and Maintenance**, and then click System.

- Installing updates before you shut down your computer is another way to keep your computer up to date and more secure. This option is available only in Microsoft Windows XP Service Pack 2 (SP2) and only if important updates have been downloaded but not yet installed. Do not turn off or unplug your computer while updates are installing. Windows will automatically turn off your computer after the updates are installed.

- Only users with administrator privileges may add or remove programs, including Windows updates. It is strongly recommended that you log out of the computer administrator account when you are not performing tasks that require administrator privileges. If you are logged on as an administrator when your computer is the target of a virus or malicious user, the attack can cause extensive damage. For example, it might be able to reformat your hard drive, delete all your files, or create a new administrator account so the attacker can take over your computer. For more information about user accounts and why you should not run your computer as an administrator, see Help and Support.

# Windows Update privacy statement

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Update privacy statement**
Last updated: 4/15/2004

View the latest version of this privacy statement at the Windows Update Web site (http://www.microsoft.com/).

Microsoft is committed to protecting your privacy.

**What data is collected—and why?**
Windows Update collects general system information from your computer with each visit, so that you receive the updates that work best with your computer. The information is also used to generate aggregate statistics about how the Windows Update Web site is used and which systems need support, so that we can improve our service. This information includes:

- Computer make and model
- Version information for the operating system, browser, and any other Microsoft software for which updates might be available
- Plug and Play ID numbers of hardware devices
- Region and language setting
- Globally Unique Identifier (GUID)
- Product ID and Product Key
- BIOS name, revision number, and revision date

Your Internet Protocol (IP) address is logged when you connect to the Windows Update site, but this address will only be used to generate aggregate statistics.

**How is this data used?**
Windows Update collects the Product ID and Product Key to confirm that you are running a validly licensed copy of Windows. The Product ID and Product Key collected are not retained after you are finished using Windows Update, unless the Product ID is not valid.

To generate accurate statistics, Windows Update evaluates a Globally Unique Identifier (GUID) that is stored on your computer to uniquely identify it. The GUID does not contain any information that can be used to identify you. A GUID is assigned and tracked in the following cases:

To provide customers with the best possible service, Windows Update tracks and records the number of individual computers that visit the site and whether the download and installation of specific updates succeeded or failed. Windows Update records the GUID of the computer that attempted the download, the ID of the item that was requested, whether updates were required, and the configuration information listed above.

Windows Update logs an additional GUID if you provide responses about whether help and troubleshooting articles were useful in resolving your problem. This allows Windows Update to provide you with increasingly helpful and relevant information.

Microsoft collects information about the pages our customers visit within microsoft.com, including Windows Update. This information might include: your IP address, browser type, operating system, domain name, the time at which you accessed the site, and referring Web site addresses. This site visitation data is identified only by a unique ID number used solely for this purpose.

**About surveys**
Occasionally you might be invited to participate in a survey about the way you use the Windows Update Web site. Each survey includes a privacy statement that details the terms and use of any information submitted with that survey.

# Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Licensing**

This section provides information about the licensing program for the Microsoft® Windows Server 2003 family.

- Before you begin setting up a licensing model, see Licensing Checklists.
- To find features that have been changed in the Windows Server 2003 family, see New ways to do familiar Licensing tasks.
- For tips on setting up licensing, see Best practices for Licensing.
- For help with specific tasks, see Licensing How To ....
- For general information about licensing, see Licensing Concepts.
- For problem-solving instructions, see Licensing Troubleshooting.
- For information about required licenses for your Windows Server 2003 operating system deployment, see the Microsoft Web Site.

**Note**

- This section does not contain information about Terminal Server licensing. For information about Terminal Server licensing, see Terminal Server Licensing.

# Licensing Checklists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklists**

- Checklist: Configure licensing on a server
- Checklist: Set up licensing for the enterprise

# Checklist: Configure licensing on a server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configure licensing on a server**

This checklist shows the steps that are required to configure licensing on a local server. It also lists several optional steps that you might need to take after licensing is configured. To configure licensing on a remote server, see Checklist: Set up licensing for the enterprise.

| | Step | Reference |
|---|---|---|
| | Review key concepts. | Administering and tracking licenses |
| | Add Per Server licenses by using the **Licensing** option in Control Panel. | Add Per Server licenses on the local server |
| | Configure replication on a server. | Licensing replication; Configuring licensing replication; Configure licensing replication on the local server |
| | (Optional) Delete Per Server licenses by using the **Licensing** option in Control Panel. | Delete Per Server licenses on the local server |
| | (Optional) Change the licensing mode from Per Server to Per Device or Per User on a server. | Change the local server to Per Device or Per User licensing |

# Checklist: Set up licensing for the enterprise

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Set up licensing for the enterprise**

When you create a Windows Server 2003 operating system site, license logging is also set up for the site. However, you might need to change the licensing setup for the site, or for individual servers in the site. To configure licensing locally on a server, using **Licensing** in Control Panel, see Checklist: Configure licensing on a server.

This checklist shows the steps that are required to configure licensing on a remote server.

| | Step | Reference |
|---|---|---|
| | Review key concepts. | Administering licensing for the enterprise |
| | View license information for the enterprise. | Find the site license server for a site; View licensing for a site |
| | Select the licensing mode for servers in a site or change the licensing mode for a server to Per Device or Per User. | Change the licensing mode for a server to Per Device or Per User licensing |
| | Configure replication for servers in a domain. | Tracking Your Organization's Licenses; Configure replication for a server |
| | Create license groups when the number of users is not the same as the number of devices. | License groups; Create a new license group |
| | Change the site license server. | Change the site license server for a site |

# New ways to do familiar Licensing tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The user interface for Licensing in the Windows Server 2003 family is similar to that in Windows 2000 or Microsoft Windows NT 4.0. The following table lists the tasks that are different.

| **If you want to** | **In Windows NT 4.0** | **In the Windows Server 2003 family and Windows 2000** |
|---|---|---|
| Change the master server | Use **Licensing** in Control Panel or **Licensing** in **Administrative Tools**. | Not defined for Windows Server 2003 operating systems or Microsoft Windows 2000 domain. For more information, see Licensing replication or Configure replication for a server. |
| Change the site license server | Not defined for Windows NT 4.0 domain. | Open Active Directory Sites and Services. For more information, see Licensing replication, Change the site license server for a site, or Configure replication for a server. |

# Best practices for Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

Consider the following factors when configuring and tracking licensing for your organization:

- **Per Device or Per User licensing mode is the best option if your clients frequently use multiple servers on the network.**

  The Per Device or Per User licensing mode enables all network devices or users to access all the servers on a network. The number of simultaneous connections to any server is unlimited. Per Device or Per User is the normal licensing mode for a server product that is installed on multiple servers in a network.

  For more information, see the Microsoft Web Site .

- **Per Server is the best licensing option when a server product is installed on only one server accessed at any time by no more than a subset of your users.**

  Per Server connections to a particular server are allocated on a first-come, first-served basis, and are limited to the number of Client Access Licenses allocated to the server. This might be more economical for a single-server network or for a server product that is accessed on one server by only one department or group in an organization. As your network grows, you are allowed a one-time conversion to Per Device or Per User licensing.

  For more information, see the Microsoft Web Site .

- **If you install a server product on a single server and you are uncertain which licensing mode is appropriate, choose Per Server.**

  As your network grows, or when you install the product on additional servers, you can make a one-time switch from Per Server to Per Device or Per User licensing. The licensing agreement does not permit the reverse switch from Per Device or Per User to Per Server licensing.

- **When the number of users is different from the number of devices, create a license group to allocate licenses for Per Device or Per User licensing.**

  Per Device or Per User licensing requires one Client Access License for each device. However, the License Logging service assigns and tracks licenses by user name. You should create license groups to correctly allocate licenses and track usage when multiple users share one or more devices or when one user has multiple devices.

  For more information, see License groups.

- **To replicate license data from a server running Windows NT 4.0 to the licensing database for a** Windows Server 2003 **operating system site, specify the site license server as the enterprise server for replication on the Windows NT 4.0 domain controller.**

  By default, Windows NT 4.0 servers replicate to the domain controller or to an enterprise licensing server. On all servers running Windows Server 2003 , the License Logging service replicates automatically to the site license server. In the replication options for a Windows NT 4.0 domain controller, always choose to replicate to the enterprise server and always specify the site license server as the enterprise server.

  For more information, see:

  - Configuring licensing replication
  - Configuring Windows NT 4.0 licensing replication

# Licensing How To ...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Manage Licensing on the Local Server
- Manage Licensing for an Enterprise
- Manage Products and Product Licenses
- Manage User Licensing

# Manage Licensing on the Local Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage licensing on the local server**

- Add Per Server licenses on the local server
- Delete Per Server licenses on the local server
- Change the local server to Per Device or Per User licensing
- Configure licensing replication on the local server

# Add Per Server licenses on the local server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add Per Server licenses on the local server**

1. On the server you want to configure, open Choose Licensing Mode.
2. In **Product**, select the product for which you want to add licenses.
3. Click **Add Licenses**.
4. In **Product**, select the product.
5. In **Quantity**, type the number of new licenses purchased by your organization, and then click **OK**.
6. If you agree to the licensing terms, select the **I agree that** check box, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon. In this case, click **License.**
- You can set the number of Per Server connections to 0 for a Windows Server 2003 operating system if it is used only as an operating system for an application and does not provide basic network services (such as file sharing, print sharing, remote access, and authenticated access).
- This procedure is only for registering the purchase of Client Access Licenses on a server running in Per Server mode.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete Per Server licenses on the local server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete Per Server licenses on the local server**

1. On the server you want to configure, open Choose Licensing Mode.
2. In **Product**, click the server product from which you want to remove licenses.
3. Click **Remove Licenses**.
4. Under **Serial Number**, click the certificate you want to change.
5. In **Number of Licenses to remove**, type the number of licenses you want to remove, and then click **Remove**.
6. To close the dialog box, click **Cancel**.

   Clicking **Cancel** closes the dialog box but does not cancel any changes.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon. In this case, click **Licensing**.
- After removing licenses for a product, you can allocate them to a different server.
- This procedure can also be performed remotely with the Licensing administrative tool. For more information, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Manage Licensing on the Local Server

# Change the local server to Per Device or Per User licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the local server to Per Device or Per User licensing**

1. On the server you want to configure, open Choose Licensing Mode.
2. In **Product**, click the product for which you want to change the licensing mode.
3. Click **Per Device or Per User**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon. In this case, click **Licensing**.
- The Per Device or Per User licensing mode requires a Client Access License for every device or user that connects to the selected server product. After a device or user is licensed, it can access any server running the product. Typically, this is more economical on networks where clients connect to more than one server.
- If you are uncertain which mode to use, leave the server product in **Per Server** mode. The license agreement allows a one-time, one-way change from Per Server to Per Device or Per User licensing. You cannot switch from Per Device or Per User to Per Server.
- If you are performing a one-time change from Per Server to Per Device or Per User licensing mode, the Client Access Licenses allocated to the server in Per Server mode can be added to the pool of Per Device or Per User licenses available for client devices or users accessing the server product on any server in the site. Use Licensing in Administrative Tools to add Per Device or Per User licenses for the product.
- This procedure can also be performed remotely with the Licensing administrative tool. For more information, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure licensing replication on the local server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure licensing replication on the local server**

1. On the server you want to configure, open Choose Licensing Mode.
2. Click **Replication**.
3. Under **Replication Frequency**, specify the desired interval for replicating licensing information to the site license server:

   To manually specify a time for daily replication on this server, click **Start At**, and then enter a time.

   Click **Start Every**, and then enter the interval at which the system should stagger the start times if multiple servers are set to this option.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon. In this case, click **Licensing**.
- If you select **Start At** under **Replication Frequency** and multiple servers replicate to the site license server, you must vary the starting times on each server to balance the load. Replication might not start until 15 minutes after the specified time.
- The default is **Start Every** with a 24-hour interval. You can change this to an interval from one to 72 hours.
- This procedure can also be performed remotely with the Licensing administrative tool. For more information, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage licensing for an enterprise**

- Find the site license server for a site
- View licensing for a site
- View licensing for a Windows NT 4.0 domain
- View licensing for a server
- Change the licensing mode for a server to Per Device or Per User licensing
- Configure replication for a server
- Change the site license server for a site

# Find the site license server for a site

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find the site license server for a site**

1. Open Active Directory Sites and Services.
2. In the console tree, click the site you want to configure.

   **Where?**

   - Active Directory Sites and Services/Sites/*Site*

3. In the details pane, click **Licensing Site Settings**.
4. On the **Action** menu, click **Properties**.
5. Under **Licensing Computer**, read the **Computer** and **Domain** for the site license server.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- The default site license server is the first domain controller created in the site, but the site license server does not have to be a domain controller. For optimal performance, however, it is recommended that the site license server and domain controller be in the same site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View licensing for a Windows NT 4.0 domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view licensing for a Windows NT 4.0 domain**

1. Open Licensing.
2. On the **License** menu, click **Select Domain**.
3. In **Domain**, enter the name of the domain to administer.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.
- After you select a domain, Licensing displays the data pertaining to the server to which licensing information for the domain is replicated. For a Windows NT 4.0 domain, this is the enterprise server specified for licensing replication on the primary domain controller. If no enterprise server is specified, this is the primary domain controller for the domain.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the licensing mode for a server to Per Device or Per User licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the licensing mode for a server to Per Device or Per User licensing**

1. Open Licensing.
2. On the **Server Browser** tab, expand the domain name.
3. Right-click the site license server in the domain, and then click **Properties**.
4. On the **Products View** tab, click the product, and then click **Edit**.
5. In **Choose Licensing Mode**, click **Per Device or Per User**, and then click **OK**.
6. After reading the information in **Per Device or Per User Licensing**, select the check box to agree to be bound by the license agreements for this product, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**. In this case, click **License.**
- The Per Device or Per User licensing mode requires a Client Access License for every device or user that connects to the selected server product. Licensed devices or users can access any server running the product. Typically, this is more economical on networks where client devices or users connect to more than one server.
- If you are uncertain which mode to use, leave the server product in Per Server mode. The license agreement allows a one-time, one-way change from Per Server to Per Device or Per User licensing. You cannot switch from Per Device or Per User to Per Server.
- If you are performing the one-time change from Per Server to Per Device or Per User licensing mode, the Client Access Licenses allocated to the server in Per Server mode can be added to the pool of Per Device or Per User licenses available for client devices or users accessing the server product on any server in the site.
- To perform this procedure locally on a server, click **Licensing** in Control Panel.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure replication for a server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure replication for a server**

1. Open Licensing.
2. On the **Server Browser** tab, expand the domain.
3. Right-click the server to manage, and then click **Properties**.
4. Click the **Replication** tab.
5. Under **Replication Frequency**, specify the interval at which licensing information is replicated to the site license server:
   - To manually specify a time for daily replication on this server, click **Start At** and enter a time.
   - To manually set an interval of time between licensing information replication, click **Start Every** and enter the desired interval.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.
- If you select **Start At** under **Replication Frequency** and multiple servers replicate to the site license server, you must vary the starting times on each server to balance the load. Replication might not start until 15 minutes after the specified time.
- Windows Server 2003 operating systems replicate automatically to a domain controller, and domain controllers replicate to the site license server. If you have a standalone server in a Windows NT 4.0 domain, that server replicates to the primary domain controller. The option to specify a master server applies only to servers running Windows NT 4.0 and is unavailable when you are managing a server running Windows 2000 or Windows Server 2003.
- When you are managing a server running Windows NT 4.0, you can use the **Master Server** options to specify where the server replicates. For more information, see "Licensing replication" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the site license server for a site

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the site license server for a site**

1. Open Active Directory Sites and Services.
2. In the console tree, click the site you want to configure.

   **Where?**

   - Active Directory Sites and Services/Sites/*Site*

3. In the details pane, click **Licensing Site Settings**.
4. On the **Action** menu, click **Properties**.
5. Under **Licensing Computer**, to select a different server to be the site license server, click **Change**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Active Directory Sites and Services, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Sites and Services**.
- To retain the licensing history for your enterprise, stop the License Logging service on the new site license server, and then copy the following files from the old site license server to the same location on the new site license server:

  - *Systemroot*\System32\Cpl.cfg, which contains the purchase history for your organization.
  - *Systemroot*\Lls\Llsuser.lls, which contains user information about the number of connections.
  - *Systemroot*\Lls\Llsmap.lls, which contains license group information.

  Restart the License Logging service after you copy these files. This transfer must be completed immediately after you change to the new site license server, or you might lose licensing data replicated from other servers.

- For optimal performance, install the site license server in the site whose licenses you want to manage. The default site license server is the first domain controller created in the site, but the site license server does not have to be a domain controller.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Manage products and product licenses**

- View product license information
- Add Per Device or Per User client access licenses
- Delete Per Device or Per User client access licenses
- Add Per Server client access licenses
- Delete Per Server client access licenses

# View product license information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view product license information**

1. Open Licensing.
2. On the **Products View** tab, right-click the server product name.
3. Click **Properties**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.
- The three tabs in the **Properties** dialog box for a server product show the following information.

| Tab | Shows |
|---|---|
| **Clients** | Users have used the server product in Per Device or Per User licensing mode. |
| **Purchase History** | The date, quantity, and administrator for license purchases. You can add or delete licenses. |
| **Server Browser** | The license mode for servers in the site and the number of licenses for Per Server mode. You can add or remove Per Server licenses, change the licensing mode, or configure replication of licensing information. |

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add Per Device or Per User client access licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add Per Device or Per User client access licenses**

1. Open Licensing.
2. On the **License** menu, click **New License**.
3. In **Product**, click the server product you want to manage.
4. In **Quantity**, type the number of licenses purchased.
5. In **Comment**, you can type a note to aid in identifying the purchase.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.
- Client access licenses added in Per Device or Per User licensing mode are added to the pool of licenses for Windows Server 2003 operating systems. As devices or users access the product anywhere in the site, they are allocated licenses from the pool, one license for each device or user. After the pool of available licenses is depleted, license violations occur when additional devices or users access the product.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Add Per Device or Per User client access licenses

# Add Per Server client access licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add Per Server Client Access Licenses**

1. Open Licensing.
2. On the **Server Browser** tab, expand **Enterprise**, the domain name, and then the server you want to manage. The list of server products installed on the server is displayed.
3. Right-click the server product for which you want to add licenses, and then click **Properties**.
4. Click **Add Licenses**.
5. In **Quantity**, type the number of licenses to add.
6. After reading the information in **Per Server Licensing**, select the check box to agree to be bound by the license agreements for this product, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**. In this case, click **License.**
- Client Access Licenses added in Per Server mode allow for connections to a server product on a particular server. When a user connects to the server product on that server, the connection consumes a license. When the user disconnects from the server product, the License Logging service makes the license available to another user.
- You can set the number of Per Server connections to 0 for a Windows Server 2003 operating system if it is used only as an operating system for an application and does not provide basic network services (such as file sharing, remote access, and authenticated access).
- This procedure can also be performed locally on a server with the Licensing option in Control Panel. For more information, click **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Revoke a user's Client Access License for a product

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To revoke a user's Client Access License for a product**

1. Open Licensing.
2. Click the **Products View** tab.
3. Right-click the product, and then click **Properties**.
4. On the **Clients** tab, click the user.
5. Click **Revoke**, and then click **Yes.**

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.
- Revoking a license returns it to the pool of available Per Device or Per User licenses for the server product.
- You might want to revoke a user's license if the usage statistics show that the user does not access the product often enough to warrant retaining the Client Access License.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a user from a license

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a user from a license**

1. Open Licensing.
2. On the **Clients** tab, select the name of the user.
3. On the **License** menu, click **Delete**, and then click **Yes**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.
- Deleting a user releases licenses allocated to the user to the respective product license pools for Microsoft server products. Perform this procedure when a user has been removed from the network or no longer accesses the server products regularly.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a new license group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a new license group**

1. Open Licensing.
2. On the **Options** menu, point to **Advanced**, and then click **New License Group**.
3. In **Group Name**, type a short descriptive name.
4. In **Description**, type additional details to help identify the group.
5. In **Licenses**, enter the number of licenses needed in Per Device or Per User licensing mode.
6. Click **Add**.
7. In **List Users from**, click the appropriate domain.
8. Under **Users**, select the users you want in the group, and then click **Add**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Licensing, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Licensing**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Licensing overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Licensing overview**

A software license grants you the legal right to use a piece of software. For each software program you use, you need a license, which is granted to you and documented in the license agreement. Your use of a software product is governed by the terms of the license agreement, as well as by copyright law. The unauthorized duplication of software constitutes copyright infringement, whether it is done for sale, for free distribution, or for personal use.

The license agreement that governs the use of Microsoft products is called the End User License Agreement (EULA). It is a contract between you and Microsoft. By acquiring the software and opening it, you accept the terms of the license agreement and you are granted the right to use the software. It is important to keep the EULA in your files. It is proof that you are the legal, licensed user of the software program.

You must have server licenses for a Microsoft® Windows Server 2003 operating system and for other server products. You must also have a Client Access License for each device or user that connects to that server.

The following topics provide more detailed information about licensing.

- For information about how to track licensing, see Using Licensing.
- For information about where to find additional Microsoft licensing resources, including licensing for specific Windows Server 2003 operating systems, and information about enterprise licensing, see Licensing Resources.
- For information about required licenses for your Windows Server 2003 operating system deployment, see the Microsoft Web Site.

# Using Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Licensing**

- Administering and tracking licenses
- Tracking Your Organization's Licenses

# Administering and tracking licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering and tracking licenses**

Tracking licenses manually within single domain or across multiple domains can be time consuming and expensive. Windows Server 2003 operating systems provide two utilities that automate this task and help you minimize the time and expense of license tracking. You can use these utilities to view data and manage licensing for server products and to ensure that you are complying with the Windows Server 2003 operating system licensing requirements.

**Important**

- You must be an administrator or a member of the Administrators group in order to use either the **Licensing** option in **Control Panel** or the **Licensing** tool in **Administrative Tools**.

**Licensing in Control Panel**

The **Licensing** option in Control Panel manages licensing requirements for a single computer running a Windows Server 2003 operating system. Use it locally on the computer you are managing to:

- Add or remove Client Access Licenses for a server product licensed in Per Server mode.
- Change the licensing mode from Per Server to Per Device or Per User (one time only).
- Configure the time or frequency of replication of the server's licensing information to the centralized database on the site license server.

For more information, see Manage Licensing on the Local Server.

**Licensing in Administrative Tools**

Use **Licensing** in **Administrative Tools** to manage licensing for the enterprise. It enables you to administer and track licensing data for a site in the centralized licensing database on the site license server. You can:

- View Per Server and Per Device or Per User licenses for the site or a group in the site.
- Manage the purchase or deletion of licenses for server products on network servers.
- View usage statistics for each user.
- Remotely manage licensing on servers for server products licensed in Per Server mode.
- Manage license replication on the network.

For more information, see Administering licensing for the enterprise.

# Tracking Your Organization's Licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tracking your organization's licensing**

- Administering licensing for the enterprise
- Licensing replication
- Configuring licensing replication
- Configuring Windows NT 4.0 licensing replication
- License groups
- Tracking user licenses for multiple sites

# Administering licensing for the enterprise

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering licensing for the enterprise**

To administer Windows Server 2003 operating system licensing for sites or the enterprise, use **Licensing** in **Administrative Tools**. You can track licensing data replicated to the site license server for sites or replicated to the primary domain controller for Windows NT 4.0 domains. For more information, see View licensing for a site and View licensing for a Windows NT 4.0 domain.

**Licensing** in **Administrative Tools** divides tasks into Purchase History, Products View, Clients, and Server Browser.

**Purchase History: To view license purchases**

The **Purchase History** tab in **Licensing** provides a historical overview of the licenses purchased for a site. It also shows the quantity of licenses purchased and deleted, the date of addition or deletion, and the name of the administrator who performed the action.

**Products View: To view and manage product licensing**

The **Products View** tab of **Licensing** provides licensing information for server products in a site. The information displayed for a server product depends on the licensing mode for the product.

For a product in Per Device or Per User mode, **Product View** shows how many licenses have been purchased for the product and how many licenses have been allocated to users or devices for all the products.

For Per Server mode, **Product View** shows the total number of licenses that have been purchased for each product on all the servers in the site. It also shows the maximum number of Per Server connections reached to the current date on all servers with the product in the site.

You can use both the numerical and graphical information shown in **Products View** to determine the following information about your licenses:

| Symbol | Licensing status |
|---|---|
| | The product is in compliance with legal licensing requirements. |
| | The product is not in compliance with legal license requirements. |
| | The product has reached the legal limit, and you might want to purchase additional licenses. |

In **Products View**, you can perform the following licensing tasks:

- Add new Client Access Licenses for a product
- Delete Client Access Licenses for a product
- View client accesses, purchase history, and server information for a product.

**Clients: To view and manage client licensing**

The **Clients** tab lists devices and users that have used the products in a domain or organization. For each device or user, it shows licensed and unlicensed usage of Windows Server 2003 operating systems. You can perform the following licensing tasks on this tab:

- View product usage by devices or users.
- Add new Client Access Licenses.
- Create, view, and edit license groups.

  **Important**

- Each device or user in a license group requires a client access license.

- Revoke a license allocated to a device or user.

You can use both the numerical and graphical information shown in **Clients** to determine the following licensing status:

| Symbol | Licensing status |
|---|---|
| | Users in compliance with legal licensing requirements (licensed usage). |
| | Users in violation of legal licensing requirements (unlicensed usage). |

**Server Browser: To view and manage server licensing**

The **Server Browser** tab lists all the sites, domains, and servers in your organization. It shows the Windows Server 2003 operating systems installed on each server. You can use this tab to view and configure licensing for server products on servers in any site or domain for which you have administrative authority.

Use the **Server Browser** tab to view the licensing configuration of any server in the enterprise. You can perform any of the following administrative tasks at the server level:

- View Windows Server 2003 operating systems installed on a server.

- View the licensing mode for each product on a server.

- For products in Per Device or Per User licensing mode, view the number of Client Access Licenses purchased.

- For any server product in Per Device or Per User licensing mode, add or remove Client Access Licenses for a product.

- Open and manage a selected item's properties at the server and product levels.

- For any Windows server, view and change the time or frequency of licensing replication.

- For a computer running Windows NT 4.0 Server, view and change the location where licensing replication information is stored.

The properties for each server list all the Windows Server 2003 operating systems installed on the server. For each product, you can add or remove Per Server licenses or change the licensing mode. The properties for each product show the licensing mode and, if the product is in Per Server mode, the number of licenses.

# Licensing replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Licensing replication**

An administrator can ensure an organization's legal compliance with the license agreements for Windows Server 2003 operating systems by monitoring license purchases, deletions, and usage. This licensing information is collected on a server by the License Logging service. The License Logging service is disabled by default.

The License Logging service on each server in a site replicates this licensing information to a centralized database on a server, called the site license server, for the site. A site administrator or administrator for the site license server can then use **Licensing** in **Administrative Tools** to view the licensing history for the entire site stored on the site license server.

Typically, the site license server is the first domain controller created for the site. In a large organization with multiple sites, the site license server in each site collects licensing information for that site.

To find which server is the site license server, see Find the site license server for a site. To change the site license server to a different server, see Change the site license server for a site. To view licensing information for any site on your network, see View licensing for a site.

# Configuring licensing replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring licensing replication**

On a computer running Windows 2000 Server or a Windows Server 2003 server operating system, you can configure how often licensing data is replicated to the domain controller or site license server. On a computer running Windows NT 4.0 Server, you can also configure where the data is replicated. These settings can be configured either locally on a server or remotely.

To configure licensing replication locally on a server, use the **Licensing** option in Control Panel. For more information, see Configure licensing replication on the local server. To configure replication remotely for a server in your network, use Licensing in Administrative Tools, as described in Configure replication for a server.

**Replication options**

The following table describes the options for configuring replication.

| Option | Use to | Use when |
|---|---|---|
| Start At | Specify a time each day when licensing information is replicated to the site license server. | You want to manually set up a starting time for replication on this computer.<br><br>You must vary the starting times on servers replicating to a particular master or enterprise server. |
| Start Every | Set the frequency for licensing replication. | The system staggers the times licensing data from each server is replicated. |

**Balancing the license replication load**

The **Replication Frequency** settings (**Start At** and **Start Every** in the table) affect how long licensing changes on individual servers take to propagate to the enterprise server. The default is to start every 24 hours, and the system automatically staggers replication to balance the load. You can lengthen or shorten the interval to change how quickly data is propagated.

If you want to control the time at which replication occurs, select **Start At** on each replicating server and specify a time. To balance the load, you must manually vary the starting time of each server replicating to a particular server. The actual replication might start up to 15 minutes before or after the specified time.

**Additional replication options for earlier versions of Windows servers**

Servers running Windows 2000 or Windows Server 2003 automatically replicate to the domain controller, and domain controllers replicate to the site license server. For Microsoft Windows NT 3.1 or Windows NT 4.0 servers on your network, you must configure where they replicate their licensing data. You do this with the **Master Server** options in the **Replication Configuration** dialog box. These options appear only for Windows NT 3.1 or Windows NT 4.0 Servers.

| Option | Use to | Use when |
|---|---|---|
| Domain Controller | Specify that this computer replicates to the primary domain controller. | This computer is a member server or a backup domain controller in a Windows NT 4.0 domain.<br><br>This computer is a standalone server or a primary domain controller, and you do not want to replicate further. |
| Enterprise Server | Specify that the master server is an enterprise server, and enter the name of the enterprise server. | This computer is a standalone server and part of an enterprise, and you want to replicate its licensing information directly to an enterprise-licensing database.<br><br>The computer is the primary domain controller for its domain, and you want to replicate to an enterprise-licensing database. |

For more information, see Configuring Windows NT 4.0 licensing replication and View licensing for a Windows NT 4.0 domain. To configure licensing locally on a Windows NT 3.1 or Windows NT 4.0 server, see online Help on the server.

# Configuring Windows NT 4.0 licensing replication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Windows NT 4.0 licensing replication**

A server running Windows NT Server 4.0 replicates licensing data to a designated master server. By default, a server running Windows NT Server 4.0 replicates licensing data to the domain controller in its domain. An administrator can configure the domain controller to either retain the licensing data or replicate it to a designated *enterprise server*, which collects licensing data from all domains in an enterprise. This is different from a server running Windows 2000 or Windows Server 2003 , which always replicates to the site license server.

If you are administering licensing for a Windows 2000 or Windows Server 2003 operating system site, you can still configure replication for any server running Windows NT Server 4.0 in your network. For a Windows NT 4.0 domain controller, you can select **Domain Controller** (the default setting) to retain the licensing information for the domain on the domain controller. Alternatively, you can specify that the licensing information for the domain replicate to a specified enterprise server. Preferably, you want to consolidate licensing information from a Windows NT 4.0 domain controller with other information for your enterprise. To do this, choose to replicate licensing information to an enterprise server and specify the site license server as the enterprise server.

If a server running Windows NT Server 4.0 replicates to a domain controller that then replicates to an enterprise licensing database, data can take longer to reach the site license server than with a server running Windows 2000 or Windows Server 2003 replicating directly to the site license server. For example, with a replication interval of 24 hours, information can take up to 24 hours to replicate to a domain controller and then up to 24 additional hours to replicate to a site license server. When the option to replicate to the enterprise server is available for a server that is not a domain controller, you can speed the replication process by specifying that replication should go directly to the site license server.

**Important**

- Do not do this if you want to be able to view licensing data separately for a Windows NT 4.0 domain. For more information, see View licensing for a Windows NT 4.0 domain.

For more information about replication in Windows 2000 or Windows Server 2003 operating systems, see Licensing replication. For more information about master server replication options for servers running Windows NT 4.0, see " Additional replication options for earlier versions of Windows servers" in Configuring licensing replication. To locate the site license server for a site, see Find the site license server for a site. To view replication settings for a Windows NT 4.0 Server, follow the procedure Configure replication for a server.

# License groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**License groups**

In Per Device or Per User licensing mode, a license is required for each client device or user that accesses a server product. License Logging service, rather than allocating licenses to computers, allocates them to users when they access a server product for the first time. This fulfills the legal requirement of one Client Access License for each client device only when the number of client devices is the same as the number of users on a network--most simply, when each user has one device.

Having a number of users that is different from the number of devices might provide incorrect licensing information. To obtain correct licensing information, you should organize users in *license groups*. A license group pools the licenses for devices used by users in a group. When users in a group access the server product, they use the group license and do not consume additional licenses. Thus, you can maintain the one-to-one correspondence between licenses and devices.

Create license groups to obtain correct licensing information under the following conditions:

- **Many people use one device.** This can occur when people share jobs or when employees who are working different shifts use the same device.
- **Many users use many devices, but there are more users than devices.** This situation might exist in a university's computer lab or in a retail store.
- **One user uses more than one device.** This often occurs when software developers create programs on one device and test their applications on several other devices.

To create a license group, specify the users in the group and allocate one license for each client device used to access the server. The number of licenses allocated to a group should correspond to the number of devices used by members of the group. This can be either fewer or more than the number of users.

- If 10 people are using one device, you need only one Client Access License. The group would include all of the users, but have only one license.
- If 100 users are using 10 devices, you need 10 Client Access Licenses, one for each of the 10 devices. The group would list the 100 users and have 10 Client Access Licenses.
- If one user uses 5 devices, you need a Client Access License for each device. The group would list the single user and have 5 licenses.

To create a new license group, see Create a new license group. To add, delete, or change a license group, see Edit or view a license group.

# Tracking user licenses for multiple sites

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tracking user licenses for multiple sites**

Users accessing a Windows Server 2003 operating system in more than one site might be allocated multiple licenses for the product. The License Logging service for Windows Server 2003 operating systems collects site-licensing information on the site license server for a single site. This enables a geographical or organizational unit in an organization to purchase and manage their software licenses separately. However, because each site allocates licenses to users independently of other sites, a user connecting to a product in more than one site might be allocated more than one Client Access License for the same product.

If your organization has multiple sites and you notice unexpected consumption of software licenses, you should check for multiple licenses allocated to users in different sites. To search for multiple Client Access Licenses allocated to the same user in more than one site, you must compare the product information for different sites. To compare the users listed in **Clients** for different sites, use **Licensing** in **Administrative Tools**. For more information, see View product license information.

If a user from a different site is allocated a license for a server product in both sites, you can either delete the user or revoke the license. However, do not do this if the user uses a different device for each site--for example, if the user regularly travels between corporate offices and has a different device in each location. The license allocation would then be correct.

Multiple sites for an organization normally reflect groups of users that are distinct geographically or organizationally, working on distinct subnets owned by the organization. If you find that users are constantly accessing servers in different sites, you might want to reconsider how you structure the sites or how you distribute resources among sites.

# License Logging service messages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**License Logging service messages**

You might see one or more of the following informational or error messages from the License Logging service.

**License Logging service messages**

| |
|---|
| **3 Server** *ServerName* **has requested that license database replication to it be delayed.**<br><br>Indicates that the specified Site License Server or domain controller is unable to accept replicated data at this time. License Logging service will reattempt replication in 15 minutes. |
| **4 License database replication to server** *ServerName* **has started.**<br><br>Indicates that replication to the specified Site License Server or domain controller has started successfully. |
| **5 License database replication to server** *ServerName* **has completed successfully.**<br><br>Indicates that replication to the specified Site License Server or domain controller has completed successfully. |

**Warning and error messages**

| |
|---|
| **201 No license was available for user** *UserName* **using product** *ProductName* **. Use Licensing from the Administrative Tools folder to ensure that you have sufficient licenses.**<br><br>Indicates a licensing violation. All the licenses for the specified product have been assigned to users. Use Licensing in Administrative Tools to analyze usage. You can find out how many licenses should be purchased or revoke licenses from users who are not using them. |
| **202 The product** *ProductName* **is out of licenses. Use Licensing from the Administrative Tools folder for more information on which users are out of compliance and how many licenses should be purchased.**<br><br>Indicates a licensing violation. All the licenses for the specified product have been assigned to users. Use Licensing in Administrative Tools to find out which users are out of compliance. You can find out how many licenses should be purchased or revoke licenses from users who are not using them. |
| **203 The user data could not be saved. The data is the error code.**<br><br>Indicates that changes to the user information could not be saved. The License Logging service may be able to successfully save the data later. If not, the data will be lost. Data that is replicated from other servers will be received again during the next replication. Data entered on this server will have to be re-entered. |
| **204 The license group mapping data could not be saved to LlsMap.LLS. The data is the error code.**<br><br>Indicates that changes to the license groups could not be saved. The License Logging service may be able to successfully save the data later. If not, the data will be lost. Data replicated from other servers will be received again during the next replication. Data entered on this server will have to be re-entered. |
| **205 The purchased license data could not be saved to CPL.CFG. The data is the error code.**<br><br>Indicates that changes to license purchase information could not be saved. The License Logging service may be able to successfully save the data later. If not, the data will be lost. Data replicated from other servers will be received again during the next replication. Data entered on this server will have to be re-entered. |
| **208 The saved user data could not be restored.**<br><br>Indicates that user data could not be read from a saved file. The License Logging service will overwrite the file the next time it saves information. Data that was received from other servers will be retrieved during the next replication, but data entered for this server will have to be re-entered. |

**209 The saved license group data could not be restored.**

Indicates that user data could not be read from a saved file. The License Logging service will overwrite the file the next time it saves information. Data that is received from other servers will be retrieved during the next replication, but data entered for this server will have to be re-entered.

**210 The saved purchased license data could not be restored.**

Indicates that the license groups data could not be read from a saved file. The License Logging service will overwrite the file the next time it saves information. Data that is received from other servers will be retrieved during the next replication, but data entered for this server will have to be re-entered.

**213 Replication of license information failed because the License Logging service on server** *ServerName* **could not be contacted.**

Indicates that either the indicated Site License Server or domain controller is unavailable on the network or the License Logging service on that computer is stopped. Verify that the computer is on the network and is running. If the computer is available on the network, use Services in the Computer Management System Tools to verify that the License Logging service is running on that computer.

**214 The License Logging service encountered an error while initiating replication to server** *ServerName* **.**

Indicates that the License Logging service on the indicated server was contacted, but an error occurred before replication could begin. This is probably caused by communication problems on the network. The License Logging service will retry replication every 15 minutes until it succeeds.

**215 License database replication to server** *ServerName* **was unsuccessful.**

Indicates that replication to the named server began successfully but failed to complete. This is probably caused by communication problems on the network. The License Logging service will retry replication every 15 minutes until it succeeds.

**218 The certificate database could not be saved.**

Indicates that License Logging service could not save the certificate database. Check whether the server has enough disk space.

**219 The certificate database could not be restored.**

Indicates that the database file may be corrupted. No action is required, because the database will be automatically regenerated.

**220 License database replication cannot be performed to server** *ServerName* **because the version of Windows NT installed there does not support the License Logging service.**

Indicates that the specified server is available on the network, but License Logging service is not installed, because it is running a version of Windows NT earlier than 3.51.

**221 License usage for product** *ProductName* **is nearing the maximum number of Per Server licenses purchased. Consult Licensing from the Administrative Tools folder for more information.**

Indicates that the specified product is licensed in Per Device or Per User mode. Nearly all the Client Access Licenses are assigned, and you may need to purchase additional licenses to provide for the clients connecting to this product on your network. You can also revoke licenses from clients that are no longer using the product. Use Licensing in Administrative Tools to analyze usage.

**222 License usage for product** *ProductName* **is at the maximum number of Per Server licenses purchased. New license requests cannot be granted. Consult Licensing in Administrative Tools for more information.**

Indicates that the specified product is licensed in Per Device or Per User mode. All the Client Access Licenses are being used, and you need to purchase additional licenses to provide for the client devices connecting to this product on your network. You can also revoke licenses from client devices that are no longer using the product. Use Licensing in Administrative Tools to analyze usage.

# Troubleshooting licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting licensing**
What problem are you having?

- No more connections can be made to a server product because the number of connections has reached the maximum that the server can accept.
- The number of Per Device or Per User Client Access Licenses allocated is more than the number of client devices accessing a Windows Server 2003 operating system.
- The number of Client Access Licenses allocated is fewer than the number of client devices used to access a product.
- Client Access Licenses for a product are allocated to users who belong to another site.

**No more connections can be made to a server product because the number of connections has reached the maximum that the server can accept.**
**Cause:** The server product might be configured with Per Server licensing and the number of licenses might be exhausted.

**Solution:** Check license usage for the product on the server. The user can wait until others stop accessing the product. To eliminate the problem, you can purchase more licenses for the product.

**See also:** View product license information

**The number of Per Device or Per User Client Access Licenses allocated is more than the number of client devices accessing a Windows Server 2003 operating system.**
**Cause:** A Client Access License is required for each client device or user that accesses a Windows Server 2003 operating system. Any of the following situations can consume extra licenses:

- A user who accessed a server product has been removed from the network.
- A user is still on the network, but no longer uses the server product.
- Several users access a product from a single client device.

**Solution:** To release allocated licenses, do the following:

- When you remove a user from the network, use **Licensing** in **Administrative Tools** to delete the user.
- Use **Licensing** in **Administrative Tools** to check how recently and often a user accesses a particular server product. Revoke a Client Access License if a user no longer uses the product.
- When several users share one or more client devices, create a license group to allocate the same number of Client Access Licenses among the users as there are client devices.

**See also:** View user licensing information, Delete a user from a license, Revoke a user's Client Access License for a product, or Create a new license group

**The number of Client Access Licenses allocated is fewer than the number of client devices used to access a product.**
**Cause:** A user accesses a server product from more than one device.

**Solution:** Whenever one or more users use several different devices, create a license group to allocate the pooled Client Access Licenses for the client devices to the users. This can cause more Client Access Licenses to be allocated than there are client devices accessing a product.

**See also:** Create a new license group

**Client Access Licenses for a product are allocated to users who belong to another site.**

**Cause:** License Manager tracks usage for a single site, and does not distinguish users who access a particular server product in more than one site from a single client device.

**Solution:** Use **Licensing** in **Administrative Tools** to revoke licenses or delete users from another site. Do not revoke a Client Access License from a user who uses different devices that belong to the different sites. The number of licenses then corresponds correctly to the number of client devices. If a user in a site shares a device with a user from another site (for example, a visitor from another division of the company), then create a license group to correctly allocate the corresponding Client Access License to both users.

**See also:** Tracking user licenses for multiple sites, Delete a user from a license, Revoke a user's Client Access License for a product, or Create a new license group

# Windows Installer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer**
Windows Installer makes it easy for you to manage the software installation and removal process, and modify, repair, and advertise existing applications.

- For help with specific tasks, see Windows Installer How To....
- For general background information, see Windows Installer Concepts.
- For problem-solving instructions, see Windows Installer Troubleshooting.

# Windows Installer How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Use Windows Installer packages with Windows Explorer
- Use Windows Installer packages with the Add or Remove Programs utility
- Use Windows Installer from the command line
- Configure Group Policy for Windows Installer

# Use Windows Installer packages with Windows Explorer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use Windows Installer packages with Windows Explorer**

1. Open Windows Explorer.
2. Right-click the Windows Installer package (.msi file), and then click **Install**, **Repair**, or **Uninstall**.

### Note

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Use Windows Installer packages with the Add or Remove Programs utility
Use Windows Installer from the command line

# Use Windows Installer packages with the Add or Remove Programs utility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use Windows Installer packages with Add or Remove Programs**

1. Open Add or Remove Programs in Control Panel.
2. Click **Change or Remove Programs**, click the program that you want to change or remove, and then do one of the following:
   - To change a program, click **Change**.
   - To remove a program, click **Remove**.

### Note

- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Windows Installer from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Windows Installer from the command line**

- Install a transform using the command line
- Install and advertise a product using a transform at the command line
- Install a package using the command line
- Remove a package using the command line
- Repair a package using the command line
- Advertise a package using the command line
- Create an administrative installation package from the command line
- Create an installation log file using the command line

# Install a transform using the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a transform using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec /i***package***TRANSFORMS=***TransformList*

| Value | Description |
|---|---|
| **/i** | Installs a product. |
| *package* | Specifies the name of the Windows Installer package file. |
| **TRANSFORMS=***TransformList* | Specifies what transform (.mst) files should be applied to the package. *TransformList* is a list of paths separated by semicolons. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Windows Installer Group Policy computer options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Windows Installer Group Policy computer options**

1. Open Group Policy.
2. In the console tree, click the **Windows Installer** node.

   **Where?**

   - *applicable policy name*/Computer Configuration/Administrative Templates/Windows Components/Windows Installer

3. In the details window, double-click one of the following policy settings:

   - **Disable Windows Installer**
   - **Always install with elevated privileges**
   - **Prohibit rollback**
   - **Remove browse dialog box for new source**
   - **Prohibit patching**
   - **Disable IE security prompt for Windows Installer scripts**
   - **Enable user control over installs**
   - **Enable user to browse for source while elevated**
   - **Enable user to use media source while elevated**
   - **Enable user to patch elevated products**
   - **Allow admin to install from Terminal Services session**
   - **Cache transforms in secure location on workstation**
   - **Logging**
   - **Prohibit User Installs**
   - **Turn off creation of System Restore Checkpoints**
   - **Prohibit removal of updates**
   - **Enforce upgrade components rule**
   - **Prohibit non-administrators from applying vendor signed updates**

- **Baseline file cache maximum size**

4. In the **Group Policy Property** dialog box, set the options you want to use, and then click **OK**.

### Notes

- To open Group Policy to edit the local Group Policy object, click **Start**, click **Run**, type **gpedit.msc**, and then press ENTER.
- For more information about Windows Installer Group Policy options, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Windows Installer overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer overview**

Windows Installer is a component of the Windows operating system that simplifies the application installation process.

Windows Installer manages the installation and removal of applications by applying a set of centrally defined setup rules during the installation process. You can also use this service to modify, repair, or remove an existing application. Windows Installer technology consists of the Windows Installer service for the Windows operating systems and the package (.msi) file format that contains information about application set up and installation.

Windows Installer is also an extensible software management system. It manages the installation, addition, and deletion of software components, monitors file resiliency, and maintains basic failure recovery with rollbacks. Windows Installer supports installing and running software from multiple sources, and developers can customize Windows Installer to install custom applications.

# Understanding Windows Installer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Windows Installer**
This section covers:

- Windows Installer features
- Windows Installer technologies

# Windows Installer features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer features**

With Windows Installer and the .msi package file format, software installation and removal are more reliable and resilient. Windows Installer also provides a larger set of installation options. Windows Installer performs the following tasks:

- **Restores original computer state upon installation failure--**Windows Installer keeps track of all changes made to the system during the application installation process. If the installation fails, Windows Installer can restore, or roll back, the system to its initial state.

- **Helps prevent interapplication conflicts--**Windows Installer enforces installation rules that help to prevent conflicts with shared resources between existing applications. Such conflicts can be caused when an install operation makes updates to a dynamic link library (.dll) shared by an existing application or when an operation deletes a .dll shared by another application.

- **Reliably removes existing programs--**Windows Installer can reliably uninstall any program it previously installed. It removes all of the associated registry entries and application files, except for those shared by other installed software. You can uninstall an application at any time after a successful installation. (Removal should not be confused with rollback, which restores a computer to its initial state when an installation failure has occurred.)

- **Diagnoses and repairs corrupted applications--**An application can query Windows Installer to determine whether an installed application has missing or corrupted files. If any are detected, Windows Installer repairs the application by recopying only those files found to be missing or corrupted.

- **Supports on-demand installation of application features--**Windows Installer can be configured to initially install a minimal subset of an application. Later, additional components can be automatically installed the first time the user accesses features that require those components. This is known as advertising. For example, Windows Installer could install Microsoft Word with a minimal set of features. The first time the user tried to access a mail merge function (not included with the original installation), Windows Installer would automatically install the mail merge component. Similarly, Windows Installer can also purge components that go unused in an application. For example, Windows Installer could be configured to remove the mail merge component if it goes unused for 60 days.

- **Supports unattended application installation--**Installation packages can be configured to require no installation process interaction from the user. During the installation process, Windows Installer can query the computer for desktop attributes, including determining whether any applications were previously installed by Windows Installer.

- **Supports 32-bit and 64-bit applications--**32-bit applications can be installed on 64-bit machines.

- **Supports Microsoft .NET Framework--**The Microsoft .NET Framework is a new platform for building integrated, service-oriented applications that gather information from and interact with a wide variety of sources, regardless of the platforms or languages in use. The .NET Framework and the common language runtime can deliver write-once, compile-once, run-anywhere application development. Specifically, the .NET Framework delivers code reuse, code specialization, resource management, multilanguage development, security, deployment, and administration.

- **Integrated with side-by-side components--**This feature eliminates .dll version conflicts by permitting an application to be bound to the version of the component it was designed and tested with, regardless of the computer that hosts the application. Side-by-side components support the simultaneous execution of multiple versions of each component.

- **Integrated with software restriction policies--**This feature provides virus protection support, including protection from Trojan horse viruses and worms propagated through e-mail and the Web. Software restriction policies make the simple, point-and-click, active context user experience safe. Group Policy implements them as part of the list of trusted applications, and Windows Installer operates with applications permitted by these software restriction policies.

# Windows Installer technologies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer technologies**

Windows Installer technologies are divided into two parts that work in combination: a client-side installer service (Msiexec.exe) and a package file (.msi file). Windows Installer uses the information contained within a package file to install the application. Following are the Windows Installer technologies:

- **Installer service--**Windows Installer is an operating system service that allows the operating system to manage the installation process.

- **Installer program--**The Msiexec.exe program is a component of Windows Installer. This program uses a dynamic link library, Msi.dll, to read the package files (.msi), apply transforms (.mst), and incorporate command-line options. The installer performs all installation-related tasks: copying files onto the hard disk, making registry modifications, creating shortcuts on the desktop, and displaying dialog boxes to query user installation preferences when necessary.

  When Windows Installer is installed on a computer, the file association capabilities of the operating system are modified to recognize the .msi file type. When a user double-clicks a file with the .msi extension, the operating system associates the .msi file with Windows Installer and runs the Msiexec.exe application.

- **Installation package file--**Each package (.msi) file contains a relational type database that stores all the instructions and data required to install (and uninstall) the program across many installation scenarios. For example, a package file could contain instructions for installing an application when a prior version of the application is already installed. The package file could also contain instructions for installing the software on a computer where that application has never been present.

- **Transforms--**The installation process can be manipulated by applying transforms (.mst) to the installation database. A transform makes changes to elements of the database. For example, Windows Installer can use a transform file to change the language in the user interface of an application. The Windows Installer transform files modify the installation package file at installation time, and can therefore dynamically affect the installation behavior.

  If you are using Group Policy Software Installation, you should note that a transform is applied at the time of assignment or publication, in addition to the time of installation. In practical terms, this means that you should ensure the **Modifications** tab of the package properties dialog box is set up the way you want it to be before clicking **OK**. If you neglect to do this and deploy an incorrectly transformed package, then you either have to remove the software and redeploy it, or upgrade the software with a correctly transformed version.

  Customization transforms, much like patches, remain cached on the computer. These transforms are applied to the base package file whenever Windows Installer needs to perform a configuration change to the installation package. Transforms are applied only at initial installation; they cannot be applied to an application that has already been installed.

# Using Windows Installer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows Installer**
This section covers:

- Windows Installer in managed environments
- Msiexec (command-line options)
- Managing options for computers through Group Policy
- Managing options for users through Group Policy

# Windows Installer in managed environments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer in managed environments**

Windows Installer is an integral part of IntelliMirror, and a core component of the Group Policy-based change and configuration management technology. By using the IntelliMirror technologies, Group Policy, and change and configuration management, administrators can approve certain applications, specifying that all configuration operations on those applications (installation, removal, and repair) run as the local system account. The administrator has control and management of the file system and registry, and Windows Installer performs user-initiated software installations. Only applications that are approved by the administrator run with elevated privileges. For more information about Windows Installer, see Using Windows Installer.

Administrators use Active Directory, IntelliMirror, and Group Policy to assign and publish applications to groups of users or computers within the enterprise. Active Directory is a secure, distributed, partitioned, and replicated directory service that provides management services. These services include a standardized method of locating resources within the enterprise, and applying Group Policy to objects managed by Active Directory. For more information about Active Directory, see Active Directory.

# Msiexec (command-line options)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Msiexec**
Provides the means to install, modify, and perform operations on Windows Installer from the command line.

- To install or configure a product
- To use the administrative installation option
- To repair a product
- To uninstall a product
- To advertise a product
- To set logging level
- To apply an update
- To install a transform using the command line
- To install and advertise a product using a transform with the command line
- To set the user interface level
- To display copyright information for the Windows Installer
- To call the system API DllRegisterServer to self-register modules passed on the command line
- To call the system API DllUnRegisterServer to unregister modules passed on the command line

**To install or configure a product**
**Syntax**
**msiexec /i** {*Package* | *ProductCode*}

**Parameters**
**/i**
Installs or configures a product.

***Package***
Specifies the name of the Windows Installer package file.

***ProductCode***
Specifies the globally unique identifier (GUID) of the Windows Installer package.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To install a product from A:\Example.msi, type:

**msiexec /i A:\Example.msi**

**To use the administrative installation option**
**Syntax**
**msiexec /a** *Package*

**Parameters**
**/a**
Applies the administrative installation option.

***Package***
The name of the Windows Installer package file.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**To repair a product**
**Syntax**
**msiexec /f** [**p**][**o**][**e**][**d**][**c**][**a**][**u**][**m**][**s**][**v**]{*Package* | *ProductCode*}

**Parameters**
**/f**
Enables one or more of the command-line options listed in the following table.

| Command | Description |
|---|---|
| **p** | Reinstalls only if file is missing. |
| **o** | Reinstalls if file is missing or if an older version is installed. |
| **e** | Reinstalls if file is missing or an equal or older version is installed. |
| **d** | Reinstalls if file is missing or a different version is installed. |
| **c** | Reinstalls if file is missing or the stored checksum does not match the calculated value. |
| **a** | Forces all files to be reinstalled. |
| **u** | Rewrite all required user-specific registry entries. |
| **m** | Rewrites all required computer-specific registry entries. |
| **s** | Overwrites all existing shortcuts. |
| **v** | Runs from source and re-caches the local package. |

***Package***
Name of the Windows Installer package file.

***ProductCode***
Globally unique identifier (GUID) of the Windows Installer package.

**Remarks**

- This option ignores any property values that you type at the command line.
- The default parameter for this command-line option is **/fpecms**.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To repair the installation package, type:

**msiexec /fpecms Example.msi**

**To uninstall a product**
**Syntax**
**msiexec /x** {*Package* | *ProductCode*}

**Parameters**
**/x**
uninstalls a product.

***Package***
Name of the Windows Installer package file.

***ProductCode***
Globally unique identifier (GUID) of the Windows Installer package.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To remove or uninstall a package, type:

**msiexec /x Example.msi**

**To advertise a product**
**Syntax**
**msiexec /j** [{**u** | **m**}] *Package*

**msiexec** {**u** | **m**} *Package* **/t** *TransformList*

**msiexec** {**u** | **m**} *Package* **/g** *LanguageID*

**Parameters**
**/j**
Advertises a product.

**u**
Advertises to the current user.

**m**
Advertises to all users of the computer.

***Package***
Specifies the Windows Installer package file.

**/g *LanguageID***
Identifies the language.

**/t *TransformList***
Applies transform to advertised package.

**Remarks**

- This option ignores any property values that you type at the command line.
- If you want to install the application with elevated privileges, use **/jm**.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To advertise a package to all users of this computer, type:

**msiexec /jm Example.msi**

**To set logging level**
**Syntax**
**msiexec /L** [**i**][**w**][**e**][**a**][**r**][**u**][**c**][**m**][**p**][**v**][+][**!**]*LogFile***.txt**

**Parameters**
**/L**
Specifies the path to the log file.

**i**
Logs status messages.

**w**
Logs nonfatal warnings.

**e**
Logs all error messages.

**a**
Logs startup of actions.

**r**
Logs action-specific records.

**u**
Logs user requests.

**c**
Logs initial user interface parameters.

**m**
Logs out-of-memory.

**p**
Logs terminal properties.

**v**
Logs verbose output. To use **v**, specify **/L*v**.

**+**
Appends to existing file.

**!**
Flushes each line to the log.

*****
Logs all information except for the **v** option. This is a wildcard.

***LogFile* .txt**
Name and path of the text log file.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- To include the **v** option in a log file using the wildcard flag, type **/L*v** at the command prompt.
- The Windows Installer log file options can also be used with the uninstall and repair processes.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To install a package and create a log file that contains the information related to the status, out-of-memory, and error messages, type:

**msiexec /i Example.msi /Lime logfile.txt**

**To apply an update**
**Syntax**
**msiexec /p** *UpdatePackage*

**Parameters**
**/p**
Applies an update.

***UpdatePackage***
Specific update.

**Remarks**

- To apply an update to an administrative installation package, use the following syntax:

  **msiexec/p***UpdatePackage***/a***Example.msi*

- Windows Installer command-line options are not case-sensitive.

- For more information about the Windows Installer command-line options, see Related Topics.

**To install a transform using the command line**
**Syntax**
**msiexec /i** *Package* **TRANSFORMS**=*TransformList*

**Parameters**
**/i**
Installs or configures a product.

***Package***
Specifies the Windows Installer package file.

**TRANSFORMS=**
Property that is used to specify what transform (.mst) files should be applied to the package.

***TransformList***
List of paths separated by semicolons.

**Remarks**

- Windows Installer command-line options are not case-sensitive.

- For more information about the Windows Installer command-line options, see Related Topics.

**To install and advertise a product using a transform with the command line**
**Syntax**
**msiexec /i** *Package* **/j**[**u**][**m**] **/t***TransformList*

**Parameters**
**/i**
Installs or configures a product.

***Package***
Name of the Windows Installer package file.

**/j**
Advertises a product. This option ignores any property values entered on the command line.

**u**

Advertises to the current user.

**m**
Advertises to all users of this computer.

**/t**
Applies transform to advertised package.

***TransformList***
List of paths separated by semicolons.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**To set the user interface level**
**Syntax**
**msiexec /q**{**n** | **b** | **r** | **f** | **n+** | **b+** | **b-**}

**Parameters**
**/qn**
Displays no user interface.

**/qb**
Displays a basic user interface.

**/qr**
Displays a reduced user interface with a modal dialog box displayed at the end of the installation.

**/qf**
Displays the full user interface with a modal dialog box displayed at the end.

**/qn+**
Displays no user interface, except for a modal dialog box displayed at the end.

**/qb+**
Displays a basic user interface with a modal dialog box displayed at the end.

**/qb-**
Displays a basic user interface with no modal dialog boxes.

**Remarks**

- **/qb+-** is not a supported user interface level. The modal box is not displayed if the user cancels the installation.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To display the basic user interface options during the package installation of Example.msi, type:

**msiexec /qb Example.msi**

**To display copyright information for the Windows Installer**
**Syntax**
**msiexec** {**/?** | **/h**}

**Parameters**
**{ /?| /h}**
Displays the Windows Installer version and copyright information.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**To call the system API DllRegisterServer to self-register modules passed on the command line**
**Syntax**
**msiexec /y** *Module*

**Parameters**
**/y**
Calls the system API DllRegisterServer to self-register modules passed on the command line.

***Module***
Specifies the file name of module.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Remarks**

- This option is used only for registry information that cannot be added using the registry tables of the .msi file.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
The following example shows how you can use the **msiexec /y** command:

**msiexec /y my_file.dll**

**To call the system API DllUnRegisterServer to unregister modules passed on the command line**
**Syntax**
**msiexec /z** *Module*

**Parameters**
**/z**
Calls the system API DllUnRegisterServer to unregister modules passed on the command line.

***Module***
File name of module.

**Remarks**

- This option is used only for registry information that cannot be added using the registry tables of the .msi file.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
The following example shows how you can use the **msiexec /z** command:

**msiexec /z my_file.dll**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |

| | |
|---|---|
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Managing options for computers through Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing options for computers through Group Policy**
Windows Installer can be configured by using Group Policy and Active Directory to manage the computer installation options.

The following table shows policies concerned with managing the Group Policy computer options for Windows Installer. To configure these policies, start Group Policy, then in the console tree, click the **Windows Installer** node.

**Where?**

- *applicable policy name*/Computer Configuration/Administrative Templates/Windows Installer

| Policy | Details |
|---|---|
| **Disable Windows Installer** | Disables or restricts the use of Windows Installer.<br><br>This policy can prevent users from installing software on their system, or permit users to install only those programs offered by an administrator.<br><br>If you enable this policy, you can use the options in the **Disable Windows Installer** dialog box to establish an installation policy.<br><br>• **Never--**Windows Installer is fully enabled. Users can install and upgrade software. Windows Installer is enabled by default in Windows.<br><br>• **For non-managed apps only--**Users can install only those programs that an administrator assigns (offers on the desktop) or publishes (adds to Add or Remove programs).<br><br>• **Always--**Windows Installer is disabled.<br><br>**Note**<br><br>• This policy affects Windows Installer only. It does not prevent users from using other methods to install and upgrade programs. |
| **Always install with elevated privileges** | Directs Windows Installer to use system permissions when it installs any program on the system.<br><br>This policy extends to all programs the elevated privileges usually reserved for programs that have been assigned to the user (offered on the desktop) or the computer (installed automatically), or made available in Add or Remove programs in Control Panel. This policy lets users install programs that require access to directories that the user might not have permission to view or change, including directories on highly restricted computers.<br><br>If you disable this policy, or do not configure it, the system applies the current user's permissions when it installs programs that are not distributed or offered by an administrator.<br><br>**Note**<br><br>• This policy appears in both the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |

| | |
|---|---|
| **Prohibit rollback** | Prohibits Windows Installer from generating and saving the files it needs to reverse an interrupted or unsuccessful installation.<br><br>**Prohibit rollback** also prevents Windows Installer from recording the original state of the system and frequency of changes it makes during installation, and prevents Windows Installer from retaining files it intends to delete later. As a result, Windows Installer cannot restore the computer to its original state if the installation does not complete.<br><br>This policy is designed to reduce the amount of temporary disk space required to install programs. **Prohibit rollback** also prevents malicious users from interrupting an installation to gather data about the internal state of the computer or to search secure system files. However, because an incomplete installation can render the system or a program inoperable, do not use this policy unless essential.<br><br>This policy appears in both the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |
| **Remove browse dialog box for new source** | Prevents users from searching for installation files when adding features or components to an installed program.<br><br>This policy disables the **Browse** button next to the **Use feature from** list in the Windows Installer dialog box. Users must select an installation file source from the **Use features from** list configured by the administrator.<br><br>This policy applies even when the installation is running in the user's security context.<br><br>If you disable this policy or do not configure it, the **Browse** button is enabled when an installation is running in the user's security context, but only administrators can browse when an installation is running with elevated system privileges, such as installations offered on the desktop or in Add or Remove programs.<br><br>This policy affects Windows Installer only. It does not prevent users from using other browsers, such as Windows Explorer or My Network Places, to search for installation files. |
| **Prohibit patching** | Prevents users from installing patches to upgrade their programs.<br><br>Patches are updates or upgrades that replace only those program files that have changed. Because patches can be easy vehicles for malicious programs, some installations prohibit their use.<br><br>This policy applies only to installations that run in the user's security context. By default, users who are not administrators cannot apply patches to installations that run with elevated system privileges, such as those offered on the desktop or in Add or Remove programs. |
| **Disable IE security prompt for Windows Installer scripts** | Allows Web-based programs to install software on the computer without notifying the user.<br><br>By default, when a script hosted by an Internet browser attempts to install a program on the system, the system warns the user and prompts the user to either allow or refuse the installation. This policy suppresses the warning and allows the installation to proceed without user intervention.<br><br>This policy is designed for enterprises that use Web-based tools to distribute programs to their employees. However, because it might pose a security risk, it should be applied cautiously. |
| **Enable user control over installs** | Permits users to change installation options that typically are available only to administrators.<br><br>This policy bypasses some of the security features of Windows Installer. It permits installations to complete that otherwise would be halted due to a security violation.<br><br>The security features of Windows Installer prevent users from changing installation options that are typically reserved for administrators, such as specifying the directory to which files are installed. If Windows Installer detects that an installation package has permitted the user to change a protected option, it stops the installation and displays an error message. These security features operate only when the installation program is running in a privileged security context in which the installation program has access to directories that are denied to the user.<br><br>This policy is designed for less restrictive environments. It can be used to circumvent errors in an installation program that prevent software from being installed. |

| | |
|---|---|
| **Enable user to browse for source while elevated** | Permits users to search for installation files during privileged installations.<br><br>This policy enables the **Browse** button on the **Use feature from** dialog box. Users can search for installation files, even when the installation program is running, with elevated system privileges. By default, only system administrators can browse during installations with elevated privileges, such as installations offered on the desktop or displayed in Add or Remove programs.<br><br>Because the installation is running with elevated system privileges, users can browse through directories that their own permissions would not allow.<br><br>This policy does not affect installations that run in the user's security context. For more information, see the **Remove browse dialog box for new source** policy. |
| **Enable user to use media source while elevated** | Permits users to install programs from removable media, such as floppy disks and CD-ROMs, during privileged installation.<br><br>This policy permits all users to install programs from removable media, even when the installation program is running with elevated system privileges. By default, users can install programs from removable media only when the installation runs in the user's security context. During privileged installations, such as those offered on the desktop or displayed in Add or Remove programs, only system administrators can install from removable media.<br><br>This policy does not affect installations that run in the user's security context. By default, users can install from removable media when the installation runs in their own security context.<br><br>For more information, see the **Prevent removable media source for any install** policy in Managing options for users through Group Policy. |
| **Enable user to patch elevated products** | Permits users to upgrade programs during privileged installations.<br><br>This policy permits all users to install patches, even when the installation program is running with elevated privileges. Patches are updates or upgrades that replace only those program files that have changed. Because patches can easily be vehicles for malicious programs, some installations prohibit their use.<br><br>By default, only system administrators can apply patches during installations with elevated privileges, such as installations offered on the desktop or displayed in Add or Remove programs.<br><br>This policy does not affect installations that run in the user's security context. By default, users can install patches to programs that run in their own security context. For more information about prohibiting patch installations, see the **prohibit patching** policy. |
| **Allow admin to install from Terminal Services session** | Permits Terminal Services administrators to install and configure programs remotely.<br><br>By default, system administrators can install programs only when they are logged on to the computer on which the program is being installed. This policy creates a special exception for computers running Terminal Services.<br><br>This policy affects system administrators only. Other users cannot install programs remotely. |
| **Cache transforms in secure location on workstation** | Copies of transform files are saved in a secure location on the local computer.<br><br>Transform files consist of instructions to modify or customize a program during installation. By default, Windows Installer stores transform files in the Application Data directory in the user's profile. When a user reinstalls, removes, or repairs an installation, the transform file is available, even if the user is on a different computer, or isn't connected to the network.<br><br>If you enable this policy, the transform file is saved in a secure location on the user's computer instead of in the user profile. Because Windows Installer requires the transform file to repeat an installation in which the transform file was used, the user must be using the same computer or be connected to the original or identical media to reinstall, remove, or repair the installation.<br><br>This policy is designed for enterprises that must take special precautions to prevent unauthorized or malicious editing of transform files. |

| | |
|---|---|
| **prohibit User Installs** | Allows you to configure user installs. To configure this setting, set it to enabled and use the drop-down list to select the behavior you want.<br><br>If this setting is not configured, or if the setting is enabled and **Allow User Installs** is selected, the installer allows and makes use of products that are installed per user, and products that are installed per computer. If the installer finds a per-user install of an application, this hides a per-computer installation of that same product.<br><br>If this setting is enabled and **Hide User Installs** is selected, the installer ignores per-user applications. This causes a per-computer installed application to be visible to users, even if those users have a per-user install of the product registered in their user profile.<br><br>If this setting is enabled and **prohibit User Installs** is selected, the installer prevents applications from being installed per user, and it ignores previously installed per-user applications. An attempt to perform a per-user installation causes the installer to display an error message and stop the installation. This setting is useful in environments where the administrator only wants per-computer applications installed, such as on a kiosk or a Windows Terminal Server. |
| **Turn off creation of System Restore Checkpoints** | Stops Windows Installer from generating System Restore checkpoints when installing applications.<br><br>System Restore enables users, in the event of a problem, to restore their computers to a previous state without losing personal data files. By default, Windows Installer automatically creates a System Restore checkpoint each time an application is installed, so that users can restore their computer to the state it was in before installing the application.<br><br>If you disable this setting or do not configure it, Windows Installer automatically creates a System Restore checkpoint each time an application is installed.<br><br>**Note**<br><br>• This setting only applies to Windows XP Professional. |
| **Logging** | Specifies the types of events that Windows Installer records in its transaction log for each installation. The log, msi.log, appears in the *systemroot*\Temp directory. The Windows Installer logging options are listed in the following table. To indicate that an event type is recorded, enter the letter representing the event type. You can enter the letters in any order, and list as many or as few event types as you want. To disable logging, delete all of the letters from the box. If you disable this policy, or do not configure it, Windows Installer logs the default event types, represented by the letters **iweap**. You can include all possible events in the installation log file by entering **iwearucmpvo**. However, doing so will add considerable time to the installation process. |

| Mode | Log entry |
|---|---|
| **i** | Status messages |
| **w** | Non-fatal warnings |
| **e** | All error messages |
| **a** | Startup of actions |
| **r** | Action-specific records |
| **u** | User requests |
| **c** | Initial user interface parameters |
| **m** | Out-of-memory |
| **p** | Terminal properties |
| **v** | Verbose output |
| **o** | Out of disk space messages |

# Managing options for users through Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing options for users through Group Policy**

Windows Installer can be configured by using Group Policy and Active Directory to manage the user installation options.

This table shows policies concerned with managing the Group Policy user options for Windows Installer. To configure these policies, start Group Policy, then in the console tree, click the **Windows Installer** node.

**Where?**

- *applicable policy name*/User Configuration/Administrative Templates/Windows Installer

| Policy | Details |
|---|---|
| **Always install with elevated privileges** | Directs Windows Installer to use system permissions when it installs any program on the system.<br><br>This policy extends to all programs the elevated privileges usually reserved for programs that have been assigned to the user (offered on the desktop) or the computer (installed automatically), or made available in Add or Remove Programs in Control Panel. This policy lets users install programs that require access to directories that the user might not have permission to view or change, including directories on highly restricted computers.<br><br>If you disable this policy, or do not configure it, the system applies the current user's permissions when it installs programs that are not distributed or offered by an administrator.<br><br>**Note**<br><br>• This policy appears both in the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |
| **Search order** | Specifies the order in which Windows Installer searches for installation files.<br><br>By default, Windows Installer searches the network first, then removable media (floppy drive, CD-ROM, or DVD), and finally, the Internet (URL).<br><br>To change the search order, enable the policy, and then type the following letters for each file source in the order that you want Windows Installer to search. For example, if you want to search the network, the Internet, and then removable media, type **num**. To exclude a file source, omit or delete the letter representing that source type.<br><br>• **n** - Adds the network in the source file search.<br><br>• **m** - Adds the removable media in the source file search.<br><br>• **u** - Adds the Internet in the source file search. |

| | |
|---|---|
| **Prohibit rollback** | Prohibits Windows Installer from generating and saving the files it needs to reverse an interrupted or unsuccessful installation.<br><br>This policy prevents Windows Installer from recording the original state of the system and sequence of changes it makes during installation. It also prevents Windows Installer from retaining files it intends to delete later. As a result, Windows Installer cannot restore the computer to its original state if the installation does not complete.<br><br>This policy is designed to reduce the amount of temporary disk space required to install applications. It also prevents malicious users from interrupting an installation to gather data about internal state of the computer or to search secure system files. However, because an incomplete installation can render the system or an application inoperable, this policy should not be used unless it is essential.<br><br>**Note**<br><br>• This policy appears in both the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |
| **Prevent removable media source for any install** | Prevents users from installing programs from removable media.<br><br>If a user tries to install a program from removable media, such as CD-ROMs, floppy disks, or DVDs, a message informs the user that the feature cannot be found.<br><br>This policy applies even when the installation is running in the user's security context.<br><br>If you disable or do not configure this policy, users can install from removable media when the installation is running in their own security context, but only system administrators can use removable media when an installation is running with elevated system privileges, such as installations offered on the desktop or in Add or Remove Programs. |

# Windows Installer Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The installation package does not install correctly.
- The installation process stops before completing the installation.

**The installation package does not install correctly.**
**Cause:** The installation packaged has been corrupted.

**Solution:** Repair the installation package by using the Windows Installer repair option.

**See also:** Repair a package using the command line

**The installation process stops before completing the installation.**
**Cause:** Windows Installer was not able to read the installation package, or conditions on your computer prevented the package from being installed successfully.

**Solution:** Windows Installer creates entries in the Windows event log. To view the log, do the following:

1. Open Event Viewer.
2. Review the application log for Windows Installer entries.

**Notes**

- To open Event Viewer, click **Start**, point to **Settings**, and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Event Viewer**.
- You can configure Windows Installer to create a custom installation log file.

**See also:** Create an installation log file using the command line

# Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services**
Remote Installation Services (RIS) is an optional component that is included in the Microsoft® Windows Server 2003™ family operating systems.

You can use RIS to create installation images of operating systems or of complete computer configurations, including desktop settings and applications. You can then make these installation images available to users at client computers. You can also specify which RIS server will provide installations to a given client computer, or you can allow any RIS server to provide the installation.

When you use RIS, a CD-ROM is not required for installation of an operating system on a client computer. The client computers must support remote booting with the Pre-Boot eXecution Environment (PXE) ROM, or they must be started with a remote-startup floppy disk and contain a network adapter that is supported by that disk.

You can use RIS to create automated installation images of Windows Server 2003 family operating systems, Windows XP, and Windows 2000.

- Before you begin using RIS, see Checklist: Installing Remote Installation Services.
- For tips about using RIS, see Best practices for Remote Installation Services.
- For help with specific tasks, see Remote Installation Services How To....
- For general background information, see Remote Installation Services Concepts.
- For problem-solving instructions, see Troubleshooting Remote Installation Services.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Checklist: Installing Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Installing Remote Installation Services**

| Step | Reference |
|---|---|
| Review key concepts. | Remote Installation Services Concepts |
| Ensure that both your server and client hardware meet the Remote Installation Services (RIS) hardware requirements. | Remote Installation Services system requirements |
| Ensure that your network is based on TCP/IP, and that a Domain Name System (DNS) server exists on the network. You do not need to use the Microsoft version of DNS. | Install a DNS server; Configure a new DNS server |
| Ensure that an authorized Dynamic Host Configuration Protocol (DHCP) server exists on the network. You do not need to use the Microsoft version of DHCP. A non-Microsoft DHCP server does not need to be authorized. | Install a DHCP server; Checklist: Installing a DHCP server |
| Ensure that Active Directory exists on the network. | Active Directory Overview; Using the Active Directory Installation Wizard |
| Run the Remote Installation Services Setup Wizard. | Install Remote Installation Services |

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Best practices for Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Follow best practices for network security in any network that includes PXE-enabled client computers.**

- For more information, see PXE architecture, RIS, and security considerations.

**Use the appropriate number of Remote Installation Services (RIS) servers on your network.**

- In a small local area network (LAN)--for example, one physical subnet without a router--a single RIS server can serve all Pre-Boot eXecution Environment (PXE) remote boot-enabled client computers up to the network bandwidth or server resource limitations.

  In a routed environment, use the settings that are available when you prestage clients to direct each client to be serviced by the RIS server that is in closest proximity to it. Also, set the Dynamic Host Configuration Protocol (DHCP) forwarding option to allow your routers to forward client requests to the RIS servers. In branch offices, if the only links to the branch site are low-speed links, use a RIS server at the branch site. Do not use RIS over low-speed links on a wide area network (WAN).

**Install RIS on a physical disk separate from the one on which the operating system is installed.**

- Installing RIS on a disk separate from the one on which the operating system is installed will help ensure optimal performance.

**Learn how to control the number of installation options and operating system choices a user can access within the Client Installation Wizard.**

- Restricting installation options increases the number of successful operating system installations that can be completed without assistance from technical support or administrative staff. By default, RIS presents one installation option and operating system option to the user. For more information about other installation options, see Installation options available through RIS.

  To maintain appropriate security and simplify the client installation process for users, review information in the *Windows Server 2003 Deployment Kit* regarding settings in .osc and .sif files. For details, see "Designing RIS Installations" at the Microsoft Windows Resource Kits Web site.

  For information about the Setup Manager tool and .sif files, see deploy.chm in \Support\Tools\deploy.cab on the Windows CD.

**Use the Remote Installation Preparation Wizard (RIPrep) image format to deploy a standard corporate desktop configuration across different types of client hardware throughout your organization.**

- With the Remote Installation Preparation image format, administrators can replicate the installation image of an existing client computer, including locally installed applications and operating system configuration changes, to an available RIS server on the network. After the installation image is replicated, it can be installed remotely by any supported client computer. When you create new images using RIPrep, the image is available only to clients that have the same type of Hardware Abstraction Layer (HAL). Images that were created using RIPrep are available to all clients that are authorized to view them. For more information, see Creating an installation image with RIPrep.

**Use RIS with computers that contain the PXE-based remote boot ROM.**

- For computers that do not contain the PXE-based remote boot ROM, use the remote boot floppy generator (Rbfg.exe) to

create a floppy disk. You can then use the RIS feature for these computers. For more information on the PXE-based remote boot ROM, see PXE architecture.

**When using the Client Installation Wizard, use standard ASCII characters for user name, password, and domain name information.**

- The Client Installation Wizard does not support extended ASCII character sets (such as those containing ü é and other non-standard characters). You should therefore limit the characters used for user name, password, and domain name information to standard ASCII characters (OEM characters 32-126).

# Remote Installation Services How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install Remote Installation Services
- Manage Remote Installation Services
- Add RIS Client Installation Images
- Manage RIS Client Computers
- Manage Security for Remote Installation Services

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Install Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Remote Installation Services**

1. If you have not already installed Remote Installation Services through Control Panel or through an unattended Setup answer file, open Add or Remove Programs and use **Add/Remove Windows Components** to install the RIS component.

2. Open the Remote Installation Services Setup Wizard.

3. In the wizard, click **Next**.

You are prompted for the following information:

**Remote Installation Services Drive and Directory**
Enter the disk drive and directory where you want to install Remote Installation Services (RIS). The disk should be dedicated to the RIS server and contain enough space to store as many client images as you plan to host with this server. The recommended minimum amount of space is four gigabytes.

**Initial Settings**
Select **Respond to client computers requesting service** if you want the RIS server to begin responding to client computers as soon as you finish the wizard. Select **Do not respond to unknown client computers** if you want the RIS server to respond only to prestaged client computers in Active Directory. You can change these settings later.

**Source Path**
Enter the location of the client images. This can be either the compact disc or a shared folder that contains the installation files.

**Friendly Description and Help Text**
Enter the friendly description for the client computer installation. This description will be displayed to users or clients of this server. The Help text describes the operating system installation choices to users or clients of RIS.

**Notes**

- To perform this procedure, you must be a member of the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Add or Remove programs, click **Start**, click **Control Panel**, and then double-click **Add or Remove programs**.

- This topic does not apply to Windows Server 2003, Web Edition.

- To start the Remote Installation Services Setup Wizard, click **Start**, point to **Programs**, point to **Administrative Tools**, and then click **Remote Installation Services Setup**.

- The Installation Wizard might prompt you to restart the computer if RIS was added after Setup.

- For information about the technologies that RIS requires to identify network computers (for example, DHCP and other technologies), see Related Topics.

- For information about RIS system requirements, including important information about requirements for the partition on which you install RIS, see Related Topics.

- To manage a RIS server from a computer running Windows XP, install the Windows Server 2003 Administration Tools Pack on the computer running Windows XP. To manage a RIS server from any remote computer, use Remote Desktop

for Administration. For more information, see Related Topics.

- Do not use Network Load Balancing in front of the RIS server. If you do, RIS will not work. This is because the computer will appear to Active Directory as if it has two Internet Protocol (IP) addresses and is therefore a multihomed computer. Similarly, a computer with more than one network adapter is also multihomed, and cannot be used as a RIS server.

- Installation images that are stored in locations other than *Server_name*\REMINST\Setup*Language*\Images

  and referenced through junction points cannot be used with the Single Instance Store (SIS) because the SIS groveler agent does not work with junction points.

- RIS does not currently support the Encrypting File System (EFS). The Distributed File System (DFS) is not supported as a target location. You can, however, run RIS on a computer that is also running DFS.

- To ensure that all of the services have started successfully, open Event Viewer and review the entries for System Log and Application Log. For more information about using Event Viewer, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage Remote Installation Services**

- Configure Remote Installation Services
- Configure settings for new clients for RIS
- Manage client installation images
- Manage troubleshooting tools
- Verify the Remote Installation Services configuration

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Configure Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Remote Installation Services**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

3. Click **Properties**, and then in the **Properties** dialog box, click the **Remote Install** tab.
4. In the **Remote Install** dialog box, select or clear check boxes as needed:

   - **Respond to client computers requesting service**

     Select this option to enable the RIS server to begin responding to client computers. Clear it to prevent the RIS server from responding.

   - **Do not respond to unknown client computers**

     Select this option if you want this RIS server to respond only to prestaged client computers in Active Directory. Clear it if you want this RIS server to respond to any client computer requesting remote installation.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- This topic does not apply to Windows Server 2003, Web Edition.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- For information about prestaging clients, see Related Topics.
- To manage a RIS server from a computer running Windows XP, install the Windows Server 2003 Administration Tools Pack on the computer running Windows XP. To manage a RIS server from any remote computer, use Remote Desktop for Administration. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure settings for new clients for RIS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure settings for new clients for RIS**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

3. Click **Properties**. In the **Properties** dialog box, click the **Remote Install** tab, and then click **Advanced Settings**.
4. In the **Advanced Settings** dialog box, click the **New Clients** tab.
5. In **Generate client computer names using**, either select the client computer naming format you want to use, or click **Customize** to create a client computer naming format.
6. To specify where to create the client computer account, click one of the following options:

   - **Default directory service location**
   - **Same location as that of the user setting up the client computer**
   - **The following directory service location**

7. If you chose the last option, click **Browse** and specify where to create the computer accounts.

**Notes**

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- This topic does not apply to Windows Server 2003, Web Edition.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- This procedure applies only to client computer accounts that are not prestaged.
- After performing this procedure, be sure to assign the appropriate permissions to users who install from RIS on the client computer. This is necessary so that users can create computer accounts within the chosen domain or organizational unit. For more information, see Related Topics.
- To manage a RIS server from a computer running Windows XP, install the Windows Server 2003 Administration Tools Pack on the computer running Windows XP. To manage a RIS server from any remote computer, use Remote Desktop for Administration. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

#### To manage troubleshooting tools

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

3. Click **Properties**, and then in the **Properties** dialog box, click the **Remote Install** tab.
4. Click **Advanced Settings**, and then click the **Tools** tab.
5. In the **Tools** dialog box, click **Tool**.
6. Click one of the following options:

   - **Remove**
   - **Properties**
   - **Refresh**

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- This topic does not apply to Windows Server 2003, Web Edition.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- You can use this procedure to view the list of tools or remove a tool from the list. For more information about maintenance and troubleshooting tools and options for RIS, see Related Topics.
- To manage a RIS server from a computer running Windows XP, install the Windows Server 2003 Administration Tools Pack on the computer running Windows XP. To manage a RIS server from any remote computer, use Remote Desktop for Administration. For more information, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Verify the Remote Installation Services configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To verify the Remote Installation Services configuration**

1. Make sure you have the installation CDs available. You might be prompted for them during the process of verifying the server.

2. Go to the Remote Installation Services (RIS) server you want to verify, or use Remote Desktop for Administration to connect to the RIS server you want to verify.

3. Open Active Directory Users and Computers.

4. In the console tree, right-click the RIS server whose configuration you want to verify.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

5. Click **Properties**, and then in the **Properties** dialog box, click the **Remote Install** tab.

6. Click **Verify Server**. The Check Server Wizard opens.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- This topic does not apply to Windows Server 2003, Web Edition.

- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.

- Use Verify Server if the server seems to be failing or is behaving inconsistently, or if you need to restore a RIS volume from backup.

- If you need to restore a RIS volume from backup, verify the server configuration before you restore the volume.

- You can only use Verify Server locally on a RIS server, or by connecting to that server through Remote Desktop for Administration. You cannot use Verify Server if you are performing RIS administration tasks from a remote server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add RIS Client Installation Images

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Add RIS client installation images**

- Add a new client operating system installation image
- Associate an unattended setup answer file with a RIS installation image
- Create a Remote Installation Preparation Wizard image

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Add a new client operating system installation image

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a new client operating system installation image**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

3. Click **Properties**, and then, in the **Properties** dialog box, click the **Remote Install** tab.
4. Click **Advanced Settings**, and then click the **Images** tab.
5. Click **Add**.
6. Click **Add a new installation image**, and then click **Next** to start the Remote Installation Services Setup Wizard.
7. Click **Next**, and then type the location of the installation files. The location can be either a compact disc or a shared folder.
8. Type the name of the folder for the new installation image.
9. Enter the friendly description and Help text, and then click **Next**.
10. Specify whether you want to use new .osc screens and back up the previous .osc screens, use new .osc screens and overwrite the previous screens, or leave the previous .osc screens in place.
11. Review the installation summary, and then click **Finish**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- This topic does not apply to Windows Server 2003, Web Edition.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- After completing this procedure, you can associate an unattended setup answer file with the installation image. For more information, see Related Topics.
- For information about .osc screens and how they relate to installation options made available through RIS, see Related Topics.
- You cannot perform this procedure remotely. It must be performed locally on the RIS server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Associate an unattended setup answer file with a RIS installation image

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To associate an unattended setup answer file with a RIS installation image**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

3. Click **Properties**, and then in the **Properties** dialog box, click the **Remote Install** tab.
4. Click **Advanced Settings**, and then click the **Images** tab.
5. Click **Add**.
6. Click **Associate a new answer file to an existing image**, and then click **Next**.
7. Click one of the following options:

   - **Windows image sample files**
   - **Another remote installation server**
   - **An alternate location**

8. Select the installation image to which the answer file will be associated, and then click **Next**.
9. Select the answer file that you want to associate with the installation image, and then click **Next**.
10. Enter the friendly description and Help text, and then click **Next**.
11. Review the settings summary, and then click **Finish** to complete the process.

**Notes**

- To perform this procedure, you must have permission to write to the folder that contains the RIS folders and files (the default name for the folder is RemoteInstall). For more information about the permissions and group membership needed to perform this task and other tasks related to RIS administration, see Related Topics.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- This topic does not apply to Windows Server 2003, Web Edition.

- The installation images that appear in the list in the Add Wizard include flat images only. Flat images are images that were created with the Remote Installation Services Setup Wizard. They do not include images created with the Remote Installation Preparation (RIPrep) Wizard.

- For more information about installation options available through RIS, and the ways these options can be controlled through unattended setup answer files (.sif files), see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a Remote Installation Preparation Wizard image

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a Remote Installation Preparation Wizard image**

1. Install the operating system on the client computer that you will use to create the installation image. You can install it using either Remote Installation Services (RIS) or the product CD. For more information, see Related Topics.

2. Install any additional applications and modify the local configuration settings of the source client computer.

   **Important**

   - Before starting the RIPrep utility, be sure to remove all confidential information from the source client computer.

3. Click **Start**, and then click **Run**.

4. Type the Universal Naming Convention (UNC) path of the RIPrep utility, and then click **OK**.

   Example:

   *Server_name*\REMINST\Admin\I386\RIPrep.exe

5. Read the information provided in the Remote Installation Preparation Wizard Welcome screen, and then click **Next**.

6. Type the server name to which this image will be copied, and then click **Next**. By default this is the current RIS server from which you are running the wizard.

7. Type the name of the folder on the RIS server to which this installation image will be copied, and then click **Next**.

8. Type the friendly description and the Help text, and then click **Next**. This information is displayed by the Client Installation Wizard when RIS clients request network services.

9. After you type the friendly description and the Help text, a screen might appear showing that multiple user profiles were detected, or that services are running that RIPrep determines should be stopped, but which it cannot stop. The screen lists the services that are running and should be stopped.

   If this screen appears, do one of the following:

   - It is recommended that you stop all programs or services on the source computer before proceeding. Review the list of programs or services that are currently running on the source computer, close any running applications, and then click **Next**.

   - If you choose not to stop the programs, skip the screen; to do so, click **Next**.

10. Review the settings summary, and then click **Next**.

11. Review the information from **Completing the Remote Installation Preparation Wizard**, and then, to replicate the source computer installation image onto the RIS server, click **Next**.

**Important**

- A 64-bit version of the Remote Installation Preparation (RIPrep) Wizard is included with the 64-bit version of Windows Server 2003, Enterprise Edition. For more information about using the RIPrep Wizard to create an installation image of a 64-bit operating system, see article 891128, "Updated Remote Installation Service (RIS) functionality in Windows Server 2003 Service Pack 1," in the Microsoft Knowledge Base.

- You cannot use RIPrep to create an image of a Windows 2000 operating system if Internet Information Services (IIS) is installed.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the computer where you create the configuration that RIPrep copies, or you must have been delegated the appropriate authority. Members of the Domain Admins group might also be able to perform this procedure. You must also have permission to write to the RIS folders on the RIS server (the default name for the folder that contains all the RIS folders is RemoteInstall). One way of ensuring that you have permission to write to the RIS folders on the RIS server is to be explicitly assigned the permission. Another way is to have membership in the local Administrators group on the RIS server. For more information, see Default local groups and Default groups.

- This topic does not apply to Windows Server 2003, Web Edition.

- The source computer shuts down when the image replication process is complete.

- The abbreviated Setup program runs automatically when you restart the source computer. Complete the setup process if you want to use this client computer to create another installation image.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage RIS Client Computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage RIS client computers**

- Prestage client computers
- Remove existing client computers
- Find RIS client computers
- Locate the GUID for client computers
- Perform a network installation using RIS
- Create a remote boot disk

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Prestage client computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prestage client computers**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable organizational unit that will contain the new client computer.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain/Applicable organizational unit*

3. Click **New**, and then click **Computer**.
4. Type the client computer name, click **Next**, and then click **This is a managed computer**.
5. In the text entry field, type the client computer's globally unique identifier (GUID), and then click **Next**.
6. Click one of the following options to specify which server or servers will support this client computer:

   - **Any available Remote Installation Services (RIS) server**

     Selecting this option specifies that this client computer can be serviced by any RIS server.

   - **The following RIS server**

     Selecting this option designates a specific server to service this client computer.

**Notes**

- To select the sequence **New** and then **Computer**, you must have Create Computer Objects permissions for the Computers container in Active Directory. Membership in the Account Operators group provides these permissions. As a security best practice, instead of logging on as a member of Account Operators or an administrative group, consider using Run as to perform this procedure. For more information about permissions and group memberships required for tasks related to RIS administration, see Related Topics. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- This topic does not apply to Windows Server 2003, Web Edition.
- Make sure you have the client computer GUID before you start this procedure. For information about how to locate the GUID, see Related Topics.
- You can predetermine how a specific client computer network account is identified, by prestaging the client computer account object within Active Directory. This information is used to identify and route the client computer during a RIS installation.
- You can use prestaging as one part of a security strategy for RIS because with prestaging, you can prevent unknown client computers (computers that are not prestaged) from being installed through RIS. For information about other

security considerations, related to PXE architecture and RIS, see Related Topics.

- You must also set the permissions required by the users of the prestaged client computer. For more information on setting these permissions, see Related Topics.

- When a client computer is being prestaged into a domain with multiple domain controllers, the replication delay of the client computer account information can cause a client computer to be serviced by another RIS server. For more information on controlling information replication, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove existing client computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove existing client computers**

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the applicable client computer account.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable client computer account*

3. Click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- This topic does not apply to Windows Server 2003, Web Edition.

- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Working with MMC console files

# Find RIS client computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To find RIS client computers**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

3. Click **Properties**, and then in the **Properties** dialog box, click the **Remote Install** tab.
4. In the **Remote Install** dialog box, click **Show Clients**.
5. Scan the list for the appropriate client computer. If you know the globally unique identifier (GUID) of the client computer, you can also type the GUID and then click **Find Now**.

## Notes

- To perform this task, the only access required is read access to the domain. Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- This topic does not apply to Windows Server 2003, Web Edition.
- The Show Clients feature searches for all client computers that are prestaged for this RIS server.
- When using the Show Clients feature in multiple RIS server environments, the search results might include client computers from multiple servers that have similar names. For example, if you have multiple RIS servers with computer names such as RISsvr1, RISsvr10, and RISsvr100, and you search for RISsvr1, the list will display the client computers that install from all three servers.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Locate the GUID for client computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To locate the GUID for client computers**

- The computer's globally unique identifier (GUID) (sometimes called the universally unique identifier [UUID]) appears in the following areas:
    - A label on the side of the computer case.
    - A label within the computer case.
    - The basic input/output system (BIOS) of the client computer. You can collect this information through the Windows Management Instrumentation (WMI) interface by using the universally unique identifier (UUID) value of the Win32_ComputerSystemProduct class. For more information about this, see the MSDN Library at the Microsoft Web site.
    - Network traffic from the client computer. You can use a network utility to sniff the network traffic and locate the DHCPDiscover packet; within that field will be the 128-bit, 16-byte GUID/UUID.

## Notes

- The computer's GUID is supplied by the manufacturer. For more information on the computer's GUID, see "RIS client computer properties" in Related Topics.
- This topic does not apply to Windows Server 2003, Web Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Perform a network installation using RIS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To perform a network installation using RIS**

1. After the Client Installation Wizard starts, press ENTER to continue the process.

2. Enter the user name, password, and domain name into the appropriate fields, pressing TAB to move from one field to the next.

3. Several options are available through the Client Installation Wizard; Automatic Setup is the default display option. The other three options are available only if you have changed the Default Domain Policy in Group Policy to allow them.

   - **Automatic Setup**

     This option predefines the computer name and a location in a container within Active Directory for the client computer accounts.

   - **Custom Setup**

     With this option selected, users can define a unique name for this computer and specify where the computer account will be created within Active Directory.

   - **Restart Setup**

     This option restarts an operating system installation attempt if it fails prior to completion.

   - **Maintenance and Troubleshooting**

     With this option selected, users can access tools from the Client Installation Wizard.

4. Follow any additional instructions that appear on the screen.

**Important**

- The RIS administrator can control some of the choices and screens seen by users of RIS client computers. For more information about installation options available through RIS, see Related Topics.

**Notes**

- A user who performs this procedure must first have a valid user name, password, and domain name. The user must also have appropriate permissions. For example, if the computer account has not been prestaged, the user must have permission to create the computer account within the appropriate domain or organizational unit. If the computer account has been prestaged, other permissions must be set. For more information, see Related Topics.

- This topic does not apply to Windows Server 2003, Web Edition.

- It is recommended that a user logging on to a RIS client computer type the user name, password, and domain name in the respective fields. Users should not combine user name and domain name with the @ symbol in between.

- A network installation using RIS can be initiated by either the user of a Pre-Boot eXecution Environment (PXE) remote boot-enabled client computer or by a special remote boot disk provided for pre-Net PC/PC98 computers.

- To invoke a network service boot (network installation using RIS) on client computers that are not remote-boot enabled, insert the boot disk into the disk drive and start the client computer. The client computer must have a Peripheral Component Interconnect (PCI)-based network adapter from the list of specific adapters supported. To determine which network adapters RIS supports, use the boot disk–generating utility. For more information, see the topic about creating a remote boot disk in Related Topics.

- The client computer's basic input/output system (BIOS) must be configured to use the network adapter as its primary boot device.

- When running the Client Installation Wizard, use only standard ASCII characters (OEM characters 32-126) for user name, password, or domain name information. The Client Installation Wizard does not support extended ASCII character sets (such as those containing ü, é, and other extended characters).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Working with MMC console files

# Create a remote boot disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a remote boot disk**

1. Click **Start**, and then click **Run**.
2. Type the Universal Naming Convention (UNC) path of the Rbfg.exe utility, and then click **OK**.

   Example:

   *Server_name*\REMINST\Admin\I386\RBFG.exe
3. Insert a formatted disk into the disk drive.
4. Click **Create Disk**.
5. When the disk is ready, click **Close**, and then remove the disk from the disk drive.

### Important

- Use the remote boot disk on client computers that do not have a remote boot-enabled ROM. A computer on which you use the remote boot disk must have a Peripheral Component Interconnect (PCI)-based network adapter supported by the Rbfg.exe utility. PC Card adapters, CardBus adapters, and adapters that are not PCI-based are not supported. You can view the list of supported network adapters by starting the Rbfg.exe utility (as described in this procedure) and clicking **Adapter List**.
- Some network adapters supported by the Rbfg.exe utility might not be supported by the operating system you plan to install on the client computer. For more details, see the documentation for that operating system. To determine which network adapters are supported by the Windows Server 2003 family operating systems, see Support Resources in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

### Note

- This topic does not apply to Windows Server 2003, Web Edition.

# Manage Security for Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage security for Remote Installation Services**

- Set permissions required by RIS users who use prestaged client computers
- Allow a user or group to create a RIS managed computer account in the domain
- Set Group Policy for client installation options
- Allow or prevent the installing of a RIS image by a user or group
- Allow or prevent the viewing and installing of a RIS image by a user or group
- Set permissions for administrators who manage client installation images for RIS

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Set permissions required by RIS users who use prestaged client computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions required by RIS users who use prestaged client computers**

1. Open Active Directory Users and Computers.
2. On the **View** menu, ensure that **Advanced Features** is checked.
3. In the console tree, right-click the applicable client computer account.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable client computer account*

4. Click **Properties**.
5. In the **Properties** dialog box, click the **Security** tab, and then click **Add**.
6. In the **Select Users, Computers or Groups** dialog box, type the name of the user or group that will use Remote Installation Services (RIS) to install the prestaged client computer, and then click **OK**.
7. Click the user or group you have added.
8. Under **Allow**, ensure that **Read** and **Reset password** are selected, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- This topic does not apply to Windows Server 2003, Web Edition.
- If you set these permissions for a group, remember to add users to that group.
- For client computer accounts that are prestaged in another Active Directory folder location, expand the Active Directory Users and Computer console and select the appropriate client computer accounts.
- This procedure pertains to prestaged client computers. For client computers that are not prestaged, the user must be able to create a computer account in the domain. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow a user or group to create a RIS managed computer account in the domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow a user or group to create a RIS managed computer account in the domain**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the applicable domain.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*

3. Click **Delegate control**.
4. In the Delegation of Control Wizard, click **Next**.
5. In the **Users or Groups** dialog box, click **Add**.
6. In the **Select Users, Computers, or Groups** dialog box, type the name of the **User** account or the **Security Group** (preferred) that contains the users who create Remote Installation Services (RIS) managed computer accounts in the domain (that is, who install from RIS on client computers that are not prestaged).
7. Click **OK**, and then click **Next**.
8. In **Tasks to Delegate**, click **Join a computer to the domain**, and then click **Next**.
9. Review the delegation of control summary information, and then click **Finish**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- This topic does not apply to Windows Server 2003, Web Edition.
- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.
- This procedure pertains to RIS client computers that are not prestaged. For information about setting permissions that pertain to prestaged client computers, see Related Topics.
- If you performed this procedure for a group, remember to add users to that group.
- It is recommended that you limit the user to a specific container in which the RIS server is configured to create clients. Otherwise, the user will be able to create computer objects in any container in the domain.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**

# Set Group Policy for client installation options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set Group Policy for client installation options**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or the applicable organizational unit.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)

3. Click **Properties**, and then click the **Group Policy** tab.
4. In the **Group Policy** dialog box, click the Group Policy object, and then click **Edit** to start Group Policy.
5. Click **User Configuration**, click **Windows Settings**, and then click **Remote Installation Services**.
6. Double-click the **Choice Options** object, and then select from among the following Client Installation Wizard choices:

   - **Automatic Setup**

     Use this option if you want to predefine the computer name and a location within Active Directory for the client computer accounts. (Another alternative is prestaging client computer accounts.) For more information about computer names and the options for predefining them, or for information about prestaging, see Related Topics.

   - **Custom Setup**

     Use this option to allow users to define a unique name for this computer and specify where the computer account will be created within Active Directory.

   - **Restart Setup**

     This option restarts an operating system installation attempt if it fails prior to completion.

   - **Tools**

     This option gives users the ability to access tools, including the Recovery Console, from the Client Installation Wizard. For more information about maintenance and troubleshooting tools and options for RIS, see Related Topics.

7. Click one of the following Group Policy options for each of the Client Installation Wizard choices selected in the previous step:

   - **Enabled**

     Use this option to offer the installation option to users to whom this policy applies.

   - **Disabled**

If this option is set for a specific installation option, users affected by this policy cannot access that installation option within the Client Installation Wizard.

- **Not Configured**

  Use this policy to accept the policy settings of the parent container. For example, if the administrator for the entire domain has set Group Policy that is specific to Remote Installation Services, and the administrator of this container has chosen the Not Configured option, the policy that is set on the domain is applied to all users who are affected by that policy.

8. In the **Choice Options Properties** dialog box, click **OK** to apply your changes.

9. Close Group Policy, and then, in the **Group Policy** dialog box, click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- This topic does not apply to Windows Server 2003, Web Edition.

- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.

- The **Not Configured** installation choice is the default setting.

- **Automatic Setup** is the default display option for users of client computers during the Client Installation Wizard process.

- The security settings that have been set on a domain controller through Group Policy within the Active Directory Users and Computers console might not take effect for the defined user or group accounts for up to eight hours.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow or prevent the installing of a RIS image by a user or group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow or prevent the installing of a RIS image by a user or group**

1. Open Active Directory Users and Computers.
2. On the **View** menu, ensure that **Advanced Features** is checked.
3. In the console tree, right-click the applicable Remote Installation Services (RIS) server.

   **Where?**

   - Active Directory Users and Computers/*Applicable domain*/*Applicable organizational unit* (such as Computers)/*Applicable RIS server*

4. Click **Properties**.
5. In the **Properties** dialog box, click the **Remote Install** tab, and then click **Advanced Settings**.
6. In the **Remote Installation Services Properties** dialog box, click the **Images** tab.
7. In the **Images** dialog box, click the installation image that you want to add or remove from the choices available to a user or group, and then click **Properties**.
8. Click **Permissions**.
9. Click the **Security** tab and do one of the following:

   - To make this installation image available to a group or user that does not appear in the **Group or user names** box, click **Add**. In **Select Users, Computers, or Groups**, type the name of the group or user, click **OK**, and then click the name of the group you just added.
   - To check or change the permissions of this installation image for an existing group or user, click the name of the group or user.

   **Important**

   - The **Group or user names** box always includes **SYSTEM**. Do not remove this entry, and do not change the permissions on it. This entry is necessary for RIS.

10. Do one of the following:

    - To prevent the selected group or user from installing this image, click **Remove**.
    - To allow the selected group or user to install this image, under **Allow**, ensure that **Read & Execute** and **Read** are selected.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For information about assigning appropriate permissions so that a RIS administrator who is not a member of these groups can perform this procedure, see Related Topics.

- This topic does not apply to Windows Server 2003, Web Edition.

- To open Active Directory Users and Computers, click **Start**, click **Run**, type **dsa.msc**, and then click **OK**. For information about creating a shortcut so you can easily open Active Directory Users and Computers with **runas**, see Related Topics.

- For information about creating new installation images, see Related Topics.

- **Authenticated Users** appears by default in **Group or user names**. This means that all authenticated users can install a RIS image. To allow a more limited group (instead of all authenticated users) to install a RIS image, add the appropriate group and allow the permissions described in this procedure. Click **Authenticated Users**, and then click **Remove**.

- With products in the Windows Server 2003 family, **Authenticated Users** does not by default contain anonymous users or guests. The **Everyone** group contains guests. As described in this procedure, it is recommended that you exclude **Everyone** from the list of groups for which permissions are assigned on the RIS image, and use **Authenticated Users** or a more restricted group for assigning these permissions. For more information about differences in default security settings for groups such as **Authenticated Users** (as compared to the settings in earlier operating systems), see Related Topics.

- If you leave **SYSTEM** but remove all other names from **Group or user names**, no one will be able to perform remote installations with this image.

- If you previously restricted permissions on the folder and subfolders containing the image, you must adjust those permissions, not just the permissions described in this procedure, to allow intended users to install the image. For instructions on how to do this, see the topic about allowing the viewing and installing of a RIS image in Related Topics.

- Setting permissions as described in this procedure affects the user's ability only to install a particular RIS image. For information about how to exert greater control and affect not only the user's ability to install a particular RIS image, but also the user's ability to see the files in that image, see Related Topics. To prevent confusion, once you have chosen a particular approach, it is recommended that you continue to use that approach whenever modifying permissions for images.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow or prevent the viewing and installing of a RIS image by a user or group

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow or prevent the viewing and installing of a RIS image by a user or group**

1. On the Remote Installation Services (RIS) server, open Windows Explorer.
2. Click the folder that contains the RIS folders and files. (The default name for the folder is RemoteInstall.)
3. Click the **Setup** folder.
4. Click the folder for the language of the installation image you want to confirm or change access to, and then click the **Images** folder.
5. Right-click the folder that contains the image that you want to confirm or change access to, and click **Properties**.
6. Click the **Security** tab.
7. For best security, if several names appear in **Group or user names**, and one of those groups is **Everyone**, click that group and then click **Remove**

   **Important**

   - The **Group or user names** box always includes **SYSTEM**. Do not remove this entry, and do not change the permissions on it. This entry is necessary for RIS.

8. Do one of the following:

   - In **Group or user names**, if you see the name of a group or user for whom you want to confirm or change access to a RIS image, click the name of the group or user.
   - In **Group or user names**, if you do not see the name of a group or user for whom you want to confirm or change access to a RIS image, click **Add**. Type the name of the group or user, click **OK**, and then click the name of the group or user.

9. Do one of the following:

   - To prevent the selected group or user from viewing and installing this image, click **Remove**.
   - To allow the selected group or user to view and install this image, under **Allow**, ensure that **Read & Execute**, **List Folder Contents**, and **Read** are selected.

10. When the list of group and user names and their permissions match the access you want to allow or prevent, click **Advanced**.
11. Select the check box marked **Replace permission entries on all child objects with entries shown here that apply to child objects**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

- This topic does not apply to Windows Server 2003, Web Edition.

- **Authenticated Users** appears by default in **Group or user names**. This means that all authenticated users can view and install a RIS image. To allow a more limited group (instead of all authenticated users) to view and install a RIS image, add the appropriate group and allow the permissions described in this procedure. Then click **Authenticated Users** and click the **Remove** button.

- With products in the Windows Server 2003 family, **Authenticated Users** does not, by default, contain anonymous users or guests. The **Everyone** group contains guests. As described in this procedure, it is recommended that you exclude **Everyone** from the list of groups for which permissions are assigned on the RIS image; then use **Authenticated Users** or a more restricted group for assigning these permissions. For more information about differences in default security settings for groups such as **Authenticated Users** (as compared to the settings in earlier operating systems), see Related Topics.

- If you leave **SYSTEM** but remove all other names from **Group or user names**, no one will be able to perform remote installations with this image.

- Using this procedure, you can control the user's ability to install a particular RIS image, as well as the user's ability to see the files in that image. You might want to exert less control, however. You can do this by changing permissions that, unless overridden by this procedure, affect the user's ability only to install (not see) a particular RIS image. For more information about this, see Related Topics. Once you have chosen a particular approach, it is recommended that you continue to use that approach whenever modifying permissions for images; this will help prevent confusion.

- If you prevent a user from viewing or reading the files in an image, you also prevent the user from installing the image.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set permissions for administrators who manage client installation images for RIS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions for administrators who manage client installation images for RIS**

1. Create a list of people who will manage user access to client installation images for Remote Installation Services (RIS). The list might include the same people who will manage accounts for prestaging for RIS.

2. Create a group account (or determine the name of the group account if it already exists), and make the people on the list members of the group.

3. On a computer from which you can set folder permissions for the RIS server containing the installation images that will be managed by the group, open Windows Explorer.

4. Right-click the folder that contains the RIS folders and files (the default name for the folder is RemoteInstall).

5. Click the **Setup** folder.

6. Click the folder for the language of the installation image that you want to set permissions for.

7. Click the **Images** folder.

8. Do one of the following:

   - If you want the group that you created to manage all images in the **Images** folder, right-click the **Images** folder and then click **Properties**.

   - If you want the group that you created to manage only certain images in the **Images** folder, right-click a folder that contains an image that you want the group to manage, and then click **Properties**.

9. Click the **Security** tab.

10. Do one of the following:

    - If the group you created for those who manage client installation images does not appear in the **Group or user names** box, click **Add**. Type the name of the group, and then click **OK**.

    - If the group you created for those who manage client installation images appears in the **Group or user names** box, click the name of the group.

11. In the **Permissions for User or Group** box, under **Allow**, make sure the **Full Control** check box is selected.

12. When the list of group and user names and their permissions match the access you want to allow or prevent, click **Advanced**.

13. Select the check box marked **Replace permission entries on all child objects with entries shown here that apply to child objects**.

14. If you have another folder for which you want to set permissions, navigate to the folder and repeat the process for

setting the permissions.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- This topic does not apply to Windows Server 2003, Web Edition.
- Consider using this procedure if there are people in your organization who manage accounts and permissions but do not configure other aspects of RIS. You can use this procedure to place those who manage accounts and permissions in a group such as Account Operators instead of putting them in a group such as Domain Admins or Enterprise Admins. For more information setting appropriate permissions for RIS administrators, see Related Topics.
- Managing user access to client installation images includes the following:
    - Associating an unattended setup answer file with an installation image
    - Allowing or preventing the installing of a RIS image by a user or group
    - Allowing or preventing the viewing and installing of a RIS image by a user or group
- For security reasons, set these permissions on the folder, as described in this procedure, not on the shared folder. Permissions on a folder are controlled by the NTFS file system, which provides greater security than permissions set on a shared folder.
- For information about creating a group or adding a member to a group, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remote Installation Services Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Remote Installation Services (RIS). It covers the following topics:

- Remote Installation Services overview
- Understanding Remote Installation Services
- Using Remote Installation Services
- Remote Installation Services Resources

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services overview**
Remote Installation Services (RIS) is a change-and-configuration-management feature that is included in the Microsoft® Windows Server 2003 family operating systems.

You can use RIS to provide on-demand, image-based, operating system installations. This occurs over a network connection from a RIS server to a client computer. RIS can simplify the management of operating systems and applications and improve failure recovery.

You can use RIS to do the following:

- Provide an operating system to users on demand. When a user starts a client computer, even if that computer contains no operating system, the RIS server can respond by installing an operating system over the network; no CD is required. To support this, client computers must use the Pre-Boot eXecution Environment (PXE), a remote-boot technology that allows the client computer to begin a boot sequence from the network adapter. For more information about the process through which RIS installs an operating system, see PXE architecture and Technologies and components used by Remote Installation Services.

- Provide operating system images that include specific settings and applications--for example, an image that complies with a corporate desktop standard. A particular group of users can be offered the image or images that you designate for that group. For more information, see Creating an installation image with RIPrep.

- Create automated installation images of products in the Windows Server 2003 family, as well as images of Windows XP and Windows 2000. For more information on the operating systems RIS supports, see Operating systems supported by Remote Installation Services.

In addition to using RIS in the ways already described, you can combine RIS with IntelliMirror features, such as user documents and settings, Software Installation, and Group Policy. This can improve the efficiency of computer management in your organization and reduce the number of technical support service calls. For more information about combining these features, see IntelliMirror.

For information on another alternative for starting a remote computer, see Emergency Management Services.

**Notes**

- RIS is not included in the Windows Server 2003, Web Edition operating system. For more information, see Overview of Windows Server 2003, Web Edition.

- This topic does not apply to Windows Server 2003, Web Edition.

# Understanding Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Remote Installation Services**
This section covers:

- Technologies used by Remote Installation Services to identify network computers
- Remote Installation Services Architecture

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Technologies used by Remote Installation Services to identify network computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Technologies used by Remote Installation Services to identify network computers**
Remote Installation Services (RIS) requires several supporting technologies that identify computers on the network. The following three technologies are included as components in the Windows Server 2003 family:

- Dynamic Host Configuration Protocol (DHCP)
- Domain Name System (DNS)
- Active Directory

DHCP and DNS need not be Microsoft versions to work with RIS. You must use the Microsoft version of Active Directory when using RIS, however. DHCP, DNS, and Active Directory can be installed (along with RIS) on one server or on several servers. (You are installing Active Directory when you make a server a domain controller.) Before adding RIS to a server that provides DHCP, DNS, or Active Directory, it is recommended that you consider server load and server performance.

RIS also depends on a unique identifier that computer manufacturers assign to each computer. This identifier, which is called the globally unique identifier (GUID), is also known as the universally unique identifier (UUID). As its name suggests, it gives each computer a unique identity. Each RIS client computer connects to the RIS server through the network and identifies itself by its GUID/UUID. To find a computer's unique identifier, see Locate the GUID for client computers.

When RIS detects a client computer's request for service, it responds in one of the following two ways, depending on how you have set up your network:

- A RIS server that you have designated for that client computer recognizes the client computer from its unique identifier and responds with the available installation choices.
- Any RIS server answers all network service requests from client computers.

For information on specifying how RIS responds to requests, see Remote Installation Services administration overview.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services Architecture

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services architecture**
This section covers:

- Technologies and components used by Remote Installation Services
- PXE architecture
- Remote Installation Services directory service planning
- Remote Installation Services system requirements
- Remote Installation Services boot disk
- Network service boot

For information about the sequence of steps through which you create an installation image by using the Remote Installation Preparation (RIPrep) Wizard, see Creating an installation image with RIPrep.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Technologies and components used by Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Technologies and components used by Remote Installation Services**

Remote Installation Services (RIS) uses or depends upon a variety of technologies and components.

**Network infrastructure**

RIS depends on a network infrastructure that can identify computers on the network. RIS therefore requires that DHCP, DNS, and Active Directory be available on the network.

**Remote-boot technology**

RIS uses remote-boot technology to allow a computer with no operating system to begin a boot sequence from the network adapter, after which an operating system can be installed across the network. This remote-boot technology is called the Pre-Boot eXecution Environment (PXE). For more information, see Network service boot and PXE architecture. For client computers that are not PXE-enabled--that is, pre-Net PC/PC98 computers--you can use a special remote boot disk if the client computer has a supported network adapter. For more information, see Remote Installation Services boot disk and Create a remote boot disk.

**Technology to create an installation image**

RIS includes technology that you can use to create an image of an operating system that will be installed on client computers. You can create the image in one of two formats: a flat image or a Remote Installation Preparation Wizard (RIPrep) image format. Use the flat image option to create an image directly from a set of operating system files-- for example, the files on a CD. Use the RIPrep image format to create an image that includes an operating system with specific settings and applications-- for example, an image that complies with a corporate desktop standard. For more information, see Add a new client operating system installation image and Creating an installation image with RIPrep.

**Technologies for communication between RIS client and server**

RIS includes technologies that establish communication between a client that has begun a PXE boot sequence and the RIS server that contains installation images available to that client. For this process, RIS uses DHCP to provide the client with an Internet Protocol (IP) address. RIS then downloads the Client Installation Wizard, which prompts the user to log on and provides a menu of installation options customized for that user. You can control these images through Group Policy. For more information about the Client Installation Wizard, see Client Installation Wizard and Installation options available through RIS.

**Services added by RIS**

When RIS is enabled, the following services are automatically added to the server:

- **Remote Installation (BINLSVC)**

  This service listens for client network service requests and provides overall management of the RIS environment. BINLSVC ensures that the correct files are passed to the client computer. It also ensures that when the settings for a prestaged client specify that it is to be answered by a particular RIS server, the response comes from the specified server. If the client computer has not been prestaged, BINLSVC creates the client computer account object within Active Directory.

- **Trivial File Transfer Protocol Daemon (TFTPD)**

  RIS server uses the Trivial File Transfer Protocol Daemon (TFTPD) to download the initial files required for the remote installation process to begin. The most common file downloaded to the client using TFTPD is Startrom.com, which is responsible for bootstrapping the client computer. The default version of Startrom.com then prompts the user to press F12 to initiate a network installation. If the user responds to the prompt, the Client Installation Wizard is downloaded to begin the remote installation process.

- **Single Instance Store (SIS)**

  Single Instance Store (SIS) reduces the overall storage required on the RIS volume. The SIS drivers contain a feature,

called a groveler agent, that scans the RIS volume for duplicate files. If the SIS groveler finds duplicate files, it copies the original file into the SIS and leaves a link file in its place. The link file contains information about the original file, such as its current location, size, and attributes. If an image contains duplicate files, those duplicates are copied into the store; as a result, less disk space is required on the RIS server.

SIS has two limitations: it cannot act upon any files that are referenced through junction points, and it cannot be used with any file system except NTFS file system, which is the file system to use on RIS servers.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# PXE architecture

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PXE architecture**

Remote Installation Services (RIS) uses the Dynamic Host Configuration Protocol (DHCP) that follows the Pre-Boot eXecution Environment (PXE) architecture to bootstrap a client computer.

When a new PXE remote boot-enabled client computer starts for the first time, it uses the DHCP to request an Internet Protocol (IP) address and the IP address of an active RIS server. As part of the initial request, the client computer sends out its globally unique identifier (GUID), which identifies the client computer within Active Directory.

After the client computer receives an IP address from the DHCP server, it then requests service from a RIS server. The request to the RIS server is a broadcast, which means all of the RIS servers on the network will receive the request. If the RIS server is allowed to answer, it queries its preferred domain controller for the client computer's GUID. If the server fails to find the GUID, it queries the global catalog for the forest. If the GUID is found in either location, the client computer is considered "known." If the GUID is not found, it is considered "unknown." In this case --that is, the query by the RIS server found no computer account object in Active Directory with this computer's GUID --only RIS servers that are configured to answer unknown clients will do so.

If the client is known, all the available RIS servers query the domain to determine whether the client computer account has been prestaged with settings that specify that the client computer is to be answered by a particular server. If so, only the designated server answers the service request. The other servers respond by telling the client which server will answer it. This is called a referral. If the client computer account settings do not require the client computer to be answered by a particular server, all RIS servers answer it if they are aware of this client and configured to answer it. Each RIS server then offers its own files to download.

For information on configuring how RIS servers respond to client computers, see Configure Remote Installation Services. For information on prestaging clients computers and configuring the setting that specifies whether the client computer is to be answered by a particular server, see Prestage client computers.

After the client computer receives a reply to its service request, it initiates a Trivial File Transfer Protocol (TFTP) download of the bootstrap program. The Remote Installation Services implementation of this program is called Startrom.com (located at *RIS_server_name*\REMINST\oschooser\i386\startrom.com).

After Startrom.com has been downloaded, the client computer runs it. The default version of Startrom.com then prompts the user to press F12 to initiate a network installation. If the user fails to press F12 within three seconds, the network boot is stopped, and the client computer attempts to start up from the next available boot device. When the user presses F12, the client computer uses TFTP to download the Client Installation Wizard. The wizard then requests the user to log on to the network. For more information about user choices available during remote installation, see Perform a network installation using RIS and Installation options available through RIS.

For information about security limitations related to the PXE standard, see PXE architecture, RIS, and security considerations.

**Considerations for 64-bit client computers**

For 64-bit client computers, Startrom.com is not required and the F12 prompt is not provided to the user. The 64-bit client computer simply downloads the Extensible Firmware Interface (EFI) version of the Client Installation Wizard (located at *RIS_server_name*\REMINST\oschooser\ia64\oschoice.efi) when the user selects a remote installation option during computer startup.

The 64-bit client computers can request service from RIS servers even if the servers are configured not to answer clients. These client computers can request service if they have received a referral from one of the other RIS servers in the same forest.

### Note

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services directory service planning

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services directory service planning**
The Remote Installation Services (RIS) environment relies on a well-designed and well-planned Active Directory architecture. Normally, determining the physical location of a server can be a challenge. This can become even more difficult when you must find and configure several servers that are located in different buildings, different offices, or on different floors. Using Active Directory, however, can simplify this process.

In a given domain, Active Directory provides organizational units or containers that you can use to organize users and resources into logical administrative groups. This makes it easier to locate and configure servers at multiple locations. For more information on planning Active Directory architecture, see Organizational units.

You can verify a RIS server using the **Verify Server** command, which is available only locally on a RIS server or by connecting to that server through Remote Desktop for Administration. The computer account object is located in the Computers container when the RIS server is a member server of a domain. For performance reasons, it is recommended that you install RIS on a member server, not a domain controller. For more information, see Verify the Remote Installation Services configuration.

To manage a RIS server from a computer running Windows XP, install the Windows Server 2003 Administration Tools Pack on the computer running Windows XP. For more information, see Windows Server 2003 Administration Tools Pack.

To manage a RIS server from any remote computer, use Remote Desktop for Administration. For more information, see Using Remote Desktop for Administration for remote server administration.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services system requirements

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services system requirements**
This section describes the system requirements for Remote Installation Services (RIS) servers, client computers, and network adapters.

**Server hardware requirements**

- The server hardware must meet minimum requirements for the product version of the Windows Server 2003 family that you are installing. For example, if you are installing Windows Server 2003, Enterprise Edition, your computer must meet the minimum requirements for this product. For more information, see Windows Server 2003, Enterprise Edition: System requirements.
- 4-gigabyte (GB) or larger disk drive for RIS server folder tree.
- 10 or 100 Mb/sec Windows-compatible network adapter that supports TCP/IP (100 Mb/sec recommended). A RIS server cannot be a multihomed computer; that is, it can contain only one network adapter.

**Client computer hardware requirements**

- The client computer must meet the minimum requirements for the operating system that is to be installed.
- Pre-Boot eXecution Environment (PXE) DHCP-based boot ROM version 1.00 or greater.

**Supported client network adapters**
To obtain a list of network adapters that RIS supports, run the Rbfg.exe utility. For additional information, see Create a remote boot disk.

**Additional considerations**

- RIS requires a significant amount of disk space. You should dedicate an entire partition to the RIS folder tree.
- RIS cannot be installed on the same partition as the system volume or boot volume.
- The volume on which you install RIS must be formatted with the NTFS file system.
- RIS does not currently support the Encrypting File System (EFS). The Distributed File System (DFS) is not supported as a target location; however, you can run RIS on a computer that is also running DFS.
- Windows Catalog contains a compilation of systems and hardware that have been extensively tested for stability and compatibility with products in the Windows Server 2003 family. The information in Windows Catalog is the guide Microsoft Product Support Services uses to determine whether a system is supported for use with the Windows Server 2003 family. For more information about hardware compatibility, see Support resources.

### Note

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services boot disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services boot disk**
The Remote Installation Services (RIS) boot disk is used with client computers that do not have a remote boot-enabled ROM. The boot disk simulates the Pre-Boot eXecution Environment (PXE) boot process for computers that lack a formal remote boot ROM. For more information about the PXE boot process, see PXE architecture.

The boot disk is analogous to a boot ROM, which uses the floppy drive to install the operating system from the RIS server. The remote boot disk-generating utility (Rbfg.exe) is located in the following folder:

*Server_name*\REMINST\Admin\I386\Rbfg.exe

The boot disk must be placed before the hard disk in the boot sequence in order for the boot disk to work.

To use the remote boot disk on a client computer that does not have a remote boot-enabled ROM, insert the disk into the disk drive and start the client computer. The client computer must have a Peripheral Component Interconnect (PCI)-based network adapter from the list of specific adapters supported. To determine which network adapters RIS supports, use the boot disk-generating utility. For more information, see Create a remote boot disk.

For more information about performing a client installation, see Perform a network installation using RIS.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Network service boot

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network service boot**
A network service boot can be initiated by either the user of a Pre-Boot eXecution Environment (PXE) remote boot-enabled client computer or by a special remote boot disk provided for pre-Net PC/PC98 computers.

To invoke the network service boot request, the user presses a particular key (for example, F12) when prompted during the client computer startup sequence. The client computer receives an Internet Protocol (IP) address from the DHCP server, requests a network service boot, and then downloads the Client Installation Wizard.

For more information about how a remote service boot is carried out through PXE, see PXE architecture.

For more information about user choices and actions during a network service boot, see Perform a network installation using RIS.

The user is prompted for user name, password, and domain name during the initial phase of the Client Installation Wizard process. Remote Installation Services uses Group Policy within Active Directory to determine which installation options are appropriate for the user. The user is then given a list of operating system installation choices that are determined by the user's credentials or security group membership.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Using Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Remote Installation Services**
This section covers:

- Remote Installation Services server authorization
- Running the Remote Installation Services Setup Wizard
- Using Risetup from the command line
- Remote Installation Services administration overview
- Creating an installation image with RIPrep
- RIS client computer properties
- Security Information for Remote Installation Services
- Advanced Configuration Settings
- The Remote Installation Process

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services server authorization

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services server authorization**
The Remote Installation Services (RIS) server authorization feature prevents unauthorized RIS servers from being added to a network where Active Directory is in use.

You can use RIS to specify which RIS servers can accept and process requests, and which RIS servers can only service clients on the network. Before a RIS server can accept requests, it must be authorized to run in Active Directory. To authorize a RIS server in Active Directory, you must first log on with an account that is a member of the **Enterprise Admins** group in the domain where you want the RIS server to be authorized. You should run **RISETUP -Check** to authorize the server.

When a RIS server attempts to start on the network, Active Directory is queried and the Internet Protocol (IP) address is compared to the list of authorized RIS servers. If a match is found, the RIS server is authorized and can start on the network. If a match is not found, the server is not authorized. In this case, RIS will not answer.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Running the Remote Installation Services Setup Wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Running the Remote Installation Services Setup Wizard**

Before running the Remote Installation Services Setup Wizard, you must ensure that you have an account in the Administrators group on the server on which you want to run the wizard. You should also be sure to complete all prerequisite steps outlined in Checklist: Installing Remote Installation Services.

You can select Remote Installation Services (RIS) as an optional component after completing Setup. To do this, use Add or Remove programs in Control Panel. You can also install RIS during Setup if Setup is run using an unattended answer file. In this case, after you have selected RIS, the Setup Wizard guides you through the necessary steps of installation and configuration. For complete instructions on installing RIS, see Install Remote Installation Services.

The Setup Wizard presents the following options:

- The first time the wizard is run, you will be prompted for a location for the \RemoteInstall directory tree. This location must be on an NTFS file system volume and cannot be on the system volume or boot volume.

- **Respond to client computers requesting service**

  Select this option to enable the RIS server to begin responding to client computers. Clear this option to prevent the RIS server from responding.

- **Do not respond to unknown client computers**

  Select this option if you want this RIS server to respond only to known (prestaged) client computers. Clear this option if you want this RIS server to respond to any client computer requesting remote installation.

  Prestaging can be one element of your security strategy for RIS. This is because you can use prestaging to prevent unknown client computers from being installed through RIS. For information about security considerations related to PXE architecture and RIS, see PXE architecture, RIS, and security considerations.

- The Setup Wizard prompts you for the location of the installation files. This can be either the compact disc or a network location that contains the installation files.

- The Setup Wizard prompts you for a directory name to which the installation files should be copied on the RIS server. You should name the directory something that represents the operating system you are copying--for example, WindowsXP.pro.

- The Setup Wizard prompts you for a friendly description and Help text describing this operating system installation image. The friendly description and Help text is displayed to users during the client installation process on a remote boot-enabled client computer. Enter a description of the operating system installation choice. One example of a friendly description would be "Windows XP Professional for Sales Staff." The Help text is displayed when the user selects the friendly description within the Client Installation Wizard.

- The Setup Wizard displays the summary information of the setup process. To change any of this information, click **Back**.

**Note**

# Using Risetup from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Risetup from the command line**
With Risetup, you can manage a server running Remote Installation Services (RIS) from the command line. You can use Risetup to add new installation images or to verify a server and ensure that it is running properly.

To run Risetup, at a command prompt, type:

**risetup**

For complete information on using Risetup, see Risetup.

For information about other command-line utilities, see Command-line reference A-Z.

For background information about RIS, see Remote Installation Services Concepts.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Risetup

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Risetup**

Manages a server running Remote Installation Services (RIS). Adds new installation images or verifies a server to ensure that it is running properly.

**Syntax**

risetup [-add] [-check] [/auto *FileName.inf*]

**Parameters**

| Parameter | Explanation |
|---|---|
| -add | Adds a new installation image to the Remote Installation Services (RIS) server. |
| -check | Verifies that the server is functioning properly. Also, runs only the server portion of Risetup, which resolves most problems related to a RIS server that is not running properly. |
| /? | Displays help at the command prompt. |
| /auto *FileName.inf* | Configures the server in an unattended manner as defined by *FileName.inf*. The path to the folder location of the .inf file must be under 255 characters.<br><br>The following table lists the lines of an example .inf file and explains each line: |

| Lines in the example .inf file | Requirement and explanation |
|---|---|
| `[Version]Signature = "$Windows NT$"` | Required. Heading and version line. |
| `[Risetup]` | Required. Heading. |
| `RootDir = "f:\RemoteInstall"` | Required. Drive and folder that contain the Remote Installation files and folders. You must include this line every time RISetup is run. If RIS is already installed, the path must remain unchanged from the current path for the RIS installation. The maximum number of bytes is 127. |
| `Source ="e:\"` | Required. Path to the source CD or shared folder from which to create an installation image. The maximum number of bytes allowed for this line is 260. For information about the supported operating systems for this type of image (a flat image), see Related Topics. |
| `Directory = "Windows_XP_Pro"` | Required. Directory in which to place the new installation image. The maximum number of bytes is 39. |
| `Description = "Windows XP"` | Required. Short description of the installation image. The maximum number of bytes is 65. |
| `HelpText = "For English-speaking users."` | Required. Long description of the installation image. The maximum number of bytes is 260. |
| `Screens = "overwrite"` | Required. Action to perform on existing .osc files, which contain text that displays in screens seen by users of the Client Installation Wizard. Specify only one of the following choices:<br><br>"overwrite"<br><br>"backup"<br><br>"leavealone" |

| | |
|---|---|
| `Architecture = "x86"` | Required. Can be one of:<br>• **x86** for an image that will be installed on x86 computers<br>• **ia64** for an image that will be installed on Itanium-based computers.<br>• **amd64** for an image that will be installed on x64-based computers. |
| `Language = "English"` | Required. Language of the image. |

**Examples**

To reauthorize the RIS server in Active Directory, type:

**RISETUP -Check**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Remote Installation Services administration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Installation Services administration overview**
To administer Remote Installation Services (RIS), you use the property pages that reside on specific objects within Active Directory.

To access the property pages, right-click the server object you want to administer, and then click **Properties**. For more information on configuring RIS, see Configure Remote Installation Services.

You can set the following options from the **Remote Install** property page:

**Client servicing**

You can specify either that servers respond to all clients requesting service, or that they respond only to known (prestaged) clients. Use the following options to specify how the RIS server responds to requests for service from client computers:

- **Respond to clients requesting service.** If you select this option, RIS is enabled and will respond to client computers requesting service.

- **Do not respond to unknown client computers.** If you select this option, the RIS server responds only to prestaged client computers in Active Directory. Otherwise, the RIS server responds to any client computer requesting remote installation.

For more information about prestaging, see Prestage client computers.

**Verify Server**

Select this option if the server seems to be failing or is behaving inconsistently, or if you need to restore a RIS volume from backup. This option brings up a wizard that checks to determine whether all of the settings, services, and configuration options are correctly set and functioning.

Before you select this option, make sure you have the installation compact discs available. You might be prompted for them during the Verify Server procedure.

You can only use Verify Server locally on a RIS server, or by connecting to that server through Remote Desktop for Administration. You cannot use Verify Server if you are performing RIS administration tasks from a remote server.

For more information, see Verify the Remote Installation Services configuration.

**Important**

- If you are verifying the server configuration because you need to restore a RIS volume from backup, you must verify the server configuration before you restore the volume.

**Show Clients**

If you select this option, you can search for RIS clients within Active Directory.

Selecting this option displays a list of client computers sorted by their globally unique identifier (GUID). The list also includes client computers that have been prestaged.

For more information, see RIS client computer properties.

**Advanced Settings**

If you select this option, you can control how a client computer is installed. The advanced setting options are as follows:

- **Automatic client computer account naming format**

- **Active Directory location of client computer accounts**

- **Manage the installation images and pre-operating system maintenance tools installed on this RIS server**

For more information, see Advanced Configuration Settings.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Creating an installation image with RIPrep

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating an installation image with RIPrep**

With the Remote Installation Preparation (RIPrep) Wizard, you can create an image of an existing installation and replicate that image to an available Remote Installation Services (RIS) server on the network. To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. You must also have permission to write to the RIS folders on the RIS server (the default name for the folder that contains all the RIS folders is RemoteInstall).

One way to ensure that you have permission to write to the RIS folders on the RIS server is to be explicitly assigned the permission. Another way is to have membership in the local Administrators group on the RIS server. For more information, see Default local groups and Default groups.

1. It is recommended that you start by using RIS to install the operating system that you have chosen for the installation image. RIPrep can be used to create images only for the particular operating systems it supports, however. For complete information on which operating systems RIPrep supports, see Operating systems supported by Remote Installation Services.

   It is not necessary to install the operating system using RIS; you can install it from the CD instead.

2. After you have installed the operating system, you should install the client computer applications that you want to deploy with clients.

   **Important**

   - If you want to install applications that do not comply with the Windows Installer technology, this is the step at which you should do so. You can also install applications that do comply with the Windows Installer technology.

3. After you have installed the appropriate client computer applications, you should configure the source computer to conform to any required company desktop standards. For example, you might want to define specific screen colors, set the background bitmap to a company-based logo, remove any games installed by the base operating system, or configure Internet Explorer proxy settings. To save your desktop configuration, copy to the Default User profile the profile of the user who was logged in while the configuration changes were made. For instructions on how to copy user profiles, see Copy a user profile.

   **Important**

   - Before starting the Remote Installation Preparation Wizard, be sure to remove all confidential information from the source client computer.

4. You should then close all applications and run the Remote Installation Preparation Wizard. For more information, see Create a Remote Installation Preparation Wizard image.

5. The wizard configures the source computer to a generic state, removing anything that is unique to the client installation, such as the computer's unique security identifier (SID), computer name, and any registry settings unique to the client source computer.

6. The wizard then prompts you for the installation information required by the image-creation process. This information includes the location where the client installation image should be replicated, the name of the directory it should be copied to on the server, and a friendly description and associated Help text that will describe the installation image to users who run the Client Installation Wizard.

Because of memory limitations during the remote boot process, there are limits to the total text you can provide for a set of installation image choices. With a relatively large number of installation image choices, the friendly descriptions and Help text must be limited in length; with fewer choices, the friendly descriptions and Help text can be longer. It is not unusual to encounter these limits to total text when the number of installation image choices for client computers reaches approximately 12 to 16.

7. After the replication is complete, the installation image is automatically added to the list of available operating system installation options and is available to client computers that use the remote boot technology. When you create new images using RIPrep, the image is available only to client computers that have the same type of Hardware Abstraction Layer (HAL). Images that were created using RIPrep are available to all clients that are authorized to view them.

   **Note**

   - A remote boot-enabled client computer need not contain hardware that is identical (other than the HAL) to that of the source computer used to create the installation image. The Remote Installation Preparation Wizard uses the Plug and Play feature to detect any differences between the source and destination computers' hardware during the image installation process. This ensures that, for any Plug and Play device, the correct device driver is installed.

8. You can control the installation choices available to clients by setting access control permissions on the installation image .sif files or, for greater control, on the folders that contain the installation image. For more information, see Allow or prevent the installing of a RIS image by a user or group and Allow or prevent the viewing and installing of a RIS image by a user or group.

**Factors to consider when planning for RIPrep**

The following sections describe factors to consider when planning to create an installation image with RIPrep. These include:

- Requirements for the RIPrep replication process
- Installation images, the product identification number, and licensing
- Disk characteristics on the source client computer and the destination computers

**Requirements for the RIPrep replication process**

When planning to run RIPrep, it is important to understand requirements that must be met by the source client computer, the image, and the medium onto which the image is replicated.

- The Remote Installation Preparation Wizard currently supports the replication of a single disk and a single boot partition of an installation to a single RIS server. This means that the operating system and all of the applications that make up the standard installation image must reside on a single partition of the source client computer.
- The files on the source client computer must not be encrypted. Replication of encrypted files is not supported.
- Modifications to replicated installation images are not supported.
- The wizard allows source image replication only to available RIS servers. Currently, source replication to alternate drives or media types is not supported.

**Installation images, the product identification number, and licensing**

- When you use the Remote Installation Preparation Wizard (RIPrep) to create an installation image of a client computer that was originally installed using a retail version of the operating system, you must modify the RIS unattended setup answer file (sif) to include the product identification number (PID). The PID is the unique identification number specific to each copy of the operating system.

  If the PID is not entered in the .sif file, the installation process will stop and prompt the user for the product identifier

information during the installation of that RIPrep image. To prevent prompting your users for the PID, add the product identifier to the [UserData] section of the .sif file associated with this installation image.

For example, you would type the following (including the dashes and quotation marks) into the [UserData] section of the .sif file:

**ProductKey = "xxxxx-xxxxx-xxxxx-xxxxx-xxxxx"**

For more information about product activation, see Windows Product Activation.

- The source client computer will shut down when the image replication process is complete. The abbreviated Setup program runs automatically when the source computer restarts. You must complete the setup process if you want to use this client computer to create another installation image. You can create additional installation images only three times if you are using a Retail PID. A volume licensing PID permits you to create installation images more than three times, however.

- All copies of Microsoft software made or installed using RIS must be properly licensed. All copies of non-Microsoft software made or installed using RIS must also be properly licensed; it is the licensee's obligation to ensure that non-Microsoft software is licensed to make any such copies.

**Disk characteristics on the source client computer and the destination computers**

When planning to run RIPrep, it is important to study the disk configuration that exists on the source client computer and then compare it to the disk configurations on the client computers on which the image will be installed. The following requirements apply:

- The destination computer's disk capacity must be equal to or greater than that of the source computer.

- The RIPrep installation image maintains the volume and partition characteristics of the disk on the source computer.

  The following example illustrates this, but describes the use of the file allocation table (FAT) and FAT32 file systems, which are not recommended. The recommended file system for RIS is the NTFS file system. The example is as follows. If you create an installation image from a source computer with a 2-gigabyte (GB) FAT volume, and you then install the image on a client computer with a 4-GB drive, the resulting installation will format the drive as a 4-GB volume using FAT32. The change in the destination computer file system type is dictated by the limits of the FAT file system. This type of change in the destination computer file system type (from FAT to another file system) does not work if the destination volume is larger than 32 GB. For destination volumes larger than 32 GB, the source computer must use the NTFS file system. For more information about file system compatibility and limitations, see Choosing a file system: NTFS, FAT, or FAT32.

- Disk preparation of the destination computer must be identical to that of the source computer; any remaining disk capacity on the destination computer will be formatted unless you follow the instructions in the next item in this list. For example, if the source computer's disk capacity is 1 GB and the disk capacity of the destination computer is 2 GB, the entire 2 GB will be formatted on the destination computer.

- You can change the information in the .sif file associated with an installation image to restrict the disk reformatting so that it will be the same as that which the source computer used to create the installation image. For example, open the Riprep.sif file located in the *Server_name*\REMINST\Setup*Applicable language*\Images*Applicable image name*\I386\Templates\Riprep.sif folder and modify the **UseWholeDisk** parameter to equal **NO**. When a client computer installs this image, the disk will be formatted to match the capacity of the source computer, and the remainder of the destination computer's disk will be unformatted.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# RIS client computer properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**RIS client computer properties**

Remote Installation Services (RIS) uses property pages to contain information about RIS client computers. For information about viewing a list of client computers, see Find RIS client computers. To view or change information about RIS client computers, you can right-click a client listing, and then click **Properties**.

**The computer's unique identifier (GUID)**

One important property that appears on the property pages is the computer's globally unique identifier (GUID), also known as the universally unique identifier (UUID). The RIS server uses this identifier to locate a client computer. The following list provides more details about the GUID:

- The GUID is supplied by the client computer manufacturer. For information about how to find the GUID on a computer, see Locate the GUID for client computers.

- When you enter a GUID, you usually enter it in the display format, {*dddddddd-dddd-dddd-dddd-dddddddddddd*}, where *d* is a hexadecimal text digit. There are 8 digits before the first hyphen, 4 digits in each of the next three groups of digits, and 12 digits after the last hyphen. This is illustrated in the following example:

  {67452301-AB89-EFCD-0123-456789ABCDEF}

- The GUID uses only hexadecimal text digits and hyphens; that is, the characters in the following list (not case sensitive):

```
0 1 2 3 4 5 6 7 8 9
a b c d e f - A B C D E F
```

- Do not type spaces in a GUID.

- The GUID can also be entered in wire format. In a GUID in wire format, the initial 16 digits are transposed as compared to a GUID in display format. The following example compares wire format to display format:

  GUID in wire format: 0123456789ABCDEF0123456789ABCDEF

  Same GUID in display format: {67452301-AB89-EFCD-0123-456789ABCDEF}

**Finding client computers**

Each client computer is identified by its GUID. In Active Directory, you can use the Show Clients feature to display a list of client computers sorted by their GUIDs. The list includes client computers that have been prestaged. The search can be conducted over the entire Active Directory structure or limited to a specific domain. (For more information on GUIDs, see Locate the GUID for client computers and Prestage client computers.)

The Show Clients search process appends a wildcard search attribute to the current RIS server computer name. For example, if the RIS server is named RISsvr1, the Show Clients feature will use RISsvr1* for the server name.

When you use the Show Clients feature in multiple RIS server environments, the search results might include client computers from multiple servers. For example, if you have multiple RIS servers with computer names such as RISsvr1, RISsvr10, and RISsvr100, and you search for RISsvr1, the list will display the client computers that install from all three servers.

For more information about searching Active Directory for RIS client computer accounts, see Find RIS client computers.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Security Information for Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security information for Remote Installation Services**
This section provides background information about the following security topics:

- PXE architecture, RIS, and security considerations
- Choosing appropriate group memberships for RIS administrators
- Setting the LAN Manager Authentication Level on a network that includes RIS

For specific information on how to set permissions and user rights for Remote Installation Services (RIS), see Manage Security for Remote Installation Services.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# PXE architecture, RIS, and security considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PXE architecture, RIS, and security considerations**
The Pre-Boot eXecution Environment (PXE) architecture used by Remote Installation Services (RIS) presents some security risks that are inherent in PXE due to its design. PXE is an industry standard, so any remote-installation method that uses PXE carries the same risks.

These security risks include the following:

- PXE does not provide a way to prevent an unknown server from performing remote installations on PXE-enabled client computers. If a server can establish a connection with the clients, it can perform remote installations on them.

- PXE does not provide a way to fully prevent packet spoofing. This means that packets sent by an attacker could be received by a client computer and incorporated into that client computer's installation.

- PXE does not provide a way to prevent an unknown PXE-enabled computer from installing from a server if the PXE-enabled computer can connect to the network. RIS provides some security not inherent in PXE, however, because RIS performs remote installation only after the user has logged on. A user who lacks a valid user name and password cannot use RIS to perform an installation.

  In addition, you can achieve a somewhat greater degree of security with RIS if you prestage your client computers and configure your RIS servers to respond only to known (prestaged) clients. Then, if an intruder succeeds in connecting an unknown, PXE-enabled client computer to your RIS server, no installation files will be sent to that client computer. The intruder will not gain information about the configuration you use on your RIS client computers. For more information about prestaging, see Prestage client computers.

Because of these security issues, it is recommended that you place protections around any network that contains PXE-enabled client computers.

You can take steps, such as those described in the following list, to ensure that computers controlled by people outside of your organization cannot make a connection to PXE-enabled clients:

- Use a firewall, and configure it appropriately.

- Use appropriate auditing and monitoring to detect intrusions into the network.

- Restrict physical access to the network.

- Use strong passwords throughout your organization.

- Follow other best practices for secure networks.

For more information about the preceding recommendations, see Best practices for security for security and also the Best practices for installing and upgrading the operating system topic in Getting Started.

For information about the sequence of events that occurs when a client computer is started with PXE, see PXE architecture.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Choosing appropriate group memberships for RIS administrators

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Choosing appropriate group membership for RIS administrators**

If there are people in your organization whose responsibilities include configuring Remote Installation Services (RIS) servers and creating installation images, make those people members of an administrative group such as Domain Admins or Enterprise Admins. This will allow them to carry out all RIS configuration tasks. For the single task of completing installation of a RIS server in a way that authorizes the RIS server in Active Directory, membership in Enterprise Admins is required. For more information about authorization, see Remote Installation Services server authorization.

Administrators in your organization should also be provided with user accounts that are not in any administrative group. With such accounts, administrators can follow the security best practice of logging on as a user and then using Run as to perform administrative tasks. For more information, see Using Run as and Create a shortcut using the runas command.

Whenever possible, choose group memberships and assign permissions in a way that provides only necessary access to domain accounts and resources. For example, perhaps there are people in your organization whose responsibilities include managing accounts and permissions, but do not include configuring RIS servers or creating client installation images. Instead of giving these people membership in a group such as Domain Admins or Enterprise Admins, give then membership in a group such as Account Operators and grant them permissions for folders on the RIS server. For more information, see Default local groups and Default groups.

The following table illustrates the group membership and permissions required for people who manage only the tasks of RIS related to permissions, computer accounts, and user accounts:

| **Tasks** | **Permission or group membership required for the administrator who performs those tasks** |
|---|---|
| Managing client installation images, including:<br>• Associating an unattended setup answer file with an installation image.<br>• Allowing or preventing the installing of a RIS image by a user or group.<br>• Allowing or preventing the viewing and installing of a RIS image by a user or group.<br><br>For more information about these tasks, see:<br>• Manage Security for Remote Installation Services | Full Control on the **Images** folder, or on one or more subfolders within the **Images** folder.<br><br>For more information, about setting this permission, see:<br>• Set permissions for administrators who manage client installation images for RIS |

| | |
|---|---|
| Managing accounts in domains where prestaging is used, including:<br>• Prestaging client computers.<br>• Setting permissions required by RIS users who use prestaged client computers.<br>• Removing an account for a computer that is no longer being prestaged.<br><br>For more information about these tasks, see:<br>• Prestage client computers<br>• Set permissions required by RIS users who use prestaged client computers | Membership in Account Operators.<br><br>For more information, see:<br>• Default groups<br>• Add a member to a group |

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Setting the LAN Manager Authentication Level on a network that includes RIS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Setting the LAN Manager Authentication Level on a network that includes RIS**

You can use the LAN Manager Authentication Level to set a level that specifies whether certain authentication protocols are available for network communication. When a user logs on at a RIS client, Remote Installation Services (RIS) uses either the first version of the NTLM authentication protocol or the second version, NTLMv2. Of the two protocols, NTLMv2 is significantly more secure because of the way it handles encryption keys.

For information about choosing the most appropriate LAN Manager Authentication Level in a network that includes RIS, see the table that appears later in this topic. For information about the different levels and how to view or change the setting, see Network security: LAN Manager authentication level.

When you set the LAN Manager Authentication Level, you should consider both your requirements for network security and your requirements for using a variety of operating systems. If you select the highest level (**Send NTLMv2 response only\refuse LM & NTLM**), only NTLMv2, the more secure protocol, is used; all computers involved in authentication must run software that supports NTLMv2. If you select a lower level (**Send NTLM response only**), NTLMv2 is used whenever possible, and NTLM is used only when required--that is, when one or more computers involved in authentication do not support NTLMv2.

The LAN Manager Authentication Level that is most appropriate depends upon which operating system is installed on the domain controllers, on the RIS servers, and on the clients you want to install. The following table provides criteria you can use to determine the appropriate LAN Manager Authentication Level.

| Criteria for "Send NTLM response only" | Criteria for "Send NTLMv2 response only\refuse LM & NTLM" |
|---|---|
| **Domain controllers: any**<br><br>Domain controllers can include those running a Windows 2000 Server operating system without a specific service pack. They do not have to be limited as described in the other column of this table. | **Domain controllers: run either a Windows 2000 Server operating system with a specific service pack, or they run a Windows Server 2003 operating system.**<br><br>In order to work with this authentication level, domain controllers must run either a Windows 2000 Server operating system with a specific service pack, or they must run a Windows Server 2003 operating system. For information about the service pack required in order to run a Windows 2000 Server operating system with this authentication level, search the Knowledge Base at the Microsoft Web site.<br><br>In addition, RIS servers and clients must also meet the requirements in this table. |
| **RIS servers: any**<br><br>RIS servers can include those that run Windows 2000. They do not have to be limited to those running Windows Server 2003. | **RIS servers: run Windows Server 2003 only**<br><br>In order to work with this authentication level, all RIS servers must run Windows Server 2003. **Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Advanced Configuration Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Advanced configuration settings**
The advanced configuration settings of Remote Installation Services (RIS) determine how RIS creates client computer names, manages operating system images, and manages diagnostic tool applications.

This section covers:

- Advanced settings for new clients
- Advanced settings for installation images
- Maintenance and troubleshooting tools and options
- Computer names

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Advanced settings for new clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Advanced settings for new clients**

You can use the advanced settings of Remote Installation Services (RIS) to configure settings for new clients. With advanced settings, you can define a policy that provides each remote installation client computer with a name that is unique on the network. For information on how to do this, see Computer names.

You can use advanced settings to determine the default directory service container in which the client computer machine account objects will be stored. You can also group client computers within a specific Active Directory domain or organizational unit.

A user setting up the client computer and using advanced settings must have the appropriate user rights to create computer accounts within Active Directory. For more information, see Allow a user or group to create a RIS managed computer account in the domain.

**Computer account location**

This option is available in advanced settings. Use it if you want to define the default Active Directory container for all remote installation client computer accounts prior to installation. To specify a location, select one of the following:

**Default directory service location**

Specifies that the client computer account object is created in the Computers container by default during the domain join operation. The client computer becomes a member of the same domain as the RIS server installing the client.

**Same location as that of the user setting up the client computer**

Specifies that the client computer account object is created within the same Active Directory container as the user setting up the computer. For example, if a user logs on whose user account currently resides within the Users container, the client computer account is also created within the Users container.

**The following directory location**

With this option, you can predetermine where client computer account objects are created in Active Directory. This option affects all client computers installed from this server.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Advanced settings for installation images

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Advanced settings for installation images**
You can use Remote Installation Services (RIS) to manage the operating system installation options for RIS users. During the base installation of RIS, you are prompted to add a default operating system installation image to the remote installation-enabled server. This image installation process copies the compact disc contents and directory structure to the RIS server.

The unattended installation process uses text files--which are called setup information (.sif) files --to store the configuration settings for the installation image. The information contained in the .sif file is processed each time a client computer uses the Client Installation Wizard to choose the installation image. By modifying the .sif file for the installation image, you can predetermine the configuration settings for each client installation image. For example, if all of your client computers have the same type of display devices, you can set the screen resolution prior to installation by modifying the [Display] information of the .sif file. For more information on unattended Setup, see the Microsoft Windows Preinstallation Reference, located in \Support\Tools\deploy.cab on the CD for products in the Windows Server 2003 family.

**Important**

- The information you put in the [ImageType] field of the .sif file is limited to 64 bytes. If you put in more than 64 bytes, the installation will fail.

For additional information about ways you can use .sif files, see Installation options available through RIS.

If you are creating an installation image using the Remote Installation Preparation Wizard (RIPrep), you can also use a .sif file to change how the client computer disk drive is partitioned. While the Client Installation Wizard is running, the installation image that the user selects is copied to the client computer. If the default disk preparation of the destination computer is not identical to that of the source computer, any remaining disk capacity on the destination computer is partitioned. For example, if the source computer disk capacity is 1 gigabyte (GB) and the disk capacity of the destination computer is 2 GB, the entire 2 GB are formatted on the destination computer.

By changing the information in the .sif file associated with an installation image, you can restrict the disk reformatting to be the same as the source computer used to create the installation image. For example, suppose you open the Riprep.sif file and modify the UseWholeDisk parameter to **NO**. When a client computer installs this image, the disk is formatted to match the capacity of the source computer. The disk and source computer then become identical. The rest of the destination computer's disk remains unformatted.

For additional background information about how RIPrep works, see Creating an installation image with RIPrep. For instructions on running RIPrep, see Create a Remote Installation Preparation Wizard image.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Maintenance and troubleshooting tools and options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Maintenance and troubleshooting tools and options**
You can control whether Remote Installation Services (RIS) offers certain types of maintenance and troubleshooting tools at the beginning of a remote installation. Although the client computer's hard disk might be empty prior to installing the operating system, the computer can still be managed with these maintenance and troubleshooting tools. The tools can therefore be useful not only to users, but also to administrators and technical support staff.

The maintenance and troubleshooting tools also give administrators an easy way to update a client computer system--for example, by the flashing of the basic input/output system (BIOS)--before or after the operating system installation.

If tools are provided to you by an independent software vendor (ISV) or original equipment manufacturer (OEM), you can control whether users are able to use these tools. You do this with the Tools tab of Advanced settings in RIS. (ISVs and OEMs make the tools available through external setup programs.) The tools appear in the list on the Tools tab and become available to administrators and users when they run the Client Installation Wizard. For information about viewing the Tools tab of Advanced settings in RIS, see Manage troubleshooting tools.

You can also make the Recovery Console available to a user of a RIS client computer if the client computer is configured to support it. When the Recovery Console is available to a user, it is displayed in the Client Installation Wizard under "Maintenance and Troubleshooting." For information on using RIS to start the Recovery Console, see Remote Installation Services Resources.

The Remote Installation Services (RIS) tools feature includes the following options:

- **Remove**

  Removes the template setup information file (.sif) associated with the currently selected tool. The .sif file contains the friendly description text, which explains the tool's purpose to the users of a RIS client computer. If you choose the Remove option, the template file is deleted, and, although the tool remains on the disk, it is not offered to RIS clients when they run the Client Installation Wizard.

  **Important**

  - If you want to make a tool temporarily unavailable, or you want to make it available only to certain users, do not remove it; doing so deletes the .sif file associated with the tool. Instead, use the **Properties** option and restrict permissions on the .sif file associated with the tool (**Read** and **Read & Execute** permissions are required by tool users).

- **Properties**

  Provides access to property information for the selected tool. Use this option to change the friendly description text and to retrieve specific details about the selected tool. You can also use this option to change permissions for the tool.

- **Refresh**

  Refreshes the contents of the display window.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Computer names

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Computer names**

You can use the advanced settings of Remote Installation Services (RIS) to define the naming policy that gives each client computer a unique name. This unique name, which is used to identify the client computer on the network, is similar to the network basic input/output system (NetBIOS) name used in previous versions of Windows and Windows NT.

When you define your naming policy, you can either choose from a list of automatic naming options (for example, **First initial, last name**), or you can click the **Customized** button and create a customized naming policy. If you want to ensure that each client computer is given a unique computer name, choose from the list of automatic naming options. All of the automatic naming options that are based on the user's name (for example, **First initial, last name**) add an incremental number at the end to ensure that the computer name is unique.

To create a custom naming policy, click **Customize**. You can then select one of the options in the following list to create the customized computer name automatically.

**%First**
The user's first name is used as the computer name.

**%Username**
The user name is used as the computer name.

**%[ 0][ *n*] #**
The computer name includes an incremental number containing *n* digits. To include zero-padding in the incremental number, type a zero as shown. For example, if you use %03#, a three-digit number in the range from 001 through 999 is used.

**%Last**
The user's last name is used as the computer name.

**%MAC**
The network card media access control address is used as the computer name.

**Important**

- Do not create a naming convention that could result in duplicate computer names. One way to avoid duplication in computer names is to use the incremental number option described in the previous list.

When you are defining your computer naming policy, you can limit the length of computer names by adding a numerical value to the text string. For example, if you want to limit the computer name to three characters of the user's last name with a two-digit incremental number appended, you would use the string: **%3Last%02#** Thus, for the fifth computer user whose last name is Smith, the corresponding computer name would be Smi05.

You can use customized naming options separately, or you can combine them. For example, if you want the computer name to consist of the first three letters of the user's first name, followed by the first three letters of the user's last name, followed by a three-digit incremental number, use the following string:**%3First%3Last%03#**

For instructions on how to configure the computer naming format, see Configure settings for new clients for RIS.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# The Remote Installation Process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The remote installation process**
This section covers:

- Client Installation Wizard
- Installation options available through RIS
- Operating systems supported by Remote Installation Services
- Controlling client installations through Group Policy

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Client Installation Wizard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Client Installation Wizard**

Users of a remote boot-enabled client computer can use the Client Installation Wizard to select installation options, operating systems, and maintenance and troubleshooting tools.

The wizard prompts the user for a user name, password, domain name, and other information as required. After the user's credentials have been validated, the wizard displays the installation options that are available to the user. After the user selects an option, the selected operating system installation image is copied to the client computer's local hard disk. You can predetermine some installation options using Group Policy.

Users of the Client Installation Wizard must type only standard ASCII characters (OEM characters 32-126) for user name, password, or domain name information. The Client Installation Wizard does not support extended ASCII character sets (such as those containing ü, é, or other extended characters).

For more information, see the following:

- For more information about how a user logs on through the Client Installation Wizard and performs a remote installation, see Perform a network installation using RIS.
- For information about using Group Policy to control some installation options, see Controlling client installations through Group Policy.

As an administrator, you can edit .osc files to determine which screens the Client Installation Wizard presents to the user. For more information about .osc files, see see "Designing RIS Installations" at the Microsoft Windows Resource Kits Web site. For basic information about other ways you can control some of the choices and screens seen by users of RIS client computers, see Installation options available through RIS.

**Important**

- By default, the client computer's hard disk is reformatted during the operating system installation. Therefore, all locally stored files are removed during installation. To prevent the loss of important data, you should back up your files before installation. You can also choose not to reformat the computer's hard disk during installation.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Installation options available through RIS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installation options available through RIS**
The Client Installation Wizard is a text-based setup wizard that guides the user through the remote installation process. You can use Group Policy to control which installation options are offered to users. For more specific information about this, see Controlling client installations through Group Policy.

You can specify that the user be presented with automatic setup or custom setup, or that a previous setup attempt be restarted. You can also specify that the user be given maintenance and troubleshooting options.

**Automatic Setup**
Use this option if you want to predefine the computer name and a location within Active Directory for the client computer accounts. For more information about computer names and the options for predefining them, see Computer names. You can also prestage the client computer; for more information about this, see Prestage client computers.

**Custom Setup**
Use this option to allow users to define a unique name for this computer and specify where the computer account will be created within Active Directory. Typically, you use custom setup for users outside of your own organization who are setting up computers.

**Restart setup ("Restart a Previous Setup Attempt" in the Client Installation Wizard)**
This option restarts a failed operating system installation attempt if the installation procedure fails during text-mode setup. This option does not copy files from where the previous installation attempt failed. However, the user is not required to answer any questions that were already answered during the previous setup attempt.

**Tools ("Maintenance and Troubleshooting" in the Client Installation Wizard)**
This option gives users access to tools that are used to maintain and troubleshoot client computers. These tools include memory virus scanners, updating the flashing for system basic input/output system (BIOS), and computer diagnostic utilities. In addition, if Recovery Console has been made available to a client computer, and if the client computer is configured to support the Recovery Console, it is displayed in the Client Installation Wizard under "Maintenance and Troubleshooting." For more information about maintenance and troubleshooting tools, see Maintenance and troubleshooting tools and options.

**Additional options and other considerations**

- Remote Installation Services (RIS) does not fully support unattended installations on computers that contain Microsoft Internet Security and Acceleration (ISA) devices or devices that are non-Plug and Play.

- Users who are setting up a remote boot-enabled client computer are not offered installation choices when automatic setup is their only installation option. For more information, see Controlling client installations through Group Policy.

- The unattended installation setup answer files (.sif) are text files that describe the installation process for an installation image. An unattended installation template, which you can customize, is provided by RIS. The .sif file must be associated with one of the available installation images. For information about associating a .sif file with an installation image, see Associate an unattended setup answer file with a RIS installation image. For information about creating unattended installation files and automating installations, see "Automating and Customizing Installations" at the Microsoft Windows Resource Kits Web site.

  One of the things you can control through a .sif file is the enabling of the Administrator account (which by default is disabled when the client joins the domain). If you do this, be sure to use a tool called Setup Manager to ensure that the Administrator password is encrypted in the .sif file before being transmitted over the network. For information about this, see the following:

  - For specific information about working with .osc and .sif files for RIS, see "Designing RIS Installations" at the Microsoft Windows Resource Kits Web site.

  - For information about Setup Manager, see Deploy.chm in \Support\Tools\deploy.cab on the Windows CD.

- By default, the Client Installation Wizard uses the Welcome.osc file located in \RemoteInstall\OSChooser to manage client installation image choices. For multiple language installation image options, you must remove the Welcome.osc file and rename the MultiIng.osc file to Welcome.osc. The Client Installation Wizard then provides the user with a menu of multiple language choices. You can also edit Welcome.osc to create custom language options. For more information about .osc files, see "Designing RIS Installations" at the Microsoft Windows Resource Kits Web site.

- For most client computers, the user must press a particular key (for example, F12) to initiate the remote installation process. Some client computers have settings in the basic input/output system (BIOS) that cause a prompt to be displayed when it is time for the user to press the key. Not all client computers display a prompt. By default, RIS causes a prompt to be displayed on the client computer, telling the user to press F12. To change this so that RIS does not cause a prompt to be displayed, in *RIS_server_name*\REMINST\oschooser\i386, rename Startrom.com to Startrom.old, and then rename Startrom.n12 to Startrom.com.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Operating systems supported by Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Operating systems supported by Remote Installation Services**
You can use Remote Installation Services (RIS) to enable automated installations of an operating system on new or existing client computers.

Two types of operating system images are supported by the Client Installation Wizard: flat image and the Remote Installation Preparation Wizard (RIPrep) image formats.

Using a flat image is similar to setting up a client directly from the installation CD, except that the operating system image source files reside on an available RIS server. For information about creating a flat image, see Add a new client operating system installation image.

When you create an RIPrep image, you can install the necessary client computer applications and configure the client computer settings, such as monitor settings and network printers. For background information about RIPrep, see Creating an installation image with RIPrep. For instructions on how to run RIPrep, see Create a Remote Installation Preparation Wizard image.

The Client Installation Wizard displays both the flat image and RIPrep image formats in the list of available installation options. The installation process begins when the user of the client computer selects one of the displayed operating system images.

The table below lists the operating systems supported by Remote Installation Services. It also shows the image type that is supported for each operating system.

| Operating system | Flat image | RIPrep image |
|---|---|---|
| Windows XP Professional | X | X |
| Windows Server 2003, Standard Edition | X | X |
| Windows Server 2003, Web Edition | X | X |
| Windows Server 2003, Enterprise Edition | X | X |
| 64-bit version of Windows Server 2003, Enterprise Edition | X | X |
| Windows 2000 Professional | X | X |
| Windows 2000 Server | X | X |
| Windows 2000 Advanced Server | X | X |

**Important**

- A 64-bit version of the Remote Installation Preparation (RIPrep) Wizard is included with the 64-bit version of Windows Server 2003, Enterprise Edition. For more information about using the RIPrep Wizard to create an installation image of a 64-bit operating system, see article 891128, "Updated Remote Installation Services (RIS) functionality in Windows Server 2003 Service Pack 1," in the Microsoft Knowledge Base.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Controlling client installations through Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Controlling client installations through Group Policy**

You can use the Group Policy snap-in to control whether the user of a RIS client computer must supply a computer name during installation, whether the remote installation attempt should be restarted if it fails, and whether users have access to tools before the operating system is installed. Group Policy is applied to sites, domains, and organizational units, and can be inherited within Active Directory. For more information on Group Policy, see Group Policy overview.

The Group Policy options for the Client Installation Wizard are as follows:

**Automatic Setup**

Use this option if you want to predefine the computer name and a location within Active Directory for the client computer accounts. For more information about computer names and the options for predefining them, see Computer names. You can also prestage client computers; for more information, see Prestage client computers.

**Custom Setup**

Use this option to allow users to define a unique name for this computer and specify where the computer account will be created within Active Directory.

**Restart Setup**

This option restarts an operating system installation attempt if it fails prior to completion.

**Tools**

Use this option to allow users to access tools from the Client Installation Wizard. For more information about how tools are made available, see Maintenance and troubleshooting tools and options.

For each of the Client Installation Wizard choices, the following options are available:

**Enable**

Users to whom this policy applies are offered this installation option.

**Not Configured**

The policy settings of the parent container apply to this option. For example, if you choose **Not Configured** and the administrator for the entire domain has set Group Policy specific to Remote Installation Services, the policy that is set on the domain is applied to all users who are affected by that policy.

**Disabled**

Users affected by this policy cannot access this installation option.

For procedural information on controlling access through Group Policy, see Set Group Policy for client installation options.

For information on the options offered by the Client Installation Wizard, see Installation options available through RIS.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Installation Services Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

- For more information about deploying Remote Installation Services (RIS), see "Designing RIS Installations" at the Microsoft Windows Resource Kits Web site. For information about the Resource Kits, see Using the Windows Deployment and Resource Kits.
- For information about unattended installation, see deploy.chm in \Support\Tools\deploy.cab on the Windows CD.
- For information about compatible hardware, Windows Update, and product support, see Support resources.
- For information about starting the Recovery Console from RIS, see article Q222478, "Creating a Template to Run Recovery Console Using a Remote Install Server," in the Microsoft Knowledge Base.
- For information about using File Replication service (FRS) to replicate RIS images, see article Q273594, "How to: Replicate RIS Images Using DFS and NTFRS," in the Microsoft Knowledge Base.
- For information about configuring a router to forward DHCP packets to a client computer, see article Q257579, "PXE Clients Do Not Receive an IP Address from a DHCP Server Across a Router," in the Microsoft Knowledge Base.

**Note**

- This topic does not apply to Windows Server 2003, Web Edition.

# Troubleshooting Remote Installation Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting Remote Installation Services**

What problem are you having?

- I am not sure I have the correct Pre-Boot eXecution Environment (PXE) ROM version.
- I am not sure whether the client computer has received an Internet protocol (IP) address and has contacted the Remote Installation Services (RIS) server.
- I am trying to locate the globally unique/universally unique identifier (GUID/UUID) on a client computer so I can prestage the client computer within Active Directory for use with RIS.
- Command settings are not being processed during the unattended installation.
- Language choice options do not appear during the Client Installation Wizard session.
- The client computer is prestaged to a RIS server but is being serviced by a different server.
- I have client computers that use the older remote boot protocol, Remote program Load (RPL)-based ROMs.
- I am investigating questions of security related to the Pre-Boot portion of the PXE-based remote boot ROM.
- I am evaluating methods for replicating all of the operating system installation images currently located on one RIS server to other RIS servers on the network to achieve consistency across all client installations.
- I am evaluating whether to place a RIS server and another vendor's remote boot server on the same network.
- I want to manage the RIS servers remotely from computers running Windows XP Professional on my network.
- I want to add more network adapters to the RIS boot disk.
- I want to know whether I can use the Active Directory object attributes to create a naming format that can be used with the RIS automatic computer naming feature.
- After the restoration of a backup of a RIS volume, RIS does not function properly.
- I created an image on my RIS server, but the installation image does not appear in the list of available operating system installation options when I attempt to install the image on a client computer.
- I created an image using the Remote Installation Preparation (RIPrep) Wizard, started the Add Wizard, and clicked Associate a new answer file to an existing image, but I do not see the RIPrep image in the list in the Add Wizard.
- I am evaluating the use of RIPrep in a situation where I want to preserve the file attributes and security settings defined on the source computer.
- I want to use RIPrep in a situation where there are hardware differences between the source computer that is used to create the RIPrep based installation image and the destination computer that will install the image.
- I am evaluating whether I can use RIPrep to support an installation on multiple disks or multiple partitions on the client computer.

- I am evaluating the use of RIPrep in a situation where the disk sizes differ between the source computer used to create the image and the destination computer that will receive the image.

**I am not sure I have the correct Pre-Boot eXecution Environment (PXE) ROM version.**
**Solution:** When the Net PC or client computer containing a remote boot ROM starts, the version of the PXE ROM appears on the screen. Remote Installation Services (RIS) supports .99n or greater PXE ROMs, except in a few situations that require the .99L version. You might be required to obtain a newer version of the PXE-based ROM code from your original equipment manufacturer (OEM) if you have problems with the existing ROM version installed on a client computer.

**I am not sure whether the client computer has received an Internet protocol (IP) address and has contacted the Remote Installation Services (RIS) server.**
**Solution:** When the client computer boots, you will see the PXE boot ROM begin to load and initialize. The following sequence occurs with most PC98 and Net PCs, PXE ROM-based computers, and the computers using the RIS boot disk.

**Remote Boot ROM Load Sequence:**

**Step 1:**

The client computer displays the message "DHCP." This indicates that the client is requesting an Internet protocol (IP) address from the DHCP server. This can also mean that the client has obtained an IP address from the DHCP server and is awaiting a response from the RIS server. To verify that the client is receiving an IP address, check the IP leases that have been granted on your DHCP server.

**Troubleshooting**

If the client does not receive the message, an IP address might not have been received or the Remote Installation (BINLSVC) server might not be responding. Consider the following:

- Is the DHCP server available and has the service started? The DHCP server and remote installation servers must be authorized in Active Directory before they can provide IP addresses. Check to ensure that the service has started and that other clients that are not remote boot-enabled are receiving IP addresses on this segment.

- Does the DHCP server have a defined IP address scope, and has it been activated?

- Is there a router between the client and the DHCP server that is not allowing DHCP packets through?

- Are there any error messages in the event log under the system log for DHCP?

**Step 2:**

When the client receives an IP address from the DHCP server, the message might change to "BINL." This indicates that the client successfully leased an IP address and is now waiting to contact the RIS server. The client will eventually time out and post the error message "No Bootfile received from DHCP, BINL, or Bootp."

**Troubleshooting**

If the client does not receive the BINL message, this indicates the client is not receiving a response from the RIS server. Consider the following:

- Is the server available and has Remote Installation Services started? RIS servers must be authorized before they can respond to client computers. Run **Risetup -Check** to authorize a RIS server. For more information, see Remote Installation Services server authorization.

- Are other remote boot-enabled clients receiving the Client Installation Wizard? If so, this client computer either is not supported or is having remote boot ROM-related problems. Check the version of the PXE ROM on the client computer. Also, check Active Directory to see whether the administrator has prestaged this client computer to a RIS server that is offline or unavailable to the client computer.

- Has an additional network card been added to the RIS server? If so, the server must be re-authorized in Active Directory. Run **RISETUP -Check** to re-authorize the server.

- Is a router between the client and the RIS server not allowing the DHCP-based requests or responses through? The RIS

server communicates by way of the DHCP packet type during the initial service request/response sequence. You might need to configure the router to forward the DHCP packets. For more information, see article Q257579, "PXE Clients Do Not Receive an IP Address from a DHCP Server Across a Router," in the Microsoft Knowledge Base.

- Are there any error messages in the event log under the system or application logs specific to Remote Installation (BINLSVC), Domain Name System (DNS), or Active Directory?

- Does the client computer have an account in Active Directory? If not, the RIS server might be configured to respond only to known client computers.

- Is the RIS server also a DHCP server, and does it have multiple network adapters? If so, then there must be a scope for the subnet of each network adapter. For more information, see Configuring scopes.

**Step 3:**

The client then changes to Trivial File Transfer protocol (TFTP) or prompts the user to press a particular key (for example, F12). This indicates that the client has contacted the RIS server and is waiting to receive the first image file-CIW. You might not see the BINL and TFTP message on some computers because this sequence can occur very rapidly.

**Troubleshooting**

If the client computer does not get a response from the RIS server, the client will time out and send an error message saying that it did not receive a file from DHCP, BINL, or TFTP. In this case, the RIS server did not answer the client computer. Do the following:

- Stop and restart Remote Installation (BINLSVC). To do so, click **Start**, and then click **Run**. In the **Run** dialog box, type **cmd** in the text field, and click **OK**. In the console window, type the following:

  **Net Stop BINLSVC**

  **Net Start BINLSVC**

- Check the RIS server properties to ensure that the **Respond to client computers requesting service** option is selected and that **Do not respond to unknown client computers** is cleared unless you have prestaged the client computer in Active Directory prior to starting the client computer.

- If the client computer does not receive an answer after it has attempted to stop and restart the service, and you have checked the remote installation server object properties to ensure that the correct settings have been set, check the event log on the RIS server for any errors relating to DHCP, DNS, and RIS (BINLSVC).

- Check the TFTP Daemon to ensure that it has actually started, and check the event log to see if there are any TFTP errors.

**Step 4:**

At this point, the client should have downloaded and displayed the Client Installation Wizard application; a Welcome screen greeting the user should appear.

**I am trying to locate the globally unique/universally unique identifier (GUID/UUID) on a client computer so I can prestage the client computer within Active Directory for use with RIS.**
**Solution:** The GUID/UUID for most client computers that are PC98 or Net PC-compliant is provided in the system basic input/output system (BIOS) of the computer. Computer manufacturers are encouraged to ship either a floppy disk containing a comma-separated file or spreadsheet that includes a mapping of serial numbers to GUIDs/UUIDs. You can use this information to script the prestaging of client computers within Active Directory.

The GUID/UUID also appears on the outside of the computer. If it does not appear in the expected locations, one method for discovering it is to use a network utility to sniff the network traffic of the client computer and locate the DHCPDiscover packet; within that field will be the 128-bit, 16-byte GUID/UUID. Another method is to use the Windows Management Instrumentation (WMI) interface-- specifically, the universally unique identifier (UUID) value of the Win32_ComputerSystemproduct class. For more information about this, see the MSDN Library at the Microsoft Web site.

**Command settings are not being processed during the unattended installation.**

**Cause:** Incorrect directory information is being used. Correct directory information is required when the "OemPreinstall = yes" setting in a .sif file is being used.

**Solution:** Change the directory information to \\RemoteInstall\Setup*applicable_language*\Images*applicable_name*\$oem$.

**Language choice options do not appear during the Client Installation Wizard session.**
**Cause:** By default, RIS uses the Welcome.osc file to manage client installation image choices. To make multiple language installation image options available, you must replace the default Welcome.osc file with the Multilng.osc file.

**Solution:** The Client Installation Wizard uses the Welcome.osc file located in the \\RemoteInstall\OSChooser folder to manage client installation image choices. When you remove the Welcome.osc file and rename the Multilng.osc file to Welcome.osc, the Client Installation Wizard will also offer a menu of language choices to the user. You can edit the Welcome.osc file to create custom language options.

**The client computer is prestaged to a RIS server but is being serviced by a different server.**
**Cause:** When you prestage a client computer into a domain with multiple domain controllers, the replication delay of the client computer account information can cause a client computer to be serviced by another RIS server.

**Solution:** You can either wait for the computer account information to be propagated during the next scheduled replication session, or you can modify the replication frequency between your domain controllers. For more information on configuring replication, see Replication overview.

**I have client computers that use the older remote boot protocol, Remote program Load (RPL)-based ROMs.**
**Solution:** There is no support for the older RPL-based remote boot, so computers using this cannot use RIS. RIS uses the PXE DHCP-based remote boot ROMs.

**I am investigating questions of security related to the Pre-Boot portion of the PXE-based remote boot ROM.**
**Solution:** There are inherent security limitations with PXE. The entire boot ROM sequence and operating system installation or replication process is not secure for packet type encryption, client or server spoofing, or wire sniffer-based mechanisms. You should exercise caution when using RIS on your corporate network. Allow only authorized RIS servers on your network. Also, control the number of administrators who are allowed to install or configure RIS servers. For more information, see Security Information for Remote Installation Services.

**I am evaluating methods for replicating all of the operating system installation images currently located on one RIS server to other RIS servers on the network to achieve consistency across all client installations.**
**Solution:** RIS does not currently provide a mechanism for replication of operating system images from one RIS server to another. There are several alternative mechanisms you can use, however. One solution is to use the strong replication features of the Systems Management Server product. This product provides for scheduled replication, compression, and low-speed link features. You can also use other vendor solutions for operating system image replication. If you do this, however, ensure that the replication mechanism you choose supports maintaining the file attributes and security settings of the source images.

**I am evaluating whether to place a RIS server and another vendor's remote boot server on the same network.**
**Solution:** You can place multiple-vendor remote boot/installation (RB/RI) servers on one physical network. It is important to understand, however, that the remote boot PXE ROM code is not currently able to detect the difference between vendors' RB/RI servers. As a result, when a remote boot-enabled client computer starts and requests the Internet protocol (IP) address of an RB/RI server, all of the available servers will respond to that client; thus, the client has no way to ensure that it is being serviced by a specific RB/RI server.

With RIS, however, an administrator can prestage client computers into Active Directory and determine which RIS server will service a client computer. By configuring the RIS server to answer only known (prestaged) client computers, the administrator is assured that the client will be serviced by the correct RIS server.

Not all of the other RB/RI vendors are able to ignore service requests. You might need to isolate the specific vendors' servers on the network so that clients are not answered by these vendors' RB/RI servers.

**I want to manage the RIS servers remotely from computers running Windows XP Professional on my network.**
**Solution:** If you are an administrator in the domain, and you have installed the Windows Server 2003 Administration Tools Pack on the computer running Windows XP Professional, you can administer most of the RIS configuration settings. There are some items that you cannot manage, however. For example, you cannot remotely add more operating system installation images to the RIS servers from a computer running Windows XP Professional.

**I want to add more network adapters to the RIS boot disk.**
**Solution:** For this release of RIS, the Rbfg.exe utility cannot be modified to accommodate additional network adapters. Updates to Rbfg.exe can be made available through the same distribution channels that are used for other software updates and feature packs, however. You can obtain information about possible updates to Rbfg.exe (and the network adapter support in those updates) in the same way that you obtain information about other software updates.

**I want to know whether I can use the Active Directory object attributes to create a naming format that can be used with the RIS automatic computer naming feature.**
**Solution:** This is not supported. Although the existing attributes supported with the automatic computer naming feature do use Active Directory, not all Active Directory object attributes are currently supported.

**After the restoration of a backup of a RIS volume, RIS does not function properly.**
**Cause:** Backup restored the volume without a Single Instance Store (SIS) directory.

**Solution:** Verify the configuration of the RIS volume, then restore the volume again.

For information about how to verify the configuration of a RIS volume, see Verify the Remote Installation Services configuration.

For information about how to back up and restore SIS directories, see "Backup and Restore" at the Microsoft Windows Resource Kits Web site.

**I created an image on my RIS server, but the installation image does not appear in the list of available operating system installation options when I attempt to install the image on a client computer.**
**Cause:** The client computer has a different type of hardware abstraction layer (HAL) than the image.

**Solution:** When you use RIPrep to create new images, RIPrep ensures that the images viewed by the client computers are only those that are compatible with the computer. A client computer must have the same type of hardware abstraction layer (HAL) as the image. If it does not, the image will not appear in the list of available operating system installation options.

**Cause:** Permissions have been set that prevent users from seeing a particular installation image.

**Solution:** For information about setting permissions that permit or deny access to installation images, see Allow or prevent the installing of a RIS image by a user or group and Allow or prevent the viewing and installing of a RIS image by a user or group.

**I created an image using the Remote Installation Preparation (RIPrep) Wizard, started the Add Wizard, and clicked Associate a new answer file to an existing image, but I do not see the RIPrep image in the list in the Add Wizard.**
**Solution:** The installation images that appear in the list in the Add Wizard include only flat images; that is, those images created with the Remote Installation Services Setup Wizard. The list does not include images created with the Remote Installation Preparation (RIPrep) Wizard.

**I am evaluating the use of RIPrep in a situation where I want to preserve the file attributes and security settings defined on the source computer.**
**Solution:** RIPrep supports this. The file attributes and security settings that are defined on the source computer are preserved on the destination computer that installs that image. For more information about RIPrep, including information about requirements for the RIPrep replication process, see Creating an installation image with RIPrep.

**I want to use RIPrep in a situation where there are hardware differences between the source computer that is used to create the RIPrep based installation image and the destination computer that will install the image.**
**Solution:** You can use RIPrep in a situation where hardware on the source computer and the destination computer is different. The one limitation is that the computers must use the same type of Hardware Abstraction Layer (HAL). For example, if the source computer is an Advanced Configuration Power Interface (ACPI)-based computer, it uses a HAL that includes ACPI. If you attempt to install this RIPrep image on a computer that is not based or enabled on ACPI, the operating system installation process will fail.

**I am evaluating whether I can use RIPrep to support an installation on multiple disks or multiple partitions on the client computer.**
**Solution:** In this release of Remote Installation Services, the RIPrep utility supports only a single disk with a single partition. You can use RIPrep to make an image of a computer that contains more than one partition or disk, but RIPrep will only image the system partition.

**I am evaluating the use of RIPrep in a situation where the disk sizes differ between the source computer used to create the image and the destination computer that will receive the image.**
**Solution:** For details about working with different disk characteristics on the source client computer and the destination computer, see Creating an installation image with RIPrep.

### Note

- This topic does not apply to Windows Server 2003, Web Edition.

# Remote Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Administration**
Using tools included with Microsoft® Windows Server 2003 family operating systems CDs, you can remotely manage your system servers running Microsoft® Windows 2000 and Windows Server 2003 family operating systems. You can also remotely manage Windows Server 2003 family operating systems from a computer using Microsoft® Windows® XP Professional.

- For general information, see Remote administration overview.
- For tips about managing your server remotely, see Remote Administration Best practices.
- For other sources of information, see Remote Administration Resources.

# Remote administration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote administration overview**

The following table presents remote management tasks and links to information about the tools. Unless indicated otherwise, these tools are used on Microsoft® Windows Server™ 2003 operating systems and, in some cases, Microsoft® Windows® XP Professional.

| Task | Tools | Comments |
|---|---|---|
| Manage several servers by performing similar tasks. | Microsoft Management Console<br><br>Author an MMC console file<br><br>Work with MMC and saved console files | You can use appropriate saved MMC consoles, if available, or you can create custom MMC consoles for tasks you frequently either delegate or perform. |
| Log onto one computer remotely and manage it as if you were there. | Remote Desktop Connection | In addition to Windows Server 2003 operating systems, this feature can be used with Microsoft® Windows® 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Switch among several computers that you want to log on to remotely. | Remote Desktops snap-in | In addition to Windows Server 2003 operating systems, this feature can be used with Windows 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Administer a server running Windows Server 2003 from any computer on your network. | Remote Desktop for Administration | In addition to Windows Server 2003 operating systems, this feature can be used with Windows 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Manage servers from Windows XP Professional. | Windows Server 2003 Administration Tools Pack Overview<br><br>Remote Desktop Connection | Windows Server 2003 Administration Tools Pack must be installed on Windows XP Professional to permit server management using these tools. The Remote Desktop feature must be enabled on servers to permit use of the Remote Desktop Connection. |
| Manage your Web server using a Web browser on a remote computer. | Using Web Interface for Remote Administration | Use Internet Explorer, version 6 or later, for remote administration using Web Interface. Web Interface is not installed by default for Web servers. |
| Assist in real time an operator on a remote computer running Windows Server 2003 family operating system, Windows XP Professional or Microsoft® Windows® XP Home Edition. | Administering Remote Assistance (www.microsoft.com) | The Remote Assistance connection requires explicit permission from the connected user, and both computers must be running Windows XP Professional or Windows Server 2003 operating systems. |
| Connect to a remote computer when that computer cannot access a network or is not in a functional state because of hardware or software failure. | Telnet | All commands must be entered through the command line. Capabilities are limited, and security is minimal. |

| | | |
|---|---|---|
| Manage disk space on servers by copying files to a library of magnetic tapes or magneto-optical disks. | Remote Storage | Some Windows components require configuration before they can be used and will be displayed in the **Add or Remove Windows Components** in **Add or Remove programs** in **Control Panel**. Remote storage requires installation. |

**Notes**

- Depending on the Group Policy settings on your network, you might not be able to perform some of these tasks.
- Some features require that specific ports be opened on the server in order for the role to be administered remotely. For information about these port requirements, see Service overview and network port requirements for the Windows Server system (http://go.microsoft.com/fwlink/?LinkID=61531) and Windows Firewall Settings (http://go.microsoft.com/fwlink/?LinkID=38651).
- You can use command-line tools to automate many processes and tasks. For more information, see Automating processes and tasks.
- You must physically access each computer to restart, change hardware, and enable the Remote Desktop feature. Once the Remote Desktop feature has been enabled, it will remain enabled.
- For an explanation of the various Remote Desktop terminologies, see Remote Administration using Terminal Services.
- For more information about remote administration, see the following:
    - Common Administrative Tasks
    - New Features
    - Quick Guide for Finding Tools
    - Remote Administration Resources

# Remote Administration Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**To perform many tasks on a single, remote server, use Remote Desktop for Administration.**

- To remotely administer a server running a Windows Server 2003 family operating system, you do not need to install Terminal Server. Instead, use Remote Desktop for Administration. On these operating systems, Remote Desktop for Administration is on by default but is not enabled. After you enable remote connections, Remote Desktop for Administration allows you to administer your server from any computer on your network running Windows Server 2003 family, Windows XP Professional, and Windows 2000. Windows Server 2003 , Web Edition, does not support remote administration.

- You can use Remote Desktop with Windows 2000 Server. You need to install Terminal Services for Remote Administration as described in the Windows 2000 Help.

  For more information, see Enable or disable Remote Desktop and Remote Desktop for Administration.

**To do similar tasks on many servers, use MMC snap-ins.**

- Most of the administration tools provided with Windows Server 2003 family operating systems are Microsoft Management Console (MMC) snap-ins that can be used to administer remote servers as well as your local computer. The advantages of using MMC include the following:

  - You can create a console with the tools you use for the tasks you do most often.

  - You can set the focus for a tool to any of the servers you administer, and switch between servers and tools within a single MMC console.

  For more information, see Microsoft Management Console.

**To manage servers running Windows Server 2003 family operating systems from a computer using Windows XP Professional , use Windows Server 2003 Administration Tools Pack**

- Windows Server 2003 Administration Tools Pack when installed on Windows XP Professional (ordinarily a client operating system) provides many remote management tools for managing your servers.

- Windows Server 2003 Administration Tools Pack comes as adminpak.msi on the Windows Server 2003 family operating system and is easily installed from the server CD onto Windows XP Professional by installing the .msi from the server to the Windows XP Professional operating system.

- The Administration Tools Packs in the Windows Server 2003 family and Windows 2000 are not mutually compatible. You must use the Windows 2000 Administrative Tools to administer Windows 2000, and the Windows Server 2003 Administration Tools Pack to administer the Windows Server 2003 family operating system.

  For more information, see Windows Server 2003 Administration Tools Pack Overview.

# Remote Administration Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**
The following resources provide additional information about remote administration.

**Windows Server 2003 Resource Kit**
The Microsoft Windows Server 2003 Resource Kit contains additional tools that you can use for remote administration.

**Microsoft Platform Software Development Kits (SDK)**
For technical information about Active Directory Scripting Interfaces (ADSI), Microsoft Management Console (MMC), Windows Management Instrumentation (WMI) Software Development Kits (SDK), see the Microsoft Web site.

**TechNet**
TechNet is a service that contains resources for information technology (IT) professionals. This includes access to articles written by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software.

For more information, see Microsoft TechNet.

# Terminal Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services**
Terminal Services provides remote access to a Microsoft® Windows® desktop through "thin client" software, allowing the client computer to serve as a terminal emulator. Terminal Services transmits only the user interface of the program to the client. The client then returns keyboard and mouse clicks to be processed by the server. Each user logs on and sees only their individual session, which is managed transparently by the server operating system and is independent of any other client session. To connect to a computer via Terminal Services, use Remote Desktop Connection (the new Terminal Services client). For more information, see Remote Desktop Connection.

Terminal Server uses Terminal Services technology to provide an effective and reliable way to distribute Windows-based programs with a network server. With Terminal Server, a single point of installation allows multiple users access to the desktop of a computer running one of the Microsoft Windows Server™ 2003 family operating systems, where they can run programs, save files, and use network resources. Terminal Server is not installed by default. For more information about Terminal Server, see Terminal Server. (Terminal Server is not available on Windows Server 2003, Web Edition.)

**Important**

- It is not necessary to install Terminal Server for remote administration of your server. Remote Desktop for Administration is installed by default. To use Remote Desktop for Administration, you must first enable remote connections. For more information, see Enable or disable Remote Desktop. For more information about Remote Desktop for Administration, see Remote Desktop for Administration.

Terminal Server has its own method for licensing clients that log on to terminal servers, separate from the licensing method for clients running one of the Windows Server 2003 family operating systems. Clients must receive a valid license issued by a license server before they are allowed to log on to a Terminal Server. For more information about Terminal Server Licensing, see Terminal Server Licensing.

A Terminal Services connection provides the link clients use to log on to a session on the server. A TCP/IP connection is configured on port 3389 when Terminal Services is installed. Using Terminal Services Configuration, you can change the default properties of the connection, as well as other settings that apply to Terminal Services sessions. For more information about Terminal Services configuration, see Terminal Services Configuration.

User accounts can be set up and managed for a specific computer using Local Users and Groups or for a domain of computers using Active Directory Users and Computers. For more information about Terminal Services user properties, see Terminal Services User Properties.

Terminal Services Manager can be used to view information about terminal servers that reside in trusted domains. Use this tool to monitor users, sessions, and applications on each terminal server, and to carry out assorted actions to manage the server. For more information about Terminal Services Manager, see Terminal Services Manager.

# Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server**
On Microsoft® Windows Server™ 2003 family operating systems, the Terminal Server feature gives users at client computers throughout your network access to Windows-based programs installed on terminal servers. With Terminal Server, you can provide a single point of installation that allows multiple users access to the Windows Server 2003 family operating system desktop, where they can run programs, save files, and use network resources, all from a remote location, as if these resources were installed on their own computers.

For computers running Microsoft® Windows® XP or Windows Server 2003 family operating systems, the Terminal Services client program (Remote Desktop Connection) is already installed. Remote Desktop Connection can also be installed on other 32-bit Windows-based operating systems.

Terminal Server is not included in Microsoft® Windows Server™ 2003, Web Edition.

- Before you begin using Terminal Server, see Checklists: Setting up Terminal Server.
- To find features that have been moved in this release, see New ways to do familiar Terminal Server tasks.
- For tips about using Terminal Server, see Terminal Server Best practices.
- For help with specific tasks, see Terminal Server How To....
- For general background information, see Terminal Server Concepts.
- For problem-solving instructions, see Troubleshooting Task Scheduler.

**Important**

- It is not necessary to install Terminal Server for remote administration of your server. Remote Desktop for Administration is installed by default. To use Remote Desktop for Administration, you must first enable remote connections. For more information, see Enable or disable Remote Desktop. For more information about Remote Desktop for Administration, see Remote Desktop for Administration.

**Note**

- For additional information about deploying Terminal Server, see "Hosting Applications with Terminal Server" at the Microsoft Windows Resource Kit Web site.

# New ways to do familiar Terminal Server tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for Terminal Services. The user interface for performing these tasks is different in Windows Server 2003 family operating systems from the way it was in Microsoft Windows NT® 4.0 or Microsoft Windows® 2000.

Please choose your upgrade path:

- Windows NT 4.0 to one of the Windows Server 2003 family operating systems
- Windows 2000 to one of the Windows Server 2003 family operating systems

**Windows NT 4.0 to one of the Windows Server 2003 family operating systems**

| If you want to | In Windows NT 4.0 use | In Windows Server 2003 family operating systems use |
|---|---|---|
| Connect to a terminal server | **Terminal Services Client** in **Program Manager** | Open Remote Desktop Connection.<br><br>For more information, see Remote Desktop Connection |

# Terminal Server Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### Best practices

- Install Terminal Server on a standalone server and not on a domain controller.

  Installing Terminal Server on a domain controller can affect the performance of the server because of the additional memory, network traffic, and processor time required to perform the tasks of a domain controller in a domain.

- Install Terminal Server on an NTFS file system partition.

  NTFS provides greater security for users in a multisession environment who access the same data structures.

- When shutting down a terminal server, use the **tsshutdn** command instead of the **Shut Down** option on the **Start** menu. This will shut down the server in a controlled manner. The **Shut Down** option on the **Start** menu does not notify users before ending user sessions and is not recommended. Ending a user's session without warning can result in loss of data at the client. For more information about using **tsshutdn**, see Tsshutdn.

- Back up your license server regularly.

  Backing up your license server regularly protects data from accidental loss due to hardware or storage failure. Create a duplicate copy of the data on your hard disk and then archive the data on another storage device such as a removable disk or tape. In the event that the original data on your hard disk is accidentally erased or overwritten, or becomes inaccessible because of a hard disk failure, you can easily restore the data from the archived copy.

#### Program installation

- Use **Add or Remove Programs** in Control Panel to install applications on the terminal server. Using this method, you can install programs for multisession use. For more information about installing applications on a terminal server, see Starting the installation.

- After you install Terminal Server, do not use **Add or Remove Programs** to switch Terminal Server on and off.

  Terminal Server installs programs for use in a multisession environment. Programs that were installed while Terminal Server was installed might not work correctly when Terminal Server is uninstalled. Instead, reinstall all programs for use without Terminal Server if you decide to remove the component.

- Check for application compatibility scripts before installing programs for use with Terminal Server.

  Many commonly used programs have been tested for compatibility. Some programs require minor changes to the installation. Scripts are available for these programs and must be run after the program installation is complete. Scripts are located in the systemroot in \Application Compatibility Scripts\Install.

#### Configuring Terminal Services

- **Use Terminal Services Group Policy to configure one or more terminal servers, or to manage Terminal Server user settings.** Terminal Server Group Policies can be applied on individual computers or on groups of computers belonging to a single organizational unit.

#### Managing users

- **Use Terminal Services-specific groups**

Create User Groups that are specifically for Terminal Services users. Maintaining users through groups is much easier and less time consuming than managing users individually.

Windows Server 2003 family server operating systems contain a default User group called Remote Desktop Users, which has been specifically created to manage Terminal Server users. This group is not populated by default. You must add users to the Remote Desktop Users group if you want them to be able to establish remote connections.

- **Use Terminal Services-specific profiles**

  Assign a separate profile for logging onto Terminal Services. Many of the common options that are stored in profiles, such as screen savers and animated menu affects, are not desirable when using Terminal Services. Assigning a specific profile allows users to get the most out of the system they are using without expending additional server resources. For information about assigning a Terminal Services specific profile, see Change a user's Terminal Services profile path.

- **Use mandatory profiles**

  Use a mandatory Terminal Services profile that is created to suit the needs of all of the different types of clients and that provides the best server performance. Be aware that 16-bit computers and Windows-based terminals might not support some screen resolutions.

- **Set time limits**

  Setting limits on the duration of client connections can improve server performance. You can set the limits on how long a session lasts, how long a disconnected session is allowed to remain active on the server, and the time allowed for a session to remain connected, yet idle. For information about setting session limits, see Configuring session limits.

- **Use the Starting program option**

  If you have users who need access to only one application on the terminal server, use the **Starting program** option to restrict users to that application. For more information, see Specify a program to start on session connection.

- **Create preconfigured connection files for users or groups of users**

  To make connecting to Terminal Services easier, you can supply users with preconfigured connection files. Collections of connection files can also be made either for different departments within your organization or for different job titles. preconfigured connection files are created using Remote Desktop Connection. For more information, see Managing Terminal Services connection files.

# Terminal Server How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install Terminal Server
- Disable Terminal Services connections
- Uninstall Terminal Server
- Deploy Applications
- Deploy Client Software
- Use Client Software

# Install Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Terminal Server**

1. Open Configure Your Server Wizard.
2. Click **Next** and follow the instructions on the **Preliminary Steps** screen.
3. Click **Next**, and on the **Server Role** screen, select **Terminal Server**.
4. Click **Next** and follow the instructions in the wizard.
5. Some programs might not work correctly when Terminal Server is installed. If so, you must reinstall these programs for multisession access using **Add or Remove Programs** after Terminal Server is installed. For more information, see Program Compatibility.

**Warning**

- Terminal Server Licensing is a required component that licenses clients on a terminal server. You must install Terminal Server Licensing or your terminal server will stop accepting connections from unlicensed clients 120 days from the date of the first client logon.

  You should not install Terminal Server Licensing on the same computer with Terminal Server.

  For more information on Terminal Server Licensing, see Terminal Server Licensing.

**Important**

- When you install Terminal Server using the Configure Your Server Wizard, as a security precaution the Internet Explorer Enhanced Security Configuration is set by default to prevent Administrators from downloading files or running ActiveX controls from the Web. If you want to change this setting to either permit all users to download files or run ActiveX controls or prevent all users from doing so, use **Add/Remove Windows Components** in **Add or Remove Programs**. This setting applies to servers running one of the Windows Server 2003 family operating systems. For more information, see Terminal server role: Configuring a terminal server and Internet Explorer Enhanced Security Configuration.

**Important**

- You must use the Remote Desktop Users group to control remote connection permissions for Terminal Server. For more information, see Managing Terminal Services users and Add users to the Remote Desktop Users group.

**Important**

- It is not necessary to install Terminal Server for remote administration of your server. Remote Desktop for Administration is installed by default. To use Remote Desktop for Administration, you must first enable remote connections. For more information on enabling remote connections, see Enable or disable Remote Desktop and Enabling users to connect remotely to the server.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For

more information, see Default local groups, Default groups, and Using Run as.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

- You can also use **Add or Remove Programs** to install Terminal Server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable Terminal Services connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable Terminal Services connections**

1. Click the **System** in Control Panel.

2. On the **Remote** tab, clear the **Allow users to connect remotely to your computer** check box, and then click **OK**.

   The terminal server no longer accepts new connections, but existing connections are maintained until closed by the users. This allows administrators to shut down a terminal server gradually.

## Notes

- You must be logged on as Administrator or a member of the Administrators group to disable Terminal Services connections.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Uninstall Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To uninstall Terminal Server**

1. Open Add or Remove Programs in Control Panel.
2. Click **Add or Remove Windows Components** to open the Windows Components wizard.
3. In the Windows Components wizard, deselect the **Terminal Server** check box, and then click **Next**.
4. Follow the instructions in the wizard.

### Important

- Use this procedure only if you want to completely uninstall Terminal Server. To disable Terminal Services connections temporarily (for example, to install an application on a terminal server), you can do so using the **Remote** tab in System Properties and clearing the **Allow users to connect remotely to your computer** checkbox.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Deploy Applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploy applications**

- Install a program using Add or Remove Programs
- Install a program using the change user command

# Install a program using Add or Remove Programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a program using Add or Remove Programs**

1. Log on to the terminal server as an administrator and close all programs.
2. Open Add or Remove Programs in Control Panel.
3. In **Add or Remove Programs**, click **Add New Programs**.
4. Select the method to install the program and follow the instructions in the wizard.
5. The installation wizard will guide you through the rest of the installation process. For security purposes, install the program on an NTFS file system partition.
6. If applicable, edit and run the program installation script.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- If you are prompted to restart the computer to finish the installation, click **Finish** in **Add or Remove Programs** before accepting the prompt to restart the computer. It might be necessary to log on as the same user after the server has been rebooted in order to finish the application installation properly. Do not allow other users to log on before this step has been completed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Deploying Applications

# Install a program using the change user command

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a program by using the change user command**

1. Log on to the terminal server as an administrator and close all applications.
2. To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
3. Type **change user /install** and press ENTER.
4. Install the program on a local NTFS file system formatted drive as directed by the installation program.
5. At the command prompt, type **change user /execute** when installation is complete.
6. If applicable, edit and run the program installation script.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If prompted by a program to install an additional program, you can leave your initial program running.
- You can type **change user /query** at the **Command Prompt** to see whether execute mode is enabled and .ini file mapping is on.
- You should use **Add or Remove Programs** to install programs whenever possible.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Deploy Client Software

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploy client software**

- Share the client setup folder at the server
- Create a connection file
- Install the 32-bit Terminal Services Client (Remote Desktop Connection)

# Share the client setup folder at the server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To share the client setup folder**

1. On a computer that is running one of the Windows Server 2003 family operating systems, open Windows Explorer.
2. Browse to the systemroot\System32\Clients\Tsclient\win32 folder, where *systemroot* is the folder containing your Windows installation files (for example, C:\Windows\System32\Clients\Tsclient\win32).
3. Right-click the \win32 folder, click **Sharing and security**, check **Share this folder**, and then click **OK**.

### Note

- To share folders and drives, you must be logged on as a member of the Administrators, Server Operators, or Power Users group.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install the 32-bit Terminal Services Client (Remote Desktop Connection)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install the 32-bit Terminal Services Client (Remote Desktop Connection)**

1. At a command prompt, type *drive*:setup (where drive is the letter of the drive containing the Terminal Services Client disk or path to shared installation files), and press ENTER.

2. Follow the instructions in the Wizard.

## Notes

- Remote Desktop Connection is already installed on Windows XP and Windows Server 2003 family operating systems.

- To use Group Policy to deploy Remote Desktop Connection, assign the program on a per-computer basis to a terminal server. For more information, see article Q324750, "HOW TO: Assign Software to a Specific Group By Using a Group Policy in Windows Server 2003" in the Microsoft Knowledge Base.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Remove the Terminal Services Client
Terminal Services Client Overview

# Remove the Terminal Services Client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove the Terminal Services Client**

1. In the **Terminal Services Client group**, click **Uninstall**.
2. In the **Terminal Services Client Setup** dialog box, click **Remove All** to remove all Terminal Services Client files from your client computer.
3. Click **Yes** to confirm the removal.
4. In the **Terminal Services Client - Restart Windows** dialog box, click **Restart Windows** to complete.

### Note

- If you installed the client from a floppy disk, you must place the installation disk in the drive during this procedure. Placing the disk in the drive during uninstall reactivates the disk so that it can be used to install the client for another user.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use Terminal Services shortcut keys

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Use Terminal Services shortcut keys**
If you choose not to apply Windows key combinations to your terminal server sessions, you can use these Terminal Services shortcut keys to perform many of the same functions.

| Shortcut key | Description |
|---|---|
| ALT+PAGE UP | Switches between programs from left to right. |
| ALT+PAGE DOWN | Switches between programs from right to left. |
| ALT+INSERT | Cycles through the programs in the order they were started. |
| ALT+HOME | Displays the **Start** menu. |
| CTRL+ALT+BREAK | Switches the client between a window and full screen. |
| CTRL+ALT+END | Displays the **Windows Security** dialog box. |
| ALT+DELETE | Displays the **Windows** menu. |
| CTRL+ALT+Minus (-) symbol on the numeric keypad | Places a shadow copy of the active window, within the client, on the terminal server clipboard (provides the same functionality as pressing PrintScrn on a local computer.) |
| CTRL+ALT+Plus (+) symbol on the numeric keypad | Places a shadow copy of the entire client window area on the terminal server clipboard (provides the same functionality as pressing ALT+PrintScrn on a local computer.) |

**Note**

- On an NEC98, these shortcut keys are different in two cases:
  - CTRL+ALT+BREAK is replaced by CTRL+GRPH+VF2.
  - CTRL+ALT+END is replaced by CTRL+GRPH+VF1.

# Terminal Services overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services overview**

Terminal Services provides remote access to a Microsoft® Windows® desktop through "thin client" software, allowing the client computer to serve as a terminal emulator. Terminal Services transmits only the user interface of the program to the client. The client then returns keyboard and mouse clicks to be processed by the server. Each user logs on and sees only their individual session, which is managed transparently by the server operating system and is independent of any other client session. Client software can run on a number of client hardware devices, including computers and Windows-based terminals. Other devices, such as Macintosh computers or UNIX-based workstations, can use additional third-party software to connect to a server running Terminal Server.

Terminal Services is the underlying technology for several features and components of Microsoft Windows Server™ 2003 family operating systems. Among these are Terminal Server and Remote Desktop for Administration.

Terminal Server provides an effective and reliable way to distribute Windows-based programs with a network server. With Terminal Server, a single point of installation allows multiple users to access the desktop on a server running one of the Windows Server 2003 family operating systems. Users can run programs, save files, and use network resources as if they were sitting at that computer. For more information on using Terminal Server for multisession application hosting, see Using Terminal Server to host applications centrally.

Remote Desktop for Administration (formerly known as Terminal Services in Remote Administration mode) provides remote access to the desktop of any computer running one of the Windows Server 2003 family operating systems, allowing you to administer your server--even a Microsoft Windows 2000 server--from virtually any computer on your network. For more information on using Remote Desktop for Administration for remote server administration, see Remote Desktop for Administration.

**Terminal Services benefits:**

- **Brings** Windows Server 2003 **family operating systems to desktops faster.** Terminal Services helps bridge the gap while older desktops are migrated to Microsoft Microsoft® Windows® XP Professional, providing a virtual desktop experience of any Windows Server 2003 family operating system to computers that are running earlier versions of Windows. Terminal Services clients are available for many different desktop platforms including Microsoft MS-DOS®, Windows-based terminals, Macintosh, and UNIX. Additionally, a Web-based version of the Terminal Services client (Remote Desktop Web Connection) provides Terminal Services connectivity to computers with Web access and an Internet Explorer browser. (Connectivity for MS-DOS, Macintosh, and UNIX-based computers requires additional software.)

- **Takes full advantage of existing hardware.** Terminal Services extends the model of distributed computing by allowing computers to operate as both thin clients and full-featured personal computers simultaneously. Computers can continue to be used as they have been within existing networks while also functioning as thin clients capable of emulating the Windows XP Professional desktop.

**Terminal Server benefits:**

- **Centralized deployment of programs.** With Terminal Server, all program execution, data processing, and data storage occur on the server, centralizing the deployment of programs. Terminal Server ensures that all clients can access the same version of a program. Software is installed only once on the server, rather than on every desktop throughout the organization, reducing the costs associated with updating individual computers. For more information on centralized deployment of programs, see Using Terminal Server to host applications centrally.

**Remote Desktop for Administration benefits:**

- **Remote administration.** Terminal Services Remote Desktop for Administration provides remote administration for Windows Server 2003 family operating systems, giving system administrators a method of remotely managing their server from any client over a LAN, WAN or dial-up connection. Up to two remote sessions, plus the console session, can be accessed simultaneously. Terminal Server licensing is not required to use this feature.

# Using Terminal Server to host applications centrally

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Terminal Server to host applications centrally**

Terminal Server provides an effective and reliable way to distribute Windows-based programs by making them available on a network server. With Terminal Server, a single point of installation allows multiple users to access the desktop of a server running one of the Windows Server 2003 family operating systems. Users can run programs, save files, and use network resources as though they were sitting at that computer. Terminal Server delivers the Windows desktop and Windows-based applications to computers that might not typically be able to run Windows operating systems.

**Note**

- Terminal Server is not included in Windows Server 2003, Web Edition.

**Ease of use**

| Feature | Description | For more information, see: |
|---|---|---|
| **Improved client: Remote Desktop Connection** | Renamed **Remote Desktop Connection**, the Terminal Services client features a more streamlined user interface that allows you to connect to terminal servers, change connection settings, save connection information, and connect to a remote computer. The old Terminal Services Client Connection Manager tool is no longer needed, although you can still use any connections that were created with that tool. With Remote Desktop Connection, users can create connection files, which are predefined connections to servers for either a single program or full desktop access, and save them in **My Documents**. You can ensure that the same version of a single program is being used across the computing environment by creating a connection file and distribute it along with the Remote Desktop Connection client software. | Remote Desktop Connection overview |
| **Automated local printer support** | Terminal Services can both add and automatically reconnect printers attached to Terminal Services clients. | Providing client access to local printers |
| **Drive and file system redirection** | Users can see their local drives while logged on to a terminal server. In Microsoft Windows Explorer, users' local drives appear in the session folder tree as <driveletter> on <client>. | Providing client access to the local file system |
| **Audio redirection** | Users of a terminal server can direct audio output from the terminal server to the audio device on their local computer. | Providing client access to server audio |
| **Clipboard redirection** | Users can cut and paste between the programs running on the local computer and the terminal server. | Shared clipboard |
| **Performance enhancements** | Enhancements to caching, including persistent caching, packet utilization, and frame size, provide significant performance improvements over earlier versions of Terminal Services. | Bitmap caching |
| **Roaming disconnect support** | This feature enables users to disconnect from a session without logging off. A session can remain active while disconnected, enabling the user to reconnect to the existing session from another computer or at a later time. Logon is required for reconnection, keeping each session secure at all times. | Log off or disconnect |
| **Multiple logon support** | Users can log on to multiple sessions simultaneously from one or more clients, to multiple terminal servers, or to a single server multiple times. As a result, the user can do several tasks concurrently or run multiple unique desktop sessions. | Terminal Services User Properties |

**Manageability**

| Feature | Description | For more information, see: |
|---|---|---|
| **Terminal Services Group Policies** | With the addition of Terminal Services Group Policies, administrators can use one tool (Group Policy) to manage Terminal Services-related settings throughout an organization. Terminal Services nodes have been added to the Computer and User section of the Administrative Group Policy template (System.adm). | Configuring Terminal Services with Group Policy |
| **Terminal Services WMI provider** | The Windows Management Instrumentation (WMI) provider for Terminal Services allows you to use scripts to manage, configure, and troubleshoot terminal servers remotely, bypassing the Terminal Services tools, command-line options, and other management methods. | Configuring Terminal Services with WMI |
| **Session remote control** | Support staff can either view or control another Terminal Services session. Keyboard input, mouse movements, and display graphics are shared between two Terminal Services sessions, giving support staff the ability to diagnose and resolve configuration problems, as well as provide user training from a remote location. This feature is particularly useful for organizations with branch offices. | Using remote control |
| **Load balancing** | Terminal Services Connection Management (TSCM), combined with load balancing technology, allows Terminal Services clients to connect to the least busy member of a group of terminal servers. Session Directory services ensure that disconnected sessions are reconnected to the same server where the original connection was established. | Load balancing and terminal servers |
| **Terminal Services Web Client: Remote Desktop Web Connection** | Remote Desktop Web Connection is an ActiveX control that provides virtually the same functionality as the full Remote Desktop Connection client, but is designed to deliver this functionality over the Web. When embedded in a Web page, Remote Desktop Web Connection can host a Terminal Services client session even if the full client is not installed on the user's computer. | About Remote Desktop Web Connection |
| **Microsoft Windows Installer (MSI) package for client deployment** | Remote Desktop Connection can be installed with Windows Installer. Windows Installer provides a quick and efficient means for deploying client software to target computers, using either a network-based share point or Microsoft IntelliMirror. | About the Terminal Services Client MSI Setup Package |
| **Windows-based terminals** | Windows-based terminals are available from a variety of manufacturers. They use a custom implementation of the Microsoft Windows CE operating system and the Remote Desktop Protocol (RDP). | |
| **Terminal Server Licensing** | Terminal Server Licensing helps system administrators and purchasing offices track clients and their associated licenses. | Terminal Server Licensing |
| **Distributed File System (DFS) support** | Support for Distributed File System (DFS) enables users to connect to a DFS share, and administrators to host a DFS share from a terminal server. | Distributed File System overview |
| **Terminal Services Manager** | Administrators can use Terminal Services Manager to query and manage Terminal Services sessions, users, and processes. | Terminal Services Manager |
| **Terminal Services Configuration** | Terminal Services Configuration allows you to create, modify, configure, and delete Remote Desktop Protocol (RDP) connections. You can also use Terminal Services Configuration to view and set terminal server settings. | Terminal Services Configuration |
| **Integration with Local Users and Groups and Active Directory Users and Computers** | Administrators can create accounts for Terminal Services users the same way they create accounts for users on any Windows Server 2003 family operating system. Extra fields exist for specifying information specific to Terminal Services, such as the Terminal Services Profile Path and Home Directory. | Terminal Services users |

| | | |
|---|---|---|
| **Integration with System Monitor** | Integration with System Monitor enables administrators to monitor Terminal Services system performance, including tracking processor use, memory allocation, and paged memory usage and swapping per-user session. | Performance monitoring |
| **Messaging support** | Administrators can alert users to important information, such as system shutdowns, upgrades, or new programs. | Send a message to a user |
| **Remote administration with Remote Desktop for Administration** | Any member of the Administrators group with access to the Terminal Services administrative utilities can remotely manage all aspects of a server. Remote Desktop for Administration is installed automatically on all Windows Server 2003 family operating systems. | Remote Desktop for Administration |
| **Configurable session time-out** | Administrators can reduce server resource usage by configuring session time-outs. Administrators can specify the length of an active session and how long a session can remain idle on the server. | Configuring session limits |

**Security**

| Feature | Description | For more information, see: |
|---|---|---|
| **Security modes** | Terminal Server can run in one of two security modes, depending on the applications you plan to run:<br><br>**Full Security**<br>Select this option to take advantage of new security features in Windows Server 2003 family operating systems and provide the most secure environment for your terminal server.<br><br>**Relaxed Security**<br>This option allows access to the system registry, enabling most legacy applications to run as they did under Windows 2000, Terminal Server Edition. | Choosing the security mode for a terminal server |

| | | |
|---|---|---|
| **Encryption** | Terminal Services has four levels of encryption.<br><br>• By default, Terminal Services connections between any of the Windows Server 2003 family operating systems and client computers running the Remote Desktop Connection client are encrypted with **High** (128-bit) encryption.<br><br>• The **FIPS Compliant** encryption level encrypts and decrypts data sent from client to server and from server to client with the Federal Information Processing Standard (FIPS) encryption algorithms using the Microsoft cryptographic modules. If FIPS compliance has already been enabled by the **System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing** Group Policy, administrators cannot change the encryption level for Terminal Services connections either by changing the Terminal Services **Set client connection encryption level** Group Policy setting or by using Terminal Services Configuration.<br><br>• For legacy clients that support only low levels of encryption, administrators can set the encryption level to **Client Compatible.**<br><br>• The **Low** level encrypts data sent from the client to the server using 56-bit encryption.<br><br>**Important**<br><br>• Data sent from the server to the client is not encrypted.<br><br>In addition, the Terminal Services logon process includes change password, unlock desktop, and unlock screen saver features. The logon process is encrypted, ensuring secure transfer of user name and password. | Configuring authentication and encryption System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing |
| **Limit logon attempts and connection time** | Administrators can limit the number of user logon attempts to prevent unauthorized access to a server. Additionally, the connection time of an individual user or a group of users can be limited. | Terminal Services Configuration |

# Terminal Services administrative tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services administrative tools**
In addition to the standard administrative tools, the following Terminal Services tools, tool extensions, and commands for administering Terminal Services connections, computers, and users are included in all of the Windows Server 2003 family operating systems.

- Terminal Services Group Policies.
- Terminal Services Manager.
- Terminal Services Configuration.
- Remote Desktops MMC snap-in.
- Active Directory Users and Computers and Local Users and Groups extensions.
- Terminal Server Licensing.
- System Monitor counters.
- Task Manager additional fields.
- Multiuser support in Add or Remove Programs.
- Commands.

**Terminal Services Group Policies**
Use Terminal Services Group Policies to configure individual terminal servers or groups of terminal servers, or to assign policies for Terminal Server users or user groups. For more information, see Configuring Terminal Services with Group Policy.

**Terminal Services Manager**
Use Terminal Services Manager to manage and monitor users, sessions, and processes on any server running Terminal Services on the network. Use it to:

- Display information about servers, sessions, users, and processes.
- Connect to and disconnect from sessions.
- Monitor sessions.
- Reset sessions.
- Send messages to users.
- Log off users.
- Terminate processes.

For more information about Terminal Services Manager, see Terminal Services Manager.

**Terminal Services Configuration**
During the installation of a Windows Server 2003 family operating system, a connection is configured for the Remote Desktop

Protocol (RDP). This connection provides the link clients use to log on to a session on the server for either Remote Desktop for Administration or Terminal Server connections. After installation, you can use Terminal Services Configuration (Tscc.msc) to change the properties of this connection on the local computer or to add new connections.

**Note**

- Many of these settings can also be set with Terminal Services Group Policy or Windows Management Instrumentation (WMI), in which case Terminal Services Configuration settings are overridden.

Use Terminal Services Configuration to:

- Name a connection.
- Specify a connection type.
- Specify a connection transport and transport properties.
- Set the maximum number of sessions allowed.
- Enable or disable logons through the connection.
- Set connection time-outs.
- Set the level of encryption.
- Set whether to disconnect broken connections.
- Enable or disable session remote control.
- Enable or disable automatic logons.
- Specify a program to run when a user logs on.
- Override user profile settings for wallpaper.
- Set permissions on the connection.
- Set client device mapping and connection parameters.

For more information about Terminal Services Configuration, see Terminal Services Configuration.

**Remote Desktops MMC snap-in**
This Microsoft Management Console (MMC) Remote Desktops snap-in allows you to create connections to multiple terminal servers, configure them to run specific programs upon connecting, and switch easily between Terminal Services connections by clicking the connection in the console tree. A special MMC version of the Terminal Services client displays the desktop of the selected computer in the MMC results pane.

For more information about the Remote Desktops snap-in, see Remote Desktops snap-in.

**Active Directory Users and Computers and Local Users and Groups extensions**
Terminal Services extends Active Directory Users and Computers and Local Users and Groups to allow you to control Terminal Services features for each user. You can also use Terminal Services Group Policies to control these features, although settings you have specified might be overridden.

Use the Terminal Services extension to:

- Set the path to the Terminal Services user profile for each user.
- Enable or disable logons.

- Set time limits on session.
- Set whether to disconnect or reset a broken connection.
- Enable or disable remote control.
- Specify a program to run when a user logs on.
- Make client drives and printers connect at logon.

**Terminal Server Licensing**
Use Terminal Server Licensing to register and track licenses for Terminal Server clients. For more information, see Terminal Server Licensing.

### Important

- You must install Terminal Server Licensing or your terminal server will stop accepting connections from unlicensed clients 120 days from the date of the first client logon.

**System Monitor counters**
Terminal Services extends System Monitor by adding User and Session objects and their counters. You can use these objects and counters to monitor the resources that a user or session consumes. Terminal Services also adds counters to the Process and System objects.

For more information on System Monitor, see System Monitor overview.

**Task Manager additional fields**
Terminal Services provides two additional fields, **ID** (session ID) and **User**, to Task Manager for monitoring and ending processes for all sessions.

**Multiuser support in Add or Remove Programs**
Add or Remove programs ensures that applications are installed for use in a multisession environment.

**Commands**
The following table shows the commands you can use to manage Terminal Services at the command prompt.

| Command | Function |
|---|---|
| Change logon | Temporarily disable logons to a terminal server. |
| Change port | Changes COM port mappings for MS-DOS program compatibility. |
| Change user | Changes the .ini file mapping for the current user. |
| Cprofile | Removes user-specific file associations from a user's profile. |
| Flattemp | Enables or disables flat temporary directories. |
| Logoff | Ends a client session. |
| Msg | Sends a message to one or more clients. |
| Mstsc | Runs Remote Desktop Connection. |
| Query process | Displays information about processes. |
| Query session | Displays information about Terminal Services sessions. |
| Query termserver | Lists Terminal Services servers on the network. |

| | |
|---|---|
| Query user | Displays information about users logged on to the system. |
| Register | Registers a program so that it has special execution characteristics. |
| Reset session | Allows you to reset (delete) a session from the terminal server. |
| Shadow | Allows you to monitor or remotely control an active session of another user. |
| Tscon | Connects to another existing Terminal Services session. |
| Tsdiscon | Disconnects a client from a Terminal Services session. |
| Tskill | Terminates a process. |
| Tsprof | Copies user configuration and changes profile path. |
| Tsshutdn | Shuts down a Terminal Services server. |

# Deploying Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying Terminal Server**

This section provides information about deploying Terminal Server:

- Installing Terminal Server
- System Planning

# Installing Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing Terminal Server**

This section covers information about installing Terminal Server:

- Before Installing Terminal Server
- Choosing the security mode for a terminal server
- Switching Terminal Services on and off
- Managing Terminal Services from the command line

When you install one of the Windows Server 2003 family operating systems, Remote Desktop for Administration is installed automatically. With Remote Desktop for Administration, you can create up to two concurrent remote connections to your server for remote administration and other tasks. To use Remote Desktop for Administration, you must first enable remote connections. For more information, see Enable or disable Remote Desktop.

To use Terminal Services for multiuser application hosting, you must install the Terminal Server component using the **Configure Your Server Wizard**. (Terminal Server is not included in Windows Server 2003, Web Edition.)

For information on using Remote Desktop for Administration, see Remote Desktop for Administration.

# Before Installing Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Before installing Terminal Server**

Review the following information before you install Terminal Server:

- Read System Planning for system sizing and performance considerations.
- Read "Hosting Applications with Terminal Server" at the Microsoft Windows Resource Kit Web site.
- Plan to install Terminal Server on a standalone server, not on a domain controller. When installed on a domain controller, Terminal Server performance is affected because of the additional memory, network traffic, and processor time required to perform the tasks of a domain controller in a domain.
- Install Terminal Server on a server installed on an NTFS file system partition. NTFS provides greater security for users in a multisession environment.
- Understand the effect of the Internet Explorer Enhanced Security Configuration setting on users of a terminal server. When you install Terminal Server using the Configure Your Server Wizard, this setting prohibits Administrators from downloading files or ActiveX controls from the Web by default as a security precaution. However, all non-Administrator users can download files or ActiveX controls. After you install Terminal Server, you can change this setting to allow both Administrators and non-Administrator users to perform these tasks, or to prevent all users from performing these tasks. Use **Add/Remove Windows Components** in **Add or Remove Programs** to change this setting. This setting applies to servers running one of the Windows Server 2003 family operating systems. For more information, see Terminal server role: Configuring a terminal server and Internet Explorer Enhanced Security Configuration.
- Install the programs you want to use with Terminal Server *after* Terminal Server is installed. This allows Terminal Server to register the programs for multisession access, making the programs easier to manage. For more information about installing programs, see Installing Programs.

For instructions on installing Terminal Server, see Install Terminal Server

# Installing Terminal Services in remote administration mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing Terminal Services in remote administration mode**
It is no longer necessary to install Terminal Services in Remote Administration mode (now called Remote Desktop for Administration). When you install one of the Windows Server 2003 family operating systems, Remote Desktop for Administration is installed automatically. To use Remote Desktop for Administration, you must first enable remote connections. For more information, see Enable or disable Remote Desktop.

For information on using Remote Desktop for Administration, see:

- Remote Desktop for Administration

# Choosing the security mode for a terminal server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Choosing the security mode for a terminal server**
In Windows 2000 and Windows Server 2003 family operating systems, you can choose one of two security modes:

- Relaxed security: Windows NT 4.0/Terminal Server Edition permissions compatibility mode
- Full security: Windows 2000/Windows Server 2003 family operating systems permissions mode

In both modes, the TERMINAL SERVER USER security descriptor is applied to many keys in the registry and directories in the file system. The difference between the two modes is based on the way the security descriptor is applied.

- In Relaxed Security mode, the security descriptor is added to each member of the Users group. On Windows NT 4.0, when a user's permissions are evaluated to determine access to a file or registry entry, the presence of the security descriptor authorizes access.

  This application of the security descriptor allows members of the Users group to run programs that otherwise might not work at all in the more rigorous Full Security permissions mode used on Windows 2000 and Windows Server 2003 family operating systems. However, when you choose Relaxed Security mode, any user on the system can change files and registry settings in many places throughout the system, although others users' data files may not be visible. A malicious user could exploit this situation by replacing a known and trusted program with a program of the same name but some bad intent.

- By contrast, Full Security mode does not apply the descriptor to each user. Instead, applications must be written to run in the context of an ordinary user. When in doubt, you should choose Full Security mode and test your applications in that mode.

  **Important**

  - Use Relaxed Security mode only if your test results indicate that it is necessary.

For information on changing the security mode, see Switch default permissions for application compatibility.

# Switching Terminal Services on and off

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Switching Terminal Services on and off**
To disable Terminal Services connections temporarily (for example, to install an application on a terminal server), go to the **Remote** tab in System Properties and clear the **Allow users to connect remotely to your computer** checkbox. (This checkbox is cleared by default when you install any of the Windows Server 2003 family operating systems.) When you disable remote connections, Terminal Services remains active on the computer, but no new remote connections are accepted.

If Terminal Server is installed on your computer, you can also uninstall it by using **Add or Remove programs**. When you do so, the computer is returned to its default state, Remote Desktop for Administration.

**Caution**

- Many older applications were not designed for multiple users and need to be modified before they will run properly on a terminal server. If you decide to uninstall Terminal Server using **Add or Remove programs**, the applications you installed and configured to run on a terminal server might not run the next time you install Terminal Server. You must configure or install the application again. For this reason, you should not use **Add or Remove programs** to temporarily disable Terminal Server.

**Note**

- For more information on disabling Terminal Services connections using the **Remote** tab in System Properties, see Disable Terminal Services connections

# Managing Terminal Services from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Terminal Services from the command line**

You can manage users, sessions, processes, and terminal servers by using command-line utilities. The following table lists the Terminal Services administrative utilities that you can invoke from the command line.

| Command | Function |
|---|---|
| Change logon | Disables, temporarily, logons to a terminal server. |
| Change port | Changes COM port mappings for MS-DOS program compatibility. |
| Change user | Changes the .ini file mapping for the current user. |
| Cprofile | Removes user-specific file associations from a user profile. |
| Flattemp | Enables or disables flat temporary directories. |
| Logoff | Logs off a user from a session and deletes the session from the server. |
| Msg | Sends a message to a user or group of users. |
| Mstsc | Displays the Remote Desktop Connection to establish a connection with a Terminal Server. |
| Query process | Displays information about processes running on a terminal server. |
| Query session | Displays information about sessions on a terminal server. |
| Query termserver | Displays a list of all terminal servers on the network. |
| Query user | Displays information about user sessions on a terminal server. |
| Register | Registers applications to execute in a global context on the system. |
| Reset session | Resets a session to known initial values. |
| Shadow | Monitors another user's session. |
| Tscon | Connects to another existing terminal server session. |
| Tsdiscon | Disconnects a client from a terminal server session. |
| Tskill | Ends a process. |
| Tsprof | Copies user configuration and changes profile path. |
| Tsshutdn | Shuts down a terminal server. |

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools.

# System Planning

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System planning**
This section presents information on system sizing and system components that can help you decide on a hardware configuration for a terminal server that gives your users optimal performance.

- System sizing
- Peripherals that affect performance
- Application performance
- Performance monitoring
- Load balancing and terminal servers

**Note**

- For additional information about deploying Terminal Server, see "Hosting Applications with Terminal Server" at the Microsoft Windows Resource Kit Web site.

# System sizing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System sizing**

Most computer users can be placed into one of three categories:

- **Light users.** A light user typically runs one program at a time--for example, a word processing program or a line-of-business program.
- **Structured task users.** A structured task user simultaneously runs two or more programs but does not frequently switch between programs. This user runs programs whose data-processing demands on the system are not heavy--for example, productivity programs such as word processing and an Internet browser.
- **Power users.** A power user is a more sophisticated user who runs three or more programs, and often has several active at the same time. A power user runs programs whose data processing demands on the system are heavy, such as detailed queries on large databases.

When determining how powerful your servers need to be, consider the types of users who will be using them. Light users place the lightest load on computational resources while power users consume the most computational resources. Also consider the types of programs your server runs. Keep in mind that a terminal server shares executable resources between individual users, just as any of the Windows Server 2003 family operating systems shares executable resources (.dll, .exe, and so on) between individual programs. As a result, the memory requirements for additional users running the same program are typically less than the requirements for the first user to load the application.

For adequate performance, a terminal server requires a Pentium or higher processor. A terminal server requires a minimum of 128 MB RAM, plus additional RAM for each user to support running each user's programs on the server. An additional 10 MB RAM is recommended for each light user and up to 21 MB RAM for each power user.

In general, processor and memory requirements scale linearly: You can support double the number of users on a multiprocessor-capable Pentium system by doubling the number of processors and doubling the amount of memory. Purchasing a system that supports multiple processors, even if you initially purchase only one processor, allows you to add capacity easily as your requirements grow.

Performance can vary depending on the programs you run on a terminal server. To judge the processing power and RAM required for each user, test your system by running the programs you use.

The bus architecture in single and multiprocessor systems also affects system performance. The ISA (AT bus) architecture is low bandwidth and is not recommended for a terminal server. Use a higher-performance bus, such as EISA, MCA, PCI, PCI-X, or InfiniBand for best performance. All of these buses support the sustained high data transfer rates typically required when running Terminal Server.

Peripherals can affect the performance of a terminal server. For more information, see Peripherals that affect performance.

# Peripherals that affect performance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Peripherals that affect performance**

Hard-disk throughput also affects the performance of a terminal server. SCSI disk drives and adapters, especially devices compatible with Fast SCSI and SCSI-2, have significantly better throughput than ST-506, IDE, or ESDI disk drives and adapters.

For highest disk performance, consider using a SCSI RAID controller. RAID (Redundant Array of Independent Disks) controllers place data on multiple disks to increase disk performance and improve data reliability.

Although the Remote Desktop Protocol (RDP) used with a terminal server causes minimal network load, a high-performance network adapter is recommended. This is particularly important if many users require either access to data stored on network servers or run client/server programs. Consider using two network adapters, dedicating one to RDP traffic only.

If a multiport asynchronous communication adapter is installed for supporting dial-up users, be sure to use an intelligent (microprocessor-based) adapter to both reduce interrupt overhead and increase throughput.

Applications can also affect performance. For more information, see Application performance.

# Application performance

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Application performance**

Windows Server 2003 family operating systems are 32-bit environments, whereas Microsoft Windows 3.11 is a 16-bit environment. The Windows Server 2003 family operating systems run 16-bit programs through a process called Windows on Windows (WOW), translating 16-bit programs in enhanced mode. This process causes 16-bit programs to consume additional system resources. Running 16-bit programs on a terminal server can reduce the number of users a processor can support by 40 percent and increase the memory required for each user by 50 percent. For this reason, use 32-bit versions of programs whenever possible.

Here are additional considerations for installing programs on a terminal server:

- Some video active applications can decrease performance. Turn off the video effects of an application for better performance.
- MS-DOS applications are not recommended because they can consume all of the available CPU.
- Application features that are always on and run in the background, such as automatic spelling and grammar checking in Microsoft Word, require more system resources.

For more information about 16-bit and 32-bit programs, see Comparing 16-bit and 32-bit programs. For more information about installing programs on a terminal server, see Installing Programs.

# Performance monitoring

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Performance monitoring**
Use the performance monitoring tools supplied with the Windows Server 2003 family operating systems to monitor system performance and the effects of configuration changes on system throughput. Some of the most important measurements for performance monitoring include:

- Processor utilization
- Hard-disk I/O rates
- Memory utilization
- Pagefile activity

A good way to estimate how many users a server can support is to measure system performance with two to five users on the system, and then scale the results.

Terminal Services adds the Terminal Services User and Terminal Services Session objects and their counters to the set of objects you can observe using System Monitor.

For more information about performance monitoring, see "WSRK System Performance and Troubleshooting Guide Part One: Operating System Performance" at the Microsoft Windows Resource Kit Web site.

# Load balancing and terminal servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Load balancing and terminal servers**
Load Balancing pools the processing resources of several servers using the TCP/IP networking protocol. You can use this service with a cluster of terminal servers to scale the performance of a single terminal server by distributing sessions across multiple servers. Session Directory (included in Windows Server 2003, Enterprise Edition and Windows Server 2003, Datacenter Edition) keeps track of disconnected sessions on the cluster, and ensures that users are reconnected to those sessions.

**Terminal Services Connection Management**
Terminal Services Connection Management works with your load balancing service to ensure that users are transparently reconnected to the original server hosting their disconnected Terminal Server sessions. The components of Terminal Services Connection Management are:

- A network load-balancing solution (Network Load Balancing, Domain Name System (DNS) round-robin, or a third-party solution).
- Two or more terminal servers, logically grouped into a Terminal Server cluster.
- A session directory server. This computer can be any running Windows Server 2003, Enterprise Edition, or Windows Server 2003, Datacenter Edition, that is visible on the network and running the Terminal Services Session Directory service. As a Best Practice, make the Session Directory server a highly available network server that is not itself running Terminal Server.

The Terminal Server Connection Management process is as follows:

1. When the user logs on to the terminal server cluster, the terminal server receiving the initial client logon request sends a query to the session directory server.
2. The session directory server checks the username against its database and sends the result to the requesting server.
    - If the user has no disconnected sessions, logon continues at the server hosting the initial connection.
    - If the user has a disconnected session on another server, the client session is passed to that server and logon continues.
3. When the user logs on to the disconnected session, the session directory is updated.

**Terminal Services Session Directory**
The Terminal Services Session Directory service is a database that keeps track of sessions on terminal servers in a cluster and provides the information used at connection time to connect users to existing sessions.

When the Session Directory service starts up, it creates the "Session Directory Computers" local group. By default, this group is not populated. You must choose the individual computers or groups you want to participate in the Session Directory service, and then manually Changing group memberships to the Session Directory Computers group.

For more information about configuring Session Directory settings, see Configure Session Directory settings and "Hosting Applications with Terminal Server" at the Microsoft Windows Resource Kit Web site. For more information about adding members to a security group, see Changing group memberships.

**To start Session Directory service**

1. Open Services.

2. Double-click **Terminal Services Session Directory Properties**.

3. To start the service, click **Start**. To ensure that the service runs each time the server boots, in **Startup Type**, click **Automatic**.

### Note

- To open the Services snap-in manually, click **Start**, point to **Administrative Tools**, and then click **Services**.

#### To create a Terminal Server Cluster

1. Open the Group Policy object for the organizational unit that contains the terminal servers you want to participate in the cluster.

2. In Administrative Templates, in the Windows Components/Terminal Services/Session Directory folder, enable the Session Directory Active setting.

3. In the Session Directory Server setting, click Enable, type the name of the server running the Session Directory service, and then click **OK**.

4. In the Session Directory Cluster name setting, click Enable, specify a name for this Terminal Server cluster, and then click **OK**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Deploying Applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying applications**

To deploy an application for use by Terminal Server users, you install it on the terminal server.

For information about program considerations, see Program Considerations

For information about installing programs for use on a terminal server, see Installing Programs

For information about compatibility of programs with Terminal Server, see Program Compatibility

# Program Considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Program considerations**
Consider the following before selecting and installing programs on Terminal Server.

- Assigned and published programs
- Comparing 16-bit and 32-bit programs
- System resource considerations
- Programs starting programs

**Note**

- For additional information about deploying Terminal Server, see "Hosting Applications with Terminal Server" at the Microsoft Windows Resource Kit Web site.

# Assigned and published programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Assigned and published programs**

Windows Server 2003 family operating systems provide Windows Installer for deploying programs within your organization. You can assign a program to either computers or users, or you can publish programs to users. For more information on using Windows Installer to install programs, see Managing options for computers through Group Policy.

Because Terminal Server is designed to provide multisession access to programs, additional consideration is needed before deploying applications in environments that contain terminal servers.

Applications are installed on the terminal server, and are available to any user with remote access to the terminal server. Terminal Server cannot accept published programs because they are published on a per-user basis. Additionally, assigned programs must be assigned on a per-computer basis, rather than on a per-user basis.

When installing assigned programs, members of the Administrators group on the terminal server can install the program from either the console session or from a remote session.

**Caution**

- Program installation often requires restarting the computer. Always ensure that no users are logged on to the terminal server before starting any program installation.
- If the program is installed from a remote session, the session is disconnected or reset if the program installation requires rebooting the server. When the server reboots, your session is reset and you need to again log on to the terminal server to ensure that the program is correctly installed.
- Whenever possible, install programs from the console session.

**Deploying programs on terminal servers by using Windows Installer**

Microsoft Windows Installer installs programs at different levels, depending on how the .msi package was created. Many .msi packages require minimal installation where only a small number of program components are installed. When a user first invokes the program, there are enough components installed for Windows Installer to know where to find the remainder of the components and install the program. For Terminal Server, members of the Users security group cannot invoke a Windows Installer installation. Therefore, it is important to install these programs locally. To do this, a transform file (.mst) can be used. Transform files appear as modifications to .msi packages and tell Windows Installer which bits to install locally. Since transform files might not be available for all programs, you can either ensure that all necessary components are fully installed during installation or create a transform file. For more information on transform files, see Windows Installer technologies.

Legacy programs can also be repackaged as Windows Installer programs, using tools that capture the changes made to the system when the program is installed. These changes are then used to create an .msi package for the legacy program. This method allows you to continue using programs developed specifically for your organization.

# Comparing 16-bit and 32-bit programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Comparing 16-bit and 32-bit programs**

Terminal Server supports 16-bit and 32-bit Windows-based programs. Running 16-bit programs can reduce the number of users a processor supports by 40 percent and increase the memory required for each user by 50 percent. In addition, some 16-bit programs must be able to write to the directory where the program .ini file is stored. Most 32-bit programs use the registry to read and write program settings and need only to write to specific registry values. For both performance and security reasons, 32-bit programs are recommended whenever possible.

For more information about application performance, see Application performance.

# System resource considerations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**System resource considerations**

Because Terminal Server is designed for multisession use, you should limit the number of installed programs that require large amounts of system resources. Consider restricting user or group access to certain program types, disabling unnecessary features that require the most resources, or installing these programs on separate servers.

Check system requirements for each program carefully and remember that RAM and CPU requirements increase with the number of sessions running. While there is not a true one-to-one correlation between these, this gives you a basis for projecting program performance.

For more information, see System Planning.

# Programs starting programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Programs starting programs**

Some programs enable users to start other programs. For example, Microsoft Access has a toolbar that can be used to start other Microsoft Office programs. In this situation, you should disable toolbar access to other programs from the program that is installed on the terminal server.

Many Microsoft products include the Microsoft System Information (Msinfo.exe) program. There is the potential that users can breach security or gather system information, such as server hardware configuration, with this program. Set file permissions on the Microsoft System Information program so that only administrators can use it to gather system configuration information, aid in problem resolution, and start programs by the appropriate users.

For more information about setting file permissions, see Set, view, change, or remove permissions on files and folders.

# Installing Programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Installing programs**
This section covers:

- Getting ready to install programs
- Starting the installation
- Testing the installation

**Note**

- For additional information about deploying Terminal Server, see "Hosting Applications with Terminal Server" at the Microsoft Windows Resource Kit Web site.

# Getting ready to install programs

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Getting ready to install programs**

You should install programs on a terminal server before giving clients access to the terminal server. Doing so ensures that you can test each program before clients access it, and can reduce the time it takes to perform program tuning.

If you are installing a program after clients have been granted access, you must ensure that there are no users logged on to the terminal server during installation. You can send clients a message detailing the time and duration of the installation and then disable all connections before starting.

For more information about currently connected sessions, see Terminal Services Manager Overview.

For more information about sending messages to users, see Send a message to a user.

For more information about disabling a connection, see Disable a Terminal Services connection.

**Note**

- When installing programs, log on using an administrator account.

# Starting the installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Starting the installation**

Use either of the following methods to install programs for multisession Terminal Server access:

- Use **Add or Remove Programs** in Control Panel (recommended).
- Use the **change user** command at the command prompt before and after installing the program.

One of the primary functions of the **change user** command is to ensure that program files are installed to the systemroot rather than the windows subdirectory of the user's home directory (%homepath%\windows). This makes the programs available for multisession access.

Before the program is installed, type **change user /install** at the command prompt to place the system in install mode and turn off .ini file mapping. The system then records how the setup APIs initially install the program.

After the program is installed, type **change user /execute** at the command prompt to return the system to execute mode, restore .ini file mapping, and redirect user-specific data to the user's home directory.

When the user opens the program, user-specific registry setting files (.ini, .dll, .ocx, and so on) are propagated as needed to the user's home directory.

**Add or Remove Programs**, which runs the **change user** command, is the preferred method of installing programs. Enter **change user** at the command prompt only when you install a program by another method and want to ensure multisession access. For example, when Internet Explorer prompts you to install an add-on program, use **change user** at the command prompt to ensure that the program is installed for multisession access.

For more information, see Install a program using Add or Remove Programs.

**Important**

- Microsoft provides scripts for some programs that need tuning in order to work correctly in a multisession environment. Before installing a program, see the Microsoft Web Site for a list of programs that require scripts and information about how to use them.

**Notes**

- Do not copy program files from one directory to another or manually edit the registry during installation.
- Install programs on the terminal server local drive rather than on a file server. This improves program performance by reducing network traffic.
- Install programs on NTFS file system drives rather than on FAT drives. You can only set file permissions on NTFS drives.

# Testing the installation

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Testing the installation**

Some programs installed using **change user** might not work at first because of the locked-down state of the system. Some 16-bit programs must be able to write to the directory where the program .ini file is stored. Some 32-bit programs create registry entries that are needed for proper operation.

Enable event logging and then log onto the server using a temporary user account created to mimic the user or users that will be accessing the program. Start the program and go through the basic procedures for using it. Then, use Event Viewer to determine which files or directories need Write access and which registry keys require Read access by the user for correct operation.

**Note**

- This process might not find all files, directories, and registry keys for which access is required by the application in all user scenarios. The only way to ensure that you have accounted for all access requirements is to perform tasks manually.

Consider creating two user accounts and testing with each account before proceeding. This allows you to make changes to program preferences and templates, while ensuring that those changes do not affect other users of the same group.

Keep track of all files, and any issues that arise. For information about how to tune programs for multisession use, see Program Compatibility.

# Program Compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Program compatibility**
Many programs, particularly older ones, were not designed for multisession use. As a result, some programs need to be tuned before they can run on a terminal server.

Microsoft provides installation scripts for some programs that have known installation issues. Run the scripts after the application installation process is complete and before running the application the first time.

**Application compatibility scripts**
Many commonly used applications have been tested for compatibility with Terminal Server. For maximum performance on a terminal server, some applications require minor changes after installation. Scripts are available for these applications and must be run after the application installation is complete. The scripts are located in systemroot in \Application Compatibility Scripts\Install.

Many newer applications, such as Microsoft Office XP, do not require modification to work properly with Terminal Server. For information about specific applications requiring modification for compatibility with Terminal Server, see the Microsoft Web Site.

**Note**

- For information about specific script capabilities and how to modify them for custom installations, refer to the notes within the script for the application you are installing. You can modify scripts by using a text editor such as **Notepad**.

In addition to running scripts, you might need to perform some additional tuning. The following topics describe some of the changes that might be required:

- Registry settings
- File and directory issues
- Program compatibility flags

# Registry settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Registry settings**
Programs store configuration information in a system database called the registry. For configuration purposes, the two most important sections of the registry are labeled HKEY_LOCAL_MACHINE and HKEY_CURRENT_USER.

You should store information that pertains to the entire system in HKEY_LOCAL_MACHINE. For example, a program might store the following information in this section:

- The components of a program that were installed.
- The path used to load program components.
- The path to a shared database. For example, a point-of-sale program where all users reference the same database.

Programs store user-specific information in the HKEY_CURRENT_USER section, which is part of the user profile. When a user logs on, a profile is loaded into the system registry where it becomes HKEY_CURRENT_USER. When the user logs off, any changes to HKEY_CURRENT_USER are written back to the user profile. A program might store the following types of information in this section:

- Per-user paths are particularly important for multiuser operation. For example, paths to custom dictionaries, mailboxes, configuration files, and temporary directories.
- Per-user preference settings. For example, some users might want to enable background spell checking while others might want to disable it.

**Per-user data in HKEY_LOCAL_MACHINE**
Problems arise if programs store per-user data in HKEY_LOCAL_MACHINE instead of HKEY_CURRENT_USER. If a program stores personal preferences, such as color and font size, in HKEY_LOCAL_MACHINE, users are not able to specify custom preferences.

**Settings created when a program is run**
A program might create HKEY_CURRENT_USER registry settings the first time a user runs the program, rather than during installation. If you do not run the program while install mode is still active, the HKEY_CURRENT_USER settings are not copied to HKEY_LOCAL_MACHINE. The first time each user runs the program, HKEY_CURRENT_USER will be loaded with the default settings. Depending on the program, this might or might not be appropriate. If the default settings are not sufficient, they need to be corrected for each user individually.

To avoid this problem, run the program once before clicking **Finish** in **Add\Remove Programs** (or before running **change user /execute**). This will cause the program to create the necessary registry settings.

If you have already left install mode and have not run the program, re-enter install mode with **change user /install** and run the program. If you have already run the program while in execute mode, create another administrator account, log on with this new account, run **change user /install**, run the program, and then run **change user /execute** to leave install mode. For more information about the change user command, see Change user.

# File and directory issues

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File and directory issues**
The files and directories a program creates and uses might present problems if the program was not originally designed for a multiuser environment.

**Files that store per-user data**
A program might use a single path for a file that contains per-user data. In some cases, this can mean that if one user updates this file, it affects all users. More severe problems include preventing multiple users from running the program simultaneously and corruption of the file, which can cause the program to fail for all users.

**Note**

- Most files do not contain per-user data and are safe to share. Some files can be classified either way, depending on the system administrator's preference. For instance, document template files can be made read-only and safely shared. Or, users can have their own set of template files that they can update as desired.

If you have difficulty finding a shared file, you can use file auditing to track successful write operations.

Another path issue arises when programs store files in public directories such as systemroot. Some public directories have read-only permission for nonadministrative users, which prevents accidental modification of common files. However, if a program attempts to write a file into one of these shared directories, the program fails.

A frequent symptom of this problem is a program that can be successfully executed by an administrative user, but fails for a nonadministrative user. To isolate this problem, use file auditing to log all write operations that fail.

Some programs use temporary directories to store information that relates to the current user. The program might not create a separate directory for each user, thus causing temporary data for multiple users to be stored in a single location. If the program is not intelligent about handling this data, one user can delete data that is still needed by another user.

**Updating the path**
When you identify a file that stores per-user data, update the path so that a copy of the file resides in each user's home directory.

Programs can store a file path in several places, including:

- HKEY_LOCAL_MACHINE
- HKEY_CURRENT_USERS
- A configuration file
- Hard-coded within the program itself

Some per-user files are generated by the program. Other per-user files, such as document templates, must be provided for the user by copying them into the user's home directory. If you specified the path as a subdirectory of the user's home directory, you might need to create the subdirectory as well.

Per-user tasks can be performed in a script that is run during logon. The script checks the user's home directory to determine whether the files or directories in question already exist. If not, it can copy them from a master. Using a script allows you both to update current users with a new program and to set up new users.

**Permissions and accessibility**
Another path-related issue arises when a program cannot locate files in or below systemroot.

This problem occurs with some programs that use the **GetWindowsDirectory()** function to determine the name of the directory where Terminal Server was installed. Programs that use this function benefit from an automatic remapping. The function returns the Windows subdirectory of the user's home directory.

This automatic remapping can be disabled with a program compatibility flag. This is appropriate if the files under systemroot are being used only for read access. For more information about compatibility flags, see Program compatibility flags.

# Program compatibility flags

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Program compatibility flags**

Program compatibility flags are registry entries that provide the system with information about compatibility issues for particular programs. Some of these entries are created by default. Administrators can create new entries or change existing entries to alleviate many program compatibility issues.

Following is a list of compatibility flags that can be stored under

HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\ Windows NT\CurrentVersion\Terminal Server\ Compatibility\Applications*app_name*

The keys are created using the program's executable name and the flag is stored as a **DWORD** value.

| Value | Description |
|---|---|
| 0x00000001 | MS-DOS-based program |
| 0x00000002 | OS/2-based program |
| 0x00000004 | Windows-based 16-bit program |
| 0x00000008 | Windows-based 32-bit program |
| 0x0000000C | Windows-based 16-bit and 32-bit program |
| 0x0000000F | Any version of a program |
| 0x00000010 | Return user name instead of computer name for **GetComputerName**. |
| 0x00000020 | Return Terminal Server build number instead of Windows 2000 build number for **GetVersion**. |
| 0x00000040 | Synchronize user .ini file to system version.* |
| 0x00000080 | Do not substitute user \Windows directory.** |
| 0x00000100 | Disable registry mapping for program or registry key. |
| 0x00000200 | Per-object user/system global mapping |
| 0x00000400 | Return system \Windows directory instead of user \Windows directory for **GetWindowsDir**. |
| 0x00000800 | Limit the reported physical memory for **GlobalMemoryStatus**. |
| 0x00001000 | Log object creation to file. |
| 0x20000000 | Do not put program to sleep on unsuccessful keyboard polling (Windows-based 16-bit programs only). |

* This setting adds new entries from the system version of the .ini file to the user's version, but does not delete any existing entries in the user's .ini file. By default, the user's .ini file is deleted when it is out of date with the system version.

** This setting requires that the user's \Windows directory not be substituted for the system root directory for any paths inside the .ini file when the system version of the .ini file is copied to the user's \Windows directory. It is recommended that you make this substitution so that the program uses the user's \Windows directory for all of the modifications it makes to data or .ini files.

For more information about registry settings, see Registry settings.

# Deploying Client Software

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Deploying client software**
This section provides information about setting up and configuring Remote Desktop Connection (formerly known as the Terminal Services client) on client computers.

**Important**

- You should install the latest version of Remote Desktop Connection. If you are using the Windows 2000 32-bit Terminal Services Client, you should upgrade to the version of Remote Desktop Connection that is provided with each of the Windows Server 2003 family operating systems.

- About the Terminal Services Client MSI Setup Package

- Remote Desktop Web Connection

# About the Terminal Services Client MSI Setup Package

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**About the Terminal Services Client MSI Setup Package**
The Terminal Services Client MSI Setup package is a tool for deploying Remote Desktop Connection (formerly known as the Terminal Services client) and associated files on computers running earlier versions of Windows. These versions include Microsoft Windows 2000 Server, Microsoft Windows 2000 Professional, Microsoft Windows NT 4.0, Microsoft Windows 98, and Microsoft Windows 95. The MSI Setup package can also be placed on a share for distribution to workstations running Windows 2000 by using Microsoft IntelliMirror.

For procedural information on installing the client with the MSI setup package, see:

- Share the client setup folder at the server
- Install the 32-bit Terminal Services Client (Remote Desktop Connection)

For more information on using Group Policy, see Group Policy overview.

**Note**

- Remote Desktop Connection is installed automatically with Windows XP and Windows Server 2003 family operating systems.

# Remote Desktop Web Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktop Web Connection**
Remote Desktop Web Connection is an ActiveX control that provides virtually the same functionality as the full Terminal Services client, but it is designed to deliver this functionality over the Web. When embedded in a Web page, Remote Desktop Web Connection can host a client session with a terminal server, even if the full Terminal Server client is not installed on a user's computer.

For more information, see Deploying Remote Desktop Web Connection.

# Terminal Services Client Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services Client overview**
The Terminal Services Client is a thin client that delivers the 32-bit functionality of Microsoft® Windows Server™ 2003 family operating systems to a wide range of desktop hardware devices. The client appears as a window within the local desktop environment. It contains only the minimum amount of software necessary to establish a connection to the server and present the user interface. All other operating system functions, as well as applications, run on the server. The client can be run on a range of desktop hardware:

- Computers running Microsoft Windows 95, Microsoft Windows 98, Microsoft Windows ME, Microsoft Windows NT 4.0, Microsoft Windows 2000 or Microsoft Windows Server 2003 operating systems.
- Windows-based Terminal devices (embedded).

For more information about Remote Desktop Connection, the new Terminal Services client, see Remote Desktop Connection overview.

For information about specific client features, see:

- Bitmap caching
- Shared clipboard
- Providing client access to local printers
- Log off or disconnect
- Managing Terminal Services connection files
- Using a dial-up connection to access a terminal server

**Note**

- The Terminal Services Client was known as the Terminal Server Client in Windows NT 4.0.

# Remote Desktop Connection overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Desktop Connection overview**
Remote Desktop Connection (formerly known as the Terminal Services client) is installed by default on all Windows Server 2003 family operating systems. You can use Remote Desktop Connection to connect to terminal servers, or to the desktop of a computer running one of the Windows Server 2003 family operating systems or Windows XP for remote administration.

Remote Desktop Connection allows you to create and configure your connection, save your connection settings to a file, and open and edit your saved connection files, all in the same program. For more information on Remote Desktop Connection, see Remote Desktop Connection.

### Notes

- When you install a Windows XP or one of the Windows Server 2003 family operating systems, Remote Desktop Connection is installed, but not enabled. For more information on enabling remote connections, see Enable or disable Remote Desktop.

- To use Group Policy to deploy Remote Desktop Connection, assign the program on a per-computer basis to a terminal server. For more information, see article Q324750, "HOW TO: Assign Software to a Specific Group By Using a Group Policy in Windows Server 2003" in the Microsoft Knowledge Base.

# Bitmap caching

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Bitmap caching**

Bitmap caching places commonly used bitmaps, such as the one that displays the **Start** button, in a file on the client computer. This improves performance by minimizing the amount of display information that must be passed over a connection.

Bitmap caching is enabled on a per-session basis from the client software and requires 10MB of free hard-drive space on the client computer.

For more information, see Configure bitmap caching.

# Shared clipboard

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shared clipboard**

On Windows Server 2003 family operating systems, Terminal Services provides seamless clipboard sharing. Clipboard contents can be available to applications locally on a user's computer and to programs within a Terminal Services session.

The shared clipboard synchronizes its contents with the local clipboard and can be viewed using the Windows ClipBook Viewer (clipbrd.exe). For example, you can copy text from a document within a session, and paste it into a document on your local computer. You cannot, however, copy and paste files or folders. The shared clipboard is intended only for data such as text and graphics.

Clipboard sharing can be disabled using Terminal Services Group Policies or Terminal Services Configuration. For more information, see Managing drive, printer, and device mappings for clients.

For more information about the ClipBook Viewer, see ClipBook Viewer overview.

# Providing client access to local printers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing client access to local printers**
Terminal Services provides printer redirection, which routes printing jobs from the terminal server to a printer attached to the client computer, or to a network printer available to the client computer.

Print redirection is enabled by default, but it can be disabled using Terminal Services Group Policies (see Configuring Terminal Services with Group Policy) or on a per-connection basis using Terminal Services Configuration (see Connect client drives and printers at logon).

There are two ways to provide client access to local printers:

- Automatic printer redirection--for Remote Desktop Connection.
- Manual printer redirection--for 16-bit clients, Windows-based Terminals, and local printers that require drivers other than those shipped with Windows Server 2003 family operating systems.

### Notes

- Bidirectional printing is not supported.
- Redirected printers are available for use with applications running on the server. Redirected printers appear in the Printers folder in Control Panel.
- Clients see only their own redirected printers in the **Printers** dialog box.

**Automatic printer redirection**
For Remote Desktop Connection, printer redirection is automatic when the local printer uses a driver that is installed on the server.

When a client logs on to Terminal Services, local printers attached to LPT, COM, and USB ports on the client computer are automatically detected and a local queue is created on the server. The client computer printer settings for the default printer and some properties, such as printing on both sides of the page, are used by the server.

Information about the client's local printers and settings are saved on the client computer. On subsequent logons, the printer queue is created using the information stored on the client computer.

### Warning

- When a client disconnects or ends the session, the printer queue is deleted and any incomplete or pending print jobs are lost.

If a printer driver is not found on the server, an event is logged and the client printer is not created. To make the printer available, the driver must be manually installed on the server.

**Manual printer redirection**
Administrators can manually redirect printers that are attached to LPT and COM ports on the client's local computer so they can be used with Remote Desktop Connection.

### Note

- Manual redirection of printers connected through USB ports is not supported.

To manually redirect a client printer, contact your administrator and provide the name of your computer (or IP address for a Windows-based Terminal). The client must be connected to the terminal server during manual redirection.

The administrator uses **Add Printers** in **Printers** in Control Panel to manually add the printer. The administrator uses the client computer name to select the printer port from the list of available ports in **Add Printer**. Ports for all clients currently connected to the server appear in the **Port** list. Terminal Services client ports are listed as follows:

| Port | Description |
|---|---|
| TS | computername:*PortX* (where *Port* is the type of port and *X* is the port number) |

When a client disconnects or ends the session, the printer queue is deleted, and any incomplete or pending print jobs are lost. Information about client local printers and settings are saved on the client computer. On subsequent logons, the printer queue is created using the information stored on the client computer.

**Notes**

- When automatic redirection for 32-bit client printers fails, an event is logged. Typically, this event in the log contains information about the reason for redirection failure and, if applicable, which server-side driver is missing.
- When the client disconnects or logs off, the printer queue is deleted, and incomplete or pending print jobs are lost.
- After the initial manual redirection, printers are automatically redirected during subsequent logons.

# Providing client access to the local file system

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing client access to the local file system**

On Windows Server 2003 family operating systems, Terminal Services provides client drive redirection, making the local file system available on the remote desktop within a Terminal Services session. If drive redirection is specified, client drives appear in Windows Explorer with the designation "tsclient <driveletter>".

When you install Terminal Server, client drive mapping is disabled by default. To enable this feature, use Terminal Services Group Policies or the Terminal Services Configuration tool.

# Providing client access to server audio

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Providing client access to server audio**

On Windows Server 2003 family operating systems, Terminal Server administrators can enable users to play server audio on their local computers. This feature is disabled by default when you install Terminal Server. To enable it, configure the **Allow audio redirection** policy in Terminal Services Group Policies. You can also enable audio redirection locally using the Terminal Services Configuration tool. For more information, see Connect client drives and printers at logon.

# Log off or disconnect

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Log off or disconnect**

Terminal Services provides two options when closing a client session: you can either log off or disconnect.

Disconnecting leaves the session running on the server. You can reconnect to the server and resume the session. If you are running a task on the server, such as running a time consuming query on a database, you can start the task and disconnect from the session. Later, you can log back onto the server, reenter the session, and check the results. This is especially helpful when operating over a remote access connection on a long-distance toll line. For information about how to disconnect from a Terminal Services session, see Disconnect without ending a session.

Network administrators can limit the amount of time a disconnected session is allowed to remain on the server. For more information, see Set time-out settings for disconnected, active, and idle sessions.

Logging off ends the session running on the server. Any applications running within the session will be closed and unsaved changes made to open files will be lost. The next time you log onto the server, a new session is created. For information about how to log off from a Terminal Services session, see Log off and end the session.

If printer redirection is enabled for the session, when the session is disconnected or logged off, the printer queue is deleted and any incomplete or pending print jobs are lost.

# Managing Terminal Services connection files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Terminal Services connection files**

Remote Desktop Connection allows administrators and users to set up predefined connection files to servers for single program or full desktop access. By using Remote Desktop Connection, you can save connection information and settings to a connection file that is saved in the My Documents/Remote Desktops folder with the .rdp extension. This way, for example, an administrator who wants to provide a single line-of-business program across the computing environment can create the connection file, and distribute that file to all desktops.

For information on how to use the Remote Desktop Connection to save connection settings to a file, see Create a connection file.

# Using a dial-up connection to access a terminal server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using a dial-up connection to access a terminal server**

If you have remote access to a network that contains terminal servers, you can access those terminal servers using a dial-up connection from a remote location.

To use remote access to connect to a terminal server, you must first configure a dial-up connection on your computer. Then you can connect to the network where the terminal server resides and use Remote Desktop Connection to create a connection to the terminal server itself. You can then log on to the terminal server as usual.

Administrators can grant users the ability to reconnect to a session if the connection is broken, for example, if a phone connection is interrupted. For more information, see Set time-out settings for disconnected, active, and idle sessions to allow reconnection on a per-connection basis or Change settings for when a session limit is reached or a connection is broken on a per-user basis.

# Troubleshooting Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The connection does not automatically log on to the server. I am prompted for my User name and Password on connection.
- Installation of an .msi package fails from a remote Terminal Services session.
- Installed program does not work correctly.
- Client fails to connect with "This initial program cannot be started" message.

**The connection does not automatically log on to the server. I am prompted for my User name and Password on connection.**
**Cause:** Encryption enhancements for Windows 2000 and Windows Server 2003 family operating systems cause the Windows NT 4.0 version of the Terminal Services client not to recognize the user name and password in the automatic logon portion of the connection file.

**Solution:** From the Windows NT 4.0 version of Client Connection Manager, right-click the connection and select **Properties**. On the **General** tab, check **Automatic logon** and type the User name, Password, and Domain.

**Installation of an .msi package fails from a remote Terminal Services session.**
**Cause:** You must be logged in as a member of the Administrators group to install .msi packages for Terminal Services from a remote session.

**Solution:** Log on as a member of the Administrators group or use Run as to install the .msi package.

**See also:** Install a program using Add or Remove Programs

**Installed program does not work correctly.**
**Cause:** The program was installed before Terminal Server was installed.

**Solution:** Uninstall the program, and reinstall using either **Add or Remove Programs** or the **change user** command.

**See also:** Starting the installation

**Cause:** The program was installed using **change user /execute** rather than **change user /install**.

**Solution:** Uninstall the program, and reinstall using either **Add or Remove Programs** or the **change user /install** command.

**See also:** Starting the installation

**Cause:** Program compatibility scripts were not run properly.

**Solution:** Run the program scripts again.

**See also:** Program Compatibility

**Client fails to connect with "This initial program cannot be started" message.**
**Cause:** The client connection might have been configured to start a program upon connection, but the program path and filen ame are incorrect.

**Solution:** Check the properties for the client connection to ensure that the program path and file name are correct, and that the program exists in this location on the server.

**Cause:** The server administrator might have specified a program to start upon connection, using Group Policy, Terminal Services Configuration, or other Terminal Services administration tools.

**Solution:** Check the server configuration to ensure that the program path and file name specified for this user are correct,

and that the program exists in this location on the server.

# Terminal Server Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server Licensing**
A valid license, issued by a Terminal Server license server, is required before a client is permitted to log on to a terminal server.

**Important**

- The Terminal Server Licensing method is separate from the licensing method used for Microsoft® Windows Server 2003 operating system clients. For more information on licensing for Windows Server 2003 operating systems, see Licensing.

A license server stores all client licenses. A terminal server must be able to connect to an activated license server before clients can be issued permanent licenses. When you activate a license server, Microsoft provides the server with a digital certificate that validates server ownership and identity. By using this certificate, a license server can make transactions with Microsoft and receive client licenses for your terminal servers. If you install a license server but do not activate it, that server only issues temporary licenses.

For small deployments, it is acceptable to install both the terminal server and Terminal Server Licensing on the same physical computer. However, for larger deployments consider installing Terminal Server Licensing on a separate server. Note that one license server can serve many terminal servers concurrently.

**Important**

- You must configure Terminal Server Licensing correctly in order for your terminal server to continue to accept connections from clients. To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent client access license (CAL), or after 120 days, whichever comes first.

Before installing the license server, determine which of the two license server roles you require—a Domain license server or an Enterprise license server. By default, a license server is installed as an Enterprise license server. For more information, see Terminal Server license server roles.

After installing the license server, you must activate it and install CALs by using the Terminal Server License Server Activation Wizard. For information about activating a license server, see Activating a Terminal Server license server.

The following resources provide additional information about Terminal Server and Terminal Server Licensing.

- For information about deploying Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627)

- For detailed information about Terminal Server Licensing, see Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

- For help with specific tasks, see Terminal Server Licensing How To....

- For general conceptual information, see Terminal Server Licensing Concepts.

**Note**

- You can use any computer running one of the Windows Server 2003 operating systems to administer servers remotely with Remote Desktop for Administration (formerly Terminal Services in Remote Administration mode). You do not need to install Terminal Server. A Terminal Server license server and the Terminal Server Licensing administrative tool are not required for Remote Desktop for Administration. For more information, see Remote Desktop for Administration.

# Terminal Server Licensing How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install Terminal Server Licensing
- Configure a Terminal Server License Server
- Configure a Terminal Server to Receive Licenses

# Install Terminal Server Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Terminal Server Licensing**

1. Open Add or Remove Programs in Control Panel.

2. Click **Add/Remove Windows Components** to start the Windows Components wizard.

3. In **Windows Components**, select **Terminal Server Licensing**, and then click **Next**.

4. In **Terminal Server Licensing Setup**, do one of the following:

   - Click **Your entire enterprise** to choose an Enterprise license server. You can only install an Enterprise license server on a domain controller or a member server in a domain, not on a stand-alone server. This role is published to Active Directory.

   - Click **Your domain or workgroup** to choose a Domain license server. If you select this option, the computer on which you install the license server does not have to be a domain controller. However, if you want the license server to be automatically discovered by terminal servers that communicate with it, the computer on which you install the license server must be a domain controller. If the computer on which you plan to install the license server is in a workgroup, it can only be automatically discovered by terminal servers on the same subnet.

   For more information about Terminal Server license server roles and the license server discovery process, see Terminal Server license server roles.

5. Provide the file system location where the license server database should be installed on the Terminal Server license server, click **Next**, and then click **Finish**.

   The default location for the license server database is systemroot\System32\LServer.

**Important**

- Before you install Terminal Server Licensing, verify that the operating system of the license server is compatible with the operating system of the terminal server. Note the following:

  - A license server running Windows Server 2000 cannot issue client access licenses (CALs) to terminal servers running Windows Server 2003 operating systems.

  - A license server running a Windows Server 2003 operating system can issue CALs to terminal servers running Windows Server 2000 or Windows Server 2003, or to terminal servers running Windows Server 2000 and terminal servers running Windows Server 2003 in a mixed environment.

**Notes**

- If you are installing a Domain license server, you must be a member of the Administrators group on the local computer. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

  If you are installing an Enterprise License Server, you must meet one of the following conditions:

  - You must be a member of the Enterprise Admins group in Active Directory.

- You must have the right to create the TS-Enterprise-License-Server object in the same site in which the license server will reside in Active Directory.

As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

- Terminal Serviceslicensingopen

- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://www.microsoft.com/) and Windows Server 2003 Terminal Server Licensing (http://www.microsoft.com/).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a Terminal Server License Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure a Terminal Server license server**

- Activate a Terminal Server License Server
- Purchase client access licenses
- Install Client Access Licenses
- Deactivate a Terminal Server license server
- Reactivate a Terminal Server license server
- Change Terminal Server license server properties

# Activate a Terminal Server License Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Activate a Terminal Server license server**

The Microsoft Clearinghouse is the facility that Microsoft maintains to activate license servers, issue client access licenses (CALs) to license servers, and to reactivate license servers. You can activate a Terminal Server license server by using one of three methods: Automatic, Web Browser, or Telephone. For instructions on activating a license server and locating a telephone number to contact the Clearinghouse, see the following procedures:

- Locate the Microsoft Clearinghouse telephone number for your country or region
- Activate a Terminal Server license server by using the telephone
- Activate a Terminal Server license server automatically
- Activate a Terminal Server license server by using a Web browser

# Locate the Microsoft Clearinghouse telephone number for your country or region

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To locate the Microsoft Clearinghouse telephone number for your country or region**

- When the Terminal Server license server is running
- When the Terminal Server license server is not running

**When the Terminal Server license server is running**

1. Open **Terminal Server Licensing**.
2. In the details pane, right-click the Terminal Server license server, and then click **Properties**.
3. On the **Installation Method** tab, in the **Installation Method** list, click **Telephone**.
4. In **Select Country or Region**, click your country or region, and then click **OK**.
5. In the details pane, right-click the license server, click **Install Licenses**, and then click **Next**.
6. Note the phone number that is displayed, and then click **Cancel**.
7. To change the server installation method from Telephone to another value, in the details pane, right-click the license server, click **Properties**, change the installation method as needed on the **Installation Method** tab, and then click **OK**.

**When the Terminal Server license server is not running**

1. Open **Terminal Server Licensing.**
2. In the details pane, right-click the Terminal Server license server, and then click **Activate Server** to start the Terminal Server License Server Activation Wizard.
3. On the **Welcome** page, click **Next**.
4. On the **Connection Method** page, in **Activation method**, click **Telephone**, and then click **Next**.
5. On the **Country or Region** page, click your country or region, and then click **Next**.

## Notes

- The Microsoft Clearinghouse is the facility that Microsoft maintains to activate license servers, issue CALs to license servers, recover CALs, and reactivate license servers. It is not the facility for purchasing CALs. For instructions on purchasing CALs, see Related Topics.
- After you purchase CALs, make sure to retain the License Purchase Agreement information. Having this information with you will facilitate communication with the Microsoft Clearinghouse, should you need assistance with recovering CALs or other Terminal Server Licensing tasks that are supported by the Clearinghouse.
- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing

(http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Activate a Terminal Server license server by using the telephone

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate a Terminal Server license server by using the telephone**

1. Open Terminal Server Licensing.
2. In the console tree, right-click the Terminal Server license server you want to activate, and then click **Activate Server** to start the Terminal Server License Server Activation Wizard.
3. In the **Activation method** list, select **Telephone**, and then click **Next**.
4. Follow the instructions in the wizard.

### Important

- To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent client access license (CAL), or after 120 days, whichever comes first. For more information about the licensing grace period, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- Terminal Serviceslicensingopen
- Licensing wizard properties, such as installation method and company information, set during the activation process can be changed later.
- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Activate a Terminal Server license server automatically

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate a Terminal Server license server automatically**

1. Open Terminal Server Licensing.

2. In the console tree, right-click the Terminal Server license server you want to activate, and then click **Activate Server** to start the Terminal Server license server Activation Wizard.

3. In the **Activation method** list, select **Automatic connection (recommended)**, and then click **Next**.

4. Follow the instructions in the wizard.

   If necessary, at a later time you can change any license server properties, such as activation method and company information, that you set during the activation process.

**Important**

- If the Internet Explorer Enhanced Security Configuration setting is in effect on your Terminal Server license server, you must add the Microsoft Clearinghouse Web site (https://activate.microsoft.com/) to the Trusted sites zone in Internet Explorer before you can activate your Terminal Server license server. If you try to connect to the Microsoft Clearinghouse Web site and it is not yet a trusted site, you are prompted to specify whether to add it to the Trusted sites zone.

  For more information, see Internet Explorer Enhanced Security Configuration.

**Important**

- To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent client access license (CAL), or after 120 days, whichever comes first. For more information about the licensing grace period, see Terminal Server Licensing grace period.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

# Purchase client access licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To purchase client access licenses**

- In the United States, call (800) 426-9400 or visit the Licensing Program Reseller Web site (http://go.microsoft.com/fwlink/?LinkID=26222).
- In Canada, call the Microsoft Resource Centre at (877) 568-2495.
- If you are outside the United States or Canada and have Internet access, please review the Worldwide Microsoft Licensing (http://go.microsoft.com/fwlink/?LinkID=26223) Web sites or contact your local Microsoft subsidiary on the Microsoft Worldwide Home Web site (http://go.microsoft.com/fwlink/?LinkID=26226).

**Note**

- You must purchase CALs and install them on the computer running Terminal Server Licensing. The Terminal Server license server then issues them to terminal servers for distribution to clients. For more information about purchasing and installing CALs on a license server, see Related Topics.
- Verify that you have purchased enough CALs for the Terminal Server license server and that the Terminal Server Licensing mode matches the type of CAL available on the license server. Terminal Server licensing modes determine the type of CAL that a license server issues to a client. In Windows Server 2003, two types of CALs are available: Per User and Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used.
- After you purchase CALs, make sure to retain the License Purchase Agreement information. Having this information with you will facilitate communication with the Microsoft Clearinghouse, should you need assistance with recovering CALs or other Terminal Server Licensing tasks that are supported by the Clearinghouse. The Microsoft Clearinghouse is the facility that Microsoft maintains to activate license servers, issue CALs to license servers, recover CALs, and reactivate license servers. For information about how to locate the Microsoft Clearinghouse telephone number for your region, see Related Topics.
- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install Client Access Licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Install client access licenses**

You can install client access licenses (CALs) by using one of three methods: the Internet, a Web browser, or telephone. Installing CALs by using the Internet is the easiest method. For instructions on installing CALs, see the following procedures:

- Install client access licenses automatically
- Install client access licenses by using a Web browser
- Install client access licenses by using the telephone
- Repeat the installation of a client access license

# Install client access licenses automatically

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install client access licenses automatically**

1. Open Terminal Server Licensing.

2. Verify that the installation method for the Terminal Server license server is set to **Automatic connection (recommended)** by right-clicking the Terminal Server license server for which you want to install client access licenses (CALs), and then clicking **Properties**. On the **Installation Method** tab, change the installation method if necessary.

3. In the console tree, right-click the Terminal Server license server for which you want to install CALs, click **Install Licenses** to start the Terminal Server CAL Installation Wizard, and then click **Next**.

   The previous steps are not necessary if the Terminal Server CAL Installation Wizard is already started.

4. In **Program and Client License Information**, provide the required information for your licensing program to receive your CALs, and then click **Next**.

   The Microsoft Clearinghouse processes your request, and installs the encrypted CALs on your Terminal Server license server.

5. Click **Finish** to complete the process.

   The Terminal Server license server can now issue licenses to clients that connect to a Terminal server.

## Notes

- Terminal Serviceslicensingopen

- You cannot install CALs until your Terminal Server license server is activated.

- Contact the Microsoft Clearinghouse if you receive an error during the CAL installation process. To find the nearest phone number, you must first go to **Licensing Wizard Properties**, select **Telephone** as the installation method, and then click **OK.** Then, right-click the Terminal Server license server and click **Install licenses** to display the appropriate number.

- On computers running one of the Windows Server 2003 operating systems, you can install Per Device and Per User CALs. Per User CALs, however, are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. On computers running the Windows 2000 Server operating system, you can install Per Device and Internet Connector CALs.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install client access licenses by using a Web browser

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install client access licenses by using a Web browser**

1. Open Terminal Server Licensing.

2. Verify that the installation method for the Terminal Server license server is set to **Web Browser** by right-clicking the Terminal Server license server for which you want to install client access licenses (CALs), and then clicking **Properties**. On the **Installation Method** tab, change the installation method if necessary.

3. In the console tree, right-click the Terminal Server license server for which you want to install client access licenses, click **Install Licenses** to start the Terminal Server CAL Installation Wizard, and then click **Next**.

   The previous steps are not necessary if the Terminal Server CAL Installation Wizard is already started.

4. Connect to the Terminal Server Licensing web site (https://activate.microsoft.com). You can connect to this site on any computer that has Internet access.

   On the **Windows Terminal Services** Web page, click **Install Client Access License Tokens** and then click **Next**.

5. Provide the following required information:

   - License server ID, a 35-digit number, in groups of 5 numerals, which is displayed in the Terminal Server CAL Installation Wizard.
   - Purchase method (License Program)
   - Last name or surname
   - First name or given name
   - Company name
   - Country or region

   You can also provide the optional information requested, such as company address, e-mail address, and phone number. In the organizational unit field, you can describe the unit within your organization that this server will serve.

   Click **Next**.

6. Type the CAL numbers in the **License Codes:** boxes. If you have more than 5 numbers, type the first 5 and then click **Add**. Continue typing additional numbers and clicking **Add** until all numbers are entered, and then click **Next**.

7. On the next page, verify that all of the information you have entered is correct, and then click **Next** to submit your request to the Microsoft Clearinghouse. The Web page then displays a CAL ID generated by the Microsoft Clearinghouse.

8. Type the CAL ID in the **Enter the license key pack ID in the boxes below. This ID is obtained from the Terminal Server Licensing Web site** text box, and then click **Next**.

   The CALs are installed on your Terminal Server license server.

9. Click **Finish** to complete the process.

The Terminal Server license server can now issue licenses to clients that connect to a terminal server.

## Notes

- Terminal Serviceslicensingopen
- You cannot install CALs until your Terminal Server license server is activated.
- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install client access licenses by using the telephone

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install client access licenses by using the telephone**

1. Open Terminal Server Licensing.

2. Verify that the installation method for the Terminal Server license server is set to **Telephone** by right-clicking the Terminal Server license server for which you want to install client access licenses (CALs), and then clicking **Properties**. On the **Installation Method** tab, change the installation method if necessary.

3. Right-click the Terminal Server license server for which you want to install client access licenses, click **Install Licenses** to start the Terminal Server CAL Installation Wizard, and then click **Next**.

   The previous steps are not necessary if the Terminal Server CAL Installation Wizard is already started.

4. Call the Customer Support Center at the number that is displayed on the **Obtain client license key pack** page of the wizard, and give the representative your Terminal Server license server ID and the required information for the licensing program under which you purchased client licenses. The representative then processes your request to install CALs, and gives you a unique ID for the CAL.

5. In **Type the client access license ID in the boxes below**, type the CAL ID provided by the representative, and then click **Next**.

   The client access licenses are installed on your Terminal Server license server.

6. Click **Finish** to complete the process.

   The Terminal Server license server can now issue licenses to clients that connect to a terminal server.

## Notes

- Terminal Serviceslicensingopen

- You cannot install CALs until your Terminal Server license server is activated.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Repeat the installation of a client access license

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To repeat the installation of a client access license**

1. Open Terminal Server Licensing.

2. In the console tree, right-click the Terminal Server license server for which you want to reload the client access license (CAL), point to **Advanced**, and then click **Repeat Last Installation**. The Licensing Wizard starts.

3. In **Information Needed**, confirm that the required information is correct, and then click **Next**.

   Your request is sent to the Microsoft Clearinghouse for processing.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- Terminal Serviceslicensingopen

- You cannot repeat the installation of a CAL by using the Web Browser installation method.

- You might need to reinstall Terminal Server CALs in situations such as the following:

  - A catastrophic failure or any other event that causes the loss of or corruption to the licensing database, when a known good backup is not available. In this case, you must reinstall Terminal Server Licensing, reactivate the license server, and then reinstall the previously issued CALs.

  - If you upgrade or migrate a Windows 2000 license server to Windows Server 2003. In this case, you must reinstall the Windows 2000 Terminal Server CALs on the Windows Server 2003 license server.

    In each of these cases, you must call the Microsoft Clearinghouse to reinstall the appropriate CALs. For information about how to call the Clearinghouse, see Locate the Microsoft Clearinghouse telephone number for your country or region.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

# Deactivate a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To deactivate a Terminal Server license server**

- Using the Automatic method
- Using the telephone method

**Using the Automatic method**

1. Open Terminal Server Licensing.
2. In the console tree, right-click the Terminal Server license server you want to deactivate, point to **Advanced**, and then click **Deactivate Server**. The Terminal Server License Server Wizard starts.
3. In **Required Information**, confirm that your name, phone number, company, and country or region are correct, and then click **Next**.

   Your request to deactivate the Terminal Server license server is sent to the Microsoft Clearinghouse for processing.
4. Click **Finish**.

**Using the telephone method**

1. Open Terminal Server Licensing.
2. In the console tree, right-click the Terminal Server license server you want to deactivate, point to **Advanced**, and then click **Deactivate Server**. The Terminal Server License Server Wizard starts.
3. Select **Telephone**, and then click **Next.**
4. Specify your location, and then click **Next.**
5. Call the telephone number displayed in the wizard, and give the Customer Support representative the Product ID that is displayed below the telephone number.
6. In the boxes in the wizard, type the 35-digit confirmation code provided by the Customer Support representative, and then click **Next.**
7. Click **Finish**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- Terminal Serviceslicensingopen
- For information about the Microsoft privacy statement, see Terminal Server license management and your privacy.
- You cannot deactivate a Terminal Server license server by using the Web Browser connection method.

- You might need to deactivate a Terminal Server license server when the certificate of the server has expired or becomes corrupted, or when the server is being redeployed. However, you will be prompted to reactivate the Terminal Server license server when its registration has expired.

- When you deactivate a Terminal Server license server, you will not be able to license additional clients from this server until it is reactivated.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

# Reactivate a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reactivate a Terminal Server license server**

1. Open Terminal Server Licensing.

2. In the console tree, right-click the Terminal Server license server you want to reactivate, point to **Advanced**, and then click **Reactivate Server**. The Terminal Server License Server Wizard starts.

3. In **Information Needed**, confirm that your name, phone number, and e-mail address are correct.

   In **Reason**, select the appropriate reason for reactivating the license server, and click **Finish**.

   Your request to reactivate the license server is sent to the Microsoft Clearinghouse for processing.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- Terminal Serviceslicensingopen

- For information about the Microsoft privacy statement, see Related Topics.

- When reactivating a license server by using the telephone, you will receive a telephone call confirming that the license server has been reactivated.

- When a license server is reactivated, a record of your licenses is retained. Licenses that were already issued remain valid, and any un-issued licenses are also valid, but must be reissued through the Microsoft Clearinghouse.

- You must reactivate a license server when its registration has expired.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Configure a Terminal Server to Receive Licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure a Terminal Server to receive licenses**

- Configure the Terminal Server Licensing mode
- Set preferred Terminal Server license servers
- Connect to a Terminal Server license server

# Configure the Terminal Server Licensing mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the Terminal Server Licensing mode**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click **Terminal Server Licensing Mode**.
3. Click **Enabled**.
4. Click either **Per User** or **Per Device**, and then click **OK**.

   A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices.

### Important

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- This Group Policy setting is only available on Windows Server 2003 with Service Pack 1.
- Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator, and then open Group Policy by using the **Active Directory Users and Computers** snap-in.
- Group Policy overrides the configuration set with the Terminal Services Configuration tool.
- By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.
- Users can create more than one session by specifying a different program to start on connection for each session.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.

2. In the console tree, click **Server Settings**.

3. In the details pane, right-click **Licensing Mode**, and then click **Properties**.

4. Select either **Per User** or **Per Device**, and then click **OK**.

   A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices.

## Notes

- Terminal Servicesccopen

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

- By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. # Set preferred Terminal Server license servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set preferred Terminal Server license servers**
At a stand-alone server:

- Using Group Policies (best practice)
- Using Terminal Services Configuration
- Using the registry

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click **Use the specified Terminal Server license servers**.
3. Click **Enabled**.
4. Enter the names of the Terminal Server license servers you want this Terminal Server to contact first when attempting to obtain client access licenses (CALs), and then click **OK**.

### Important

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Related Topics.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- This Group Policy setting is only available on Windows Server 2003 with Service Pack 1, or with the Service Pack 1 versions of System.adm Group Policy template files installed in your Terminal Server environment.
- Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator. Then, you must open Group Policy through the **Active Directory Users and Computers** snap-in.
- You can also set preferred license servers by using a Windows Management Instrumentation (WMI) script. For three scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see "Preferred License Server WMI Scripts" in Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220). .

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.

3. In the details pane, right-click **License server discovery mode**, and then click **Properties**.

4. Click **Use these license servers**, and enter the names or IP addresses of the license servers in the text box, separating them with commas.

5. Click **Check names**, make any necessary corrections, and click **OK**.

### Notes

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

- This feature is only available on Windows Server 2003 with Service Pack 1.

- You can also set preferred license servers by using a Windows Management Instrumentation (WMI) script. For three scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see "Preferred License Server WMI Scripts" in Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

#### Using the registry

1. Click **Start**, click **Run**, type **regedit**, and then click **OK**.

2. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\TermService\Parameters**

3. On the **Edit** menu, point to **New**, click **Key**, and then type **LicenseServers** to name the new key.

4. Locate, and then click, the following key in the registry:

   **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\TermService\Parameters\LicenseServers**

5. On the **Edit** menu, point to **New**, click **Key**, and then type ***ServerName*** where *ServerName* is the NetBIOS name of the license server that you want to use, and then press **ENTER**.

   The new key name can be any of the following designations that represent the license server:

   - The NetBIOS name of the server

   - The fully-qualified domain name (FQDN) of the server

   - The IP address of the server

6. Restart your computer

### Notes

- You can also set preferred license servers by using a Windows Management Instrumentation (WMI) script. For three scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see "Preferred License Server WMI Scripts" in Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

- For more information about Terminal Server, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627)

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect to a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to a Terminal Server license server**

1. Open Terminal Server Licensing.
2. On the **Action** menu, click **Connect**.
3. In **Server**, type the name of the Terminal Server license server to which you want to connect, and then click **OK**.

## Notes

- Terminal Serviceslicensingopen
- When Terminal Server Licensing opens, it locates all license servers in your workgroup or domain.
- To connect to a license server, a terminal server must have the **Access this computer from the network** logon right for the target license server. Additionally, if the License Server Security Group setting in Group Policy is enabled, the terminal server computer account must be a member of this group. Enabling this Group Policy setting and applying it to your license server creates a local group called Terminal Services Computers. The license server issues licenses only to the terminal servers in this group. You must add both the terminal servers for which you need to provide licenses and any license servers that might need to acquire licenses to this group for each license server. For more information, see Related Topics.
- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Terminal Server Licensing overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server Licensing overview**
Terminal Server has its own method for licensing clients that log on to terminal servers, separate from the licensing method for Microsoft® Windows Server 2003 family operating system clients. When a client connects to a terminal server, the terminal server determines if a client access license (CAL) is needed. The terminal server then requests a CAL from the Terminal Server license server, and then the CAL is issued to the client by the terminal server. Although Terminal Server provides a licensing grace period during which no license server is required, after the grace period ends, clients must receive a valid CAL issued by a license server before they can log on to a terminal server.

**Important**

- If you use Remote Desktop for Administration, two concurrent connections can log on. You do not need a Terminal Server license server for these connections. For more information on Remote Desktop for Administration, see Remote Desktop for Administration overview.

**Prerequisites**
To use Terminal Server, you must also have at least one license server. For small deployments, it is acceptable to install both the Terminal Server and Terminal Server Licensing service on the same physical computer; however, for larger deployments, it is recommended that Terminal Server Licensing be installed on a separate server.

Before installing Terminal Server Licensing, verify that the operating system of the license server will be compatible with the operating system of the terminal server. Note the following:

- A Windows 2000 license server cannot issue CALs to terminal servers running Windows Server 2003 operating systems.

- A license server running a Windows Server 2003 operating system can issue CALs to terminal servers running Windows Server 2000 or Windows Server 2003, or to terminal servers running Windows Server 2000 and terminal servers running Windows Server 2003 in a mixed environment.

After you install Terminal Server Licensing, you must activate the license server so that the license server can issue permanent CALs for Terminal Server clients. After the license server is activated and you purchase CALs, it provides a secure way to install, and issue permanent CALs to Terminal Server clients. If you do not activate a license server, it issues temporary CALs, which allow clients to connect to the terminal server for 90 days.

**Terminal Server Licensing Components**
Following are descriptions of the primary Terminal Server Licensing components:

**Microsoft Clearinghouse**
The Microsoft Clearinghouse is the facility that Microsoft maintains to activate license servers, issue CALs to license servers, recover CALs, and reactivate license servers. The Clearinghouse stores information about all activated license servers and CALs that have been issued. This information helps you track client usage of the terminal servers within your organization to ensure that you have purchased a sufficient number of CALs. The Clearinghouse is accessed directly when you choose the Internet (Automatic) activation method in the Terminal Server Licensing Activation Wizard. If you do not have Internet connectivity, you can also contact the Clearinghouse by phone. For more information, see Locate the Microsoft Clearinghouse telephone number for your country or region.

You cannot purchase CALs through the Microsoft Clearinghouse. For information about purchasing CALs, see Purchase client access licenses. After you purchase CALs, make sure to retain the License Purchase Agreement information. Having this information with you will facilitate communication with the Microsoft Clearinghouse, should you need assistance with recovering CALs or other Terminal Server Licensing tasks that are supported by the Clearinghouse.

**License server**
A license server stores all client licenses. A terminal server must be able to connect to an activated license server before clients can be issued permanent CALs.

Before installing the license server, determine which of the two license server roles you require—a Domain license server or an

Enterprise license server. During Terminal Server Licensing setup, you select one of these roles. By default, a license server is installed as an Enterprise license server. For more information, see Terminal Server license server roles.

**Important**

- You must configure Terminal Server Licensing correctly in order for your terminal server to continue to accept connections from clients. To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first. For more information, see Terminal Server Licensing grace period.

To activate a license server, use the Terminal Server License Server Activation Wizard. When you activate a license server, Microsoft provides the server with a limited-use digital certificate that validates server ownership and identity. Microsoft uses the X.509 industry standard certificate for this purpose. The license server then uses this certificate to obtain and issue CALs to clients. For information about activating a license server, see Activating a Terminal Server license server.

**Terminal server**

A terminal server is a server on which the Terminal Server component of the Windows Server 2003 operating system is installed. A terminal server gives clients access to Windows-based applications that run entirely on the server, and supports multiple client sessions on the server. If a client does not have a license, the terminal server requests one from the license server. For instructions on installing Terminal Server, see Installing Terminal Server.

**Note**

- You can use any computer running Windows Server 2003 family operating systems to administer servers remotely with Remote Desktop for Administration (formerly Terminal Services in Remote Administration mode). You do not need to install Terminal Server. A license server and the Terminal Server Licensing administrative tool are not required for Remote Desktop for Administration. For more information about Remote Desktop for Administration, see Remote Desktop for Administration.

**Client licenses**

After the Terminal Server Licensing grace period ends, you must purchase and install the appropriate number of CALs for each device or user that needs connect to a terminal server. In addition, you must verify that the Terminal Server Licensing mode that you specify matches the type of CAL available on the license server. Terminal Server Licensing modes determine the type of CAL that a license server issues to a client. In Windows Server 2003, two types of CALs are available: Per User and Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running a Windows Server 2003 operating system. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device.

When the Per Device licensing mode is used, and a client logs on to a terminal server for the first time, the terminal server issues the client a temporary license by default. When a client logs on to a terminal server for the second time, if the license server is activated and enough Per Device CALs are available, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.

For instructions on configuring the Terminal Server Licensing mode, see Configure the Terminal Server Licensing mode. For information about the types of licenses supported by a license server that runs Windows Server 2003 family operating systems, see Required licenses.

**Resources**

For more information about Terminal Server and Terminal Server Licensing, see:

- Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627)

# Terminal Server Licensing grace period

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server Licensing grace period**

To allow ample time for you to deploy a Terminal Server license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent client access license (CAL), or after 120 days, whichever comes first. For information about the client licenses that are supported by a license server that runs Windows Server 2003 family operating systems, see Required licenses.

The license server issues CALs to the terminal server, which in turn issues them to clients. In order for a license server to issue permanent CALs, you must activate the license server and then purchase and install the appropriate number of permanent CALs. For information about how to activate a license server, see Activate a Terminal Server License Server. For information about how to purchase CALs, see Purchase client access licenses. If a license server is not activated, it issues temporary licenses. These temporary licenses allow clients to connect to the terminal server for 90 days. There is no limit to the number of temporary licenses that a license server can issue, but a single client is only issued a temporary license once. After the temporary license expires, the client can only connect to the terminal server if the license server can issue a permanent CAL, or if the terminal server is still within its licensing grace period.

Terminal Server Licensing modes determine the type of CAL that a license server issues to a client. In Windows Server 2003, two types of CALs are available: Per User and Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device.

By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.

For each permanent Per Device CAL that is issued, an expiration period is applied. This expiration period is a random number of days between 52 to 89 days after the license is issued. The terminal server always attempts to renew these CALs seven days before they expire. This functionality facilitates the automatic recovery of Per Device CALs that are lost due to hardware failure, operating system reinstallation, and other, similar events. For more information about the expiration period for Per Device CALs and about recovering CALs, see Recovering client access licenses on a Terminal Server license server.

For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Controlling the issuance of Terminal Server licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Controlling the issuance of Terminal Server licenses**

By default, a Terminal Server license server issues a license to any computer that requests one. For security reasons, you might want to restrict the issuance of licenses to specific computers or groups. You can use the **license server Security Group** Group Policy setting to control which servers are eligible to receive licenses.

**Terminal Services Computers**, a local security group, is created by default the first time Terminal Server Licensing is started. When the target computer is a domain controller, this group is a domain local group. For more information about enabling this policy setting, see Control the issuance of Terminal Server licenses.

By default, the **Terminal Services Computers** security group is not populated. You must choose the computers or groups you want to receive licenses and manually add them to this group. Any changes you make to the membership of this group take effect only after you stop and restart the Terminal Server Licensing service. For more information about adding members to a security group, see Changing group memberships.

The most efficient way to manage Terminal Server computer accounts is to create a global group that contains the accounts of all terminal servers that must be licensed. Then, add this global group to the local (or domain local) **Terminal Services Computers** group. This method allows a domain administrator to manage a single list of computer accounts.

For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Understanding Terminal Server Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Terminal Server Licensing**

- Required licenses
- Terminal Server Licensing administrative tool
- Terminal Server license management and your privacy

# Required licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Required licenses**

You must obtain the necessary licenses as part of your deployment of Terminal Server on your network. A license server that runs a Windows Server 2003 operating system supports the following types of licenses:

- **Windows Server 2003 Terminal Server Device CALs**. These CALs are purchased for devices that connect to a terminal server running a Windows Server 2003 operating system.

- **Windows Server 2003 Terminal Server User CALs**. These CALs are purchased for users who connect to a terminal server running a Windows Server 2003 operating system.

- **Windows Server 2003 Terminal Server External Connector Licenses**. These licenses are purchased to allow unlimited by external users (for example, business partners) to a terminal server running a Windows Server 2003 operating system. Terminal Server External Connector licenses are not managed; therefore, to use these licenses, you must set your terminal server to Per User mode. For instructions on configuring the Terminal Server Licensing mode, see Configure the Terminal Server Licensing mode.

- **Windows 2000 Terminal Services CALs**. These licenses are purchased for devices that connect to a Windows 2000 terminal server.

- **Windows 2000 Terminal Services Internet Connector Licenses**. These licenses are purchased to allow up to 200 simultaneous anonymous connections to a Windows 2000 terminal server by non-employees across the Internet.

- **Windows 2000 Built-in Licenses**. Clients that are running Windows 2000 Professional or Windows XP are issued a license from the built-in pool of licenses when connecting to a Windows 2000 terminal server.

- **Temporary Licenses**. When a Windows Server 2003 family terminal server requests a Windows Server 2003 Per Device CAL, or when a Windows 2000 terminal server requests a Windows 2000 CAL, and the license server has no licenses, it issues a temporary license to the connecting client (if the client device has no license). The license server tracks the issuance and expiration of these licenses. Temporary licenses are designed to allow ample time for you to deploy a license server, and they allow unlicensed clients to connect to the terminal server for 90 days. There is no limit to the number of temporary licenses that a license server can issue, but a single client is only issued a temporary license once. After the temporary license expires, the client can only connect to the terminal server if the license server can issue a permanent CAL, or if the terminal server is still within its licensing grace period.

**Important**

- For a license server to function correctly, the operating system of the license server must be compatible with the operating system of the terminal server. Note the following:

    - A Windows 2000 license server cannot issue CALs to terminal servers running Windows Server 2003 operating systems.

    - A license server running a Windows Server 2003 operating system can issue CALs to terminal servers running Windows Server 2000 or Windows Server 2003, or to terminal servers running Windows 2000 and terminal servers running Windows Server 2003 in a mixed environment

**Notes**

- Verify that you have purchased enough CALs for the Terminal Server license server and that the Terminal Server Licensing mode matches the type of CAL available on the license server. Terminal Server Licensing modes determine the type of CAL that a license server issues to a client. In Windows Server 2003, two types of CALs are available: Per User and

Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device. Per User CALs, however, are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used.

- By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Terminal Server Licensing administrative tool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server Licensing administrative tool**
The Terminal Server Licensing administrative tool can help you manage Terminal Server licenses. Using Terminal Server Licensing, you can perform the following tasks after connecting to a Terminal Server license server:

- Activate a Terminal Server license server.
- Install client access licenses (CALs).
- Reactivate a license server.
- Deactivate a license server.
- Repeat the installation of CALs.
- Change the properties of the license server.

To perform these tasks, you must have either Internet access or access to a telephone.

You can also use Terminal Server Licensing to connect to any Terminal Server license server on your network and view information about the licenses on that server. You can view the following Terminal Server licensing information:

- The list of installed client license key packs.
- The total number of licenses in each client license key pack, and the number of available and issued licenses in each key pack.
- The date a license was issued to each computer, and the name of the computer to which each license is issued.
- The issue and expiration dates of each temporary license and the name of the computer to which the license was issued.

When the number of clients requesting licenses from a license server exceeds the number of un-issued licenses stored on the server, you receive a reminder to purchase new licenses and register them. The reminder appears as an event in the system log of the Event Viewer.

For step-by-step procedures on using Terminal Server Licensing, see Terminal Server Licensing How To....

You can also remotely manage a license server from Windows XP computers that have the Windows Server 2003 Administration Tools Pack installed. You can install the Windows Server 2003 Administration Tools Pack, which includes the Terminal Server Licensing tool, on computers that run any of the following operating systems:

- Windows XP Professional with hotfix Q329357
- Windows XP Professional with Service Pack 1 or later
- Windows Server 2003 family

The Windows Server 2003 Administration Tools Pack is included on the Windows Server 2003 family CD. For more information, see Windows Server 2003 Administration Tools Pack Overview.

**Note**

- You cannot manage license servers running Windows Server 2003 from computers that run Windows 2000.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Terminal Server license management and your privacy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server license management and your privacy**

Microsoft asks you to activate your Terminal Server license server and client access licenses (CALs) to verify that you are a licensed user and to provide customized benefits and services. When you provide complete and accurate information, Microsoft customer service representatives can successfully re-create the licensing information on your license server if technical problems occur. This prevents the possible loss of valuable licensing information. The information you provide might also be used internally at Microsoft to perform aggregate quality testing of the Terminal Server Licensing program.

You do not need to provide all of the requested information. However, some fields are required, and if you do not provide complete information, the Microsoft Clearinghouse might be unable to activate your Terminal Server license server and install CALs.

Information provided over the Internet or World Wide Web to the Microsoft Clearinghouse is encrypted for your security and is securely stored by the Microsoft Clearinghouse in a dedicated database. Microsoft uses this information only for the reasons detailed above. This information is kept separate from information you might have provided to Microsoft in other contexts, and is not disclosed to third parties.

To access and make changes to the data provided to the Microsoft Clearinghouse in this license activation process, call your customer service representative. To find the appropriate phone number to call, select the telephone activation method in the Terminal Server License Server Activation Wizard. For information about activating a Terminal Server license server by using the telephone, see Activate a Terminal Server license server by using the telephone.

If you believe that Microsoft has not complied with these privacy principles, please notify us by postal mail at the following address:

Microsoft Corporation

Attn: Terminal Services License Management Program

One Microsoft Way

Redmond, WA 98052-6399

Commercially reasonable efforts are made promptly to determine and correct the problem.

# Using Terminal Server Licensing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Terminal Server Licensing**

- Terminal Server license server roles
- Activating a Terminal Server license server
- Purchasing and installing client access licenses on a Terminal Server license server
- Recovering client access licenses on a Terminal Server license server
- Backing up a Terminal Server license server

# Terminal Server license server roles

Updated: January 19, 2009

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Server license server roles**
A Terminal Server license server stores all client licenses. A terminal server must be able to connect to an activated license server before clients can be issued permanent client access licenses (CALs). When you activate a license server, Microsoft provides the server with a digital certificate that validates server ownership and identity. By using this certificate, a license server can make transactions with Microsoft and receive client licenses for your terminal servers. If you install a license server but do not activate it, that server only issues temporary licenses.

For small deployments, it is acceptable to install both the terminal server and Terminal Server Licensing on the same physical computer; however, for larger deployments, consider installing Terminal Server Licensing on a separate server. Note that one Terminal Server license server can serve many terminal servers concurrently.

### Important

- You must configure Terminal Server Licensing correctly in order for your terminal server to continue to accept connections from clients. To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first. For more information about the licensing grace period, see Terminal Server Licensing grace period.

Before installing a license server, determine which of the two license server roles you require—a Domain license server or an Enterprise license server. During Terminal Server Licensing setup, you select one of these roles. By default, the Enterprise license server role is selected.

If you are installing a license server in an Active Directory domain environment, you can select either the Enterprise license server or the Domain license server role. If you are installing a license server in a workgroup or a non-Active Directory domain environment, you must select the Domain license server role. To activate the license server quickly, install Terminal Server Licensing on a server that has Internet access.

**Enterprise license server**
You can only install an Enterprise license server on a domain controller or a member server in a domain, not on a stand-alone server. This role is published to Active Directory.

An Enterprise license server is an appropriate choice if your network includes several domains, and if you want to maintain one license server that can issue licenses to terminal servers across the different domains. An Enterprise license server can serve terminal servers in any domain, but the domain must be a Windows Server 2003 domain or Windows 2000 Active Directory domain. An Enterprise license server is automatically discovered by any terminal server that is in the same site as the license server. By default, an Enterprise license server only serves terminal servers in the same site.

**Domain license server**
A Domain license server is an appropriate choice if you want to maintain a separate license server for each domain. Terminal servers can access domain license servers only if they are in the same domain as the license server.

**License server discovery process**
Terminal servers use a discovery process to locate license servers. This process begins when the Terminal Server service starts. Although Terminal Server attempts to detect a license server automatically, you can explicitly specify a preferred license server to which the terminal server connects. For instructions on configuring a preferred license server through Group Policy or by modifying the registry, see Set preferred Terminal Server license servers. You can also set preferred license servers by using a Windows Management Instrumentation (WMI) script. For three scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see "Preferred License Server WMI Scripts" in Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

During the discovery process, terminal servers attempt to contact license servers in the following order:

1. Any preferred license servers that are specified in Group Policy.

2. Any Enterprise license servers or Domain license servers that are specified in the registry.

   In Windows Server 2003, the relevant registry key is **LicenseServers** , and it is located under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\TermService\Parameters**.

   In Windows 2000, the relevant registry key is **DefaultLicenseServer**, and it is located under **HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\TermService\Parameters**.

   In Windows Server 2003, you can specify multiple license servers in the registry. In Windows 2000, you can only specify one license server.

3. Enterprise license servers that are specified in Active Directory.

4. Domain license servers.

**Enterprise license server discovery**
As mentioned in this topic, an Enterprise license server is automatically discovered by any terminal server that is in the same site as the license server and by default, only serves terminal servers in the same site. You can, however, publish the license server to another site in Active Directory. A terminal server polls Active Directory every 60 minutes to locate an Enterprise license server, and continues to poll every 60 minutes, even when an Enterprise license server is located.

**Domain license server discovery**
If you are installing a Domain license server, the computer on which you install the license server must be a domain controller for it to be automatically discovered by terminal servers that communicate with it. If you install a Domain license server on a member server, you must specify this server as a preferred license server on all terminal servers that need to communicate with it. If the computer on which you plan to install the Domain license server is in a workgroup, it can only be automatically discovered by terminal servers on the same subnet.

If you install an Enterprise license server on a member server, you do not need to specify it as a preferred license server, because Enterprise license servers are automatically discovered.

When a terminal server attempts to locate a Domain license server, the terminal server queries all domain controllers within the same site. If the terminal server cannot find an available license server in the same site, the terminal server will not attempt to query any other domain controllers (for example, other domain controllers in the same domain). A terminal server attempts to locate a Domain license server every 15 minutes. After a Domain license server is located, the terminal server continues to search for a Domain license server every two hours. If the terminal server cannot locate a Domain license server, it resumes searching every 15 minutes.

## Notes

- To improve security, you should consider removing workgroups and replacing them with domains.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Activating a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Activating a Terminal Server license server**

You must activate a Terminal Server license server and then purchase and install the appropriate number of client access licenses (CALs) before the license server can issue permanent CALs to Terminal Server clients. A license server that has been installed but not activated only issues temporary licenses. These temporary licenses allow clients to connect to the terminal server for 90 days. For information about purchasing and installing CALs, see Purchasing and installing client access licenses on a Terminal Server license server.

To activate a license server, use Terminal Server Licensing. When you activate a license server, the Microsoft Clearinghouse provides the server with an X.509 digital certificate that validates server ownership and identity. Using this certificate, a license server can make subsequent transactions with the Microsoft Clearinghouse and receive permanent CALs for your terminal servers.

Information that you provide over the Internet or World Wide Web to the Microsoft Clearinghouse is encrypted for your security and is securely stored by the Microsoft Clearinghouse in a dedicated database. This information is kept separate from information you might have provided to Microsoft in other contexts, and is not disclosed to third parties. For more information, see Terminal Server license management and your privacy.

**Important**

- If the Internet Explorer Enhanced Security Configuration setting is in effect on your Terminal Server license server, you must add the Microsoft Clearinghouse Web site (https://activate.microsoft.com/) to the Trusted sites zone in Internet Explorer before you can activate your Terminal Server license server. If you try to connect to the Microsoft Clearinghouse Web site and it is not yet a trusted site, you are prompted to specify whether to add it to the Trusted sites zone. For more information, see Internet Explorer Enhanced Security Configuration.

The following table shows the three ways to activate a Terminal Server license server.

| Automatic | Web Browser | Telephone |
|---|---|---|
| This is the fastest and easiest method. To use this method, the server running Terminal Server Licensing must have an Internet connection. | Use this method to connect directly to the secure Microsoft Terminal Services Web site. This method also requires an Internet connection, but the connection can be made from any computer, not just the computer that is running Terminal Server Licensing. | If you do not have an Internet connection, use this method to contact the Microsoft Clearinghouse and receive an ID number to activate the license server by phone. For instructions on how to locate the appropriate local number to call, see Locate the Microsoft Clearinghouse telephone number for your country or region. |

For instructions on activating a license server by using any of these methods, see Activate a Terminal Server License Server.

You are required to activate a license server only once, after which the license server becomes the repository for terminal server client licenses.

**Notes**

- If you upgrade a Terminal Server license server from Windows 2000, you must reactivate it.

- The Microsoft Clearinghouse is the facility that Microsoft maintains to activate license servers, issue CALs to license servers, recover CALs, and reactivate license servers. You cannot purchase CALs from the Clearinghouse. For instructions on how to purchase CALs, see Purchase client access licenses. After you purchase CALs, make sure to retain the License Purchase Agreement. If you contact the Clearinghouse, the information in the Agreement will help them assist you.

- To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. For more information about the licensing grace period, see Terminal Server Licensing grace period.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Purchasing and installing client access licenses on a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Purchasing and installing client access licenses on a Terminal Server license server**
After a Terminal Server license server is activated, you can purchase and then install client access licenses (CALs) on that server so that it can issue those licenses to terminal servers upon request. The CALs are stored and tracked on the license server.

For instructions on purchasing CALs, see Purchase client access licenses. After you purchase CALs, make sure to retain the License Purchase Agreement information. Having this information with you will facilitate communication with the Microsoft Clearinghouse, should you need assistance with recovering CALs or other Terminal Server Licensing tasks that are supported by the Clearinghouse. The Clearinghouse is the facility that Microsoft maintains to activate license servers, issue CALs to license servers, recover CALs, and reactivate license servers.

The Clearinghouse processes your request to install and issue CALs, in the quantity requested, to your license server. Then, you install the CALs, using one of the three methods you used to activate a license server—Automatic (recommended), Web Browser, and Telephone. For instructions on installing CALs by using any of these methods, see Install Client Access Licenses. For instructions on locating the Clearinghouse telephone number if you do not have access to the Internet, see Locate the Microsoft Clearinghouse telephone number for your country or region.

Client licenses are digitally signed certificates that each client stores locally. After client licenses are installed on a license server, the server can issue licenses. When a client computer attempts to log on to a terminal server for the first time, the terminal server recognizes that the client has not been issued a license and locates a license server to issue a new license to the client. Terminal Server Licensing modes determine the type of CAL that a license server issues to a client. In Windows Server 2003, two types of CALs are available: Per User and Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device.

By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.

If you want to transfer a license from one computer to another, you must call the Microsoft Clearinghouse. According to the terms of your End User License Agreement (EULA) for Terminal Server Client Access Licenses, you can make this transfer only once.

### Notes

- You must configure Terminal Server Licensing correctly in order for your terminal server to continue to accept connections from clients. To allow ample time for you to deploy a license server, Terminal Server provides a licensing grace period, during which no license server is required. During this grace period, a terminal server can accept connections from unlicensed clients without contacting a license server. The grace period begins the first time the terminal server accepts a client connection. It ends after you deploy a license server and that license server issues its first permanent CAL, or after 120 days, whichever comes first. For more information about the licensing grace period, see Terminal Server Licensing grace period.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Recovering client access licenses on a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Recovering client access licenses on a Terminal Server license server**

After a Terminal Server license server is activated, you can purchase and then install client access licenses (CALs) on that server so that it can issue those licenses to terminal servers upon request. The terminal servers, in turn, issue licenses to clients. Terminal Server licensing modes determine the type of CAL that a license server issues. In Windows Server 2003, two types of CALs are available: Per User and Per Device. A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices. In this case, only one CAL is needed instead of a CAL for each device.

To configure the Terminal Server licensing mode, you must set the licensing mode on the terminal server to match the type of CAL that you purchase and install on the license server. To set the licensing mode on the terminal server, you can use Terminal Services Configuration. For more information, see Configure the Terminal Server Licensing mode.

When the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license by default. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.

By default, for terminal servers and license servers that are running Windows Server 2003 or Windows 2000 Service Pack 3 (or that are running Windows 2000 Service Pack 2 and earlier with the hotfix described in Microsoft Security Bulletin MS01-052 applied), an expiration period is applied for each Per Device CAL that is issued. This expiration period, which is not configurable, is a random number of days between 52 to 89 days after the license is issued. When a client connects to a terminal server, the expiration date for the CAL is checked. If the expiration is set to occur within seven days, the terminal server connects to the license server and renews the CAL. During this time, the CAL is given another expiration period of 52 to 89 days. If the license server is not available, the terminal server attempts to replace the CAL each time the client logs on to a terminal server session. After the CAL expires, the license server returns any CAL that was not renewed to the group of available CALs.

This functionality facilitates the automatic recovery of Per Device CALs that are lost due to hardware failure, operating system reinstallation, and other similar events. This functionality is also available for terminal servers and license servers running earlier versions of Windows 2000 that have the hotfix described in Microsoft Security Bulletin MS01-052 applied. For the hotfix to work correctly, you must apply it to all terminal servers and license servers in your organization.

**Important**

- CALs cannot be recovered automatically in the following cases:

    - CALs that are issued by license servers and terminal servers that are running Windows 2000 Service Pack 2 and earlier and that do not have the hotfix described in Microsoft Security Bulletin MS01-052 applied. In such cases, these CALs remain assigned to the devices to which they are issued. If the CALs are lost, you must contact the Microsoft Clearinghouse to recover them. If you do need to contact the Clearinghouse to recover CALs, make sure that you have the License Purchase Agreement information available. Having this information with you will facilitate the CAL recovery process. For information about how to contact the Clearinghouse, see Locate the Microsoft Clearinghouse telephone number for your country or region.

    - Catastrophic failure that results in the loss of the licensing database. In the event of a failure that results in the loss of the licensing database when a known good backup is not available, you must reinstall Terminal Server Licensing and reactivate the license server, and then contact the Clearinghouse to re-issue any previously issued CALs. The original CALs that were issued are based on the identification number of the license server at the time of issuance. A license server ID number is a unique 35-character alphanumeric representation of the certificate of a license server. This certificate is provided during license server activation, and it is used to obtain CALs. If the license server ID number changes, CALs that are based on the old license server ID number cannot be re-installed.

A re-issued set of CALs is displayed in the Terminal Services Licensing administrative tool as another CAL installation. Other than being a separate CAL installation, re-issued CALs are not distinguishable from an original installation.

The following problems might result from a Terminal Server licensing mode mismatch:

- If a terminal server is set to Per Device mode and the license server with which it communicates only has Per User CALs, the license server only issues temporary licenses. When the temporary licenses are close to expiration, the following message appears on the terminal server: "Your terminal services temporary client license will expire in N days. Please contact your system administrator to get a permanent license." In this case, Event ID 26, Source: Application Pop-up appears in the application event log.

- Similarly, Terminal Server clients that run Windows XP or Windows 2000 might receive the following error message, if the client cannot connect to the terminal server for this reason: "The remote session was disconnected because the local computer client access license could not be upgraded or renewed." In this case, Event ID 1011, Source TermService appears in the application event log on the terminal server.

To correct these problems, switch the Terminal Server Licensing mode from Per Device to Per User. For information about switching modes, see Configure the Terminal Server Licensing mode.

Keep in mind that even though Per User CALs are not monitored by Terminal Server, this does not remove administrators from End User License Agreement (EULA) requirements to have a valid terminal server (TS) CAL for each user. Failure to have a valid Per User CAL for each user, if Per Device CALs are not being used, is a violation of the EULA.

The following text is from the EULA for Windows Server 2003.

Two different TS CALs are available to you: "Device" and "User." Each TS Device CAL permits one Device (used by any User) to conduct Windows Sessions on any of your Servers. Each TS User CAL permits one User (using any Device) to conduct Windows Sessions on any of your Servers. You may use a mix of TS Device CALs and TS User CALs simultaneously with the Server Software in your environment. You can have a Terminal Server request Per User licenses or Per Device (default) but not both simultaneously.

- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Backing up a Terminal Server license server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Backing up a Terminal Server license server**

You should back up your Terminal Server license server regularly by using the Backup tool. This will help protect your licensing data from accidental loss if your system experiences hardware or storage failure.

When backing up a Terminal Server license server, back up the System State and Repair data, and the %systemdrive%\system32\lserver directory. Doing this ensures that data in both the registry and the license server database is backed up.

If you restore the System State data and the database to the same license server computer, any un-issued licenses are restored correctly as long as you have not replaced the operating system on the computer or removed and reinstalled Terminal Server Licensing. If you do not restore to the same computer, any un-issued licenses that are detected are not restored and an event will appear in the system log of Event Viewer. You can still restore the un-issued licenses by contacting the Microsoft Clearinghouse by phone and requesting that the licenses be reissued. When you contact the Clearinghouse, make sure that you have the License Purchase Agreement available. The information in the Agreement will facilitate the process of reissuing the licenses. For information about how to contact the Clearinghouse, see Locate the Microsoft Clearinghouse telephone number for your country or region.

For more information about using Backup, see Backup.

For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

# Terminal Services Configuration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services Configuration**

You can configure new connections for Terminal Services, modify the settings of existing connections, and delete connections by using the Terminal Services Configuration tool (TSCC.msc) or Group Policy (gpedit.msc).

- For help with specific tasks, see Terminal Services Configuration How To....
- For general background information, see Terminal Services Configuration Concepts.

# Terminal Services Configuration How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install Terminal Server
- Configure Terminal Services Connections
- Manage Terminal Services Connections
- Configure Server Settings
- Configure Group Policy Settings

# Install Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Terminal Server**

1. Open Configure Your Server Wizard.
2. Click **Next** and follow the instructions on the **Preliminary Steps** screen.
3. Click **Next**, and on the **Server Role** screen, select **Terminal Server**.
4. Click **Next** and follow the instructions in the wizard.
5. Some programs might not work correctly when Terminal Server is installed. If so, you must reinstall these programs for multisession access using **Add or Remove Programs** after Terminal Server is installed. For more information, see Program Compatibility.

**Warning**

- Terminal Server Licensing is a required component that licenses clients on a terminal server. You must install Terminal Server Licensing or your terminal server will stop accepting connections from unlicensed clients 120 days from the date of the first client logon.

  You should not install Terminal Server Licensing on the same computer with Terminal Server.

  For more information on Terminal Server Licensing, see Terminal Server Licensing.

**Important**

- When you install Terminal Server using the Configure Your Server Wizard, as a security precaution the Internet Explorer Enhanced Security Configuration is set by default to prevent Administrators from downloading files or running ActiveX controls from the Web. If you want to change this setting to either permit all users to download files or run ActiveX controls or prevent all users from doing so, use **Add/Remove Windows Components** in **Add or Remove Programs**. This setting applies to servers running one of the Windows Server 2003 family operating systems. For more information, see Terminal server role: Configuring a terminal server and Internet Explorer Enhanced Security Configuration.

**Important**

- You must use the Remote Desktop Users group to control remote connection permissions for Terminal Server. For more information, see Managing Terminal Services users and Add users to the Remote Desktop Users group.

**Important**

- It is not necessary to install Terminal Server for remote administration of your server. Remote Desktop for Administration is installed by default. To use Remote Desktop for Administration, you must first enable remote connections. For more information on enabling remote connections, see Enable or disable Remote Desktop and Enabling users to connect remotely to the server.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For

more information, see Default local groups, Default groups, and Using Run as.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

- You can also use **Add or Remove Programs** to install Terminal Server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**
Install Terminal Server Licensing
Activate a Terminal Server License Server
Install Client Access Licenses
Enable or disable Remote Desktop

# Configure Terminal Services Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure Terminal Services connections**

- Make a new connection
- Specify a maximum number of sessions that can connect to the server
- Configure Authentication and Encryption
- Specify a program to start automatically when a user logs on
- Allow a user to log on to the server automatically
- Manage Remote Control
- Configure Time-out and Reconnection Settings
- Manage Client Settings
- Manage Connection Permissions

# Make a new connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a new connection**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. On the **Action** menu, click **Create New Connection**.
4. The Terminal Services Connection wizard appears. Follow the instructions on your screen to configure the connection.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- Only one Remote Desktop Protocol (RDP) connection can be configured for each network adapter in a terminal server. Typically, the RDP connection that is configured when Terminal Services is installed is the only connection needed. You can configure additional connections using RDP if you install an additional network adapter for each connection.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify a maximum number of sessions that can connect to the server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a maximum number of sessions that can connect to the server**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Limit number of connections** setting, and then click **Enabled**.
3. In the **TS Maximum Connections allowed** box, type the maximum number of connections you want to allow, and then click **OK**.

### Important

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Note

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy by using the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to specify a maximum number of sessions, and then click **Properties**.
4. On the **Network Adapter** tab, click **Maximum connections**, type the maximum number of sessions that can connect to the server, and then click **Apply**.

### Notes

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.
- By default, the connection is configured to allow an unlimited number of sessions to connect to the server.
- Restricting the number of sessions improves performance because fewer sessions are demanding system resources.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Request a computer certificate for server authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To request a computer certificate for server authentication**

Submit an advanced certificate request for a computer certificate by using the Web

Submit a computer certificate request by using the Certificate Request Wizard

**Submit an advanced certificate request for a computer certificate by using the Web**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server that is running Windows Server 2003 and where the certification authority (CA) that you want to access is located.
3. Click **Request a certificate**.
4. Click **Advanced certificate request**.
5. Click **Create and submit a certificate request to this CA**.
6. Provide identifying information as required.
7. In the **Name** box, type the name of the terminal server for which you are requesting the certificate.
8. In **Type of Certificate needed**, click **Server Authentication Certificate**.
9. In **Key Options**, click **Create a new key set**, and then specify additional options as follows:
   - In **Cryptographic service provider (CSP)**, click **Microsoft RSA SChannel Cryptographic Provider**. This CSP supports key derivation for the SSL2, PCT1, SSL3, and TLS1 protocols.
   - In **Key usage**, click **Exchange**. Exchange means that the private key can be used to enable the exchange of sensitive information.
   - Select the **Mark Keys as exportable** check box. Doing this saves the public and private key to a PKCS #12 file. This is useful if you want to copy a certificate for use on another computer.
10. Select the **Store certificate in the local computer certificate store** check box.

    **Important**

    - This check box must be selected for TLS authentication to function.
11. Click **Submit**.
12. If you see the **Certificate Issued** Web page, click **Install this certificate**. For instructions on how to retrieve a CA certificate from a Windows Server 2003 CA, see Related Topics.
13. If you are finished using the Certificate Services Web pages, close Internet Explorer.

**Notes**

- To request a certificate, a subject must have Read and Enroll permissions on the certificate template.
- To open Internet Explorer, click **Start**, point to **All Programs**, and then click **Internet Explorer**.
- This procedure is for obtaining certificates from a Windows Server 2003 CA. For instructions on how to obtain certificates by using the Windows 2000 Certificate Services Web pages, see Related Topics. Alternatively, you can purchase a certificate from a non-Microsoft vendor and install the certificate manually.
- Use this procedure if you need to request the following certificates:
    - Certificates that are issued from a stand-alone CA.
    - Certificates that are based on a template configured to obtain the subject name from the subject.
    - Certificate types that require approval before the certificates are issued.
- You can use the second procedure in this topic, "Submit a computer certificate request by using the Certificate Request Wizard," if the certificates meet the following requirements:
    - The certificates are issued from an enterprise CA.
    - The certificates are based on templates where the subject name is generated by Windows.
    - The certificate type does not require approval before the certificates are issued.
- For a client to make a connection to the terminal server, the client must trust the root of the server's certificate. The client computers must have the certificate of the root CA that issued the server certificate in their Trusted Root Certification Authorities store, which you can view in the Certificates snap-in.

**Submit a computer certificate request by using the Certificate Request Wizard**

1. If you are submitting a computer certificate request for the local terminal server, open Certificates (Local Computer) If you are submitting a computer certificate request for a remote terminal server, open Certificates (*Servername)*.
2. In the console tree, click one of the following:
    - **Certificates (Local Computer)** (for the local terminal server)
    - **Certificates (*Servername*)** (for a remote terminal server).
3. If you are not in Certificate Purpose view mode, on the **View** menu, click **Options**, click **Certificate Purpose, and then click OK**.
4. In the details pane, under **Intended Purposes**, double-click **Server Authentication**.
5. On the **Action** menu, point to **All Tasks**, and then click **Request New Certificate** to start the Certificate Request Wizard.
6. On the **Certificate Types** page, click **Server Authentication**, and then select the **Advanced** check box.
7. On the **Cryptographic Service Provider** page, click **Microsoft RSA SChannel Cryptographic Provider**. This CSP supports key derivation for the SSL2, PCT1, SSL3, and TLS1 protocols. '
8. Select the key length. It is recommended that you use a key length of 1024 bits (the default setting) or higher.

9. Select the **Mark Keys as exportable** check box. Doing this enables you to save the public and private key to a PKCS #12 file. This is useful if you want to copy a certificate for use on another computer.

10. **Specify whether to enable strong private key protection**.

11. On the **Certification authority** page, if more than one CA is available, click **Browse**, and then click the name of the CA that will issue the certificate.

12. On the **Certificate Friendly Name and Description** page, type a friendly name for the new certificate.

13. On the wizard completion page, click **Finish**.

### Notes

- To request a certificate, a subject must have Read and Enroll permissions on the certificate template.

- To open Certificates for a computer account, click **Start**, click **Run**, type **mmc**, and then click **OK**. On the **File** menu, click **Open**, navigate to the console file that you want to open, and then click **Open**. In the console tree, click the **Certificates snap-in that contains the computer account you want**.

- If you have not already created an MMC console that contains Certificates, see Related Topics for instructions on managing certificates for a computer.

- This procedure is for obtaining certificates from a Windows Server 2003 CA. However, you can also use the Windows Certificate Request Wizard to obtain certificates from a Windows 2000 CA, or you can purchase a certificate from a non-Microsoft vendor and install the certificate manually.

- To use this procedure to request certificates, the certificates must meet the following requirements:

    - The certificates are issued from an enterprise CA.

    - The certificates are based on templates where the subject name is generated by Windows.

    - The certificate type does not require approval before the certificates are issued.

- Use the first procedure in the topic, "Submit an advanced certificate request for a computer certificate via the Web," if you need to request the following certificates:

    - Certificates that are issued from a stand-alone CA.

    - Certificates that are based on a template configured to obtain the subject name from the subject.

    - The certificate type requires approval before the certificates are issued.

- For a client to make a connection to the terminal server, the client must trust the root of the server's certificate. The client computers must have the certificate of the root CA that issued the server certificate in their Trusted Root Certification Authorities store, which you can view in the Certificates snap-in.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure authentication and encryption on the server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure authentication and encryption on the server**

- Configure the encryption level by using Group Policies
- Using Terminal Services Configuration

**Configure the encryption level by using Group Policies**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Encryption and Security**, double-click the **Set client connection encryption level** setting, and then click **Enabled**.
3. To set the encryption level, do one of the following:
   - To set the encryption level to **Client Compatible**, **High Level**, or **Low Level**, in the **Encryption Level** list, click the level that you want, and then click **OK**. For information about these encryption levels, see Note, at this end of this topic.
   - To enable FIPS compliant encryption, click **OK** to close the **Set client connection encryption level Properties** dialog box, and then navigate to **Computer Configuration**, **Windows Settings**, **Security Settings**, **Local Policies**, **Security Options**. Double-click **System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing**, and then click **Enabled**.
4. If you set the encryption level to **High Level** or if you enabled FIPS compliant encryption and you want to use Transport Level Security (TLS) 1.0 to authenticate the server, you must enable TLS by using the Terminal Services Configuration tool and meet additional configuration requirements.

   You cannot use Group Policy to enable TLS authentication. For more information, see Using Terminal Services Configuration, later in this topic.

**Important**

- Any encryption level settings that you configure in Group Policy override the configuration that you set by using the Terminal Services Configuration tool. Also, if you enable the System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing Group Policy setting, this setting overrides the **Set client connection encryption level** Group Policy setting.
- In order for clients to be able to connect to a terminal server that uses FIPS compliant encryption, you must upgrade these clients to use the RDP 5.2 (Windows Server 2003) client. You can install this client from Windows Server 2003 terminal servers. For more information, see Remote Desktop Connection for Windows Server 2003 [5.2.3790] (http://go.microsoft.com/fwlink?/LinkID=41068).
- Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator. Then, you must open Group Policy by using the **Active Directory Users and Computers** snap-in.
- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.

2. In the console tree, click **Connections**.

3. In the details pane, right-click the connection you want to modify, and then click **Properties**.

4. On the **General** tab, in **Security layer**, select a security method. The security method that you select determines whether the terminal server is authenticated to the client, and the level of encryption that you can use. You can select from these security methods.

   - The **Negotiate** method uses TLS 1.0 to authenticate the server, if TLS is supported. If TLS is not supported, the server is not authenticated.

   - The **RDP Security Layer** method uses native Remote Desktop Protocol encryption to secure communications between the client and server. If you select this setting, the server is not authenticated.

   - The **SSL** method requires the use of TLS 1.0 to authenticate the server. If TLS is not supported, the connection fails. This method is only available if you select a valid certificate, as described in Step 6.

   If you select **Negotiate** or **SSL**, for TLS to function correctly, you must also set the encryption level to **High**, or you must enable FIPS compliant encryption by using Group Policy or Terminal Server Configuration. Additional server and client configuration requirements must also be met. For more information about requirements and tasks for configuring Terminal Server to support TLS authentication, see Configuring authentication and encryption.

5. In **Encryption level**, click the level that you want. You can select **Low**, **Client Compatible**, **High**, **or FIPS Compliant**. Fo**r more information about these levels, see Notes, at the end of this topic.**

6. **To use TLS 1.0 to authenticate the server, in Certificate, click Browse, click Select Certificate, and then click the certificate that you want to use. The certificate must be an X.509 certificate with a corresponding private key. For instructions on how to verify whether the certificate has a corresponding private key, see Notes.**

7. To specify that clients log on to the terminal server by typing their credentials in the default Windows logon dialog box, select the **Use standard Windows logon interface** check box.

**Note**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

- Any encryption level settings that you configure in Group Policy override the configuration that you set by using the Terminal Services Configuration tool. Also, if you enable the System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing Group Policy setting, this setting overrides the **Set client connection encryption level** Group Policy setting.

- When you change the encryption level, the new encryption level takes effect the next time a user logs on. If you require

multiple levels of encryption on one server, install multiple network adapters and configure each adapter separately.

- To verify that certificate has a corresponding private key, in Terminal Services Configuration, right-click the connection for which you want to view the certificate, click the **General** tab, click **Edit**, click the certificate that you want to view, and then click **View Certificate**. At the bottom of the **General** tab, the statement, "You have a private key that corresponds to this certificate" should appear. You can also view this information by using the Certificates snap-in.

- The **FIPS compliant** setting (the **System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing** setting in Group Policy or the **FIPS Compliant** setting in Terminal Server Configuration) encrypts and decrypts data sent from the client to the server and from the server to the client, with the Federal Information Processing Standard (FIPS) 140-1 encryption algorithms, using Microsoft cryptographic modules. For more information, see FIPS 140 Evaluation (http://go.microsoft.com/fwlink/?LinkID=34627).

- The **High** setting encrypts data sent from the client to the server and from the server to the client by using strong 128-bit encryption.

- The **Client Compatible** setting encrypts data sent between the client and the server at the maximum key strength supported by the client.

- The **Low** setting encrypts data sent from the client to the server using 56-bit encryption.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Request a certification authority certificate for the client

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To request a certification authority certificate for the client**

1. Open Internet Explorer.
2. In Internet Explorer, connect to http://*servername*/certsrv, where *servername* is the name of the Web server running Windows Server 2003 where the certification authority (CA) you want to access is located.
3. Click **Download a CA certificate**, **certificate chain**, or **CRL**.
4. If you want to trust all the certificates issued by this CA, click **Install this CA certificate chain**. A certificate chain contains the chain of certificates that can be traced back to the root CA.
5. If you are finished using the Certificate Services Web pages, close Internet Explorer.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Internet Explorer, click **Start**, point to **All Programs**, and then click **Internet Explorer**.
- Use this procedure to ensure that clients trust the root of the server's certificate (that is, clients have the certificate of the root CA that issued the server certificate in their Trusted Root Certification Authorities store). This requirement must be met for Transport Level Security (TLS) to be used for server authentication when clients connect to a terminal server. For more information about client and server requirements and tasks for configuring Terminal Server to support TLS authentication, see Configuring authentication and encryption.
- Choosing **Install this CA certification path** is useful when you want to establish trust in a subordinate CA, but you do not currently have the certificate of the root CA in your certificate store.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure authentication on the client by using Remote Desktop Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure authentication on the client by using Remote Desktop Connection**

1. Open Remote Desktop Connection.
2. Click **Options**.
3. On the **Security** tab, in the **Authentication** list, click the authentication option that you want. You can select from the following options:

- **No authentication**. If you select this option, the server is not authenticated.
- **Attempt authentication.** If you select this option, Transport Level Security (TLS) 1.0 is used to authenticate the terminal server, if TLS 1.0 is supported and correctly configured.
- **Require authentication.** If you select this option, TLS is required to authenticate the server. If TLS is not supported or correctly configured, the connection fails. This option is only available for clients that are connecting to terminal servers running Windows Server 2003 Service Pack 1 (SP1).

**Important**

- If you plan to use TLS authentication, you must configure clients and servers correctly to support this option. Clients must:
    - Run Windows 2000 or Windows XP.
    - Use the RDP 5.2 (Windows Server 2003) client. You can install this client from Windows Server 2003 terminal servers. For more information, see Remote Desktop Connection for Windows Server 2003 [5.2.3790] (http://go.microsoft.com/fwlink?/LinkID=41068).
    - Trust the root of the server's certificate.
- For more information about client and server requirements and tasks for configuring Terminal Server to support TLS authentication, see Configuring authentication and encryption.

**Note**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Remote Desktop Connection, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.
- If you select **Attempt authentication** and the server certificate has expired or is not issued by a trusted root CA, or if the name of the certificate does not match the name of the client computer, you can choose to continue the connection without TLS server authentication. Other errors, however, will cause the connection to fail.
- Support for TLS 1.0 authentication can also be enabled on client computers through configuration and distribution of an .rdp file. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure authentication on the client by using an .rdp file

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure authentication on the client by using an .rdp file**

1. Open Remote Desktop Connection.
2. Click **Options**.
3. On the **Security** tab, in the **Authentication** list, click the authentication option that you want. You can select from the following options:
   - **No authentication**. If you select this option, the server is not authenticated.
   - **Attempt authentication.** If you select this option, Transport Level Security (TLS) 1.0 is used to authenticate the terminal server, if TLS 1.0 is supported and correctly configured.
   - **Require authentication.** If you select this option, TLS is required to authenticate the server. If TLS is not supported or correctly configured, the connection fails. This option is only available for clients that are connecting to terminal servers running Windows Server 2003 Service Pack 1 (SP1).
4. On the **General** tab, click **Save As**.
5. Enter a file name for the saved connection file, and then click **Save**. Connections are saved as Remote Desktop protocol (.rdp) files.
6. Distribute the .rdp file to client computers.

**Important**

- If you plan to use TLS authentication, you must configure clients and servers correctly to support this option. Clients must:
  - Run Windows 2000 or Windows XP.
  - Use the RDP 5.2 (Windows Server 2003) client. You can install this client from Windows Server 2003 terminal servers. For more information, see Remote Desktop Connection for Windows Server 2003 [5.2.3790] (http://go.microsoft.com/fwlink?/LinkID=41068).
  - Trust the root of the server's certificate.
- For more information about client and server requirements and tasks for configuring Terminal Server to support TLS authentication, see Configuring authentication and encryption.

**Note**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open Remote Desktop Connection, click **Start**, point to **Programs** or **All Programs**, point to **Accessories**, point to **Communications**, and then click **Remote Desktop Connection**.

- You can also edit the .rdp file by using Microsoft Notepad, where the parameter is **authentication level**. You can specify a value of 0, 1, or 2 where:

  - 0 = No authentication
  - 1 = Require authentication
  - 2 = Attempt authentication

  For example, you can enter the following:

  **authentication level:i:0**

  Where**i**specifies that the value is an integer, and **0** specifies the authentication level (in this example, no authentication).

- If you select **Attempt authentication** and the server certificate has expired or is not issued by a trusted root CA, or if the name of the certificate does not match the name of the client computer, you can choose to continue the connection without TLS server authentication. Other errors, however, will cause the connection to fail.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Specify a program to start automatically when a user logs on

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a program to start when a user logs on**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration, Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Start a program on connection** setting, and then click **Enabled**.
   - If the status is to **Not Configured**, then Terminal Services cannot start a specified initial program automatically when a client connects to a terminal server, unless an initial program is specified in the default user profile and in Remote Desktop Connection or the Terminal Services client. If an initial program is not specified, then the user must start programs by using the default desktop that is displayed during the Terminal Services session.
   - If the status is set to **Disabled**, then Terminal Services cannot start a specified initial program automatically when a client connects to a terminal server. Instead, the user must start programs by using the default desktop that is displayed during the Terminal Services session.
3. If you selected **Enabled**, in the **Program path and file name** box, type the path and file name of the program you want to start when a user logs on.
4. In the **Working Directory** box, type the working directory, and then click **OK**.

### Important

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Notes

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator. Then, you must start Group Policy by using the **Active Directory Users and Computers** snap-in.
- These policies affect every client that connects to the terminal server. To specify a program to start on a per-user basis, use the corresponding policy under **User Configuration**.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections.**
3. In the details pane, right-click the connection for which you want to specify an initial program, and then click **Properties**.

4. On the **Environment** tab, under **Initial program**, select **Start the following program when the user logs on**. This option allows you to configure an initial program for the connection.

    - If you select **Do not allow an initial program to be launched. Always show desktop**, then Terminal Services cannot start a specified initial program automatically when a client connects to a terminal server. Instead, the user must start programs by using the default desktop that is displayed during the Terminal Services session.

    - If you select **Run initial program specified by user profile and Remote Desktop Connection or Terminal Services client**, then the program that is specified in the default user profile and in Remote Desktop Connection or the Terminal Services client will run when the client connects to the terminal server.

5. If you selected **Start the following program when the user logs on**, in **Program path and file name**, type the path and file name of the program that you want to start when the user logs on to the terminal server.

6. In **Start in**, type the working directory path for the program, and then click **OK**.

### Notes

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

- Some client option settings are not applied when a connection is made to the console session of a remote computer running Windows XP. For example, if the client has specified a program to start upon connection to a remote computer, that program does not start if the connection is made to the console session of the remote computer. Instead, the default desktop appears. If the connection is made to a session other than the console session, the specified program starts as expected. The console session is the only session available for Remote Desktop on Windows XP Professional, so the default desktop always appears when a connection is made, even if the client has specified a different program.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow a user to log on to the server automatically

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow a user to log on to the server automatically**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection through which you want to allow a user to log on automatically, and then click **Properties**.
4. On the **Logon Settings** tab, click **Always use the following logon information**.

   This setting enables you to configure logon information for a user. However, you should be aware that when all users are logged in under the same account, it is more difficult to track down a user who might be causing trouble.
5. In **User name**, type the name of the user you want to allow to log on to the server automatically.
6. In **Domain**, type the name of the domain to which the user's computer belongs.
7. In both **Password** and **Confirm password**, type the user's password.
8. Click **Always prompt for password** to specify that the user is prompted for a password before logging on to the server.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Remote Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage remote control**

- Configure remote control settings
- Disable remote control

# Configure remote control settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure remote control settings**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Set rules for remote control of Terminal Services user sessions** setting, and then click **Enabled**.
3. In the **Options** box, click the desired remote control permissions, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.
- These policies affect every client that connects to the terminal server. To configure Remote Control on a per-user basis, use the corresponding policy under **User Configuration**.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to configure remote control, and then click **Properties**.
4. On the **Remote Control** tab, click Use remote control with the following settings to configure remote control for the connection.
5. To display a message on the client, asking permission to view or take part in the session, select the **Require user's permission** check box.
6. Under **Level of control**, click **View** the session to specify that the user's session can be viewed only, or click **Interact with the session** to specify that the user's session can be actively controlled with your keyboard and mouse.

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and

then double-click **Terminal Services Configuration**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

- Configuring remote control on a per-connection basis affects all sessions that use the connection. You can configure remote control on a per-user basis using the Terminal Services User Configuration Group Policies, or by using the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers.

- Changes to remote control permissions are not applied to sessions that are connected when the change is made.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disable remote control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disable remote control**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Set rules for remote control of Terminal Services user sessions** setting, and then click **Enabled**.
3. In the **Options** box, click "No remote control allowed", and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Notes**

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.
- These policies affect every client that connects to the terminal server. To configure Remote Control on a per-user basis, use the corresponding policy under **User Configuration**.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to disable remote control, and then click **Properties**.
4. On the **Remote Control** tab, click **Do not allow remote control**.

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For

more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

# Configure Time-out and Reconnection Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure time-out and reconnection settings**

- Set time-out settings for disconnected, active, and idle sessions
- Change settings for when a session limit is reached or connection is broken
- Change settings for reconnecting disconnected Citrix ICA sessions

# Set time-out settings for disconnected, active, and idle sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set time-out settings for disconnected, active, and idle sessions**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Sessions**, enable the settings you want to configure. See the policy explain text for more information.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.
- These policies affect every client that connects to the terminal server. To define Session settings on a per-user basis, use the Sessions policies under **User Configuration**.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to modify time-out settings, and then click **Properties**.
4. On the **Sessions** tab, above **End a disconnected session**, select the **Override user settings** check box. This allows you to configure time-out settings for the connection.
5. Configure the following time-out settings as appropriate:

   - In **End a disconnected session**, select the maximum amount of time that a disconnected session remains on the server. When the time limit is reached, the disconnected session ends. When a session ends, it is permanently deleted from the server. Select **Never** to allow disconnected sessions to remain on the server indefinitely.
   - In **Active session limit**, select the maximum amount of time that a user's session can remain active on the server. When the time limit is reached, either the user is disconnected from the session or the session ends. When a session ends, it is permanently deleted from the server. Select **Never** to allow the session to continue indefinitely.
   - In **Idle session limit**, select the maximum amount of time that an idle session (a session without client activity)

remains on the server. When the time limit is reached, either the user is disconnected from the session or the session ends. When a session ends, it is permanently deleted from the server. Select **Never** to allow idle sessions to remain on the server indefinitely.

### Notes

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- Group Policy overrides the configuration set with the Terminal Services Configuration tool.
- These settings affect every client that uses the connection to connect to the terminal server. To define Session settings on a per-user basis, use the User Configuration Group Policies or the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers.t

### Note

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change settings for when a session limit is reached or connection is broken

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change settings for when a session limit is reached or connection is broken**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Sessions**, double-click the **Terminate session when time limits are reached setting**, and do one of the following:

   - To ensure that users are always disconnected from the session, allowing the session to be reconnected (default behavior), click **Disabled**, and then click **OK**.
   - To configure Terminal Server to terminate sessions rather than disconnect them, click **Enabled**, and then click **OK**. See the policy explain text for more information.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Notes**

- This policy affects every client that connects to the terminal server. To define Session settings on a per-user basis, use the Sessions policies under **User Configuration**.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection you want to modify, and then click **Properties**.
4. On the **Sessions** tab, above **When session limit is reached or connection is broken**, select the **Override user settings** check box.

   This allows you to configure these settings for the connection.
5. Under **When session limit is reached or connection is broken**, do one of the following:

- Click **Disconnect from session** to disconnect the user from the session, allowing the session to be reconnected.

- Click **End session** to end the session. When a session ends, it is permanently deleted from the server. Any running applications are forced to shut down, which can result in loss of data at the client.

### Notes

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

- A connection to the server can be broken for any reason, including by request, connection error, idle time-out, or connection time-out.

- These settings affect every client that uses the connection to connect to a terminal server. To define settings on a per-user basis, use Terminal Services Group Policies or the Terminal Services Extension to Local Users and Groups.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change settings for reconnecting disconnected Citrix ICA sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change settings for reconnecting disconnected Citrix ICA sessions**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. n **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Sessions**, double-click the **Allow reconnection from original client only** setting.
3. Click **Enabled**, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Notes**

- This policy affects every client that connects to the terminal server. To define Session settings on a per-user basis, use the Sessions policies under **User Configuration**.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection you want to modify, and then click **Properties**.
4. On the **Sessions** tab, above **Allow reconnection**, select the **Override user settings** check box.

   This allows you to configure reconnection settings for the connection.
5. Under **Allow reconnection**, do one of the following:

   - Click **From any client** to allow the user to reconnect to a disconnected session from any computer.
   - Click **From previous client** to allow the user to reconnect to a disconnected session from only the client computer where the session originated.

**Note**

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

- This setting is supported only for Citrix ICA-based clients.

- By default, you can reconnect to a disconnected session from any computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Client Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage client settings**

- Connect client drives and printers at logon
- Configure settings for mapping client devices
- Limit the maximum color depth

# Connect client drives and printers at logon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect client drives and printers at logon**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Client/Server data redirection** double-click the specific setting for the feature you want to configure, and then click **Enabled**.

   - To disable the mapping of client printers in Terminal Services sessions, enable **Do not allow client printer redirection**.
   - To disable the mapping of client drives in Terminal Services sessions, enable **Do not allow client drive redirection**.
   - To disable the setting of the default client printer as the default printer in Terminal Services sessions, enable **Do not set default client printer to be default printer in a session**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Note**

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection to which you want to connect client drives and printers, and then click **Properties**.
4. On the **Client Settings** tab, under **Connection**, clear the **Use connection settings from user settings** check box.

   This allows you to configure these settings for the connection.
5. Choose from the following options:

- Select the **Connect client drives at logon** check box to reconnect to all mapped client drives while logging on. (This option is supported for clients running any of the Windows Server 2003 family operating systems.)

- Select the **Connect client printers at logon** check box to reconnect to all mapped local client printers while logging on.

- Select the **Default to main client printer** check box to print to the default printer of the client. Otherwise, the default printer of the server is used as the default printer for all client sessions.

**Notes**

- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

- These settings affect all clients that use the connection to log on to a terminal server. If you want to define settings on a per-user basis, use Terminal Services Group Policies or the Terminal Services Extension to Local Users and Groups.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure settings for mapping client devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure settings for mapping client devices**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Client/Server data redirection** double-click the specific setting for the feature you want to configure, and then click **Enabled**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.
   - To disable the redirection of clipboard data between server and client in Terminal Services sessions, enable **Do not allow clipboard redirection**.
   - To enable the redirection of audio data between the server and the client in Terminal Services sessions, enable **Allow audio redirection**. (Note that audio redirection is disabled by default in Terminal Server).
   - To disable the mapping of client COM ports in Terminal Services sessions, enable **Do not allow COM port redirection**.
   - To disable the mapping of client printers in Terminal Services sessions, enable **Do not allow client printer redirection**.
   - To disable the mapping of client LPT ports in Terminal Services sessions, enable **Do not allow LPT port redirection**.
   - To disable the mapping of client drives in Terminal Services sessions, enable **Do not allow drive redirection**.
   - To disable specifying of the default client printer as the default printer in a Terminal Services session, enable **Do not set default client printer to be default printer in a session**. The client printer is designated as the default printer for a Terminal Services session.

   **Note**

   - Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Note**

- These policies affect every client that connects to the terminal server. To define client device settings on a per-user basis, use the corresponding policies under **User Configuration**.

#### Using Terminal Services Configuration

1. Open Terminal Services Configuration.

2. In the console tree, click **Connections**.

3. In the details pane, right-click the connection for which you want to configure client device mappings, and then click **Properties**.

4. On the **Client Settings** tab, under **Disable the following**, select the appropriate check boxes:

   - **Drive mapping** to disable client-drive mapping. By default, **Drive mapping** is enabled (cleared).

   - **Windows printer mapping** to disable client Windows printer mapping. By default, **Windows printer mapping** is enabled (cleared). When enabled, clients can map Windows printers, and all client printer queues reconnect at logon. However, when both LPT and COM port mappings are disabled, you will be unable to manually add printers. When **Windows printer mapping** is disabled (checked), clients are unable to map Windows printers and client printer queues are not reconnected at logon. However, you will be able to manually reconnect printers if **LPT port mapping** or **COM port mapping** is enabled (cleared).

   - **LPT port mapping** to disable client LPT port mapping. By default, **LPT port mapping** is enabled (cleared). When enabled, client LPT ports are mapped for printing and are available in the port list of the Add Printer wizard. You need to manually create the printer to the LPT port using the Add Printer wizard. When **LPT port mapping** is disabled (checked), client LPT ports are not automatically mapped. You will be unable to manually create printers using LPT ports.

   - **COM port mapping** to disable client COM port mapping. By default, **COM port mapping** is disabled (cleared). When enabled, client COM ports are mapped for printing and are available in the port list of the Add Printer wizard. You will need to manually create the printer to the COM port using the Add Printer wizard. When **COM port mapping** is disabled (checked), client COM ports are not automatically mapped. You will be unable to manually create printers using COM ports.

   - **Clipboard mapping** to disable client clipboard mapping. By default, **Clipboard mapping** is enabled (cleared).

   - **Audio mapping** to disable client audio mapping. By default, **Audio mapping** is disabled (checked).

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

# Limit the maximum color depth

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To limit the maximum color depth

- Using Group Policies (best practice)
- Using Terminal Services Configuration

#### Using Group Policies (best practice)

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Limit maximum color depth** setting, and then click **Enabled**.
3. In the **Color Depth** box, click the desired maximum color depth, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Note

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

#### Using Terminal Services Configuration

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection on which you want to limit the maximum client color depth, and then click **Properties**.
4. On the **Client Settings** tab, select the **Limit Maximum Color Depth** check box.

   This allows you to configure settings for the connection.
5. Select the desired maximum color depth from the list, and then click **OK**

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

### Note

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have

been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

# Manage Connection Permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage connection permissions**
You can customize permissions on a per-connection basis using the Terminal Services Configuration tool.

- Add users and groups to permissions lists
- Change the permissions a user or group has to a connection
- Remove a user or group from permissions lists

**Note**

- As a best practice, set Terminal Services permissions on a per-computer basis.

# Add users and groups to permissions lists

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add users and groups to permissions lists**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to configure permissions, and then click **Properties**.
4. On the **Permissions** tab, click **Add...**.
5. On the **Select Users or Groups** dialog box, click **Locations...** to specify the search location.
6. Click **Object Types...** to specify the types of objects you want to search for.
7. Click **Check Names**.
8. When the name is located, click **OK**. The name now appears in the **Group or user names:** list on the **Permissions** tab.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- After you add a user or group, default permissions are applied. To change permissions, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the permissions a user or group has to a connection**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to change permissions, and then click **Properties**.
4. On the **Permissions** tab, click **Advanced** to open the **Advanced Security Settings** dialog box.
5. In **Permission Entries**, select the user or group for which you want to change permissions, and then click **Edit...** to open the **Permission Entry** dialog box.
6. In **Permissions**, select or clear, as appropriate, the **Allow** or **Deny** check boxes next to the permissions you want to set for the group.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- You must use the Remote Desktop Users group to control remote access to Terminal Server and Remote Desktop for Administration.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a Terminal Services connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a connection**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection you want to delete, and then click **Delete**.

   Click **Yes** to confirm that you want to delete the connection.

   **Caution**

   - If there are active sessions on the server, you are warned that these sessions end if you delete the connection. Ending an active session without warning can result in loss of data at the user's session.

   The connection is permanently deleted from the server.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Server Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure server settings**

- Delete or retain temporary folders when exiting
- Use separate temporary folders for each session
- Disable Active Desktop
- Switch default permissions for application compatibility
- Configure Session Directory settings
- Set the terminal server licensing mode
- Limit users to one remote session

# Delete or retain temporary folders when exiting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete or retain temporary folders when exiting**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Temporary folders**, double-click the **Do not delete temp folder upon exit** setting.
3. To retain users' temporary folders when a user logs off from a session, click **Enabled**. To delete users' temporary folders when a user logs off, click **Disabled**.
4. Click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Note**

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Delete temporary folders on exit**, and then click **Properties**.
4. Click **Yes** to have temporary folders deleted when a user logs off from a session, or click **No** to retain temporary folders, and then click **OK**.

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group

might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use separate temporary folders for each session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use separate temporary folders for each session**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Temporary folders**, double-click the **Do not use temp folders per session** setting.
3. To disable the creation of a separate temporary folder for each terminal server session, click **Enabled**. To enable the creation of a separate temporary folder for each terminal server session, click **Disabled**.
4. Click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Use temporary folders per session**, and then click **Properties**.
4. Click **Yes** to create a separate temporary folder for each new session or **No** if you do not want to create temporary folders for each new session.

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

# Switch default permissions for application compatibility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To switch default permissions for application compatibility**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Permission Compatibility**, and then click **Properties**.
4. Select **Full Security** to provide the most secure environment or select **Relaxed Security** to provide an environment that is compatible with most legacy applications, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- You can configure this option only when Terminal Server is installed on a server. This option does not apply to servers that are used for remote administration.
- If you select **Full Security**, Terminal Server Users will have the same permissions as members of the Users group. You should use Full Security whenever possible.
- If you select **Relaxed Security**, all Users will have full access to critical registry and file system locations. This may be necessary in order to run legacy applications.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Session Directory settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Session Directory settings**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Session Directory**, enable the **Join Session Directory** setting.
3. Enable the **Session Directory Server** setting and, in **Session Directory Server**, type the name of the server where the Terminal Services Session Directory service is running.
4. Enable the **Session Directory Cluster Name** setting and, in **Session Directory Cluster Name**, type the name of the cluster to which the Terminal Server belongs. See the policy explain text for more information.
5. Optionally, enable the **Terminal Server IP Address Redirection** setting. See the policy explain text for more information.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Session Directory**, and then click **Properties**.
4. Select the **Join session directory** check box.
5. In **Cluster name:**, type the name of the Terminal Server cluster for this terminal server.

6. In **Session directory server name:**, type the DNS name or IP address of the domain server where the Terminal Services Session Directory service is running.

   The server name must be a valid server name, and it cannot be left blank.

7. Select an IP address and network adapter from the **Network adapter and IP address session directory should redirect users to:** list.

8. Optionally, uncheck the **IP address redirection (uncheck for routing token redirection)** check box to have client devices reconnect to disconnected sessions by using the virtual IP address of the terminal server cluster. You should uncheck this check box if clients have visibility only to the virtual IP address of the cluster and cannot connect to the IP address of an individual terminal server. This option is checked by default, which enables clients to reconnect by using the individual IP addresses of the terminal servers in the Session Directory.

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the terminal server licensing mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the terminal server licensing mode**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Licensing**, and then click **Properties**.
4. Select either **Per User** or **Per Device**, and then click **OK**.

   A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- Group Policy overrides the configuration set with the Terminal Services Configuration tool. For information about how to configure the Terminal Server Licensing mode option by using Group Policy, see Configure the Terminal Server Licensing mode.
- By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.
- Users can create more than one session by specifying a different program to start on connection for each session.
- For more information about Terminal Server and Terminal Server Licensing, see Guidelines for Deploying Terminal Server (http://go.microsoft.com/fwlink/?LinkID=34627) and Windows Server 2003 Terminal Server Licensing (http://go.microsoft.com/fwlink/?LinkID=26220).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Limit users to one remote session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To limit users to one remote session**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

| **Warning** |
| --- |
| If users have been limited to one remote session, connecting to the session by using a different protocol is not supported. To access a remote session by using a different protocol, the user must log off from the current session. |

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Restrict Terminal Services users to a single remote session** setting.
3. Click **Enabled**, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.
2. In the console tree, click **Server Settings**.
3. In the details pane, right-click **Restrict each user to one session**, and then click **Properties**.
4. Check the **Restrict each user to one session** check box, and then click **OK**.

   **Note**

   - To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and

then double-click **Terminal Services Configuration**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- Group Policy overrides the configuration set with the Terminal Services Configuration tool.

- Users will always be able to create more than one session by specifying a different program to start on connection for each session.

### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Group Policy Settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure Group Policy settings**

- Ensure the session state is consistent with the client state
- Prevent automatic license upgrades
- Allow users to connect remotely using Terminal Services
- Remove the Disconnect item from the Shut Down dialog
- Remove the Windows Security item from the Start menu
- Secure Terminal Server RPC traffic
- Control the issuance of Terminal Server licenses
- Use the specified Terminal Server license servers
- Configure the Terminal Server Licensing mode
- Always prompt client for password upon connection
- Enforce removal of Remote Desktop wallpaper
- Disallow smart card device redirection

# Ensure the session state is consistent with the client state

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To ensure the session state is consistent with the client state**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Keep-Alive Messages** setting, and then click **Enabled**. select the desired **Keep-Alive interval**.
3. In the **Keep-Alive interval** box, type the desired keep-alive interval, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

Group Policy (pre-GPMC)

# Allow users to connect remotely using Terminal Services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow users to connect remotely using Terminal Services**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Allow users to connect remotely using Terminal Services** setting.
3. Do one of the following:
   - To enable Remote Desktop, click **Enabled.**
   - To disable Remote Desktop, click **Disabled**.

   If you disable Remote Desktop while users are connected to the target computers, the computers maintain their current connections, but will not accept any new incoming connections.

### Important

- When you enable Remote Desktop on a computer, you enable the capability for other users and groups to log on remotely to the computer. However, you must also decide which users and groups should be able to log on remotely, and then manually add them to the Remote Desktop Users group. For more information, see Enabling users to connect remotely to the server and Add users to the Remote Desktop Users group.
- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator. Then, you must start Group Policy by using the **Active Directory Users and Computers** snap-in.
- Alternatively, you can enable Remote Desktop by selecting the **Enable Remote Desktop on this computer** check box (on the **Remote** tab of the **System Properties** dialog box) on the target computers. For more information, see Enable or disable Remote Desktop.

  If the **Allow users to connect remotely using Terminal Services** Group Policy setting described in this procedure is set to **Not Configured**, then the **Enable Remote Desktop on this computer** setting on the **System Properties** dialog box of the target computers takes precedence. Otherwise, the Group Policy setting takes precedence.
- Be aware of the security implications of remote logons. Users who log on remotely can perform tasks as though they were sitting at the console. For this reason, you should ensure that the server is behind a firewall. For more information, see VPN servers and firewall configuration and Security information for IPSec.
- You should require all users who make remote connections to use a strong password. For more information, see Strong

passwords.

- Remote Desktop is disabled by default in Windows Server 2003 family operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# To restrict local administrators from customizing permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To restrict local administrators from customizing permissions

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Do not allow local administrators to customize permissions** setting.
3. Click **Enabled**, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Note

- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in. For information on applying Group Policy to groups of users or computers, see Configuring Terminal Services with Group Policy. For information on configuring the local Group Policy object, see Group Policy overview.

#### Information about functional differences

# Remove the Windows Security item from the Start menu

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove the Windows Security item from the Start menu**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Remove Windows Security item from Start menu** setting.
3. Click **Enabled**, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Secure Terminal Server RPC traffic

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To secure Terminal Server RPC traffic**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, **Encryption**, **RPC Security Policy**, double-click the **Secure Server (Require Security)** setting.
3. Click **Enabled**, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- The remote procedure call (RPC) interface is used for administering and configuring Terminal Services.
- If the status of this setting is Enabled, the terminal server accepts requests from RPC clients that support secure requests, and does not allow unsecured communication with untrusted clients.
- If the status of this setting is Disabled, the terminal server always requests security for all RPC traffic. However, unsecured communication is allowed for RPC clients that do not respond to the request.
- If the status of this setting is Not Configured, unsecured communication is allowed. This is the default.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Control the issuance of Terminal Server licenses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To control the issuance of Terminal Server licenses**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **License Server Security Group** setting.
3. Click **Enabled**, and then click **OK**.

   **Important**

   - You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If the status of this setting is Enabled, only the computers you add to the Terminal Services Computers security group will receive licenses. By default, this group is not populated. You must add computers or groups to this security group if you want them to receive licenses. Any changes you make to the membership of this group take effect only after you stop and restart the Terminal Server Licensing service. For more information, see Related Topics.
- If the status of this setting is either Disabled or Not Configured, the Terminal Server License Server issues a license to any computer that requests one. The Terminal Services Computers group is not deleted or changed in any way. This is the default behavior.
- Use the above procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an Administrator. Then, you must invoke Group Policy through the **Active Directory Users and Computers** snap-in.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Use the specified Terminal Server license servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click the **Use the specified Terminal Server license servers** setting.
3. Click **Enabled**.
4. Enter the names of the Terminal Server license servers you want this Terminal Server to contact first when attempting to obtain client access licenses (CALs). Then click **OK**.

### Important

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- You can also set preferred license servers by using Terminal Services Configuration (TSCC), the registry, or a Windows Management Instrumentation (WMI) script. For more information about setting preferred license servers by using TSCC or the registry, see Related Topics. For three WMI scripts that you can use to set preferred license servers, delete preferred license servers, or query preferred license servers, see "Preferred License Server WMI Scripts" in Windows Server 2003 Terminal Server Licensing (http://www.microsoft.com/).
- This Group Policy setting is only available on Windows Server 2003 with Service Pack 1, or with the Service Pack 1 versions of System.adm Group Policy template files installed in your Terminal Server environment.
- Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator. Then, you must open Group Policy through the **Active Directory Users and Computers** snap-in.
- For more information about Terminal Server, see Guidelines for Deploying Terminal Server (http://www.microsoft.com/).

#### Information about functional differences

# Configure the Terminal Server Licensing mode

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure the Terminal Server Licensing mode**

- Using Group Policies (best practice)
- Using Terminal Services Configuration

**Using Group Policies (best practice)**

1. Open Group Policy.
2. In **Computer Configuration**, **Administrative Templates**, **Windows Components**, **Terminal Services**, double-click **Terminal Server Licensing Mode**.
3. Click **Enabled**.
4. Click either **Per User** or **Per Device**, and then click **OK**.

   A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices.

### Important

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- This Group Policy setting is only available on Windows Server 2003 with Service Pack 1.
- Use this procedure to configure the local Group Policy object. To change a policy for a domain or an organizational unit, you must log on to the primary domain controller as an administrator, and then open Group Policy by using the **Active Directory Users and Computers** snap-in.
- Group Policy overrides the configuration set with the Terminal Services Configuration tool.
- By default, when the Per Device licensing mode is used, after a client logs and authenticates to a terminal server for the first time, and after the terminal server locates a license server, the terminal server issues the client a temporary license. After a client logs on and authenticates to a terminal server for the second time, if the license server is activated and at least one Per Device CAL is installed on the license server and not yet issued, the terminal server issues the client a permanent, Per Device CAL. Per User CALs are not monitored by Terminal Server. This means that even though there is a Per User CAL in the license server database, the Per User CAL is not decremented when it is used. Additionally, if you use the Per User licensing mode, when a client logs on to a terminal server for the second time, the temporary license is not upgraded to a permanent CAL.
- Users can create more than one session by specifying a different program to start on connection for each session.

**Using Terminal Services Configuration**

1. Open Terminal Services Configuration.

2. In the console tree, click **Server Settings**.

3. In the details pane, right-click **Licensing Mode**, and then click **Properties**.

4. Select either **Per User** or **Per Device**, and then click **OK**.

   A Per Device CAL gives each client computer or device the right to access a terminal server that is running Windows Server 2003. A Per User CAL gives one user the right to access a terminal server from an unlimited number of devices.

## Notes

# Terminal Services Configuration Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides information about configuring Terminal Services.

- Terminal Services Configuration Overview
- Configuring Terminal Services with Group Policy
- Configuring Terminal Services with WMI
- Configuring Terminal Services with TSCC
- Managing Sessions
- Managing Permissions on Connections
- Managing drive, printer, and device mappings for clients
- Using temporary folders with terminal servers

# Terminal Services Configuration Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services Configuration overview**
Several tools exist for configuring terminal servers, Terminal Services user settings, Terminal Services connections, and Terminal Services sessions. These tools include Terminal Services Group Policies, the Terminal Services WMI provider, the Terminal Services Configuration Tool, the Terminal Services extension to Local Users and Groups and Active Directory Users and Computers. Additionally, connection settings that are not configured at the group, computer or user level can be set in the client software itself on a per-session basis.

**Which tool should I use?**
Typically, you use the tool that gives you the most control with the least administrative overhead, given the constraints of your usage profile. For an environment containing only terminal servers running one of the Windows Server 2003 family operating systems, using Terminal Services Group Policies will allow you to configure all settings that will apply across an organizational unit or group of Terminal Services users. The Active Directory Service Interfaces (ADSI) further extend the Terminal Services extensions to Local Users and Groups and Active Directory Users and Computers by allowing you to create scripts tailored to your Terminal Services configuration requirements. You can also configure individual Windows Server 2003 family operating systems by using Group Policies on the local Group Policy object.

However, there are situations where Group Policy is not the preferred tool. In mixed environments where several different Windows platforms are present, it might be necessary to use a combination of tools--for example, configuring Windows Server 2003 family operating systems with Group Policies, while using the Terminal Services Configuration tool to configure servers that are running previous versions of Windows.

If two or more connections are present on the same computer, and you want to configure each connection differently, Group Policies cannot be used. Instead, use the Terminal Services Configuration tool, which allows you to configure Terminal Services settings on a per-connection basis.

**Configuration order of precedence**
Configuration settings take precedence in the following order. Settings higher on the list take precedence over those below:

- Computer level Group Policies (if set)
- User level Group Policies (if set)
- Local computer configuration set with Terminal Services Configuration tool
- User level policies set with Local Users and Groups
- Local client settings

**Note**

- Configuration settings applied with Terminal Services WMI operate at the same order of precedence as the same settings when set with the corresponding configuration tool. In general, Group Policy settings always override settings applied with WMI.

For more information about configuring Terminal Services with Group Policy, see Configuring Terminal Services with Group Policy.

For more information about configuring Terminal Services with Terminal Services Configuration, see Terminal Services Configuration.

For more information about configuring Terminal Services user policies with Local Users and Groups, see Managing Users with the Terminal Services Extension to Local Users and Groups.

For more information about using ADSI, see Programming interfaces and the Active Directory Programmer's Guide at the Microsoft Web site .Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# Configuring Terminal Services with Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Terminal Services with Group Policy**
You can use Group Policy to configure Terminal Services connection settings, set user policies, configure terminal server clusters, and manage Terminal Services sessions. You can enable Group Policy for users of a computer, for individual computers, or for groups of computers belonging to an organizational unit of a domain. To set policies for users of a particular computer, you must be an administrator for that computer. To set policies for an organizational unit in a domain, you must be an administrator for that domain.

**Enabling Group Policy on an individual computer**
To set Terminal Services policies setting for a particular computer or for users of that computer, open the Group Policy Object Editor snap-in to edit the local Group Policy. For more information, see Group Policy overview.

When you open the Group Policy Object Editor snap-in, click to expand Administrative Templates, and then click the Terminal Services folder containing the policies you want want to set. The settings for those policies appear in the details pane.

**Where?**

- *policy_name* Policy/Computer Configuration (or User Configuration)/Administrative Templates/Windows Components/*Terminal Services*

To determine the Enabled, Disabled, and Not Configured behavior of each policy, see the explain text for that policy in the Group Policy Object Editor snap-in.

For more information, see Group Policy overview.

**Enabling Group Policy for an organizational unit in a domain**
To set Terminal Services policies for a domain, you must use a computer that is configured as a domain controller and you must be an Administrator for that domain.

After you configure your computer as a domain controller, the Active Directory Users and Computers console appears in the Administrative Tools folder on the **Programs** menu. You can use this tool to set policies for organizational units in the domain. Before you begin, you need to confirm that **Group Policy** is selected (on the **Extensions** tab in the **Add/Remove Snap-in** dialog box). Then you need to confirm that the **Administrative Templates (Users)** extension is selected for Group Policy.

**Note**

- Terminal Services Group Policies can be used to administer only computers running one of the Windows Server 2003 family operating systems.

# Configuring Terminal Services with WMI

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Terminal Services with WMI**
In Microsoft® Windows Server 2003 family operating systems, you can use the Terminal Services WMI provider to create scripts for remote administration of terminal servers.

**About the Terminal Services WMI Provider**
The Terminal Services Windows Management Instrumentation (WMI) provider allows administrators to create customized scripts for configuring, managing, and querying terminal servers. It contains properties and methods that can perform the same tasks as the Terminal Services configuration tools and command-line utilities provided with Windows Server 2003 family operating systems, but remotely and through scripted applications.

**How the Provider Works**
Windows Management Instrumentation (WMI) defines a unified architecture for describing, accessing, and instrumenting objects. Part of this architecture is a large database of WMI classes used to carry out remote management tasks on specific objects.

A provider extends the WMI schema of classes to allow WMI to work with new types of objects. The Terminal Services Provider defines classes for querying and configuring Terminal Services.

The Terminal Services Provider is defined in %systemroot%\System32\Wbem\tscfgwmi.mof.

A general description of the classes associated with the provider can be seen in the following table. For complete list of properties and methods associated with each class, please see the embedded comments in the Terminal Services provider MOF file (tscfgwmi.mof). The contents of this file can be viewed with the Windows Management Instrumentation Tester (Wbemtest.exe), which is located in the %systemroot%\System32\Wbem\. To view the .mof file in Wbemtest, use the procedure below.

**To view the Terminal Services Provider classes in Wbemtest.exe**

1. Open Wbemtest.exe
2. Click **Connect**.
3. In **Namespace**, type **root\Cimv2**
4. Click **Connect**.
5. Click **Open Instance**.
6. In **Object Path**, type the name of the Terminal Services Provider class (see the table below for the names of the classes.) Click **OK**.
7. In **Properties**, click the name of the property you want to view, and then click **Show MOF**.

**Terminal Services WMI Classes**
The Terminal Services Provider has the following WMI classes.

| WMI Class | Description |
|---|---|
| Win32_TerminalService | The Win32_TerminalService class is a subclass of Win32_Service class and inherits all its properties and methods. In addition, Win32_TerminalService represents the Element property of the Win32_TerminalServiceToSetting association. |
| Win32_TSSessionDirectory | Defines the configuration for Win32_TSSessionDirectorySetting. This includes properties such as Session Directory store, Cluster Name and Additional parameters. |

| | |
|---|---|
| Win32_TerminalServiceSetting | Defines the configuration for TerminalServerSetting. This includes properties such as Terminal Server Mode, Licensing, Active Desktop, Permissions Capability, Deletion of Temporary folders and per-session Temporary folders. |
| Win32_Terminal | Associates a TerminalSetting and its several configuration setting groups such as: General, Logon, Session, Environment, Remote Control, Client, Network Adapter and Permission. |
| Win32_TSGeneralSetting | Defines the configuration for properties such as Protocol, Transport, Comment, Windows authentication and Encryption Level |
| Win32_TSLogonSetting | Defines the configuration for properties such as ClientLogonInfoPolicy, UserName, Domain, and Password. |
| Win32_TSSessionSetting | Defines the configuration for properties such as time limit policy for connections and session limits for active, idle, and disconnected sessions. |
| Win32_TSEnvironmentSetting | Defines the configuration for properties such as Initial program policy, Initial program path, Start in, and Client wallpaper. |
| Win32_TSRemoteControlSetting | Defines the configuration for properties such as Remote Control policy and level of control. |
| Win32_TSClientSetting | Defines the configuration for properties such as Connection policy, Windows printer mapping, Comport mapping, etc. |
| Win32_TSNetworkAdapterSetting | Defines the configuration for properties such as LAN Adapter and Maximum number of connections |
| Win32_TSNetworkAdapterListSetting | Enumerates the list of network adapters that are configurable for Win32_Terminal based on the Terminal Protocol and Transport. The properties include: TerminalProtocol, Transport, NetworkAdapterID, and Description. |
| Win32_TSPermissionsSetting | Represents an association between a Win32_Terminal and its configuration settings (Win32_TSAccount). Contains properties for adding accounts to defined permission sets and restoring default permissions. |
| Win32_TSAccount | Defines the configuration for properties such as SID, Allowed and denied permissions. |

**Important**

- This documentation describes only the classes, methods, and associations specific to Terminal Services. Top-level WMI classes (those with the CIM_ prefix) that are defined in the MOF file are not specific to Terminal Services and are described in the Platform SDK documentation for Windows Management Instrumentation (WMI).

For an overview of WMI, see WMI Overview.

For a complete description and definition of WMI, as well as technical information about developing for the WMI system, see the WMI Software Development Kit (SDK). The WMI SDK is released by MSDN as part of the Microsoft Platform SDK.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configuring Terminal Services with TSCC

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring Terminal Services with TSCC**
A Terminal Services connection provides the link clients use to log on to a session on the server. A TCP/IP connection is configured when Terminal Services is installed. Using Terminal Services Configuration, you can change the default properties of the connection or add new connections.

**Terminal Services Configuration**
When you open Terminal Services Configuration you will see that a connection has already been configured. This is called the RDP-TCP connection. Typically, this is the only connection that needs to be configured for clients to connect to the server for Remote Desktop for Administration or application sharing with Terminal Server. Only one RDP (Remote Desktop Protocol) connection can be configured for each network adapter. If you want to configure additional RDP connections, you must install additional network adapters.

With Terminal Services Configuration, you can reconfigure the properties of the RDP-TCP connection, which includes limiting the amount of time client sessions can remain active on the server, setting protection levels for encryption, and selecting which permissions you want users and groups to have. Some connection properties can also be configured on a per-user basis using Terminal Services Group Policies or the Terminal Services extension to Local Users and Groups. For example, you can set different session time limits for each user when you use the Terminal Services extension to Local Users and Groups. Using Terminal Services Configuration, you can only set session time limits on a per-connection basis, which means the same time limit applies to all users who log on to the server using the connection.

In addition to configuring connections, you can use Terminal Services Configuration to configure settings that apply to the terminal server. These include settings for temporary folders, default connection security, and licensing. For more information, see Configure Server Settings

**Citrix ICA-based client**
Terminal Services Configuration is also used to configure connections for Citrix ICA-based clients. These connections can be configured using TCP/IP, asynchronous, IPX/SPX, or NetBIOS transport protocols when the Citrix ICA protocol and Citrix ICA-based client software are added to the system.

### Important

- As a best practice, use Terminal Services Group Policies to configure connection settings wherever possible. For more information, see Configuring Terminal Services with Group Policy.

# Managing Sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing sessions**

This section provides general background information about managing Terminal Services sessions:

- Configuring authentication and encryption
- Using remote control
- Configuring session limits

# Configuring authentication and encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring authentication and encryption**

**TLS authentication overview**
Remote Desktop Protocol (RDP) provides data encryption, but it does not provide authentication to verify the identity of a terminal server. In Windows Server 2003 Service Pack 1 (SP1), you can enhance the security of Terminal Server by configuring Terminal Services connections to use Transport Layer Security (TLS) 1.0 for server authentication, and to encrypt terminal server communications. TLS is a standard protocol that is used to provide secure Web communications on the Internet or intranets. It enables clients to authenticate servers or, optionally, servers to authenticate clients. It also provides a secure channel by encrypting communications. TLS is the latest and most secure version of the Secure Sockets Layer (SSL) protocol. One important difference is that TLS 1.0 applies a Keyed-Hashing for Message Authentication Code (HMAC) algorithm, whereas SSL 3.0 applies the Message Authentication Code (MAC) algorithm. The HMAC produces an integrity check value as the MAC does, but with a hash function construction that makes the hash much harder to break.

The TLS and SSL protocols comprise two layers: the Handshake Protocol Layer and the Record Protocol Layer. For authentication purposes, the Handshake Protocol uses an X.509 certificate to provide strong evidence to a second party that helps prove the identity of the party that holds the certificate and the corresponding private key. A certificate is a digital form of identification that is usually issued by a certification authority (CA) and contains identification information, a validity period, a public key, a serial number, and the digital signature of the issuer. A CA is a mutually trusted third party that confirms the identity of a certificate requestor (usually a user or computer), and then issues the requestor a certificate. The certificate binds the requestor's identity to a public key. CAs also renew and revoke certificates as necessary. For example, if a client is presented with a server's certificate, the client computer might try to match the server's CA against the client's list of trusted CAs. If the issuing CA is trusted, the client will verify that the certificate is authentic and has not been tampered with. Finally, the client will accept the certificate as proof of identity of the server.

For more information about TLS, see SSL/TLS in Windows Server 2003 (http://go.microsoft.com/fwlink/?LinkID=19646) and RFC 2246, The TLS Protocol Version 1.0 (http://go.microsoft.com/fwlink/?LinkID=40979).

**Prerequisites for Configuring Server Authentication**
By default, Terminal Server uses native RDP encryption and does not authenticate the server. For TLS to be used for server authentication and encryption of terminal server communications, the server and client must be correctly configured.

**Server prerequisites**
For TLS authentication to function correctly, terminal servers must meet the following prerequisites:

- Terminal servers must run Windows Server 2003 SP1.
- You must obtain a certificate for the terminal server. You can do this by doing any of the following:
    - Use Windows Server 2003 Certificate Services Web Pages or Use Windows 2000 Certificate Services Web Pages.
    - Use the Windows Server 2003 Certificate Request Wizard or Windows Server 2000 Certificate Request Wizard. For more information, see Requesting certificates.
    - Purchase a certificate from a non-Microsoft vendor and install the certificate manually.

**Note**

- If you plan to obtain a certificate by using the Certificate Web pages or Certificate Request Wizard, a public key infrastructure (PKI) must be configured correctly to issue SSL-compatible X.509 certificates to the terminal server. For information about PKI configuration, see Public Key Infrastructure and Deploying a Public Key Infrastructure.Each certificate must be configured as follows:
    - The certificate is a computer certificate.

- The intended purpose of the certificate is server authentication.
- The certificate has a corresponding private key.
- The certificate has a cryptographic service provider (CSP) that can be used for the TLS protocols (for example, Microsoft RSA/SChannel Cryptographic Provider). For more information, see Microsoft Cryptographic Service Providers (http://go.microsoft.com/fwlink/?LinkID=40983).
- The certificate is stored in the terminal server's Personal store. You can view this store by using the Certificates snap-in. For more information, see Certificate stores.

**Client prerequisites**

For TLS authentication to function correctly, clients must meet the following prerequisites:

- Clients must run Windows 2000 or Windows XP.
- Clients must be upgraded to use the RDP 5.2 (Windows Server 2003) client. You can install this client-side Remote Desktop Connection package by using the %systemdrive\system32\clients\tsclient\win32\msrdpcli.msi file. The msrdpcli.msi file is located on Windows Server 2003 terminal servers. Installing this file from the terminal server installs the 5.2 version of Remote Desktop Connection to the %systemdrive\Program files\Remote Desktop directory on the destination computer. For more information, see Remote Desktop Connection for Windows Server 2003 [5.2.3790] (http://go.microsoft.com/fwlink?/LinkID=41068).
- Clients must trust the root of the server's certificate. That is, clients must have the certificate of the CA that issued the server certificate in their Trusted Root Certification Authorities store. You can view this store by using the Certificates snap-in.

**Tasks for Configuring Server Authentication**

For TLS authentication to function correctly, you must complete the following configuration tasks on terminal servers and clients. The procedure links contain step-by-step instructions for completing these tasks.

**Server Configuration Tasks**

1. Request a computer certificate for server authentication, if you do not already have a certificate that meets the requirements described in "Server prerequisites," earlier in this topic.

   If you have been granted the appropriate permissions, there are two primary ways to explicitly request certificates:

   - You can explicitly request certificates by using the Windows Server 2003 or Windows 2000 Certificate Services Web pages.
   - You can use the Windows Server 2003 or Windows 2000 Certificate Request Wizard.

   Alternatively, you can buy a certificate from a non-Microsoft vendor.

2. Configure authentication and encryption on the server. For TLS to function correctly, in Terminal Server Configuration, on the **General** tab of the **RDP-tcpProperties** dialog box, you must do the following:

   - Select a certificate that meets the requirements described in "Server prerequisites" earlier in this topic.
   - Set the **Security layer** to **Negotiate** or **SSL**.
   - Set the **Encryption level** to **High,** or enable Federal Information Processing Standard (FIPS) compliant encryption. You can enable FIPS-compliant encryption by using Group Policy as well.
   - You cannot enable TLS by using Group Policy.

**Note**

If you enable TLS authentication in a session directory farm, in order for TLS authentication to remain enabled when a terminal server connection is redirected, you must configure all of the servers that are members of the session directory farm to use one of the following settings:

- Set the **Security layer** to **SSL**.
- Set the **Security layer** to **Negotiate**. If you use this configuration, TLS authentication is only enabled if the client supports it.

**Authentication and Encryption Settings**

The following table summarizes the combinations of **Security layer** and **Encryption level** settings that are valid and invalid in Windows Server 2003 Service Pack 1, whether TLS authentication and encryption can be used, and the key strength provided by each encryption level.

| ***Security Layers*** | | **Encryption** | **Levels** | |
|---|---|---|---|---|
| | **Client Compatible** | **Low**<br><br>**RC4--56-bit** | **High**<br><br>**RC4--128-bit** | **FIPS-compliant** |
| ***Negotiate*** | Valid. The Maximum security layer and encryption level supported by the client are used. If TLS is supported for server authentication, TLS is used rather than RDP, and High or FIPS-compliant encryption level is used. | Valid | Valid | Valid |
| ***SSL (TLS 1.0)*** | Valid. TLS is required for server authentication. High or FIPS-compliant encryption level is used. If TLS is not supported, connections fail. | Not Valid. The encryption level defaults instead to Client Compatible. High or FIPS-compliant encryption level is used, if supported by client. | Valid | Valid |
| ***RDP*** | Valid. However, TLS cannot be used for server authentication. RDP encryption is used and the maximum encryption level supported by the client is used. | Valid | Valid | Valid |

For more information about encryption options, see "Determining the level of encryption," later in this topic.

**Client configuration tasks**

1. Request a certification authority certificate for the client.

   Use this procedure to request a certificate chain from a Windows Server 2003 CA. A certificate chain contains the chain of certificates that can be traced back to the root CA. The certificate that you retrieve by using this procedure is stored in the Trusted Root Certification Authorities store.

2. Configure authentication on the client by using Remote Desktop Connection or Configure authentication on the client by using an .rdp file.

   Keep in mind that clients must run Windows 2000 or Windows XP and that they must use the RDP 5.2 (Windows Server 2003) client.

**Determining the level of encryption**

For Terminal Services connections, data encryption can protect your data by encrypting it on the communications link between the client and the server. Encryption protects against the risk of unauthorized transmission interception on the link between server and client.

By default, Terminal Services connections are encrypted at the highest level of security available (128-bit). However, some older versions of the Terminal Services client do not support this high level of encryption. If your network contains such legacy clients, you can set the encryption level of the connection to send and receive data at the highest encryption level supported by the client. In order for clients to be able to connect to a terminal server that uses FIPS-compliant encryption, you must upgrade these clients to use the RDP 5.2 (Windows Server 2003) client. For more information, see Remote Desktop Connection for Windows Server 2003 [5.2.3790] (http://go.microsoft.com/fwlink?/LinkID=41068).

There are four levels of encryption available:

| **Level of encryption** | **Description** |
|---|---|
| FIPS-compliant | This level encrypts and decrypts data sent from client to server and from server to client with the Federal Information Processing Standard (FIPS) encryption algorithms using the Microsoft cryptographic modules. You can enable FIPS-compliant encryption by using Group Policy or Terminal Services Configuration. For more information, see FIPS 140 Evaluation (http://go.microsoft.com/fwlink?/LinkID=36329).<br><br>**Important**<br><br>• Any encryption level settings that you configure in Group Policy override the configuration that you set by using the Terminal Services Configuration tool. Also, if you enable the System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing Group Policy setting, this setting overrides the **Set client connection encryption level** Group Policy setting.<br><br>• You must enable FIPS-compliant encryption or set the encryption level to **High** if you plan to use TLS for server authentication. |
| High | This level encrypts data sent from client to server and from server to client by using strong 128-bit encryption. Use this level when the terminal server is running in an environment containing 128-bit clients only (such as Remote Desktop Connection clients). Clients that do not support this level of encryption will not be able to connect.<br><br>**Important**<br><br>• You must enable FIPS-compliant encryption or set the encryption level to **High** if you plan to use TLS for server authentication. |
| Client Compatible | This level encrypts data sent between the client and the server at the maximum key strength supported by the client. Use this level when the terminal server is running in an environment containing mixed or legacy clients. |
| Low | This level encrypts data sent from the client to the server using 56-bit encryption.<br><br>**Important**<br><br>• Data sent from the server to the client is not encrypted. |

# Using remote control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using remote control**

You can monitor the actions of a client logged on to a terminal server by remotely controlling the user's session from another session. Remote control allows you to either observe or actively control another session. If you choose to actively control a session, you will be able to input keyboard and mouse actions to the session. A message can be displayed on the client session asking permission to view or take part in the session before the session is remotely controlled. You can use Terminal Services Group Policies or Terminal Services Configuration to configure remote control settings for a connection and Terminal Services Manager to initiate remote control on a client session. For instructions on configuring remote control, see Configure remote control settings. For instructions on using remote control, see Remotely control a session.

Windows Server 2003 family operating systems also support Remote Assistance, which allows greater versatility for controlling another user's session. Remote Assistance also provides the ability to chat with the other user. For more information, see Windows interface administrative tool reference A-Z: Remote Assistance.

### Notes

- Remote control can also be configured on a per-user basis using Group Policies or the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers.
- The console session cannot remotely control another session, and a client session cannot remotely control the console session.
- The computer used for your session must be capable of supporting the video resolution used at the remotely controlled client session. Otherwise, the operation fails.

# Configuring session limits

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring session limits**

For a Terminal Services connection, you can limit the amount of time that active, disconnected, and idle (without client activity) sessions remain on the server. This is useful because sessions that remain running indefinitely on the server consume valuable system resources. When a session limit is reached for active or idle sessions, you can select to either disconnect the user from the session or end the session. A user who is disconnected from a session can reconnect to the same session later. When a session ends, it is permanently deleted from the server and any running applications are forced to shut down, which can result in loss of data at the client. When a session limit is reached for a disconnected session, the session ends, which permanently deletes it from the server. Sessions can also be allowed to continue indefinitely.

Session limits configured in Terminal Services Configuration apply to all sessions using a given connection. Session limits can also be configured on a per-user basis using the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers.

For information on configuring time-out and reconnection settings, see Configure Time-out and Reconnection Settings.

**Disconnected sessions**

A session is disconnected when any of the following occurs: by request, connection error, or the active or idle session limit is reached.

**Reconnecting to a disconnected session**

By default, a terminal server allows you to reconnect to a disconnected session from any computer. However, you can restrict users and allow them to only reconnect from the computer where the session originated. This option is supported only for clients that provide a serial number when connecting, such as Citrix ICA-based clients. For more information, see Change settings for reconnecting disconnected Citrix ICA sessions.

### Note

- As a best practice, use Terminal Services Group Policies to configure these settings wherever possible.

  For more information, see Configuring Terminal Services with Group Policy.

# Managing Permissions on Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing permissions on connections**
Permissions define how users and groups can access a terminal server, allowing you to secure the server. Terminal Services permissions can be handled easily on a per-computer basis, using the **Remote Desktop Users** user group and the **RemoteInteractiveLogon** right. In some cases, however, it might be necessary to manage permissions on a per-connection basis.

**Managing Permissions on a per-connection basis**
Terminal Services Configuration allows you to manage permissions on an individual connection by means of the **Permissions** tab in the connection **Properties** page.

The TCP/IP connection installed with Terminal Services comes with a set of default permissions. You can modify these default permissions by setting different permissions for different users or groups, adjusting them to fit the requirements of your organization. You must be logged on as a member of the Administrators group to manage connection permissions.

The default permissions on Terminal Services objects are as follows:

| Group | Permission |
|---|---|
| Administrators | Full control |
| LOCAL SERVICE | Service permissions |
| NETWORK SERVICE | Service permissions |
| Remote Desktop Users | User access |
| SYSTEM | Full control |
| Guest | Guest access |

For information about managing permissions for users and groups, see Adding users and groups.

For information about the types of permissions used to control access to Terminal Services, see Controlling connection access.

# Controlling connection access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Controlling connection access**

Use the permissions provided for Terminal Services to control how users and groups access the server. You can alter the default permissions to restrict individual users and groups from performing certain tasks, such as logging off a user from a session or ending sessions. You manage permissions from Terminal Services Configuration. You must be logged in as a member of the Administrators group to set permissions.

By default, there are three types of permissions: Full control, User access, and Guest access.

You can configure these by setting permissions for which users or groups can use a specific task. You can set the following permissions.

| Permission | Allows you to |
|---|---|
| Query Information | Query sessions and servers for information. |
| Set Information | Configure connection properties. |
| Remote Control | View or actively control another user's session. |
| Logon | Log on to a session on the server. |
| Logoff | Log off a user from a session. Be aware that logging off a user without warning can result in loss of data at the client. |
| Message | Send a message to another user's sessions. |
| Connect | Connect to another session. |
| Disconnect | Disconnect a session. |
| Virtual Channels | Use virtual channels. Be aware that turning off virtual channels disables some Terminal Services features such as clipboard and printer redirection. |

**Note**

- You must use the Remote Desktop Users group to control remote access to Terminal Server and Remote Desktop for Administration. For more information, see Enabling users to connect remotely to the server.

# Adding users and groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Adding users and groups**

You control how users and groups access a terminal server by setting permissions. You should assign permissions that reflect the level of access you want to permit. Before adding users and groups to permissions lists, consider what types of access are required for each individual user or group.

You can add any user, group, or computer in your network to permissions lists. If your server belongs to a domain, you can also add user accounts and global groups from both the local domain and trusted domains. Local groups in some domains can also be added.

You must use the Remote Desktop Users group to control remote connection permissions for Remote Desktop for Administration and Terminal Server. The Remote Desktop Users group allows the same access as the Users group, with the additional ability to connect remotely. By using the Remote Desktop Users group, you save administrative resources by not having to set up these rights for each user individually. For information about how to add users to the Remote Desktop Users group, see Add users to the Remote Desktop Users group.

# Full control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Full control**
Full control allows users to:

- Query information about a session.
- Modify connection parameters.
- Reset (end) a session.
- Remotely control another user's session.
- Log on to a session on the server.
- Log off a user from a session.
- Send a message to another user's session.
- Connect to another session.
- Disconnect a session.
- Use virtual channels, which provides access from a server program to client devices.

For information on controlling connection access, see Controlling connection access.

# User access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User access**

User access allows users to:

- Log on to a session on the server.
- Query information about a session.
- Send messages to other user sessions.
- Connect to another session.

For information on controlling connection access, see Controlling connection access.

# Guest access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Guest access**

Guest access allows users to:

- Log on to a session on the server.

For information on controlling connection access, see Controlling connection access.

# Service permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service permissions**

Local and Network service permissions allow:

- Query information about a session.
- Send a message to another session.

For information on controlling connection access, see Controlling connection access.

# Managing drive, printer, and device mappings for clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing drive, printer, and device mappings for clients**
Because client sessions can establish multiple data channels between client and server, users can map to local devices, such as drives and printers. By default, drive and printer mappings that a user sets in a client session are temporary and are not available the next time the user logs on to the server. However, using Terminal Services Configuration, you can specify that client mappings be restored when the user logs on. In addition, you can disable specific client devices so that a user cannot map the device. Users can map the following devices:

- Drives (this option is supported for Remote Desktop Connection clients logging on to one of the Windows Server 2003 family operating systems and for Citrix ICA connections)
- Windows printers
- LPT ports
- COM ports
- Smart cards
- Clipboard
- Audio (this option is supported for Remote Desktop Connection clients logging on to one of the Windows Server 2003 family operating systems and for Citrix ICA connections)

**Notes**

- As a best practice, use Terminal Services Group Policies to configure these settings wherever possible.

  For more information, see Configuring Terminal Services with Group Policy.

- Settings for client drive, printer, and device mappings configured in Terminal Services Configuration apply to all client sessions on the server. If you want to specify client settings on a per-user basis, use Terminal Services Group Policies or the Terminal Services extensions to Local Users and Groups.
- For clients running Remote Desktop Connection, these settings must also be configured in the client software. For more information, see Make your local disk drives available in a session, Make your local printer available in a session, Make your local serial port available in a session, and Make a smart card available in a session.

# Using temporary folders with terminal servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using temporary folders with terminal servers**

By default, a terminal server creates a separate temporary folder for each new session on the server, enabling each user to store individual temporary files. To reclaim disk space, these temporary folders are deleted when the user logs off from a session. If you want to change these default settings for a terminal server, use Group Policy (best practice) or Terminal Services Configuration to modify them. For more information, see Delete or retain temporary folders when exiting or Use separate temporary folders for each session.

# Terminal Services User Properties

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services user properties**

This topic covers managing the information contained in the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers. The following topics are included:

- For information about best practices, see Terminal Services User Properties Best practices.
- For help with specific tasks, see Terminal Services User Properties How To....
- For general background information, see Terminal Services User Properties Concepts.

# Terminal Services User Properties Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- **Use Terminal Services-specific groups**

  Create User Groups that are specifically for Terminal Services users. Windows Server 2003 family operating systems contain a default User group called Remote Desktop Users, which has been specifically created to manage Terminal Server users. Maintaining users through groups is much easier and less time consuming than managing users individually.

- **Use Terminal Services-specific profiles**

  Assign a separate profile for logging onto Terminal Services. Many common options, such as screen savers and animated menu affects, which are stored in profiles, are not wanted when you use Terminal Services. Assigning a specific profile allows users to get the most out of the system they are working with without expending additional server resources. For information about assigning a Terminal Services specific profile, see Change a user's Terminal Services profile path.

- **Use mandatory profiles**

  Use a mandatory Terminal Services profile that is created to suit the needs of all of the different types of clients and that provides the best server performance. Be aware that 16-bit computers and Windows-based Terminals might not support some screen resolutions.

- **Set time limits**

  Setting limits on the duration of client connections can improve server performance. You can set the limits on how long a session lasts, how long a disconnected session is allowed to remain active on the server, and the time allowed for a session to remain connected, yet idle. For information about setting session limits, see Sessions.

- **Use Starting program**

  If you have users who need access to only one application on the terminal server, use the Starting program option. This can be done for all users by using Terminal Services Configuration or on a per-user basis by using either the Terminal Services Extension to Local Users and Groups or Active Directory Users and Computers. For information about using Starting program, see Specify a program to start on session connection.

- **Create preconfigured connection files for users or groups of users**

  To make connecting to Terminal Services easier, you can supply users with preconfigured connection files. Collections of connection files can also be made either for different departments within your organization or for different job titles. preconfigured connection files are created using Remote Desktop Connection. For more information, see Managing Terminal Services connection files.

# Terminal Services User Properties How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Add the Terminal Services Extension to Local Users and Groups
- Add the Terminal Services Extension to Active Directory Users and Computers
- Change a user's Terminal Services profile path
- Change the path to a user's home directory
- Deny a user permissions to log on to terminal servers
- Set the maximum duration of an active session
- Set the maximum time a disconnected session remains active
- Set the maximum idle time for a session
- Change settings for when a session limit is reached or a connection is broken
- Change settings for reconnecting disconnected sessions
- Specify a program to start on session connection
- Connect Citrix ICA client drives at logon
- Connect client printers at logon
- Default to the client's main printer
- Enable remote control
- Require user's permission to observe or control sessions
- Set the level of control over a user's sessions

# Add the Terminal Services Extension to Local Users and Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add the Terminal Services Extension to Local Users and Groups**

1. Open Microsoft Management Console.
2. On the **File** menu, click **Add/Remove Snap-in**. The **Add/Remove Snap-in** dialog box appears.
3. Click **Add**. The **Add Standalone Snap-in** dialog box appears.
4. Select **Local Users and Groups**, and then click **Add**. The **Choose Target Machine** dialog box appears.
5. Select the computer to which to add this console, and then click **Finish**.
6. In the **Add Standalone Snap-in** dialog box, click **Close**.
7. In the **Add/Remove Snap-in** dialog box, click the **Extensions** tab.
8. Click **Terminal Services - Extension**, and then click **OK**.

## Notes

- You must be logged on as a computer administrator to complete this procedure.
- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- The Terminal Services extension is already included in Local Users and Groups if Terminal Server is installed on the server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add the Terminal Services Extension to Active Directory Users and Computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add the Terminal Services Extension to Active Directory Users and Computers**

1. Open Microsoft Management Console.
2. On the **File** menu, click **Add/Remove Snap-in**. The **Add/Remove Snap-in** dialog box appears.
3. Click **Add**. The **Add Standalone Snap-in** dialog box appears.
4. Select **Active Directory Users and Computers**, click **Add**, and then click **Close**.
5. In the **Add/Remove Snap-in** dialog box, click the **Extensions** tab.
6. Click **Terminal Services - Extension**, and then click **OK**.

## Notes

- You must be logged on as a computer administrator to complete this procedure.
- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- To complete this procedure, the computer must be joined to an Active Directory domain, and you must have permission to edit the Group Policy object.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change a user's Terminal Services profile path

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change a user's Terminal Services profile path**

- Using Group Policies (best practice)
- Using Terminal Services Extension to Local Users and Groups

**Using Group Policies (best practice)**

1. Choose from the following:

   - For a domain user account, from a Domain Controller, open Active Directory Users and Computers.

     In the console tree, right click the domain node, and then click **Properties**. In the Group Policy tab, double-click the Group Policy object, or click **Edit**.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
   - For a local user account, open Group Policy.

2. In the Group Policy console tree, click **Terminal Services** under **Computer Configuration**.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/Windows Components/Terminal Services

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

3. Double-click the **Set path for TS Roaming Profiles** setting, and then click **Enabled**.

4. In the **Profile path** box, type the path for Terminal Services roaming profiles, and then click **OK**.

**Important**

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Using Terminal Services Extension to Local Users and Groups**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which users are located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user whose profile path you want to change.

3. On the **Terminal Services Profile** tab, under **Profile Path:**, type the new path to the user's profile, and then click **OK**.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the path to a user's home directory

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the path to a user's home directory**

- Using Group Policies (best practice)
- Using Terminal Services Extension to Local Users and Groups

**Using Group Policies (best practice)**

1. Choose from the following:

   - For a domain user account, from a Domain Controller, open Active Directory Users and Computers.

     In the console tree, right click the domain node, and then click **properties**. In the Group Policy tab, double-click the Group Policy object, or click **Edit**.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
   - For a local user account, open Group Policy.

2. In the Group Policy console tree, click **Terminal Services** under **Computer Configuratio**n.

   **Where?**

   - Local Computer Policy/Computer Configuration/Administrative Templates/Windows Components/Terminal Services

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

3. Double-click the **TS User Home Directory** setting, and then click **Enabled**.

4. In the **Location** box, click the location for the Terminal Services home directory.

5. In the **Home Dir Root Path** box, type the root path for the Terminal Services home directory.

6. If the root path is on the network, click the drive letter for the mapped drive in the **Drive Letter** box. Click **OK**.

   **Important**

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

**Using Terminal Services Extension to Local Users and Groups**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user whose home directory you want to change.

3. On the **Terminal Services Profile** tab, do one of the following:

   - If the Terminal Services home folder is on the local server, click **Local path**, and then type the path to the home directory.

   - If the Terminal Services home directory is on a network share, click **Connect**, select a drive to connect, and then type the network path.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Deny a user permissions to log on to terminal servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To deny a user permissions to log on to terminal servers**

1. Choose from the following:

   - For a domain user account, open **Active Directory Users and Computers**.

     In the console tree, expand the domain node, and then click the folder in which the user profile is located.

   **Note**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open **Computer Management (Local)**.

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Note**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

2. Double-click the name of the user whose settings you want to change.

3. On the **Terminal Services Profile** tab, select the **Deny this user permissions to log on to any terminal server** check box, and then click **OK**.

**Important**

Clearing the **Deny this user permissions to log on to any terminal server**check box does not automatically allow the user permissions to log on to a terminal server. In addition to clearing this check box, you must also ensure that the user has been added to the Remote Desktop Users group on the appropriate terminal server, and that Remote Desktop has been enabled on the terminal server. For information about adding users to the Remote Desktop Users group, enabling Remote Desktop, and enabling users to connect to a terminal server, see Related Topics.

1. **Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set the maximum duration of an active session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the maximum duration of an active session**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account that you want to change.

3. On the **Sessions** tab, in **Active session limit**, select the amount of time to wait before the connection times out, and then click **OK**.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

Sessions

# Set the maximum time a disconnected session remains active

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the maximum time a disconnected session remains active**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users** (console tree location is: Computer Management\System Tools\Local Users and Groups\Users).

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to change settings.

3. On the **Sessions** tab, in **End a disconnected session**, select the amount of time you want to elapse before the disconnected session is reset, and then click **OK**.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Sessions

# Set the maximum idle time for a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the maximum idle time for a session**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users** (console tree location is: Computer Management/System Tools/Local Users and Groups/Users).

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

2. Double-click the user account for which you want to change settings.

3. On the **Sessions** tab, in **Idle session limit**, select the amount of time you want to elapse before the idle session times out, and then click **b**.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

# Change settings for when a session limit is reached or a connection is broken

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change settings for when a session limit is reached or a connection is broken**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to change settings.

3. On the **Sessions** tab, under **When a session limit is reached or connection is broken**, click **Disconnect from session** to allow the session to be reconnected.

   Or, click **End session** to end the session. Click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

# Change settings for reconnecting disconnected sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change settings for reconnecting disconnected sessions**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to change settings.

3. On the **Sessions** tab, under **Allow reconnection**, click **From any client** to allow connection to that session from any client computer.

   Or, clic**k From originating client only** to allow only the client computer where the session was created to reconnect to that session. This option is supported only for Citrix ICA clients. Click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Sessions

# Specify a program to start on session connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To specify a program to start on session connection**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to change the Starting program.

3. On the **Environment** tab, under **Starting program**, select the **Start the following program at logon** check box.

4. In **Program file name**, type the name of the program to start when the user logs on. You can also specify a working directory by typing the path in **Start in**. Click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- Some client option settings are not applied when a connection is made to the console session of a remote computer running Windows XP. For example, if the client has specified a program to start upon connection to a remote computer, that program does not start if the connection is made to the console session of the remote computer. Instead, the default desktop appears. If the connection is made to a session other than the console session, the specified program starts as

expected. The console session is the only session available for Remote Desktop on Windows XP Professional, so the default desktop always appears when a connection is made, even if the client has specified a different program.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect Citrix ICA client drives at logon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect Citrix ICA client drives at logon**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to connect client drives.

3. On the **Environment** tab, under **Client devices**, select the **Connect client drives at logon** check box, and then click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

- This procedure is for Citrix ICA clients only. For clients that use the Remote Desktop Protocol (RDP), client drive redirection is supported if the server is running one of the Windows Server 2003 family operating systems and the client is running Remote Desktop Connection.

- In Windows Explorer, client drives appear in the session folder tree in the form `\\TSClient\<driveletter>$` if drive redirection has been specified as a Remote Desktop Connection option on the client.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Connect client printers at logon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To connect client printers at logon

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to connect client printers.

3. On the **Environment** tab, under **Client devices**, select the **Connect client printers at logon** check box, and then click **OK**.

### Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Environment

# Default to the client's main printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To default to the client's main printer

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to change the printer default.

3. On the **Environment** tab, under **Client devices**, select the **Default to main client printer**, and then click **OK**.

### Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Environment

# Enable remote control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

#### To enable remote control

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to enable remote control.

3. On the **Remote control** tab, select the **Enable remote control** check box, and then click **OK**.

### Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
  This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Remote control

# Require user's permission to observe or control sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To require user's permission to observe or control sessions**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user is located.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user whose permission you want to require.

3. On the **Remote control** tab, select the **Require user's permission** check box, and then click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

# Set the level of control over a user's sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set the level of control over a user's sessions**

1. Choose from the following:

   - For a domain user account, open Active Directory Users and Computers.

     In the console tree, expand the domain node, and then click the folder in which the user account is located.

   **Important**

   - To perform this procedure, you must be a member of the Domain Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

   - For a local user account, open Computer Management (Local).

     In the console tree, click **Users**.

   **Where?**

   - Computer Management/System Tools/Local Users and Groups/Users

   **Important**

   - To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

2. Double-click the user account for which you want to set the level of control.

3. On the **Remote control** tab, under **Level of control**, click **View the user's session** to allow only session observation.

   Or, click **Interact with the session** to allow full remote control of the session. Click **OK**.

**Notes**

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**. This procedure works only if the server has been promoted to a domain controller.

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Terminal Services User Properties Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section covers:

- Managing Terminal Services users
- Managing Terminal Services users with Group Policy
- Terminal Services users

# Managing Terminal Services users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Terminal Services Users**
Each user who logs on to a Terminal Services session must have a user account either on the server or in a domain on the network that the server is on. The Terminal Services user account contains additional information about the user that determines when users log on, under what conditions, and how specific desktop settings are stored. Windows Server 2003 family operating systems contain a built-in User group called Remote Desktop Users, which is used to manage Terminal Services users.

**About the Remote Desktop Users group**
When you install one of the Windows Server 2003 family operating systems, the Remote Desktop Users group is one of the built-in user groups on your computer. Members of this group have the same access as members of the Users group, but they have the additional ability to log on remotely to the computer.

By default, this group is not populated when you install Terminal Server on your computer. You must choose the users and groups that you want to have permission to log on remotely to the terminal server, and manually add them to the Remote Desktop Users group. This increases the security of remote connections, and also allows you to install any required programs before users start connecting to the terminal server.

The **Select Remote Users** button on the **Remote** tab of the **System Properties** dialog box allows you to add users to the Remote Desktop Users group. However, if a server running a Windows Server 2003 family operating system is being used as a domain controller in a Windows 2000 domain, this button is disabled. This domain controller can have domain groups, but not local groups, so in this situation you cannot use this button to add users to the Remote Desktop Users group.

For information on how to add users to the Remote Desktop Users group, see Add users to the Remote Desktop Users group.

# Managing Terminal Services users with Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Terminal Services Users with Group Policy**
You can use Group Policy to configure Terminal Services user profile information. Group Policy configures these options on a per-computer basis, for easy configuration of all users who connect to a specific computer. For environments where individual user properties are not available to local administrators, using Group Policy provides an alternative to the Terminal Services Extension to Local Users and Groups.

**Important**

- You should thoroughly test any changes you make to Group Policy settings before applying them to users or computers. For more information on testing policy settings, see Resultant Set of Policy.

Use the **Set path for TS Roaming Profiles** setting to configure a network path for Terminal Services user profiles. For more information, see Change a user's Terminal Services profile path.

Use the **TS User Home Directory** setting to configure a local or network path as the root of the home directory for Terminal Services users. For more information, see Change the path to a user's home directory.

For more information about Terminal Services profiles, see Terminal Services Profile.

For general information about using Terminal Server Group Policy, see Configuring Terminal Services with Group Policy.

# Managing Users with the Terminal Services Extension to Local Users and Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing Users with the Terminal Services Extension to Local Users and Groups**
This topic covers information about managing Terminal Services users with the Terminal Services Extension to Local Users and Groups. The following topics are included:

- For help with specific tasks, see Terminal Services User Properties How To....
- For general background information, see Terminal Services User Properties Concepts.

# Terminal Services users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services users**
Each user who logs on to a terminal server must have a user account either on the server or in a domain on the network that the terminal server is on. The Terminal Services user account contains additional information about the user that determines when users log on, under what conditions, and how specific desktop settings are stored. Windows Server 2003 family operating systems contain a built-in User group called Remote Desktop Users, which has been specifically created to manage Terminal Server users.

For more information about the Remote Desktop Users group and for managing users with Group Policies, see Managing Terminal Services users.

In addition to the Terminal Services Group Policies, User accounts can be set up and managed for a specific computer using Local Users and Groups or for a domain of computers using Active Directory Users and Computers.

**Note**

- User settings set with Local Users and Groups and with Active Directory Users and Computers are overridden by Group Policy settings at both the computer and user level. For more information, see Terminal Services Configuration Overview.

The following topics describe the Terminal Services Extension tabs that appear in the **Properties** dialog box for a user:

- Environment
- Sessions
- Remote control
- Terminal Services Profile

# Environment

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Environment**
The Terminal Services Extension **Environment** tab on the **Properties** dialog box contains settings for creating the client working environment.

**Starting program**
If a starting program is specified in the user's settings, that program opens whenever the user connects to a terminal server. It is the only application that can be used by the user. When the user closes the application, the connection to the terminal server closes, as though the user has logged off of the terminal server.

You can also use Terminal Services Configuration to specify a starting program that is the only application available to all users who connect to the terminal server. For more information about setting the starting program on a connection basis, see Specify a program to start automatically when a user logs on.

**Client devices**
You can configure Terminal Services to connect local client printers at logon. When the client logs on to the server, the local printer is detected and the appropriate printer driver is installed on the terminal server. If multiple printers are connected, you can also default all print jobs to the main client printer. For more information, see Connect client printers at logon or Providing client access to local printers.

# Sessions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Sessions**

The **Sessions** tab of the Terminal Services Extension provides settings for limiting the time length of sessions based on their current state (active, idle, or disconnected). You can also specify what action to take when a session has reached a time limit.

| Time-out setting | Description |
|---|---|
| End a disconnected session | Specifies the maximum duration that a disconnected session is retained. The session is reset and can no longer be reconnected after the time limit has expired. For more information, see Set the maximum time a disconnected session remains active. |
| Active session limit | Specifies the maximum connection duration. When the time limit is reached, the session will either be disconnected, leaving the session active on the server, or reset. Set the maximum duration of an active session. |
| Idle session limit | Specifies the maximum idle time (time without connection activity) allowed before the session is disconnected or reset. The session is disconnected or reset when the interval elapses without any activity at the connection. Set the maximum idle time for a session. |

**Note**

- If **Never** is selected, the timer is disabled.

When the connection to the server is broken for any reason, including a request, a connection error, or an idle or active limit is reached, the client session is either placed into the disconnected state or it is reset. A session that is reset can no longer be activated by a user and is closed. A disconnected session is left active on the server and is available for reconnection. For more information, see Change settings for when a session limit is reached or a connection is broken.

**Disconnected sessions**

By default, a terminal server allows you to reconnect to a disconnected session from any computer. However, to allow only the original client computer to reconnect the session, you can specify that a user can only reconnect to a disconnected session from the computer where the session originated. This option is supported only for Citrix ICA clients that provide a serial number when connecting.

# Remote control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote control**
You can monitor the actions of a client logged on to a terminal server by using remote control from another session. Remote control allows you to either observe or actively control a client session. If you choose to actively control a client session, you will be able to input keyboard and mouse actions to the session. You can warn a client that you want to remotely control their session by choosing to display a message on the client that asks permission to view or take part in the session. You can use either Local Users and Groups (for local users) or Active Directory Users and Computers (for domain users) to enable Remote control for a user account. For more information about enabling remote control, see Enable remote control.

**Notes**

- You should use care when assigning permissions on connections. For more information on permissions, see Controlling connection access.
- The system console cannot remotely control a client session.
- The computer you are logged on to must be capable of supporting the video resolution used at the remotely controlled client session. Otherwise, the operation fails.
- To end remote control, press `CTRL+ASTERISK (*)`. You can define another hot key to perform this function.

# Terminal Services Profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services profile**
A Terminal Services profile to assign each user a profile is specifically created for terminal server sessions. Administrators can then create user profiles tailored to the Terminal Services environment.

The Terminal Services profile can be used to restrict access to applications by removing them from the user's **Start** menu. Administrators can also create and store network connections to printers and other resources for use during user sessions.

For more information about profiles, see User Profiles.

**Terminal Services home folder**
You can specify a path to a home folder to be used for terminal server sessions. This can be either a local folder or a network share.

**Allow logon to terminal server**
You can grant access to a specific terminal server on a per-user basis. If this option is left disabled, the user is not allowed to log onto any terminal servers.

# Terminal Services Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services Manager**
Use Terminal Services Manager to view information about terminal servers in trusted domains, including all sessions, users, and processes for each terminal server. You can also use this tool to perform various actions to manage the server.

- For help with specific tasks, see Terminal Services Manager How To....
- For general background information, see Terminal Services Manager Concepts.

# Terminal Services Manager How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Install Terminal Server
- Manage Users, Sessions, and Processes
- Work with Terminal Servers

# Install Terminal Server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install Terminal Server**

1. Open Configure Your Server Wizard.
2. Click **Next** and follow the instructions on the **Preliminary Steps** screen.
3. Click **Next**, and on the **Server Role** screen, select **Terminal Server**.
4. Click **Next** and follow the instructions in the wizard.
5. Some programs might not work correctly when Terminal Server is installed. If so, you must reinstall these programs for multisession access using **Add or Remove Programs** after Terminal Server is installed. For more information, see Program Compatibility.

**Warning**

- Terminal Server Licensing is a required component that licenses clients on a terminal server. You must install Terminal Server Licensing or your terminal server will stop accepting connections from unlicensed clients 120 days from the date of the first client logon.

  You should not install Terminal Server Licensing on the same computer with Terminal Server.

  For more information on Terminal Server Licensing, see Terminal Server Licensing.

**Important**

- When you install Terminal Server using the Configure Your Server Wizard, as a security precaution the Internet Explorer Enhanced Security Configuration is set by default to prevent Administrators from downloading files or running ActiveX controls from the Web. If you want to change this setting to either permit all users to download files or run ActiveX controls or prevent all users from doing so, use **Add/Remove Windows Components** in **Add or Remove Programs**. This setting applies to servers running one of the Windows Server 2003 family operating systems. For more information, see Terminal server role: Configuring a terminal server and Internet Explorer Enhanced Security Configuration.

**Important**

- You must use the Remote Desktop Users group to control remote connection permissions for Terminal Server. For more information, see Managing Terminal Services users and Add users to the Remote Desktop Users group.

**Important**

- It is not necessary to install Terminal Server for remote administration of your server. Remote Desktop for Administration is installed by default. To use Remote Desktop for Administration, you must first enable remote connections. For more information on enabling remote connections, see Enable or disable Remote Desktop and Enabling users to connect remotely to the server.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For

more information, see Default local groups, Default groups, and Using Run as.

- To open the Configure Your Server Wizard, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Configure Your Server Wizard**.

- Certain Windows components require configuration before they can be used. If you installed one or more of these components but did not configure them, when you click **Add/Remove Windows Components**, a list of components that need to be configured is displayed. To start the Windows Components Wizard, click **Components**.

- You can also use **Add or Remove Programs** to install Terminal Server.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Users, Sessions, and Processes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage users, sessions, and processes**

- Connect to another session
- Disconnect a Terminal Server session
- Log off a user from a session
- Send a message to a user
- Reset a session
- View status information for a session
- Remotely control a session
- End a process

# Connect to another session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to another session**

1. Open Terminal Services Manager.
2. Right-click the session to which you want to connect, and then click **Connect**.

   You are connected to the new session and disconnected from your previous session.

## Notes

- You can always connect to a session in which you are logged on with the same user account. To connect to another user's session, you must have either Full Control or User Access permission.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- You can connect to another session only from within an existing session. You must open Terminal Services Manager, or use the **tscon** command, from within a session to be able to connect to another session.
- You can connect to a session only if it is in either an active or disconnected state.
- You cannot connect to another session from the console session.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disconnect a Terminal Server session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect from a session**

1. Open Terminal Services Manager.
2. Right-click the session you want to disconnect, and then click **Disconnect**.

## Notes

- You can always disconnect from your own sessions, but you must have Full Control permission to disconnect a session belonging to another user.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- When you disconnect a session, the session remains attached to the terminal server in the disconnected state and any applications that are running continue to run. The applications remain running when the session is reconnected, with no loss of data.
- You can also use the **tsdiscon** command to disconnect a session.
- You can reset a session that is in the disconnected state, deleting the session from the server. You must have Full Control permission to do this.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Managing Permissions on Connections

# Log off a user from a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To log off a user from a session**

1. Open Terminal Services Manager.
2. On the **Users** tab, right-click the name of the user you want to log off from a session, and then click **Log Off**.

   **Caution**

   - Logging off a user from a session without warning can result in loss of data at the user's session. Instead, send a message to the user using **Send Message** on the **Actions** menu to warn the user before taking this action.

## Notes

- You can always log off from your own sessions, but you must have Full Control permission to log off another user from a session.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- When you log off a user, all processes end and the session is deleted from the server.
- You can also use the **logoff** command to log off a user from a session.
- You cannot log off a user from the console session.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Send a message to a user

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To send a message to a user**

1. Open Terminal Services Manager.
2. Right-click the session or user to which you want to send a message, and then click **Send Message**.

   The **Send Message** dialog box appears.
3. In **Message title**, type the title of the message.
4. In **Message**, type the information you want to send to the user. To start a new paragraph, press CTRL+ENTER.
5. To send the message, click **OK**.

## Notes

- You must have Message permission in order to send messages. For more information on connection permissions, see Managing Permissions on Connections.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- Use this feature to notify users of impending disconnection, server status, or other system information.
- You can send messages only to users whose sessions are in the active or connected state, including the console session.
- You can also use the **msg** command to send messages to users.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reset a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset a session**

1. Open Terminal Services Manager.
2. Right-click the session you want to reset, and then click **Reset**.

   The session is immediately deleted from the server.

## Notes

- You can always reset your own sessions, but you must have Full Control permission to reset a session belonging to another user.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- Be aware that resetting a user's session without warning can result in loss of data on the session.
- Reset a session only when it malfunctions or appears to have stopped responding.
- If you reset a listener session, all sessions that use the connection are reset.
- You can also use the **reset session** command to reset a session.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View status information for a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view status information for a session**

1. Open Terminal Services Manager.
2. Right-click the session for which you want status information, and then click **Status**.

   The session's **Status** information is displayed.
3. To refresh this information, click **Refresh Now**.

   To reset counters, click **Reset Counters**.

## Notes

- You can always view status information for your own sessions. To view status information for a session belonging to another user, you must have either Full Control or User Access permission, or be specifically assigned the Query Information advanced permission. For more information on connection permissions, see Managing Permissions on Connections.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- You cannot view status information for the console or listener sessions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remotely control a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remotely control a session**

1. Open Terminal Services Manager.
2. Right-click the session you want to monitor, and then click **Remote Control**.

   The **Remote Control** dialog box appears.
3. In **Hot key**, select the keys you want to use to end a remote control session, and then click **OK**. The default hot key is CTRL+* (using * from the numeric keypad only).

   When you want to end remote control, press CTRL+* (or whatever hot key you have defined).

## Notes

- You must have Full Control permission to remotely control another session.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- To configure remote control settings for a connection, use Terminal Services Configuration. Remote control can also be configured on a per-user basis by using the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers.
- Before monitoring begins, the server warns the user that the session is about to be remotely controlled, unless this warning is disabled. Your session might appear to be frozen for a few seconds while it waits for a response from the user.
- When you enter the remote control session, your current session shares every input and output with the session you are monitoring.
- Your session must be capable of supporting the video resolution used at the session you are remotely controlling or the operation fails.
- The console session can neither remotely control another session nor can it be remotely controlled by another session.
- You can also use the **shadow** command to remotely control another session.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# End a process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To end a process**

1. Open Terminal Services Manager.
2. On the **Processes** tab, under the **User** column, right-click the process you want to end, and then click **End Process**.

## Notes

- You must have Full Control permission to end a process.
- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- Be aware that ending a process without warning can result in loss of data at the user's session.
- You might need to end a process because the application is not responding.
- You can also use the **tskill** command to end a process.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Terminal Services Manager How To...

# Work with Terminal Servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with terminal servers**

- Connect to terminal servers
- Disconnect from terminal servers
- Find all terminal servers in a domain
- Add a terminal server to the Favorites list
- Remove a terminal server from the Favorites list

# Connect to terminal servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to terminal servers**

1. Open Terminal Services Manager.
2. Expand the domain containing the servers to which you want to connect.
3. Do one of the following:
   - To connect to a specific terminal server, right-click the server, and then click **Connect**.
   - To connect to a computer that is not displayed in the navigation pane of the Remote Desktops snap-in, right-click **All Listed Servers**, click **Connect to Computer**, specify a computer name, and then click **OK**.

## Notes

- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- You should connect to only one terminal server at a time. When a server is connected, Terminal Services Manager queries the server for information about its sessions and processes. Connecting to more than one server at a time can overload system resources.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disconnect from terminal servers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect from terminal servers**

1. Open Terminal Services Manager.
2. Expand the domain containing the servers from which you want to disconnect.
3. Do one of the following:
   - To disconnect from a specific terminal server, right-click the server, and then click **Disconnect**.
   - To disconnect from all terminal servers in the domain, right-click the domain, and then click **Disconnect from All Servers in Domain**.

## Notes

- To open Terminal Services Manager, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Manager**.
- To disconnect from all servers in all domains in your network, right-click **All Listed Servers**, and then click **Disconnect from All Servers**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

- Using Terminal Services Manager
- The Terminal Services Manager Window

# Terminal Services Manager Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal Services Manager overview**

Use Terminal Services Manager to view information about terminal servers that reside in trusted domains. Use this tool to monitor users, sessions, and applications on each terminal server, and to carry out assorted actions to manage the server. See individual procedures in Terminal Services Manager How To... for the permission levels required to perform each task.

When a user creates a session by connecting to a terminal server from a client computer, the session appears in the **Session** list in Terminal Services Manager. In addition, the name of the user who logs on by using the session appears in the **Users** list. Any applications run in the user's session can be monitored on the **Processes** list. Therefore, you can oversee all users, sessions, and processes on a terminal server from one location.

Terminal Services Manager also allows you to manage a terminal server by using the commands on the **Actions** menu. For more information, see Using Terminal Services Manager.

**Console session**

In Terminal Services Manager, the system console session is identified as session 0 in the **Session** list when you connect to a terminal server. A console session is defined as the session you connect to at the physical console of the remote computer, as though you were logging on locally instead of remotely. You can send a message to the console session, but you cannot perform any of the other administrative actions on it.

**Listener sessions**

Listener sessions are different from regular sessions. These sessions listen for and accept new Remote Desktop Protocol (RDP) client connections, thereby creating new sessions for the client requests. If you have configured more than one connection in Terminal Services Configuration, several listener sessions are available.

You have the option to reset a listener session. However, this is not recommended, because doing so resets all sessions that use the same Terminal Services connection. Resetting a user's session without warning can result in loss of data at the client.

**Idle sessions**

To optimize the performance of a terminal server, idle sessions are initialized by the server before client connections are made. These sessions are available to clients for connection. Two idle sessions are created by default. User sessions can also be in idle state. For information on configuring session limits, see Configuring session limits.

# Using Terminal Services Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Terminal Services Manager**

Terminal Services Manager is used to monitor the sessions, users, and processes of terminal servers in trusted domains. In addition to monitoring, you can manage a terminal server by using the actions provided by Terminal Services Manager. Actions are found on the **Actions** menu and are described below. Most require you to be logged in as a member of the Administrators group to perform them.

| **Action** | **Description** | **Permission Level Required** |
|---|---|---|
| Connect | Enables a user to connect to another session. Be aware that connecting to a session that is currently being used by another user might be very disruptive to that user. When you connect to another session, you are disconnected from your previous session. If you have created more than one session on a server, you can use this option to switch between these sessions. You cannot connect to another session from the system console. For more information, see Connect to another session. | User Access or Full Control |
| Disconnect | Disconnects a user from a session. The session remains attached to the terminal server in the *disconnected* state and currently running applications continue to run. When you attempt to reconnect to the server, you are reconnected to the same session from which you disconnected, even if you are reconnecting from a different computer. Applications that were left open when you disconnected remain running when you reconnect to the session, with no loss of data. This is very useful if you change locations often (for example, from work to home). For more information, see Disconnect a Terminal Server session. | Full Control |
| Send Message | Enables a user to send a message to another user's session. For example, an administrator might want to send a message to a user before disconnecting or logging off the user from a session. For more information, see Send a message to a user. | User Access or Full Control |
| Remote Control | Enables a user to observe or remotely control another user's session, allowing you to monitor the activities at the session and interact with it as needed. A user whose session you want to monitor can be warned before monitoring begins. Remote control is configured either with Terminal Services Configuration or, on a per-user basis, with the Terminal Services Extension to Local Users and Groups and Active Directory Users and Computers. You cannot remotely control another session from the console session. For more background information, see Using remote control. For information about using remote control, see Remotely control a session. | Full Control |
| Reset | Enables you to delete a session instantly. Be aware that resetting a user's session without warning can result in loss of data at that session. Reset a session only when it malfunctions or appears to have stopped responding. Resetting a listener session resets all sessions that use the connection. For more information, see Reset a session. | Full Control |
| Status | Enables you to monitor session-related counters, such as incoming and outgoing bytes and frames. Status information for console and listener sessions cannot be displayed. For more information, see View status information for a session. | User Access or Full Control |
| Log Off | Enables you to log off a user from a session on the server. Be aware that logging off a user without warning can result in loss of data at the user's session. When you log off a user, all processes end and the session is deleted from the server. For more information, see Log off a user from a session. | Full Control |
| End Process | Enables you to end a process that is running at a user's session. This is useful when an application has stopped responding. Be aware that ending a process without warning can result in loss of data at the user's session. For more information, see End a process. | Full Control |

# The Terminal Services Manager Window

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the Terminal Services Manager window**

The Terminal Services Manager window has a two-pane view. The navigation pane displays the domains, the terminal servers, and the sessions on the network. The tabs in the details pane display the results of the item selected in the navigation pane. For example, when you click a server in the navigation pane, a series of tabs appear in the details pane displaying lists of users, sessions, and processes associated with that server.

Typically, you perform tasks by selecting an item in the navigation pane and then taking action on that item in the details pane by using shortcut menus and toolbars.

For information about monitoring terminal servers, click the following:

- Viewing the users on a server or domain
- Viewing the sessions associated with a server or domain
- Viewing the processes associated with a server or domain
- Viewing the processes associated with a session
- Viewing client information
- Viewing session states

# Viewing the users on a server or domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing the users on a server or domain**

Using Terminal Services Manager, you can view information about the user's session, the state of the session, and other properties for each user on a terminal server. To view user information on a terminal server, click the server or domain in the navigation pane, and then click the **Users** tab.

Each field on the **Users** tab is described in the following table.

| Field | Description |
|---|---|
| Server | Displays the servers to which users are logged on. This field is shown only when you click a domain in the navigation pane. |
| User | Displays all users associated with the server or domain. |
| Session | Displays the sessions associated with a server or all servers in the domain. All sessions are displayed regardless of status. |
| ID | Displays the numeric ID that identifies the session to the server. |
| State | Displays the status of a session. Session states include *Active*, *Connected*, *ConnectQuery*, *RemoteControl*, *Listen*, *Disconnected*, *Idle*, *Down*, and *Init*. For more information, see Viewing session states. |
| Idle time | Displays the number of minutes that have elapsed since the last keyboard or mouse input from a session. |
| Logon time | Displays the time at which the user logged on, if applicable. |
| Comment | Provides additional information about the session, such as its location. This field is optional. |

# Viewing the sessions associated with a server or domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing the sessions associated with a server or domain**

Using Terminal Services Manager, you can view information about the user, state, and other properties of each session on a terminal server. To view a session on a terminal server, click the server or domain in the navigation pane, and then click the **Sessions** tab.

Each field on the **Sessions** tab is described in the following table.

| Field | Description |
|---|---|
| Server | Displays the servers with which the sessions are associated. This field is shown only when you click a domain in the navigation pane. |
| Session | Displays the sessions associated with a server. All sessions are displayed regardless of status. |
| User | Displays the users associated with the server or domain. |
| ID | Displays the numeric ID that identifies the session to the server. |
| State | Displays the status of a session. Session states include *active*, *conn*, *connq*, *shadow*, *listen*, *disc*, *idle*, *down*, and *init*. For more information, see Viewing session states. |
| Type | Specifies the type of client using the session or if the session is the system console. |
| Client name | Specifies the name of the client computer using the session, if applicable. |
| Idle time | Displays the number of minutes that have elapsed since the last keyboard or mouse input from a session. |
| Logon time | Displays the time at which the user logged on, if applicable. |
| Comment | Provides additional information about the session, such as its location. This field is optional. |

# Viewing the processes associated with a server or domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing the processes associated with a server or domain**

Using Terminal Services Manager, you can view current information about all processes on a terminal server. To view the processes, click the server or domain in the navigation pane, and then click the **Processes** tab.

Each field on the **Processes** tab is described in the following table.

| Field | Description |
|---|---|
| Server | Displays the servers with which the processes are associated. This field is shown only when you click a domain in the navigation pane. |
| User | Displays the users associated with the processes. |
| Session | Displays the sessions associated with the processes. All sessions are displayed regardless of status. |
| ID | Displays the numeric ID that identifies the session to the server. |
| PID | Displays the numeric ID that identifies the process to the server. |
| Image | Specifies the executable program that created the process. |

For information on how to end a process, see End a process.

# Viewing the processes associated with a session

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing the processes associated with a session**

Using Terminal Services Manager, you can view current information about all processes associated with a particular session. To view the processes, click the session in the navigation pane, and then click the **Processes** tab.

Each field on the **Processes** tab is described in the following table.

| Field | Description |
|---|---|
| ID | Displays the numeric ID that identifies the session to the server. |
| PID | Displays the numeric ID that identifies the process to the server. |
| Image | Specifies the executable program that created the process. |

For information on how to end a process, see End a process.

# Viewing client information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing client information**

Using Terminal Services Manager, you can view client information about a particular session. To view client information, click the session in the navigation pane, and then click the **Information** tab.

Each field on the **Information** tab is described in the following table.

| Field | Description |
|---|---|
| User name | The name of the person who is logged in to the session on the server. |
| Client name | The name of the client computer. |
| Client build number | The version of the software installed on the client computer |
| Client directory | The directory in which the client is installed. |
| Client product ID | Used by Citrix Metaframe. |
| Client Hardware ID | Used by Citrix Metaframe. |
| Client address | The IP address of the client. |
| Server buffers | The size of the server buffers. |
| Client buffers | The size of the client buffers. |
| Client Color Depth | The number of colors in the color palette used for the remote session. |
| Client Resolution | The video resolution of the remote session. |
| Modem Name | Used by Citrix Metaframe. |
| Encryption Level | The encryption level being used for this session. |
| Client License | Used by Citrix Metaframe. |

# Viewing session states

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Viewing session states**

The following table describes each possible state of a session.

| Session state | Description |
|---|---|
| Active | The session is connected, and a user is logged on to the server. |
| Connected | The session is connected, but there is no user logged on to the server. |
| ConnectQuery | The session is in the process of connecting. If this state continues, it indicates a problem with the connection. |
| RemoteControl | The session is in the process of remotely controlling another session. |
| Listen | The session is ready to accept a client connection. |
| Disconnected | The user is disconnected from the session, but the session is still attached to the server and can be reconnected at any time. |
| Idle | The session is initialized and ready to accept a connection. To optimize the performance of a server, two default (idle) sessions are initialized before any client connections are made. |
| Down | The session failed to initialize correctly or could not be terminated, and is not available. If this state continues, it indicates a problem with the connection of the session. |
| Init | The session is in the process of initializing. |

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a transform using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec /i***package***TRANSFORMS=***TransformList*

| Value | Description |
|---|---|
| **/i** | Installs a product. |
| *package* | Specifies the name of the Windows Installer package file. |
| **TRANSFORMS=***TransformList* | Specifies what transform (.mst) files should be applied to the package. *TransformList* is a list of paths separated by semicolons. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install a package using the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a package using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec /i** {*package* | *ProductCode*}

| Value | Description |
|---|---|
| **/i** | Installs a product. |
| *package* | Specifies the name of the Windows Installer package file. |
| *ProductCode* | Specifies the globally unique identifier (GUID) of the Windows Installer package. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a package using the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a package using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec /x** {*package* | *ProductCode*}

| Value | Description |
|---|---|
| **/x** | Uninstalls a product. |
| *package* | Specifies the name of the Windows Installer package file. |
| *ProductCode* | Specifies the globally unique identifier (GUID) of the Windows Installer package. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

# Repair a package using the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To repair a package using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec/f**[**p**][**o**][**e**][**d**][**c**][**a**][**u**][**m**][**s**][**v**] {*package* | *ProductCode*}

| Value | Description |
|---|---|
| **/fp** | Reinstalls only if the file is missing. |
| **/fo** | Reinstalls if the file is missing or if an older version is installed. |
| **/fe** | Reinstalls if the file is missing or an equal or older version is installed. |
| **/fd** | Reinstalls if the file is missing or a different version is installed. |
| **/fc** | Reinstalls if the file is missing or the stored checksum does not match the calculated value. |
| **/fa** | Forces all of the files to be reinstalled. |
| **/fu** | Rewrites all of the required user-specific registry entries. |
| **/fm** | Rewrites all of the required computer-specific registry entries. |
| **/fs** | Overwrites all of the existing shortcuts. |
| **/fv** | Runs from source and recaches the local package. |
| *package* | Specifies the name of the Windows Installer package file. |
| *ProductCode* | Specifies the globally unique identifier (GUID) of the Windows Installer package. |

## Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- The default parameter for this command-line option is **/fpecms**.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To advertise a package using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec /j**{**u** | **m**} *package*

| Value | Description |
|---|---|
| **/j** | Advertises a product. This command-line option ignores any property values entered on the command line. |
| **u** | Advertises to the current user. |
| **m** | Advertises to all users of this computer. |
| *package* | Specifies the name of the Windows Installer package file. |

## Notes

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- If you want to install the application with elevated privileges, use the **/jm** command-line option.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

# Create an installation log file using the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an installation log file using the command line**

1. Open Command Prompt.

2. Type:

   **msiexec /i** *package***/L** [**i**][**w**][**e**][**a**][**r**][**u**][**c**][**m**][**p**][**v**][**+**][**!**][*****] *LogFile***.txt**

| Value | Description |
|---|---|
| **/i** | Installs a product. |
| *package* | Specifies the name of the Windows Installer package. |
| **/L** | Indicates to log information. |
| **/Li** | Logs status messages. |
| **/Lw** | Logs nonfatal warnings. |
| **/Le** | Logs all error messages. |
| **/La** | Logs start up of actions. |
| **/Lr** | Logs action-specific records. |
| **/Lu** | Logs user requests. |
| **/Lc** | Logs initial user interface parameters. |
| **/Lm** | Out-of-memory. |
| **/Lp** | Logs Terminal properties. |
| **/Lv** | Specifies verbose output. |
| **/L+** | Appends log to the existing file. |
| **/L!** | Flushes each line to the log. |
| **/L*** | Wildcard. Logs all information except for the **v** command-line option. |
| *LogFile***.txt** | Specifies the name and path of the text log file. |

**Notes**

- To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.

- Windows Installer command-line options are not case-sensitive. For more information about **msiexec** command-line options, see Related Topics.

- To include the **v** option in a log file using the wildcard flag, type **/L*v** at the command prompt.

- The Windows Installer log file options can also be used with the uninstall and repair processes.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Group Policy for Windows Installer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure Group Policy for Windows Installer**

- Configure Windows Installer Group Policy computer options
- Configure Windows Installer Group Policy user options

# Configure Windows Installer Group Policy computer options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Windows Installer Group Policy computer options**

1. Open Group Policy.
2. In the console tree, click the **Windows Installer** node.

   **Where?**

   - *applicable policy name*/Computer Configuration/Administrative Templates/Windows Components/Windows Installer

3. In the details window, double-click one of the following policy settings:

   - **Disable Windows Installer**
   - **Always install with elevated privileges**
   - **Prohibit rollback**
   - **Remove browse dialog box for new source**
   - **Prohibit patching**
   - **Disable IE security prompt for Windows Installer scripts**
   - **Enable user control over installs**
   - **Enable user to browse for source while elevated**
   - **Enable user to use media source while elevated**
   - **Enable user to patch elevated products**
   - **Allow admin to install from Terminal Services session**
   - **Cache transforms in secure location on workstation**
   - **Logging**
   - **Prohibit User Installs**
   - **Turn off creation of System Restore Checkpoints**
   - **Prohibit removal of updates**
   - **Enforce upgrade components rule**
   - **Prohibit non-administrators from applying vendor signed updates**

- **Baseline file cache maximum size**

4. In the **Group Policy Property** dialog box, set the options you want to use, and then click **OK**.

### Notes

- To open Group Policy to edit the local Group Policy object, click **Start**, click **Run**, type **gpedit.msc**, and then press ENTER.
- For more information about Windows Installer Group Policy options, see Related Topics.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Windows Installer Group Policy user options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Windows Installer Group Policy user options**

1. Open Group Policy.
2. In the console tree, click the **Windows Installer** node.

   **Where?**

   - *applicable policy name*/User Configuration/Administrative Templates/Windows Components/Windows Installer

3. In the details window, double-click one of the following policy settings:

   - **Always install with elevated privileges**
   - **Search order**
   - **Prohibit rollback**
   - **Prevent removable media source for any install**

4. In the **Group Policy Property** dialog box, set the options you want to use, and then click **OK**.

## Notes

- To open Group Policy to edit the local Group Policy object, click **Start**, click **Run**, type **gpedit.msc**, and then press ENTER.
- For more information about Windows Installer Group Policy options, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Windows Installer overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer overview**

Windows Installer is a component of the Windows operating system that simplifies the application installation process.

Windows Installer manages the installation and removal of applications by applying a set of centrally defined setup rules during the installation process. You can also use this service to modify, repair, or remove an existing application. Windows Installer technology consists of the Windows Installer service for the Windows operating systems and the package (.msi) file format that contains information about application set up and installation.

Windows Installer is also an extensible software management system. It manages the installation, addition, and deletion of software components, monitors file resiliency, and maintains basic failure recovery with rollbacks. Windows Installer supports installing and running software from multiple sources, and developers can customize Windows Installer to install custom applications.

# Understanding Windows Installer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Windows Installer**
This section covers:

- Windows Installer features
- Windows Installer technologies

# Windows Installer features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer features**

With Windows Installer and the .msi package file format, software installation and removal are more reliable and resilient. Windows Installer also provides a larger set of installation options. Windows Installer performs the following tasks:

- **Restores original computer state upon installation failure--**Windows Installer keeps track of all changes made to the system during the application installation process. If the installation fails, Windows Installer can restore, or roll back, the system to its initial state.

- **Helps prevent interapplication conflicts--**Windows Installer enforces installation rules that help to prevent conflicts with shared resources between existing applications. Such conflicts can be caused when an install operation makes updates to a dynamic link library (.dll) shared by an existing application or when an operation deletes a .dll shared by another application.

- **Reliably removes existing programs--**Windows Installer can reliably uninstall any program it previously installed. It removes all of the associated registry entries and application files, except for those shared by other installed software. You can uninstall an application at any time after a successful installation. (Removal should not be confused with rollback, which restores a computer to its initial state when an installation failure has occurred.)

- **Diagnoses and repairs corrupted applications--**An application can query Windows Installer to determine whether an installed application has missing or corrupted files. If any are detected, Windows Installer repairs the application by recopying only those files found to be missing or corrupted.

- **Supports on-demand installation of application features--**Windows Installer can be configured to initially install a minimal subset of an application. Later, additional components can be automatically installed the first time the user accesses features that require those components. This is known as advertising. For example, Windows Installer could install Microsoft Word with a minimal set of features. The first time the user tried to access a mail merge function (not included with the original installation), Windows Installer would automatically install the mail merge component. Similarly, Windows Installer can also purge components that go unused in an application. For example, Windows Installer could be configured to remove the mail merge component if it goes unused for 60 days.

- **Supports unattended application installation--**Installation packages can be configured to require no installation process interaction from the user. During the installation process, Windows Installer can query the computer for desktop attributes, including determining whether any applications were previously installed by Windows Installer.

- **Supports 32-bit and 64-bit applications--**32-bit applications can be installed on 64-bit machines.

- **Supports Microsoft .NET Framework--**The Microsoft .NET Framework is a new platform for building integrated, service-oriented applications that gather information from and interact with a wide variety of sources, regardless of the platforms or languages in use. The .NET Framework and the common language runtime can deliver write-once, compile-once, run-anywhere application development. Specifically, the .NET Framework delivers code reuse, code specialization, resource management, multilanguage development, security, deployment, and administration.

- **Integrated with side-by-side components--**This feature eliminates .dll version conflicts by permitting an application to be bound to the version of the component it was designed and tested with, regardless of the computer that hosts the application. Side-by-side components support the simultaneous execution of multiple versions of each component.

- **Integrated with software restriction policies--**This feature provides virus protection support, including protection from Trojan horse viruses and worms propagated through e-mail and the Web. Software restriction policies make the simple, point-and-click, active context user experience safe. Group Policy implements them as part of the list of trusted applications, and Windows Installer operates with applications permitted by these software restriction policies.

# Windows Installer technologies

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer technologies**

Windows Installer technologies are divided into two parts that work in combination: a client-side installer service (Msiexec.exe) and a package file (.msi file). Windows Installer uses the information contained within a package file to install the application. Following are the Windows Installer technologies:

- **Installer service--**Windows Installer is an operating system service that allows the operating system to manage the installation process.

- **Installer program--**The Msiexec.exe program is a component of Windows Installer. This program uses a dynamic link library, Msi.dll, to read the package files (.msi), apply transforms (.mst), and incorporate command-line options. The installer performs all installation-related tasks: copying files onto the hard disk, making registry modifications, creating shortcuts on the desktop, and displaying dialog boxes to query user installation preferences when necessary.

  When Windows Installer is installed on a computer, the file association capabilities of the operating system are modified to recognize the .msi file type. When a user double-clicks a file with the .msi extension, the operating system associates the .msi file with Windows Installer and runs the Msiexec.exe application.

- **Installation package file--**Each package (.msi) file contains a relational type database that stores all the instructions and data required to install (and uninstall) the program across many installation scenarios. For example, a package file could contain instructions for installing an application when a prior version of the application is already installed. The package file could also contain instructions for installing the software on a computer where that application has never been present.

- **Transforms--**The installation process can be manipulated by applying transforms (.mst) to the installation database. A transform makes changes to elements of the database. For example, Windows Installer can use a transform file to change the language in the user interface of an application. The Windows Installer transform files modify the installation package file at installation time, and can therefore dynamically affect the installation behavior.

  If you are using Group Policy Software Installation, you should note that a transform is applied at the time of assignment or publication, in addition to the time of installation. In practical terms, this means that you should ensure the **Modifications** tab of the package properties dialog box is set up the way you want it to be before clicking **OK**. If you neglect to do this and deploy an incorrectly transformed package, then you either have to remove the software and redeploy it, or upgrade the software with a correctly transformed version.

  Customization transforms, much like patches, remain cached on the computer. These transforms are applied to the base package file whenever Windows Installer needs to perform a configuration change to the installation package. Transforms are applied only at initial installation; they cannot be applied to an application that has already been installed.

# Using Windows Installer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Windows Installer**
This section covers:

- Windows Installer in managed environments
- Msiexec (command-line options)
- Managing options for computers through Group Policy
- Managing options for users through Group Policy

# Windows Installer in managed environments

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Windows Installer in managed environments**

Windows Installer is an integral part of IntelliMirror, and a core component of the Group Policy-based change and configuration management technology. By using the IntelliMirror technologies, Group Policy, and change and configuration management, administrators can approve certain applications, specifying that all configuration operations on those applications (installation, removal, and repair) run as the local system account. The administrator has control and management of the file system and registry, and Windows Installer performs user-initiated software installations. Only applications that are approved by the administrator run with elevated privileges. For more information about Windows Installer, see Using Windows Installer.

Administrators use Active Directory, IntelliMirror, and Group Policy to assign and publish applications to groups of users or computers within the enterprise. Active Directory is a secure, distributed, partitioned, and replicated directory service that provides management services. These services include a standardized method of locating resources within the enterprise, and applying Group Policy to objects managed by Active Directory. For more information about Active Directory, see Active Directory.

# Msiexec (command-line options)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Msiexec**
Provides the means to install, modify, and perform operations on Windows Installer from the command line.

- To install or configure a product
- To use the administrative installation option
- To repair a product
- To uninstall a product
- To advertise a product
- To set logging level
- To apply an update
- To install a transform using the command line
- To install and advertise a product using a transform with the command line
- To set the user interface level
- To display copyright information for the Windows Installer
- To call the system API DllRegisterServer to self-register modules passed on the command line
- To call the system API DllUnRegisterServer to unregister modules passed on the command line

**To install or configure a product**
**Syntax**
**msiexec /i** {*Package* | *ProductCode*}

**Parameters**
**/i**
Installs or configures a product.

***Package***
Specifies the name of the Windows Installer package file.

***ProductCode***
Specifies the globally unique identifier (GUID) of the Windows Installer package.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To install a product from A:\Example.msi, type:

**msiexec /i A:\Example.msi**

**To use the administrative installation option**
**Syntax**
**msiexec /a** *Package*

**Parameters**
**/a**
Applies the administrative installation option.

***Package***
The name of the Windows Installer package file.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**To repair a product**
**Syntax**
**msiexec /f** [**p**][**o**][**e**][**d**][**c**][**a**][**u**][**m**][**s**][**v**]{*Package* | *ProductCode*}

**Parameters**
**/f**
Enables one or more of the command-line options listed in the following table.

| Command | Description |
|---|---|
| **p** | Reinstalls only if file is missing. |
| **o** | Reinstalls if file is missing or if an older version is installed. |
| **e** | Reinstalls if file is missing or an equal or older version is installed. |
| **d** | Reinstalls if file is missing or a different version is installed. |
| **c** | Reinstalls if file is missing or the stored checksum does not match the calculated value. |
| **a** | Forces all files to be reinstalled. |
| **u** | Rewrite all required user-specific registry entries. |
| **m** | Rewrites all required computer-specific registry entries. |
| **s** | Overwrites all existing shortcuts. |
| **v** | Runs from source and re-caches the local package. |

***Package***
Name of the Windows Installer package file.

***ProductCode***
Globally unique identifier (GUID) of the Windows Installer package.

**Remarks**

- This option ignores any property values that you type at the command line.
- The default parameter for this command-line option is **/fpecms**.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To repair the installation package, type:

**msiexec /fpecms Example.msi**

**To uninstall a product**
**Syntax**
**msiexec /x** {*Package* | *ProductCode*}

**Parameters**
**/x**
uninstalls a product.

***Package***
Name of the Windows Installer package file.

***ProductCode***
Globally unique identifier (GUID) of the Windows Installer package.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To remove or uninstall a package, type:

**msiexec /x Example.msi**

**To advertise a product**
**Syntax**
**msiexec /j** [{**u** | **m**}] *Package*

**msiexec** {**u** | **m**} *Package* **/t** *TransformList*

**msiexec** {**u** | **m**} *Package* **/g** *LanguageID*

**Parameters**
**/j**
Advertises a product.

**u**
Advertises to the current user.

**m**
Advertises to all users of the computer.

***Package***
Specifies the Windows Installer package file.

**/g *LanguageID***
Identifies the language.

**/t *TransformList***
Applies transform to advertised package.

**Remarks**

- This option ignores any property values that you type at the command line.
- If you want to install the application with elevated privileges, use **/jm**.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To advertise a package to all users of this computer, type:

**msiexec /jm Example.msi**

**To set logging level**
**Syntax**
**msiexec /L** [**i**][**w**][**e**][**a**][**r**][**u**][**c**][**m**][**p**][**v**][+][**!**]*LogFile***.txt**

**Parameters**
**/L**
Specifies the path to the log file.

**i**
Logs status messages.

**w**
Logs nonfatal warnings.

**e**
Logs all error messages.

**a**
Logs startup of actions.

**r**
Logs action-specific records.

**u**
Logs user requests.

**c**
Logs initial user interface parameters.

**m**
Logs out-of-memory.

**p**
Logs terminal properties.

**v**
Logs verbose output. To use **v**, specify **/L*v**.

**+**
Appends to existing file.

**!**
Flushes each line to the log.

*****
Logs all information except for the **v** option. This is a wildcard.

***LogFile* .txt**
Name and path of the text log file.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- To include the **v** option in a log file using the wildcard flag, type **/L*v** at the command prompt.
- The Windows Installer log file options can also be used with the uninstall and repair processes.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To install a package and create a log file that contains the information related to the status, out-of-memory, and error messages, type:

**msiexec /i Example.msi /Lime logfile.txt**

**To apply an update**
**Syntax**
**msiexec /p** *UpdatePackage*

**Parameters**
**/p**
Applies an update.

***UpdatePackage***
Specific update.

**Remarks**

- To apply an update to an administrative installation package, use the following syntax:

  **msiexec/p***UpdatePackage***/a***Example.msi*

- Windows Installer command-line options are not case-sensitive.

- For more information about the Windows Installer command-line options, see Related Topics.

**To install a transform using the command line**
**Syntax**
**msiexec /i** *Package* **TRANSFORMS**=*TransformList*

**Parameters**
**/i**
Installs or configures a product.

***Package***
Specifies the Windows Installer package file.

**TRANSFORMS=**
Property that is used to specify what transform (.mst) files should be applied to the package.

***TransformList***
List of paths separated by semicolons.

**Remarks**

- Windows Installer command-line options are not case-sensitive.

- For more information about the Windows Installer command-line options, see Related Topics.

**To install and advertise a product using a transform with the command line**
**Syntax**
**msiexec /i** *Package* **/j**[**u**][**m**] **/t***TransformList*

**Parameters**
**/i**
Installs or configures a product.

***Package***
Name of the Windows Installer package file.

**/j**
Advertises a product. This option ignores any property values entered on the command line.

**u**

Advertises to the current user.

**m**
Advertises to all users of this computer.

**/t**
Applies transform to advertised package.

***TransformList***
List of paths separated by semicolons.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**To set the user interface level**
**Syntax**
**msiexec /q**{**n** | **b** | **r** | **f** | **n+** | **b+** | **b-**}

**Parameters**
**/qn**
Displays no user interface.

**/qb**
Displays a basic user interface.

**/qr**
Displays a reduced user interface with a modal dialog box displayed at the end of the installation.

**/qf**
Displays the full user interface with a modal dialog box displayed at the end.

**/qn+**
Displays no user interface, except for a modal dialog box displayed at the end.

**/qb+**
Displays a basic user interface with a modal dialog box displayed at the end.

**/qb-**
Displays a basic user interface with no modal dialog boxes.

**Remarks**

- **/qb+-** is not a supported user interface level. The modal box is not displayed if the user cancels the installation.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
To display the basic user interface options during the package installation of Example.msi, type:

**msiexec /qb Example.msi**

**To display copyright information for the Windows Installer**
**Syntax**
**msiexec** {**/?** | **/h**}

**Parameters**
**{ /?| /h}**
Displays the Windows Installer version and copyright information.

**Remarks**

- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**To call the system API DllRegisterServer to self-register modules passed on the command line**
**Syntax**
**msiexec /y** *Module*

**Parameters**
**/y**
Calls the system API DllRegisterServer to self-register modules passed on the command line.

***Module***
Specifies the file name of module.

**Caution**

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on the computer.

**Remarks**

- This option is used only for registry information that cannot be added using the registry tables of the .msi file.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
The following example shows how you can use the **msiexec /y** command:

**msiexec /y my_file.dll**

**To call the system API DllUnRegisterServer to unregister modules passed on the command line**
**Syntax**
**msiexec /z** *Module*

**Parameters**
**/z**
Calls the system API DllUnRegisterServer to unregister modules passed on the command line.

***Module***
File name of module.

**Remarks**

- This option is used only for registry information that cannot be added using the registry tables of the .msi file.
- Windows Installer command-line options are not case-sensitive.
- For more information about the Windows Installer command-line options, see Related Topics.

**Examples**
The following example shows how you can use the **msiexec /z** command:

**msiexec /z my_file.dll**

**Formatting legend**

| Format | Meaning |
|---|---|
| *Italic* | Information that the user must supply |

| | |
|---|---|
| **Bold** | Elements that the user must type exactly as shown |
| Ellipsis (...) | Parameter that can be repeated several times in a command line |
| Between brackets ([]) | Optional items |
| Between braces ({}); choices separated by pipe (\|). Example: {even\|odd} | Set of choices from which the user must choose only one |
| `Courier font` | Code or program output |

# Managing options for computers through Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing options for computers through Group Policy**
Windows Installer can be configured by using Group Policy and Active Directory to manage the computer installation options.

The following table shows policies concerned with managing the Group Policy computer options for Windows Installer. To configure these policies, start Group Policy, then in the console tree, click the **Windows Installer** node.

**Where?**

- *applicable policy name*/Computer Configuration/Administrative Templates/Windows Installer

| Policy | Details |
|---|---|
| **Disable Windows Installer** | Disables or restricts the use of Windows Installer.<br><br>This policy can prevent users from installing software on their system, or permit users to install only those programs offered by an administrator.<br><br>If you enable this policy, you can use the options in the **Disable Windows Installer** dialog box to establish an installation policy.<br><br>• **Never--**Windows Installer is fully enabled. Users can install and upgrade software. Windows Installer is enabled by default in Windows.<br><br>• **For non-managed apps only--**Users can install only those programs that an administrator assigns (offers on the desktop) or publishes (adds to Add or Remove programs).<br><br>• **Always--**Windows Installer is disabled.<br><br>**Note**<br><br>• This policy affects Windows Installer only. It does not prevent users from using other methods to install and upgrade programs. |
| **Always install with elevated privileges** | Directs Windows Installer to use system permissions when it installs any program on the system.<br><br>This policy extends to all programs the elevated privileges usually reserved for programs that have been assigned to the user (offered on the desktop) or the computer (installed automatically), or made available in Add or Remove programs in Control Panel. This policy lets users install programs that require access to directories that the user might not have permission to view or change, including directories on highly restricted computers.<br><br>If you disable this policy, or do not configure it, the system applies the current user's permissions when it installs programs that are not distributed or offered by an administrator.<br><br>**Note**<br><br>• This policy appears in both the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |

| | |
|---|---|
| **Prohibit rollback** | Prohibits Windows Installer from generating and saving the files it needs to reverse an interrupted or unsuccessful installation.<br><br>**Prohibit rollback** also prevents Windows Installer from recording the original state of the system and frequency of changes it makes during installation, and prevents Windows Installer from retaining files it intends to delete later. As a result, Windows Installer cannot restore the computer to its original state if the installation does not complete.<br><br>This policy is designed to reduce the amount of temporary disk space required to install programs. **Prohibit rollback** also prevents malicious users from interrupting an installation to gather data about the internal state of the computer or to search secure system files. However, because an incomplete installation can render the system or a program inoperable, do not use this policy unless essential.<br><br>This policy appears in both the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |
| **Remove browse dialog box for new source** | Prevents users from searching for installation files when adding features or components to an installed program.<br><br>This policy disables the **Browse** button next to the **Use feature from** list in the Windows Installer dialog box. Users must select an installation file source from the **Use features from** list configured by the administrator.<br><br>This policy applies even when the installation is running in the user's security context.<br><br>If you disable this policy or do not configure it, the **Browse** button is enabled when an installation is running in the user's security context, but only administrators can browse when an installation is running with elevated system privileges, such as installations offered on the desktop or in Add or Remove programs.<br><br>This policy affects Windows Installer only. It does not prevent users from using other browsers, such as Windows Explorer or My Network Places, to search for installation files. |
| **Prohibit patching** | Prevents users from installing patches to upgrade their programs.<br><br>Patches are updates or upgrades that replace only those program files that have changed. Because patches can be easy vehicles for malicious programs, some installations prohibit their use.<br><br>This policy applies only to installations that run in the user's security context. By default, users who are not administrators cannot apply patches to installations that run with elevated system privileges, such as those offered on the desktop or in Add or Remove programs. |
| **Disable IE security prompt for Windows Installer scripts** | Allows Web-based programs to install software on the computer without notifying the user.<br><br>By default, when a script hosted by an Internet browser attempts to install a program on the system, the system warns the user and prompts the user to either allow or refuse the installation. This policy suppresses the warning and allows the installation to proceed without user intervention.<br><br>This policy is designed for enterprises that use Web-based tools to distribute programs to their employees. However, because it might pose a security risk, it should be applied cautiously. |
| **Enable user control over installs** | Permits users to change installation options that typically are available only to administrators.<br><br>This policy bypasses some of the security features of Windows Installer. It permits installations to complete that otherwise would be halted due to a security violation.<br><br>The security features of Windows Installer prevent users from changing installation options that are typically reserved for administrators, such as specifying the directory to which files are installed. If Windows Installer detects that an installation package has permitted the user to change a protected option, it stops the installation and displays an error message. These security features operate only when the installation program is running in a privileged security context in which the installation program has access to directories that are denied to the user.<br><br>This policy is designed for less restrictive environments. It can be used to circumvent errors in an installation program that prevent software from being installed. |

| | |
|---|---|
| **Enable user to browse for source while elevated** | Permits users to search for installation files during privileged installations.<br><br>This policy enables the **Browse** button on the **Use feature from** dialog box. Users can search for installation files, even when the installation program is running, with elevated system privileges. By default, only system administrators can browse during installations with elevated privileges, such as installations offered on the desktop or displayed in Add or Remove programs.<br><br>Because the installation is running with elevated system privileges, users can browse through directories that their own permissions would not allow.<br><br>This policy does not affect installations that run in the user's security context. For more information, see the **Remove browse dialog box for new source** policy. |
| **Enable user to use media source while elevated** | Permits users to install programs from removable media, such as floppy disks and CD-ROMs, during privileged installation.<br><br>This policy permits all users to install programs from removable media, even when the installation program is running with elevated system privileges. By default, users can install programs from removable media only when the installation runs in the user's security context. During privileged installations, such as those offered on the desktop or displayed in Add or Remove programs, only system administrators can install from removable media.<br><br>This policy does not affect installations that run in the user's security context. By default, users can install from removable media when the installation runs in their own security context.<br><br>For more information, see the **Prevent removable media source for any install** policy in Managing options for users through Group Policy. |
| **Enable user to patch elevated products** | Permits users to upgrade programs during privileged installations.<br><br>This policy permits all users to install patches, even when the installation program is running with elevated privileges. Patches are updates or upgrades that replace only those program files that have changed. Because patches can easily be vehicles for malicious programs, some installations prohibit their use.<br><br>By default, only system administrators can apply patches during installations with elevated privileges, such as installations offered on the desktop or displayed in Add or Remove programs.<br><br>This policy does not affect installations that run in the user's security context. By default, users can install patches to programs that run in their own security context. For more information about prohibiting patch installations, see the **prohibit patching** policy. |
| **Allow admin to install from Terminal Services session** | Permits Terminal Services administrators to install and configure programs remotely.<br><br>By default, system administrators can install programs only when they are logged on to the computer on which the program is being installed. This policy creates a special exception for computers running Terminal Services.<br><br>This policy affects system administrators only. Other users cannot install programs remotely. |
| **Cache transforms in secure location on workstation** | Copies of transform files are saved in a secure location on the local computer.<br><br>Transform files consist of instructions to modify or customize a program during installation. By default, Windows Installer stores transform files in the Application Data directory in the user's profile. When a user reinstalls, removes, or repairs an installation, the transform file is available, even if the user is on a different computer, or isn't connected to the network.<br><br>If you enable this policy, the transform file is saved in a secure location on the user's computer instead of in the user profile. Because Windows Installer requires the transform file to repeat an installation in which the transform file was used, the user must be using the same computer or be connected to the original or identical media to reinstall, remove, or repair the installation.<br><br>This policy is designed for enterprises that must take special precautions to prevent unauthorized or malicious editing of transform files. |

| | |
|---|---|
| **prohibit User Installs** | Allows you to configure user installs. To configure this setting, set it to enabled and use the drop-down list to select the behavior you want.<br><br>If this setting is not configured, or if the setting is enabled and **Allow User Installs** is selected, the installer allows and makes use of products that are installed per user, and products that are installed per computer. If the installer finds a per-user install of an application, this hides a per-computer installation of that same product.<br><br>If this setting is enabled and **Hide User Installs** is selected, the installer ignores per-user applications. This causes a per-computer installed application to be visible to users, even if those users have a per-user install of the product registered in their user profile.<br><br>If this setting is enabled and **prohibit User Installs** is selected, the installer prevents applications from being installed per user, and it ignores previously installed per-user applications. An attempt to perform a per-user installation causes the installer to display an error message and stop the installation. This setting is useful in environments where the administrator only wants per-computer applications installed, such as on a kiosk or a Windows Terminal Server. |
| **Turn off creation of System Restore Checkpoints** | Stops Windows Installer from generating System Restore checkpoints when installing applications.<br><br>System Restore enables users, in the event of a problem, to restore their computers to a previous state without losing personal data files. By default, Windows Installer automatically creates a System Restore checkpoint each time an application is installed, so that users can restore their computer to the state it was in before installing the application.<br><br>If you disable this setting or do not configure it, Windows Installer automatically creates a System Restore checkpoint each time an application is installed.<br><br>**Note**<br><br>• This setting only applies to Windows XP Professional. |
| **Logging** | Specifies the types of events that Windows Installer records in its transaction log for each installation. The log, msi.log, appears in the *systemroot*\Temp directory. The Windows Installer logging options are listed in the following table. To indicate that an event type is recorded, enter the letter representing the event type. You can enter the letters in any order, and list as many or as few event types as you want. To disable logging, delete all of the letters from the box. If you disable this policy, or do not configure it, Windows Installer logs the default event types, represented by the letters **iweap**. You can include all possible events in the installation log file by entering **iwearucmpvo**. However, doing so will add considerable time to the installation process. |

| Mode | Log entry |
|---|---|
| **i** | Status messages |
| **w** | Non-fatal warnings |
| **e** | All error messages |
| **a** | Startup of actions |
| **r** | Action-specific records |
| **u** | User requests |
| **c** | Initial user interface parameters |
| **m** | Out-of-memory |
| **p** | Terminal properties |
| **v** | Verbose output |
| **o** | Out of disk space messages |

# Managing options for users through Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing options for users through Group Policy**

Windows Installer can be configured by using Group Policy and Active Directory to manage the user installation options.

This table shows policies concerned with managing the Group Policy user options for Windows Installer. To configure these policies, start Group Policy, then in the console tree, click the **Windows Installer** node.

**Where?**

- *applicable policy name*/User Configuration/Administrative Templates/Windows Installer

| Policy | Details |
|---|---|
| **Always install with elevated privileges** | Directs Windows Installer to use system permissions when it installs any program on the system.<br><br>This policy extends to all programs the elevated privileges usually reserved for programs that have been assigned to the user (offered on the desktop) or the computer (installed automatically), or made available in Add or Remove Programs in Control Panel. This policy lets users install programs that require access to directories that the user might not have permission to view or change, including directories on highly restricted computers.<br><br>If you disable this policy, or do not configure it, the system applies the current user's permissions when it installs programs that are not distributed or offered by an administrator.<br><br>**Note**<br><br>• This policy appears both in the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |
| **Search order** | Specifies the order in which Windows Installer searches for installation files.<br><br>By default, Windows Installer searches the network first, then removable media (floppy drive, CD-ROM, or DVD), and finally, the Internet (URL).<br><br>To change the search order, enable the policy, and then type the following letters for each file source in the order that you want Windows Installer to search. For example, if you want to search the network, the Internet, and then removable media, type **num**. To exclude a file source, omit or delete the letter representing that source type.<br><br>• **n** - Adds the network in the source file search.<br><br>• **m** - Adds the removable media in the source file search.<br><br>• **u** - Adds the Internet in the source file search. |

| | |
|---|---|
| **Prohibit rollback** | Prohibits Windows Installer from generating and saving the files it needs to reverse an interrupted or unsuccessful installation.<br><br>This policy prevents Windows Installer from recording the original state of the system and sequence of changes it makes during installation. It also prevents Windows Installer from retaining files it intends to delete later. As a result, Windows Installer cannot restore the computer to its original state if the installation does not complete.<br><br>This policy is designed to reduce the amount of temporary disk space required to install applications. It also prevents malicious users from interrupting an installation to gather data about internal state of the computer or to search secure system files. However, because an incomplete installation can render the system or an application inoperable, this policy should not be used unless it is essential.<br><br>**Note**<br><br>• This policy appears in both the Computer Configuration and User Configuration folders. To make this policy effective, you must enable the policy in both folders. |
| **Prevent removable media source for any install** | Prevents users from installing programs from removable media.<br><br>If a user tries to install a program from removable media, such as CD-ROMs, floppy disks, or DVDs, a message informs the user that the feature cannot be found.<br><br>This policy applies even when the installation is running in the user's security context.<br><br>If you disable or do not configure this policy, users can install from removable media when the installation is running in their own security context, but only system administrators can use removable media when an installation is running with elevated system privileges, such as installations offered on the desktop or in Add or Remove Programs. |

# Windows Installer Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- The installation package does not install correctly.
- The installation process stops before completing the installation.

**The installation package does not install correctly.**
**Cause:** The installation packaged has been corrupted.

**Solution:** Repair the installation package by using the Windows Installer repair option.

**See also:** Repair a package using the command line

**The installation process stops before completing the installation.**
**Cause:** Windows Installer was not able to read the installation package, or conditions on your computer prevented the package from being installed successfully.

**Solution:** Windows Installer creates entries in the Windows event log. To view the log, do the following:

1. Open Event Viewer.
2. Review the application log for Windows Installer entries.

**Notes**

- To open Event Viewer, click **Start**, point to **Settings**, and then click **Control Panel**. Double-click **Administrative Tools**, and then double-click **Event Viewer**.
- You can configure Windows Installer to create a custom installation log file.

**See also:** Create an installation log file using the command line

# Remote Administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote Administration**
Using tools included with Microsoft® Windows Server 2003 family operating systems CDs, you can remotely manage your system servers running Microsoft® Windows 2000 and Windows Server 2003 family operating systems. You can also remotely manage Windows Server 2003 family operating systems from a computer using Microsoft® Windows® XP Professional.

- For general information, see Remote administration overview.
- For tips about managing your server remotely, see Remote Administration Best practices.
- For other sources of information, see Remote Administration Resources.

# Remote administration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Remote administration overview**

The following table presents remote management tasks and links to information about the tools. Unless indicated otherwise, these tools are used on Microsoft® Windows Server™ 2003 operating systems and, in some cases, Microsoft® Windows® XP Professional.

| Task | Tools | Comments |
|---|---|---|
| Manage several servers by performing similar tasks. | Microsoft Management Console<br><br>Author an MMC console file<br><br>Work with MMC and saved console files | You can use appropriate saved MMC consoles, if available, or you can create custom MMC consoles for tasks you frequently either delegate or perform. |
| Log onto one computer remotely and manage it as if you were there. | Remote Desktop Connection | In addition to Windows Server 2003 operating systems, this feature can be used with Microsoft® Windows® 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Switch among several computers that you want to log on to remotely. | Remote Desktops snap-in | In addition to Windows Server 2003 operating systems, this feature can be used with Windows 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Administer a server running Windows Server 2003 from any computer on your network. | Remote Desktop for Administration | In addition to Windows Server 2003 operating systems, this feature can be used with Windows 2000 Server. The Remote Desktop feature must be enabled on the remote computer. |
| Manage servers from Windows XP Professional. | Windows Server 2003 Administration Tools Pack Overview<br><br>Remote Desktop Connection | Windows Server 2003 Administration Tools Pack must be installed on Windows XP Professional to permit server management using these tools. The Remote Desktop feature must be enabled on servers to permit use of the Remote Desktop Connection. |
| Manage your Web server using a Web browser on a remote computer. | Using Web Interface for Remote Administration | Use Internet Explorer, version 6 or later, for remote administration using Web Interface. Web Interface is not installed by default for Web servers. |
| Assist in real time an operator on a remote computer running Windows Server 2003 family operating system, Windows XP Professional or Microsoft® Windows® XP Home Edition. | Administering Remote Assistance (www.microsoft.com) | The Remote Assistance connection requires explicit permission from the connected user, and both computers must be running Windows XP Professional or Windows Server 2003 operating systems. |
| Connect to a remote computer when that computer cannot access a network or is not in a functional state because of hardware or software failure. | Telnet | All commands must be entered through the command line. Capabilities are limited, and security is minimal. |

| | | |
|---|---|---|
| Manage disk space on servers by copying files to a library of magnetic tapes or magneto-optical disks. | Remote Storage | Some Windows components require configuration before they can be used and will be displayed in the **Add or Remove Windows Components** in **Add or Remove programs** in **Control Panel**. Remote storage requires installation. |

**Notes**

- Depending on the Group Policy settings on your network, you might not be able to perform some of these tasks.
- Some features require that specific ports be opened on the server in order for the role to be administered remotely. For information about these port requirements, see Service overview and network port requirements for the Windows Server system (http://go.microsoft.com/fwlink/?LinkID=61531) and Windows Firewall Settings (http://go.microsoft.com/fwlink/?LinkID=38651).
- You can use command-line tools to automate many processes and tasks. For more information, see Automating processes and tasks.
- You must physically access each computer to restart, change hardware, and enable the Remote Desktop feature. Once the Remote Desktop feature has been enabled, it will remain enabled.
- For an explanation of the various Remote Desktop terminologies, see Remote Administration using Terminal Services.
- For more information about remote administration, see the following:
    - Common Administrative Tasks
    - New Features
    - Quick Guide for Finding Tools
    - Remote Administration Resources

# Remote Administration Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**To perform many tasks on a single, remote server, use Remote Desktop for Administration.**

- To remotely administer a server running a Windows Server 2003 family operating system, you do not need to install Terminal Server. Instead, use Remote Desktop for Administration. On these operating systems, Remote Desktop for Administration is on by default but is not enabled. After you enable remote connections, Remote Desktop for Administration allows you to administer your server from any computer on your network running Windows Server 2003 family, Windows XP Professional, and Windows 2000. Windows Server 2003 , Web Edition, does not support remote administration.

- You can use Remote Desktop with Windows 2000 Server. You need to install Terminal Services for Remote Administration as described in the Windows 2000 Help.

  For more information, see Enable or disable Remote Desktop and Remote Desktop for Administration.

**To do similar tasks on many servers, use MMC snap-ins.**

- Most of the administration tools provided with Windows Server 2003 family operating systems are Microsoft Management Console (MMC) snap-ins that can be used to administer remote servers as well as your local computer. The advantages of using MMC include the following:

  - You can create a console with the tools you use for the tasks you do most often.

  - You can set the focus for a tool to any of the servers you administer, and switch between servers and tools within a single MMC console.

  For more information, see Microsoft Management Console.

**To manage servers running Windows Server 2003 family operating systems from a computer using Windows XP Professional , use Windows Server 2003 Administration Tools Pack**

- Windows Server 2003 Administration Tools Pack when installed on Windows XP Professional (ordinarily a client operating system) provides many remote management tools for managing your servers.

- Windows Server 2003 Administration Tools Pack comes as adminpak.msi on the Windows Server 2003 family operating system and is easily installed from the server CD onto Windows XP Professional by installing the .msi from the server to the Windows XP Professional operating system.

- The Administration Tools Packs in the Windows Server 2003 family and Windows 2000 are not mutually compatible. You must use the Windows 2000 Administrative Tools to administer Windows 2000, and the Windows Server 2003 Administration Tools Pack to administer the Windows Server 2003 family operating system.

  For more information, see Windows Server 2003 Administration Tools Pack Overview.

# Remote Administration Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**
The following resources provide additional information about remote administration.

**Windows Server 2003 Resource Kit**
The Microsoft Windows Server 2003 Resource Kit contains additional tools that you can use for remote administration.

**Microsoft Platform Software Development Kits (SDK)**
For technical information about Active Directory Scripting Interfaces (ADSI), Microsoft Management Console (MMC), Windows Management Instrumentation (WMI) Software Development Kits (SDK), see the Microsoft Web site.

**TechNet**
TechNet is a service that contains resources for information technology (IT) professionals. This includes access to articles written by support professionals at Microsoft, career and industry information, discussion groups, technical feedback, and software.

For more information, see Microsoft TechNet.

# Offline Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Offline Files**
Using Offline Files, you can continue to work with network files and programs even when you are not connected to the network.

- For help with specific tasks, see Offline Files How To....
- For general background information, see Offline Files Concepts.

# Offline Files How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Set up your computer to use Offline Files
- Make a file or folder available offline
- Change how Offline Files responds to network disconnection
- Encrypt offline files
- Make Web pages available offline

# Set up your computer to use Offline Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up your computer to use Offline Files**

1. Open My Computer.
2. On the **Tools** menu, click **Folder Options**.
3. Click the **Offline Files** tab, select the **Enable Offline Files** check box, and then do one of the following:
   - To do a full synchronization, select the **Synchronize all offline files before logging off** check box.
   - To do a quick synchronization, clear the **Synchronize all offline files before logging off** check box.

## Notes

- To open My Computer, click **Start**, and then click **My Computer**.
- A full synchronization ensures that you have the most current versions of every network file that has been made available offline. A quick synchronization ensures that you have complete versions of all of your offline files, but they might not be the most current versions.
- **Enable Offline Files** is controlled through Group Policy, as is **Amount of disk space to use for temporary offline files**. To adjust these settings, you must have the appropriate administrative credentials.
- By default, Offline Files is enabled in Windows XP Professional. However, by default, Offline Files is not enabled in the Windows Server 2003 family because Terminal Services is not compatible with Offline Files. To enable Offline Files on a server running Windows Server 2003 , right-click **My Computer**, and then click **properties**. In the **System properties** dialog box, click the **Remote** tab. Under **Remote Desktop**, clear the **Allow users to connect remotely to this computer** check box, click **OK**, and then follow the steps in this procedure.
- Even if your computer is configured to use Offline Files, you must still select the network files and folders that you want to make available offline.
- To view a list of all of the network files that are available offline, in the **Folder Options** dialog box, click the **Offline Files** tab, click **View Files**, and view the files in the Offline Files Folder.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Change how Offline Files responds to network disconnection

# Make a file or folder available offline

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a file or folder available offline**

1. Open My Computer.
2. In My Computer, click the shared network file or folder that you want to make available offline.
3. On the **File** menu, click **Make Available Offline**.
4. Follow the steps in the Offline Files Wizard.

### Important

- **Make Available Offline** appears on the **File** menu only if your computer is set up to use Offline Files. For more information about setting up your computer to use Offline Files, see Related Topics.

### Notes

- To open My Computer, click **Start**, and then click **My Computer**.
- You can make individual files from a shared network folder, or an entire shared network folder, available offline. If an entire folder is made available offline, any files placed in that shared folder will automatically be made available offline the next time the computers are synchronized.
- If a shortcut to a file is made available offline, that file is made available offline. If a shortcut to a folder is made available offline, the contents of that folder are not made available offline.
- When the status of your network connection changes, an Offline Files icon appears in the notification area, and a reminder balloon appears over the icon to notify you of the change. If the reminder balloon notifies you that you are offline, you can continue to work with your files as you normally do, or you can click the Offline Files icon in the notification area for more information about the status of your connection.
- When you open files on a shared folder marked for automatic caching, those files are automatically cached and become available to you when you are offline.
- To stop making a file or folder available offline, right-click the item, and then click **Make Available Offline** to remove the check mark.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change how Offline Files responds to network disconnection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change how Offline Files responds to network disconnection**

1. Open My Computer.
2. On the **Tools** menu, click **Folder Options**.
3. Click the **Offline Files** tab, and then click **Advanced**.
4. Under **When a network connection is lost**, do one of the following:
   - To receive notification that the network connection has been lost and to continue working with offline files, click **Notify me and begin working offline**.
   - To make offline files and folders unavailable to you when you lose a network connection, click **Never allow my computer to go offline**.

**Notes**

- To open My Computer, click **Start**, and then click **My Computer**.
- To set up individual computers to respond differently from the default settings, in the **Offline Files - Advanced Settings** dialog box, click **Add**. Under **Computer**, type the path to the computer, and then, under **When a network connection is lost**, click the setting that you want for this particular computer. For example, if you want to continue working offline by default and you do not want to work offline on any files from a particular computer on the network, you can add that computer's name under **Computer**, and then click **Never allow my computer to go offline** as the behavior for that specific computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Encrypt offline files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To encrypt offline files**

1. Open My Computer.
2. On the **Tools** menu, click **Folder Options**.
3. Click the **Offline Files** tab, and then select the **Encrypt offline files to secure data** check box.

## Notes

- To open My Computer, click **Start**, and then click **My Computer**.
- The **Encrypt offline files to secure data** check box is disabled under the following conditions:
  - You are not an administrator on the computer.
  - The local drive is not NTFS or does not support encryption.
  - Your system administrator has implemented an encryption policy for Offline Files.
  - Offline Files is not available in Windows XP Home Edition.
  - In the Windows Server 2003 family, Offline Files is not enabled by default. To enable Offline Files, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make Web pages available offline**

1. Open Internet Explorer.
2. Access the Web page or Web site you want to make available offline.
3. On the **Favorites** menu, click **Add to Favorites**.
4. In the **Add Favorite** dialog box, select the **Make available offline** check box.
5. To specify a schedule for updating that page and how much content to download, click **Customize**, and then follow the instructions in the Offline Favorite Wizard.

### Note

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Offline Files Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

- Offline Files overview
- Using Offline Files

# Offline Files overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Offline Files overview**
Using Offline Files, you can continue to work with network files and programs even when you are not connected to the network.

If you lose your connection to the network or undock your portable computer, your view of shared network resources that have been made available offline remains the same as when you were connected. You can continue to work with them as you normally do. You have the same access permissions to those files and folders as you would have if you were connected to the network. When the status of your connection changes, an Offline Files icon appears in the notification area and a reminder balloon appears over the notification area to notify you of the change.

When your network connection is restored or you dock your portable computer, any changes that you made while working offline are updated to the network by default. When you and someone else on the network have made changes to the same file, you have the option of saving your version of the file to the network, keeping the other version, or saving both.

For more information about synchronizing files with Synchronization Manager, see Synchronization Manager overview.

**Notes**

- You can initiate synchronization manually or you can set Synchronization Manager to control when offline files are synchronized with the network. Offline Files controls whether a full or quick synchronization is performed. A full synchronization ensures that you have the most current version of every network file that has been made available offline. A quick synchronization is much faster than a full synchronization, but may not provide the most current version of every network file that has been made available offline. However, a quick synchronization does ensure that a complete version of every file is available so that you can continue working.

- Any shared files or folders on a Microsoft network can be made available offline. You can make files available offline from any computer that supports Server Message Block-based (SMB) File and Printer Sharing, including Microsoft® Windows® 95, Windows® 98, Windows NT® version 4.0, Microsoft® Windows® XP, and the Windows Server 2003 family. Offline Files is not available on Novell NetWare networks.

- The system administrator can set up shared folders so that every network file you open in that shared folder is automatically made available offline, or so that only those network files you choose are made available offline.

- If a shortcut to a file is made available offline, that file is made available offline. If a shortcut to a folder is made available offline, the contents of that folder will not be made available offline.

- In the Windows Server 2003 family, Offline Files is not enabled by default. To enable Offline Files, see Set up your computer to use Offline Files.

# Using Offline Files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Offline Files**

- Working offline
- Sharing a drive or folder
- Handling file conflicts
- Encrypting offline files
- Working with Web pages offline
- Offline Files for mobile users

# Working offline

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Working offline**

Offline Files notifies you if the status of your network connection changes. When the status of your network connection changes, an Offline Files icon appears in the notification area and a reminder balloon appears over the notification area to notify you of the change. If the reminder balloon notifies you that you are offline, you can continue to work with your files as you normally do, or you can click the Offline Files icon in the notification area for more information about the status of your connection.

If you are working offline (either because you are disconnected from the network or because you undocked your portable computer), you can still browse network drives and shared folders in My Computer or My Network Places. A red X appears over any disconnected network drives. You will be able to see only those files that you made available offline and any files that you created after the network connection was lost. For more information about making a file or folder available offline, see Make a file or folder available offline.

Your permissions on the network files and folders remain the same whether you are connected to the network or working offline. For example, a read-only document on a mapped network drive would remain read-only if you were disconnected from the network.

When you are disconnected from the network, you can print to local printers, but you cannot print to shared printers on the network.

After you reconnect to the network, Synchronization Manager updates the network files with changes that you made while working offline. For more information about synchronizing files with Synchronization Manager, see Synchronizing offline items.

# Sharing a drive or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Sharing a drive or folder**

You can share a folder on your computer with other users on the network. When you share a folder, you can decide the permissions that other users will be allowed or denied when they access the files and programs in that folder over the network. You can also specify whether other users will be able to make the shared folder available offline. For more information, see Share a folder or drive.

To make shared network files and programs available offline, Offline Files stores a version of them in a cache. The computer can access this cache while disconnected from the network. There are three caching options to choose from when sharing files:

- **Only the files and programs that users specify will be available offline**

  This caching option provides offline access to only those files and programs that someone using your shared folder specifically identifies. This caching option is ideal for a shared network folder containing files and programs that are to be accessed and modified by several people. This is the default option when you set up a shared folder to be used offline.

- **All files and programs that users open from the shared folder will automatically be available offline**

  This caching option makes every file and program opened from your shared folder automatically available offline. Files and programs that are not opened are not available offline. This caching option is ideal for making files and programs available offline that are read, referenced, or run, but not changed in the process.

  Automatic caching for files and programs provides offline access to shared folders containing files and programs that are not to be changed. Automatic caching for programs reduces network traffic because offline files are opened directly, without accessing the network versions in any way, and generally start and run faster than the network versions. To provide automatic caching for files only, clear the **Optimized for Performance** check box.

  When you use automatic caching for files and programs, be sure to restrict permissions on the files and programs contained in the shared folder to read-only access.

- **Files or programs from the shared folder will not be available offline**

  All files or programs in the selected shared folder will not be available offline.

**Notes**

- Sharing folders and drives requires special security consideration. For more information, see Securing shared resources.

- The default cache size is set to 10 percent of available drive space. You can modify this setting in the **Offline Files** tab in **Folder Options**. Cache size settings affect only the autocached files. Manually cached files and programs using the **Only the files and programs that users specify will be available offline** option are restricted only by actual disk space available to the user. For more information, see Related Topics.

- By default, Offline Files stores shared network files and programs in the *systemroot*\CSC directory on the user's hard drive. For example, if your system directory is C:\WINDOWS, your cache is C:\WINDOWS\CSC.

# Handling file conflicts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Handling file conflicts**

When you synchronize files, the files that you opened or updated while you were disconnected from the network are compared to the files that are saved on the network. As long as the same files you changed have not been changed by someone else while you were offline, your changes are copied to the network. Following are common file conflict scenarios:

- If someone else made changes to the same network file that you updated offline, you can choose to keep your version, keep the version on the network, or keep both versions. If you choose to save both versions of the file, you need to provide a different file name for your version of the file.
- If you delete a network file on your computer while working offline and, in the meantime, someone else on the network is working in that file, the file is deleted from your computer, but it is not deleted from the network.
- If you change a network file while working offline and someone else on the network deletes that file, you can choose to save your version to the network or delete it from your computer.
- If you are disconnected from the network when a new file is added to a shared network folder that you have made available offline, that new file will be added to your computer when you reconnect and synchronize.

For more information about synchronizing files with Synchronization Manager, see Synchronizing offline items and Synchronization Manager.

# Encrypting offline files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Encrypting offline files**

With Offline Files, you can specify that offline files are encrypted. If you choose to encrypt offline files, only the files on your local computer are encrypted. The files on the network are not affected. Use encryption to keep offline files and folders safe from intruders who might gain unauthorized physical access to your computer.

You do not need to decrypt an encrypted file or folder before using it. However, an intruder who tries to access encrypted files or folders will be prevented from doing so.

For more information about working with encrypted files, see Encrypting File System overview and Encrypt offline files.

# Working with Web pages offline

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Working with Web pages offline**

Using Microsoft Internet Explorer, you can make Web pages or entire Web sites available offline for viewing, including related links. A wizard prompts you to specify how much content to make available offline. You can also set up a schedule to synchronize content automatically.

Making Web pages available offline is a feature of Internet Explorer and is configured separately from the Offline Files feature in Windows. The folder options you specify for Offline Files, such as encryption and synchronization, do not apply to Web pages that you make available offline. Instead, use the options that are available for offline Web pages through Internet Explorer.

For more information, see Make Web pages available offline.

# Offline Files for mobile users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Offline Files for mobile users**

If you travel frequently and rely on a portable computer to accomplish your work, Offline Files provides a way to ensure that you are working with the most current versions of the network files and that your work will be synchronized with the network when you reconnect. Using Offline Files, you can navigate through shared folders and mapped network drives regardless of whether you are connected to a network.

Follow these steps when working with Offline Files on a portable computer:

- **Make a file or folder available offline**

  Before you disconnect your portable computer from the network, you must first select the shared network files or folders that you want to use when you are disconnected and make them available offline. For more information, see Make a file or folder available offline.

- **Synchronize files when you log on to or log off from a computer**

  Set up Synchronization Manager to reflect the way you want your portable computer to synchronize your files when you log on to and log off from the network. For more information, see Synchronizing offline items when you log on to or log off from a computer.

- **Disconnect a portable computer from the network**

  After you have completed the previous tasks, you can disconnect your portable computer and begin working offline. In Windows XP Professional and the Windows Server 2003 family, the computer synchronizes automatically whenever the user suspends the computer. This policy is not controllable through the user interface.

- **Work offline**

  While working offline, you can still browse network drives and shared folders in My Computer or My Network Places. You will be able to see only those files that you made available offline and any files that you created after losing the network connection. A red X appears over any disconnected network drives. Your permissions on the network files and folders remain the same whether you are connected to the network or working offline. For more information, see Working offline.

- **Handle file conflicts**

  When you are finished working offline and you reconnect your portable computer to the network, you must synchronize your files. By synchronizing your files, you update the network files with changes that you made while working offline. By having Synchronization Manager automatically synchronize your files when you log on, you ensure that the latest file changes are reflected on the network and that any file conflicts are handled properly. For more information, see Handling file conflicts.

# User Profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User profiles**

User profiles automatically create and maintain the desktop settings for each user's work environment on the local computer.

- To find features that have been moved in the Microsoft® Windows Server 2003 family, see New ways to do User Profiles tasks.
- For tips about using user profiles, see User Profiles best practices.
- For help with specific tasks, see User Profiles How To....
- For general background information, see User Profiles Concepts.

# New ways to do User Profiles tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

The following table lists common tasks for configuring user profiles. The user interface for performing these tasks is different in this version of Windows from the way was in Windows NT 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Add a path to a user profile | **User Manager** in **Administrative Tools** | Active Directory Users and Computers, and then click **Users**. |
| View the contents of a user profile | The profile is stored in Profiles typically in C:\Windows or C:\Winnt*UserName* | Windows Explorer. The profile is stored in the \Documents and Settings*UserName* folder. |
| Copy a user profile | **System** utility in Control Panel | System Properties, click the **Advanced** tab, and then, under **User Profiles**, click **Settings**. |
| Add a home directory to a path | **User Manager** in **Administrative Tools** | Active Directory Users and Computers, and then click **Users**. |
| Add a logon script to a user profile | **User Manager** in **Administrative Tools** | Group Policy accessed through Active Directory Users and Computers |

# User Profiles best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Allow for different hardware configurations.**

- Because user profiles can be used on various types of client computers, you should keep in mind that these client computers can have different hardware configurations, particularly different video cards and display monitors.
- Because a user profile determines screen placement and window size, a workstation's display hardware affects how well the user profile works. For example, the window setup in a user profile created for a computer with a Super VGA monitor might not look correct when loaded on a computer with a regular VGA monitor.

**Use the same type of video hardware when you create or edit a user profile for a single user.**

- When you create or edit a user profile for a single user, use a computer with the same type of video hardware as the computer that the user typically uses.

**Create a single mandatory user profile for a group of users only if they all use computers with the same type of video hardware.**

- When you create a mandatory user profile for several users, create a single user profile for the whole group of users only if they all use computers with the same type of video hardware.

**Do not use Offline Folder caching on roaming user profile shared directories.**

- It is important to turn off Offline Folder caching for shared directories where roaming user profiles are stored. If you do not turn off Offline Folder caching for a user's profile, you might experience synchronization problems when both Offline Folders and roaming user profiles try to synchronize the files in a user's profile. This does not affect your ability to use Offline Folders with redirected folders such as My Documents.

**Do not use Encrypted File System (EFS) on files in a roaming user profile.**

- The Encrypted File System (EFS) is not compatible with roaming user profiles. If you encrypt profile folders or files in the user profile using EFS, the user's profile will not roam.

**Do not set disk quotas too low for users with roaming user profiles.**

- If a user's disk quotas are set too low, roaming user profile synchronization might fail. Make sure enough disk space is allocated to allow the system to create a temporary duplicate copy of a user's profile. The temporary profile is created in the user's context as part of the synchronization process, so it debits the user's quota.

**When creating a roaming profile shared directory, limit access to only those users that need access.**

- Because a users roaming profile can contain personal information such as confidential documents and EFS certificates, care should be taken to protect access to the shared directory. Restrict access to the shared directory to only those users that need access. You can also create a security group for users that have profiles on a particular shared directory, and limit access to only those users.
- Only give users the minimum amount of permissions needed.
- When creating the shared directory, hide it by putting a **$** after the share name. This hides the shared directory from casual browsers, and it will not be visible in My Network Places.

**Use at least Windows 2000 servers to host user roaming profile shared directories.**

- Because a users roaming profile contains personal information which is copied to and from a client computer, and the server hosting the roaming profile, it is important to ensure that data is protected as it travels over the network. Potential threats to the privacy and integrity of a user's data come from intercepting the data as it passes over the network, tampering with the data as it passes over the network, and spoofing the server hosting the user's data. Features such as Kerberos, IPSec, and Server Message Block (SMB) signing included in Windows 2000 and the Windows Server 2003 family can help to secure a user's data.

**Always use the NTFS file system for volumes holding user's data.**

- Configure servers hosting roaming profiles to use the NTFS File System. Unlike FAT, NTFS supports Discretionary access control lists (DACLs) and system access control lists (SACLs), which control who can perform operations on a file and what events will trigger logging of actions performed on a file.

# User Profiles How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Create a roaming user profile
- Copy a user profile
- Delete a user profile
- Create a preconfigured user profile
- Create a mandatory user profile
- Add a home folder to a profile
- Switch between a roaming and local user profile

# Create a roaming user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a roaming user profile**

1. Create a folder on the server where user profiles will be stored. This will be the top-level folder that contains all the individual user profiles.

2. Configure the folder as a shared folder and give all users **Full Control** permissions.

3. Open Active Directory Users and Computers and navigate to the individual's User object.

4. Right-click the user's name and click **Properties**.

5. Click the **Profile** tab. For the Profile Path, type the path to the shared folder where the user profile is to be stored. For example, for a user whose network name is pwest, the following path, **\\NetworkShare\Profiles\%username%**, would create a directory called pwest in the Profiles folder on the server used to store user profiles.

## Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- Use a full path in each user account:

  *****Server******ShareName******UserName*

- The user profile path location can be on any server. It does not have to be a domain controller. When the user logs on, Windows checks the user's account to see if a user profile path exits. If it does, the user profile is located by the system and copied to the local computer.

- To provide better security, user profiles and home folders should be created on an NTFS volume.

- The user account can be created in any organizational unit or container within the domain. The default location for the user account is the Users folder.

- The Windows Server 2003 family does not support the use of encrypted files within the roaming user profile.

- Roaming user profiles that are used with Terminal Services clients are not replicated to the server until the interactive user logs off and the interactive session is closed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**Concepts**

Using roaming user profiles
Working with MMC console files
Add a home folder to a profile

# Copy a user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a user profile**

1. Open System in Control Panel.
2. On the **Advanced** tab, under **User Profiles**, click **Settings**.
3. Under **Profiles stored on this computer**, click the user profile you want to copy, and then click **Copy To**.
4. Do one or more of the following:

   **To specify where the new profile will be saved**

   - In **Copy profile to**, type the location for the new profile, or click **Browse** to select the path.

   **To specify who is permitted to use the copied profile**

   a. In **Permitted to use**, click **Change**.

   b. In the **Select User or Group** dialog box, in **Enter the object name to select**, add the user, group, or built-in security principle or click **Object Types** to select an object type.

      To specify a domain to search, in the **Select User or Group** dialog box, click **Locations**, and then select the domain.

      To further narrow your search, in the **Select User or Group** dialog box, click **Advanced**.

   c. Click **OK**

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open System, click **Start**, click **Control Panel**, and then double-click **System**.
- To open System from a command line as an administrator, type:

  **runas /user:** *computername* **\Administrator "rundll32.exe shell32.dll,Control_RunDLL sysdm.cpl"**

- You cannot copy or delete a user profile that belongs to the currently logged on user or any user whose profile is in use.
- If you copy the profile to a new location, you must update the **User Profile Path** entry for the user's account to refer to this new location as well.
- You cannot use Windows Explorer or any other file management utility to copy user profiles.
- You can issue a network default user profile for all new users in the domain. For more information about creating a

preconfigured user profile, see **Related Topics**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delete a user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delete a user profile**

1. Open System in Control Panel.
2. On the **Advanced** tab, under **User Profiles**, click **Settings**.
3. Under **Profiles stored on this computer**, click the user profile you want to delete, and then click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open System, click **Start**, click **Control Panel**, and then double-click **System**.
- To open System from a command line as an administrator, type:

  **runas /user:** *computername* **\Administrator "rundll32.exe shell32.dll,Control_RunDLL sysdm.cpl"**

- You cannot copy or delete a user profile that belongs to the currently logged on user or any user whose profile is in use.
- You can delete a roaming user profile by taking ownership of the profile's folder on the domain controller and then deleting it. This does not remove roaming profile information that has been downloaded to any of the computers in that domain. Downloaded profile information must be deleted individually from each computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a preconfigured user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a preconfigured user profile**

1. Create a new user account that will be used as a template for the preconfigured user profile.

   For more information, see Create a local user account.

2. Log on as the new user, then customize the desktop and install applications to configure this user's profile for the user profile template.

3. Log off, and then log on as the administrator.

4. Open System in Control Panel.

5. On the **Advanced** tab, under **User Profiles**, click **Settings**.

6. Under **Profiles stored on this computer**, select the user that you created in step 1, and click **Copy To**.

   - If you want a domain-wide default profile, enter the path to NETLOGON\Default User on the domain controller. This creates the default user profile for the domain.

   - If you want to change the default profile for the local computer only, copy the profile to the *systemroot*\Documents and Settings\Default User folder.

7. In the **Copy To** dialog box, under **Permitted to use**, click **Change**.

8. In the **Select User or Group** dialog box, in **Enter the object name to select**, type **Everyone**.

   This sets the profile as the default for everyone in this domain.

### Caution

- If you are using a roaming profile and install a program on one computer while simultaneously logged on to another computer, you might overwrite crucial program-related registry settings stored in your roaming profile, thus preventing you from running those programs.

  For example: You are logged on to computer A and computer B. You install a program on computer B and then log off computer B. Computer B stores the shortcuts for the application, and the registry is saved to your roaming profile. Computer A does not get updated profile information until you log off and log on again.

  When you log off from computer A, however, the computer writes to the registry stored in the roaming profile (which now includes the Microsoft Windows Installer (MSI) registration for the program you installed on computer B) with the stale registry information from computer A. The program shortcuts remain in your roaming profile but the Windows Installer data stored in the registry settings is lost, preventing you from running the programs.

  You can repair your roaming profile by repairing or reinstalling the program on computer B or by installing the program on computer A.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have

been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- To open System, click **Start**, click **Control Panel**, and then double-click **System**.

- To open System from a command line as an administrator, type:

  **runas /user:** *computername* **\Administrator "rundll32.exe shell32.dll,Control_RunDLL sysdm.cpl"**

- You cannot copy or delete a user profile that belongs to the currently logged on user or any user whose profile is in use.

- The first time a user logs on, a copy of the preconfigured user profile is returned from the server instead of a copy of the default profile on the local computer. Thereafter, the user profile functions the same as a standard roaming user profile does. Each time the user logs off, the user profile is saved locally and is also copied to the server.

- The Windows Server 2003 family of operating systems does not support the use of encrypted files within the roaming user profiles.

- Roaming user profiles used with Terminal Services clients are not replicated to the server until the interactive user logs off and the interactive session is closed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Using roaming user profiles

# Create a mandatory user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a mandatory user profile**

1. Open Active Directory Users and Computers.
2. In the details section, right-click the applicable user account, and then click **Properties**.

   **Where?**

   - Active Directory Users and Computers/applicabledomain/applicable container (such as Users)/applicable user account

3. Click the **Profile** tab.
4. In **Profile path**, type the path information ending with the .man file name extension.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- A mandatory user profile is a preconfigured user profile. The user can still modify the desktop, but the changes are not saved when the user logs off. The next time the user logs on, the mandatory user profile is downloaded again. User profiles become mandatory when you rename the NTuser.dat file on the server to NTuser.man. This extension makes the user profile read-only.
- Mandatory user profiles do not allow changes to be applied to the user profile stored on the server.
- Profile management should be done preferentially by policy. Mandatory profile use, although permitted, is less manageable and more prone to create administration problems, thus it is not recommended.
- Use a full path in each user account:

  *****Server******ShareName******UserName*

  For *ShareName*, create a Profiles folder if it does not already exist, and share the folder with authenticated users allowing read-only permissions. The shared folder must be created before the user profile can be used.

- To provide better security, user profiles and home folders should be created on an NTFS volume.
- When creating a mandatory profile, make sure you set the appropriate access permissions for the user or groups of users who will use this profile.
- You can also create a mandatory user profile by using Windows Explorer to rename the NTuser.dat file to NTuser.man.
- The administrator can assign the same mandatory user profile to as many users as needed.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a home folder to a profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a home folder to a profile**

1. Open Active Directory Users and Computers.
2. In the details section, right-click the applicable user account, and then click **Properties**.

   **Where?**

   - Active Directory Users and Computers/*applicable domain*/*applicable container* (such as Users)/*applicable user account*

3. Click the **Profile** tab.
4. In **Home Folder**, type the directory folder path information.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- The Windows Server 2003 family includes a folder called My Documents, which offers an alternative to home folders, but does not replace them. All users have a My Documents folder in their user profile.
- To provide better security, user profiles and home folders should be created on an NTFS volume.
- Users can change the target folder location of their My Documents folders by clicking **Start**, right-clicking **My Documents**, clicking **Properties**, and then specifying a new location in **Target**. This capability can be enabled or disabled by the system administrator.
- You can use Group Policy to change the target folder location of any user's My Documents folder, disable a user's ability to change the target folder location, remove the My Documents icon from the desktop, and choose whether programs use My Documents or a different folder as the default location for opening and saving files.
- If you do not assign a home folder, the system uses the local user profile folder as the home folder (by default, *systemdrive*\Documents and Settings*UserName*). The home directory can use the same location as the My Documents folder.
- When you use Terminal Services on computers running Windows Server 2003 operating systems, the user profile is the default home directory.
- When creating the user's home folder, the folder corresponding to the user's account name is immediately created if it does not exist. This is in contrast to roaming user profiles, where the profile folder for the user is created after the user logs on.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Switch between a roaming and local user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To switch between a roaming and local user profile**

1. Open System in Control Panel.
2. On the **Advanced** tab, under **User Profiles**, click **Settings**.
3. Under **Profiles stored on this computer**, click the user profile you want to change, and then click **Change Type**.
4. Select **Roaming profile** or **Local profile**.

## Notes

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.
- To open System, click **Start**, click **Control Panel**, and then double-click **System**.
- To open System from a command line as an administrator, type:

  **runas /user:** *computername* **\Administrator "rundll32.exe shell32.dll,Control_RunDLL sysdm.cpl"**

- If **Roaming profile** is unavailable, the profile is a local user profile. For more information about how to create roaming user profiles, see **Related Topics**.
- If you use a roaming user profile on more than one computer simultaneously, the profile preserves the registry settings from the computer you log off from last.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# User Profiles Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about user profiles.

- New features and changes to user profiles
- User profiles overview
- Understanding User Profiles
- Using User Profiles

# New features and changes to user profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features and changes to user profiles**

The following new features and changes in the Windows Server 2003 family affect user profiles:

**New location for User Profile configuration**

User profiles is located on the **Advanced** tab of the **System Properties** dialog box.

**Error Message changes**

All events have unique identifications and details.

**Roaming profiles are saved to the server at logoff with user registry keys open**

Previously, applications that kept registry keys open at logoff time prevented the system from saving any changes to roaming profiles until those registry keys were closed. With the Windows Server 2003 family, roaming profiles that are changed during a session will save these changes even if registry keys are open.

**Delete and Copy To button availability**

The **Delete** and **Copy To** buttons are unavailable for the profile belonging to the currently logged on user or for any user whose profile is in use.

**Group Policy changes**

The following changes to Group Policy in the Windows Server 2003 family affect user profiles:

- User profiles policies now have their own node in the Group Policy.

  **Where?**

  - *Group Policy object*/User Configuration or Computer Configuration/Administrative Templates/System/User Profiles

- **Prevent Roaming Profile changes from propagating to the server--**This policy determines if the changes a user makes to their roaming profile are merged with the server copy of their profile. If this policy is set at user logon, the user will receive their roaming profile, but any changes a user makes to their profile will not be merged to their roaming profile at logoff.

- **Add the Administrator security group to roaming user profiles--**This policy allows an administrator to choose the same behavior as Windows NT version 4.0, and permit the administrators group to have full control of the user's profile directories. In Windows 2000, the default file permissions for newly generated roaming profiles are full control, or read and write access for the user, and no file access for the Administrators group.

- **Only allow local user profiles--**This setting determines whether roaming user profiles are available on a particular computer. By default, when roaming profile users log on to a computer, their roaming profile is copied to the local computer. By using this setting, an administrator can prevent users configured to use roaming profiles from receiving their roaming profile on a specific computer.

# User profiles overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User profiles overview**
On computers running Windows Server 2003 operating systems, user profiles automatically create and maintain the desktop settings for each user's work environment on the local computer. A user profile is created for each individual user when the user logs on to a computer for the first time.

**Advantages of using user profiles**
User profiles provide several advantages:

- More than one user can use the same computer. When users log on to their individual workstations, they receive the desktop settings as they existed when they logged off.
- Customization of the desktop environment made by one user does not affect another user's settings.
- User profiles can be stored on a server so that they can follow users to any computer running a Microsoft® Windows NT® or later operating system on the network. These are called roaming user profiles.

As an administrative tool, user profiles provide these options:

- You can create a default user profile that is appropriate for the user's tasks.
- You can set up a mandatory user profile that does not save changes made by the user to the desktop settings. Users can modify the desktop settings of the computer while they are logged on, but none of these changes are saved when they log off. The mandatory profile settings are downloaded to the local computer each time the user logs on. For more information on mandatory profiles, see Create a mandatory user profile.
- You can specify the default user settings that will be included in all of the individual user profiles.

**User profile types**
A user profile defines customized desktop environments, which include individual display settings, network and printer connections, and other specified settings. You or your system administrator can define your desktop environment.

Types of user profiles include:

- **Local user profile--**A local user profile is created the first time you log on to a computer and is stored on a computer's local hard disk. Any changes made to your local user profile are specific to the computer on which you made the changes.
- **Roaming user profile--**A roaming user profile is created by the system administrator and is stored on a server. This profile is available every time you log on to any computer on the network. Changes made to your roaming user profile are updated on the server.
- **Mandatory user profile--**A mandatory user profile is a roaming profile that can be used to specify particular settings for individuals or an entire group of users. Only system administrators can make changes to mandatory user profiles.
- **Temporary user profile--**A temporary profile is issued any time that an error condition prevents the users profile from being loaded. Temporary profiles are deleted at the end of each session. Changes made by the user to their desktop settings and files are lost when the user logs off.

# Understanding User Profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding user profiles**
This section covers:

- Contents of a user profile
- Settings saved in a user profile

# Contents of a user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Contents of a user profile**

Every user profile begins as a copy of Default User, which is a default user profile stored on each computer running a Windows Server 2003 family operating system. The NTuser.dat file within Default User contains Windows Server 2003 family configuration settings. Every user profile also uses the common program groups contained in the All Users folder.

The user profile folders contain various items including the desktop and Start menu. The following table lists and describes the contents of each user profile folder.

| User profile folder | Contents |
|---|---|
| Application Data | Program-specific data (for example, a custom dictionary). Program vendors decide what data to store in this user profile folder. |
| Cookies | User information and preferences. |
| Desktop | Desktop items, including files, shortcuts, and folders. |
| Favorites | Shortcuts to favorite locations on the Internet. |
| Local Settings | Application data, history, and temporary files. Application data roams with the user by way of roaming user profiles. |
| My Documents | User documents and subfolders. |
| My Recent Documents | Shortcuts to the most recently used documents and accessed folders. |
| NetHood | Shortcuts to My Network Places items. |
| PrintHood | Shortcuts to printer folder items. |
| SendTo | Shortcuts to document-handling utilities. |
| Start Menu | Shortcuts to program items. |
| Templates | User template items. |

**NTuser.dat file**

The NTuser.dat file is the registry portion of the user profile. When a user logs off of the computer, the system unloads the user-specific section of the registry (that is, **HKEY_CURRENT_USER**) into NTuser.dat and updates it. For more information about the registry, see Registry structure.

**All Users folder**

Although they are not copied to user profile folders, the settings in the All Users folder are used to create the individual user profiles. The Windows Server 2003 family supports two program group types:

- Common program groups are always available on a computer, no matter who is logged on.
- Personal program groups are private to the user who creates them.

Common program groups are stored in the All Users folder under the Documents and Settings folder. The All Users folder also contains per-computer settings for the Desktop and the **Start** menu.

## Notes

- The My Documents, My Pictures, Favorites, Start Menu, and Desktop folders are the only folders displayed in Windows Explorer by default. The NetHood, PrintHood, Local Settings, Recent, and Templates folders are hidden and do not appear in Windows Explorer. To view these folders and their contents in Windows Explorer, on the **Tools** menu, point to **Folder options**, click the **View** tab, and then click **Show hidden files and folders**.

- On computers running Windows Server 2003 operating systems with the NTFS file system, only members of the Administrators group can create, delete, or modify the common program groups.

# Settings saved in a user profile

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Settings saved in a user profile**

A user profile contains configuration preferences and options for each user.

The following table is a sample of the settings that are contained in a user profile.

| Source | Parameters saved |
|---|---|
| Windows Explorer | All user-definable settings for Windows Explorer. |
| My Documents | User-stored documents. |
| My Pictures | User-stored picture items. |
| Favorites | Shortcuts to favorite locations on the Internet. |
| Mapped network drive | Any user-created mapped network drives. |
| My Network Places | Links to other computers on the network. |
| Desktop contents | Items stored on the Desktop and shortcuts. |
| Screen colors and fonts | All user-definable computer screen colors and display text settings. |
| Application data and registry hive | Application data and user-defined configuration settings. |
| Printer settings | Network printer connections. |
| Control Panel | All user-defined settings made in Control Panel. |
| Accessories | All user-specific program settings affecting the user's Windows environment, including Calculator, Clock, Notepad, and Paint. |
| Windows Server 2003 family-based programs | Any program written specifically for Windows Server 2003 family can be designed so that it tracks program settings on a per-user basis. If this information exists, it is saved in the user profile. |
| Online user education bookmarks | Any bookmarks placed in the Windows Server 2003 family Help system. |

**Note**

- The My Documents, My Pictures, Favorites, Start Menu, and Desktop folders are the only folders displayed in Windows Explorer by default. The NetHood, PrintHood, Recent, and Templates folders are hidden and do not appear in Windows Explorer. To view these folders and their contents in Windows Explorer, from the **Tools** menu, point to **Folder options**, click the **View** tab, and then click **Show hidden files and folders**.

# Using User Profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using user profiles**
This section covers:

- Using roaming user profiles
- Local user profiles

# Using roaming user profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using roaming user profiles**

Roaming user profiles enable users to log on to computers in a domain while preserving their user profile settings. User profiles are stored at an administrator specified server location. When a user logs on and has been authenticated within the directory service, the user profile, including user settings and documents, are copied to the local computer. User profile changes made on the local computer are then captured. Changes will then be copied to the user profile stored on the server and be applied the next time the user logs on. Mandatory user profiles are similar, but do not allow changes to be copied to the user profile stored on the server. For more information about implementing roaming user profiles, see Create a roaming user profile and Create a mandatory user profile.

From Active Directory, you can assign a server location for user profiles. If you type a user profile path into a user's domain account, a copy of the user's local user profile is saved both locally and in the user profile path location when the user logs off. The next time that user logs on, the profile stored in the user profile path location is compared to the copy in the local user profile folder, and the most recent copy of the profile is opened. The local user profile becomes a roaming user profile because of the centralized domain location. The user's settings and documents are available wherever the user logs on.

If the server is not available, the local cached copy of the roaming user profile is used. If the user has not logged on to the computer before, a new local user profile is created. In either case, if the centrally stored user profile is not available when the user logs on, it is not updated when the user logs off. If the user profile is not downloaded because of server problems, it is not loaded when the user logs off.

# Local user profiles

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local user profiles**

The location of a user profile depends on whether the user is starting from a clean installation of a Windows Server 2003 family operating system or an upgrade from a previous version of Windows. The following table lists the operating system and the location of user profiles for that scenario.

| Operating system | User profile location |
|---|---|
| Windows Server 2003 family clean installation (no previous operating system) | *systemdrive*\Documents and Settings (for example, C:\Documents and Settings) |
| Windows Server 2003 family upgrade from Windows 2000 | *systemdrive*\Documents and Settings (for example, C:\Documents and Settings) |
| Windows Server 2003 family upgrade from Windows NT 4.0 | *systemroot*\Profiles (for example, C:\Windows or C:\WINNT\Profiles) |
| Windows Server 2003 family upgrade from Windows NT 3.51 | *systemdrive*\Documents and Settings (for example, C:\Documents and Settings) |
| Windows Server 2003 family upgrade from Windows 95 or Windows 98 | *systemdrive*\Documents and Settings (for example, C:\Documents and Settings) |

When no preconfigured server-based roaming user profile exists for a user, a user profile folder is created for that user when the user logs on to the computer for the first time. The contents of the Default User folder are then copied to the new user profile folder. The user profile, along with the common program group settings in the All Users folder, creates the user's desktop. When the user logs off, any changes made to the default settings during the session are saved to the new user profile folder. The user profile in the Default User folder remains unchanged.

If the user has a user account on the local computer in addition to a domain user account, or more than one domain user account, the local user profile is different for each account because different user profiles are generated for each user who logs on. When the user logs off, changed settings are saved to only one user profile, depending on which account the user used to log on to the computer.

# Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network Connections**
Network Connections provides connectivity between your computer and the Internet, a network, or another computer. With Network Connections, you can configure settings to reach local or remote network resources or functions.

Network Connections combines Microsoft® Windows® NT 4.0 Dial-Up Networking with features that were formerly located in the Network Control Panel, such as network protocol and service configuration. Each connection in the Network Connections folder contains a set of features that creates a link between your computer and another computer or network. By using Network Connections, performing a task, such as modifying a network protocol, is as easy as right-clicking a connection and then clicking **Properties**.

- Before using Network Connections, see Checklist: Configuring network connections.
- Before setting up a home or small office network, see Checklist: Setting up a home or small office network.
- To find features that have been moved, see New ways to do Network Connections tasks.
- For tips about using Network Connections, see Network Connections Best Practices.
- For help with specific tasks, see Network Connections How To....
- For general background information, see Network Connections Concepts.
- For problem-solving instructions, see Network Connections Troubleshooting.

# Checklist: Configuring network connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Configuring network connections**

| | Step | Reference |
|---|---|---|
| | Review key concepts. | Network Connections Overview |
| | Connect to a local area network. | Make a local area connection |
| | Connect to a network by using a phone line. | Make a dial-up connection by using a phone line;<br>Connect to a remote network |
| | Connect to an Internet service provider (ISP). | Make an Internet connection;<br>Connect to a remote network |
| | Connect to a private network through the Internet (virtual private network). | Make a virtual private network (VPN) connection;<br>Connect to a remote network |
| | Create a direct connection to another computer. | Make a direct network connection;<br>Connect to a remote network |
| | Let other computers connect to this computer. | Accept incoming network connections |
| | Monitor a connection. | Monitor a connection |

# Checklist: Setting up a home or small office network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Setting up a home or small office network**

| Step | Reference |
|---|---|
| Decide whether to use home and small office networking or Routing and Remote Access for your home or small office network. | Home and small office networking compared to Routing and Remote Access |
| If you decide to use home and small office networking, review home and small office networking concepts. | Home and Small Office Networking; Using Home and Small Office Networking Features |
| Decide how you want to save your Internet connection credentials (you will be prompted to select credential settings when you fist attempt to activate your Internet connection or when you run the New Connection Wizard). | Dial-up credentials |
| Familiarize yourself with the icons that indicate that Internet Connection Firewall (ICF), Windows Firewall, Network Bridge, or Internet Connection Sharing (ICS) have been enabled on a network connection. | Network connection icons |
| Enable ICF or Windows Firewall to protect your home or small office network. | Enable or disable ICF |
| Set up Network Bridge to connect network segments. | Set up Network Bridge |
| Enable ICS to provide a shared Internet connection. | Enable ICS |

**Notes**

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

# New ways to do Network Connections tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**

This table lists common tasks for Network Connections. The user interface for performing these tasks is different in this version of Windows from the way it was in Windows NT version 4.0.

**Note**

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0 use | In this version of Windows use |
|---|---|---|
| Connect to a dial-up server | **Dial-Up Networking** in My Computer | Network Connections. For more information, see Connect to a remote network. |
| Connect to a network by using a modem or ISDN line | **Dial-Up Networking** in My Computer (click **New**) | Network Connections. For more information, see Make a dial-up connection by using a phone line. |
| Connect to a network by using a virtual private network (VPN) | **Dial-Up Networking** in My Computer (click **New**) | Network Connections. For more information, see Make a virtual private network (VPN) connection. |
| Configure a computer for incoming connections | **Network** in Control Panel | Network Connections. For more information, see Accept incoming network connections. |
| Configure the TCP/IP protocol | **Network** in Control Panel | Network Connections. For more information, see Configure TCP/IP settings. |
| Configure a connection | **Dial-Up Networking** in My Computer (click **More**) | Network Connections. For more information, see Configure a connection to a remote network. |
| Add a client or service | **Network** in Control Panel | Network Connections. For more information, see Add a network component. |
| Add a protocol | **Network** in Control Panel | Network Connections. For more information, see Add a network component. |
| Add optional networking components | **Network** in Control Panel | Network Connections. For more information, see Add optional networking components. |
| Monitor incoming or outgoing connections | **Dial-Up Monitor** in Control Panel | Network Connections. For more information, see Monitor a connection. |

# Network Connections Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

The following list provides best practices for implementing Network Connections:

- **When using multiple network adapters, rename each local area connection.**

  Your operating system detects network adapters and automatically creates a local area connection in the Network Connections folder for each network adapter. If more than one network adapter is installed, you can eliminate possible confusion by immediately renaming each local area connection to reflect the network that it connects to.

  You need to add or enable the network clients, services, and protocols that are required for each connection. When you do so, the client, service, or protocol is added or enabled in all other network and dial-up connections.

- **Verify required connection settings for your network adapter.**

  If your network administrator or Internet service provider (ISP) requires static settings, you may need one or more of the following:

  - A specific IP address.
  - DNS addresses.
  - DNS domain name.
  - Default gateway address.
  - WINS addresses.

  DHCP is enabled by default. This gets your IP address and other configuration information automatically. Automated IP settings are used for all connections, and they eliminate the need to configure settings such as DNS, WINS, and so on.

  For more information about enabling DHCP, see Configure TCP/IP settings.

- **Create dial-up, VPN, or direct connections by using the New Connection wizard.**

  After you create a connection, you can copy the connections, rename them and modify the connection settings. By doing so, you can easily create different connections to accommodate multiple modems, ISPs, dialing profiles, and so on.

  For more information, see Copy a network or dial-up connection.

- **Specify the order in which network providers and protocols are accessed.**

  By changing the order of protocols bound to those providers, you can improve performance. For example, if your LAN connection is enabled to access NetWare and Microsoft Windows networks, which use IPX and TCP/IP, but your primary connection is to a Microsoft Windows network that uses TCP/IP, you can move **Microsoft Windows Network** to the top of the **Network providers** list on the **Provider Order** tab, and move **Internet Protocol (TCP/IP)** to the top of the **File and Printer Sharing for Microsoft Networks** binding on the **Adapters and Bindings** tab.

  The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

  For more information about modifying the order of network providers, see Modify the network provider order. For more information about modifying the order of protocol bindings, see Modify the protocol bindings order.

- **Only install and enable the network protocols that you need.**

  Limiting the number of protocols on your computer enhances its performance and reduces network traffic.

  If your computer encounters a problem with a network or dial-up connection, it attempts to establish connectivity by using every network protocol that is installed and enabled. By only installing and enabling the protocols that your system can use, the operating system does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.

# Network Connections How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Connect to a remote network
- Disconnect from a remote network
- Add optional networking components
- Make Network and Dial-up Connections
- Configure Network and Dial-up Connections
- Monitor Network Connections
- Set up and Manage Home and Small Office Networking

# Connect to a remote network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To connect to a remote network**

1. Open Network Connections.

2. Double-click the connection you want to connect to the network.

3. If you are prompted, in the **Connect***connection type* dialog box, type your user name, password, and logon domain.

   If **Logon domain** does not appear in this dialog box, and you want to log on to a domain, type your user name and the domain name in one of two ways:

   - Your user principal name prefix (your user name) and your user principal name suffix (your domain name), joined by the "at" sign (@). For example, user@sales.westcoast.microsoft.com.

   - Your domain name and your user name, separated by the backslash (\) character. For example, sales\user.

     Note that the suffix in the first example is a fully-qualified DNS domain name. Your administrator might have created an alternative suffix to simplify the logon process. For example, creating a user principal name suffix of "microsoft" allows the same user to log on by using the much simpler user@microsoft.com. For more information, see your system administrator.

   Instead of having to type your domain name, you can also enable Windows to include your logon domain to the **Connect***connection type* dialog box.

   a. Click **Properties** if the button is enabled.

   b. On the **Options** tab, select the **Include Windows logon domain** check box.

   Once you are connected to the network, you can minimize your connection window and use e-mail, Windows Explorer, and so on.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- To connect to a remote network you can also right-click the connection that you want to connect to the network and click **Connect**.

- Authentication happens at two levels: logging on to the local computer domain and logging on as a valid user.

- If you are on a local area network, your computer logs on to the local computer domain automatically even before you see the logon prompt. When you type your user credentials at the logon prompt, the computer checks your user credentials, opens a user context, and makes your personal data available to you. You are now logged on at both levels.

- If you are not on a local area network, the attempt to log on to the local computer domain fails silently. In this case, user logon can proceed in two ways.

  - When you log on at the logon prompt, the computer checks your cached credentials from the last time you were actually online with the domain controller. If they match, a user context associated with your name is opened. You

are now logged on to the computer as a valid user but you are not logged on to the network. To access your personal files you can now create a remote access connection by using your remote access credentials or by using your cached credentials if your computer is a member of the domain.

- Select the **Log on using dial-up networking** check box if your computer is a member of the domain. In this case, the computer will attempt to make a remote access connection before processing your credentials. Once connected it uses the user logon credentials as though you were on a local area network.

- The logon domain name you type should name the domain that the server is in. This is not the DNS domain name given by some PPP/SLIP providers.

- If you are using IP connectivity on your local network connection and on your remote connection, you may not be able to see all computers on your local network. This is because after you connect, your remote connection becomes your default path for network routing. Consequently, you see computers on the remote network, and you see other computers on the same LAN segment to which your computer is connected. But you cannot communicate with computers on networks that were previously reached through a router on your local LAN.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Disconnect from a remote network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To disconnect from a remote network**

1. Open Network Connections.
2. Right-click the connection you want to disconnect, and then click **Disconnect**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you disable a local area connection, it disables the network adapter driver until the connection is reactivated.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add optional networking components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add optional networking components**

1. Open Network Connections.
2. On the **Advanced** menu, click **Optional Networking Components**.
3. Do one of the following:
   - To install all optional networking components, select the **Management and Monitoring Tools**, **Networking Services**, and **Other Network File and Print Services** check boxes, and then click **Next**.
   - To install specific optional networking components, select its corresponding check box, and then click **Details**.

     In **Subcomponents of***component*, select the check boxes next to the components you want to install, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Examples of optional networking components include Simple Network Management Protocol (SNMP), Simple TCP/IP Services, and Print Services for UNIX.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make Network and Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make network and dial-up connections**

- Make a virtual private network (VPN) connection
- Make a local area connection
- Manage Network Connections
- Set up ISDN Connections
- Set up Dial-up Connections
- Configure Dial-up Options
- Make Internet Connections
- Make Direct Network Connections
- Set up Incoming Connections

# Make a virtual private network (VPN) connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a virtual private network (VPN) connection**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Connect to the network at my workplace**, and then click **Next**.
4. Click **Virtual Private Network connection**, and click **Next**.
5. Type a name for this connection in **Company Name**, and click **Next**.
6. If you have already established a dial-up connection, do one of the following:
   - If you need to establish a connection with your ISP or some other network before tunneling to your destination computer or network, click **Automatically dial this initial connection**, click a connection in the list, and then click **Next**.
   - If you do not want to automatically dial an initial connection, click **Do not dial the initial connection**, and then click **Next**.
7. Type the host name or IP address of the VPN server to which you are connecting, and then click **Next**.
8. Do one of the following:
   - If you want this connection to be made available to all users on this computer, click **Anyone's use**, and then click **Next**.
   - If you want to reserve the connection for your own use, click **My use only**, and then click **Next**.
9. If you want to create a shortcut for this connection on your desktop, select the **Add a shortcut to this connection to my desktop** check box.
10. Click **Finish**.

### Notes

- To make the connection available to all users, you must be logged on as Administrator or as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can create multiple VPN connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple hosts, security options, and so on.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a local area connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a local area connection**

- Typically, most computers running a member of the Windows Server 2003 family are connected to a local area network. When you start your computer, your network adapter is detected and the local area connection automatically starts. Unlike other types of connections, the local area connection is created automatically, and you do not have to click the local area connection in order to start it.

Once the local area connection is running, you can choose to disable it. To do so, do the following.

1. Open Network Connections.
2. Right-click the **LAN or High Speed Internet** connection that you want to disable.
3. Click **Disable**.

If you need to enable a disabled **LAN or High Speed Internet** connection, do the following.

1. Right-click the connection that you want to enable.
2. Click **Enable**.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- A local area connection is automatically created for each network adapter that is detected.
- If more than one network adapter is installed, you can eliminate possible confusion by immediately renaming each local area connection to reflect the network that it connects to.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage network connections**

- Copy a network or dial-up connection
- Show a network connection icon in the notification area
- Rename a network connection icon
- Repair a LAN or high-speed Internet connection

# Copy a network or dial-up connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To copy a network or dial-up connection**

1. Open Network Connections.
2. Right-click your dial-up, VPN, or direct connection, and then click **Create Copy**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You cannot copy local area and incoming connections.
- You can create multiple dial-up, virtual private network, or direct connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple modems, ISPs, dialing profiles, and so on.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Show a network connection icon in the notification area

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To show a network connection icon in the notification area**

1. Open Network Connections.
2. Right-click the icon for the network connection that you want to display in the notification area, and then click **Properties**.
3. Select the **Show icon in notification area when connected** check box, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If a network connection icon is displayed in the notification area, you can access basic connection and statistical information by pointing to the icon.
- If the **Show icon in notification area when connected** check box is selected for the shared Internet connection, an icon for the shared Internet connection appears in the notification area each time that connection is enabled. When the shared Internet connection is disabled, the icon disappears from the notification area.
- It is a good practice to select this check box when you are using wireless connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Rename a network connection icon

# Rename a network connection icon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename a network connection icon**

1. Open Network Connections.
2. Right-click the icon for the network connection that you want to rename, and click **Rename**.
3. Type a new name for the selected network connection icon.

## Notes

- You must be logged on as a member of the Administrators group to rename a network connection icon. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should rename each network connection icon with a name that is easy to remember.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Repair a LAN or high-speed Internet connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To repair a LAN or high-speed Internet connection**

1. Open Network Connections.
2. Before using the **Repair** option, try the following steps:
   - Check the status indicator lights on the DSL or cable modem to verify that the connection to your Internet service provider (ISP) is working.
   - Turn off the DSL or cable modem, and then turn it on again.
   - If your Internet connection is not working after these steps, contact your ISP.
3. If media is connected properly, under **LAN or High-Speed Internet**, right-click the connection that you want to repair, and then click **Repair**.

## Notes

- You must be a member of the Administrators group, the Power Users group, or the Network Configuration Operators group to complete this procedure. For more information, see Default local groups and Default groups.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you have more than one network adapter installed in your computer, it is recommended that you rename your Internet connection to easily identify it. For example, you could call your Internet connection "Internet connection" or use the name of your ISP.
- The **Repair** option is not available for media disconnected connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up ISDN Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up ISDN connections**

- Make a dial-up connection by using an ISDN line
- Install an ISDN adapter
- Configure ISDN settings

# Make a dial-up connection by using an ISDN line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a dial-up connection by using an ISDN line**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. In **Network Connection Type**, do one of the following:
   - Click **Connect to the Internet**. In **Internet Connection**, click **Connect using a dial-up modem**, and then click **Next**.
   - Click **Connect to the network at my workplace**. In **Network Connection**, click **Dial-up connection**, and then click **Next**.
4. Follow the instructions in the New Connection wizard.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Install an ISDN adapter

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install an ISDN adapter**

1. Install an Integrated Services Digital Network (ISDN) adapter and start your computer. If you install more than one ISDN adapter, you must restart your computer after you have installed the ISDN drivers. Otherwise, all available ISDN ports may not show up when you configure your network connection for ISDN.

2. You can use Device Manager to configure your system so that your ISDN adapter knows what type of telephone switch it is connected to. The switch type simply refers to the brand of equipment and software revision level that the telephone company uses to provide you with ISDN service. There are only a few types of switches in the world and usually just one in countries/regions other than the United States.

## Notes

- To use Device Manager, you must be logged on as an administrator or a member of the Administrators group.

- To open Device Manager, click **Start**, right-click **My Computer**, click **Manage**, and then click **Device Manager**.

- If your ISDN adapter is internal to your computer, it appears in **Network adapters**. If the ISDN adapter is external to your computer, it appears in **Modems**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure ISDN settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure ISDN settings**

1. Open Network Connections.
2. Right-click the dial-up connection that uses ISDN, and then click **Properties**.
3. On the **General** tab, in **Connect using**, click the ISDN device, and then click **Configure**.
4. In the **ISDN Configure** dialog box, do one or both of the following:
   - In **Line type**, click the line type you want to use. The line types are listed from highest to lowest quality.
   - If you want to start negotiation with the line type you selected, and then negotiate with a lower-quality line type depending on the line's condition, select the **Negotiate line type** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Depending on the type of ISDN adapter that you are using, when you click **Configure** in step 3, you may be presented with **Modem Configuration** settings.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a modem for a dial-up connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a modem for a dial-up connection**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **General** tab, under **Connect using**, click the modem you want to configure, and then click **Configure**.
4. Under **Hardware Features**, select the check box options you want to enable.
5. If you want to enable the modem speaker, select the **Enable modem speaker** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To ensure compatibility, you need to use the same kind of modem as the one connected to the remote access server, select the same initial speed, and enable the same features. If you do not select the same model, at least select a modem with the same ITU-T standard as the modem on the server.
- Selecting a feature that is not supported by your modem has no effect on its performance.
- Network Connections automatically configures connections according to the devices that are available. For example, you might use a laptop and docking station when you are in the office, with your connection configured to use the docking station modem. When you are on the road, and the docking station modem is not available, the connection is automatically configured to use the laptop's PCMCIA modem. When you return to the office and re-dock your laptop into its docking station, Network Connections detects that the docking station modem is available again, and automatically reconfigures the connection to use the docking station modem.
- Modem changes made as described in this procedure are unique to this connection. To make global changes, you will need to change each modem.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a dial-up connection by using X.25

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a dial-up connection by using X.25**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. In **Network Connection Type**, click **Connect to the Internet** or **Connect to the network at my workplace**, and then click **Next**.
4. In **Network Connection**, click **Connect using a dial-up modem** or **Dial-up connection**, and then click **Next**.
5. Follow the instructions in the New Connection wizard.
6. When the wizard is finished, right-click the new connection, and then click **Properties**.
7. On the **Options** tab, click **X.25**.
8. In **Network**, click your X.25 network provider.
9. In **X.121 address**, type the X.121 address (the X.25 equivalent of a phone number) for the server you want to call.
10. If required by the X.25 host computer, in **User Data**, type additional connection information.
11. In **Facilities**, type any additional facility options you want to request from your X.25 provider. (For example, some providers support the **/r** option to specify reverse charging.)

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- For details on facility options, consult your X.25 documentation or provider.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Start Remote Access Auto Connection Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Remote Access Auto Connection Manager**

1. Open Computer Management.
2. In the console tree, click **Services**.

   **Where?**

   - Computer Management/Services and Applications/Services

3. In the details pane, right-click **Remote Access Auto Connection Manager**, and then click **Start**.

   Under the **Status** column, **Started** appears.

### Note

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Configure redial options

# Configure Dial-up Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure dial-up options**

- Configure client callback options
- Configure autodial
- Enable logging
- Enable multiple device dialing
- Configure phone number modifiers
- Configure redial options
- Assign multiple phone numbers to a connection
- Enable operator-assisted calls or manual dialing

# Configure client callback options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure client callback options**

1. Open Network Connections.
2. On the **Advanced** menu, click **Remote Access Preferences**.
3. On the **Callback** tab, do one of the following:
   - If you do not want to use callback, click **No callback**.
   - If you want to decide whether to use callback at the time you connect, click **Ask me during dialing when the server offers**.
   - If you want to consistently use callback, click **Always call me back at the number(s) below**, and select the modem or device you want to be called back.

     If **Phone number** is blank for the device you have selected, click **Edit**, and then type the number.

     If you want to remove a modem or device from the list of possible callback devices, click the modem or device, and then click **Delete**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Your system administrator can override any callback settings that you configure. Through server settings, the administrator can deny the use of callback, allow you to set callback options, or require callback to a particular number. Contact your system administrator to determine your callback options.
- To use callback, Link Control Protocol (LCP) extensions must be enabled.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure autodial

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure autodial**

1. Open Network Connections.
2. On the **Advanced** menu, click **Remote Access Preferences**.
3. On the **Autodial** tab, select the check box next to the location where you want to enable autodial, and then click **OK**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Autodial is enabled by default in Windows XP. In support of this feature, the Remote Access Auto Connection Manager is also started by default.
- Autodial maps the resources that are required to initially make a connection, but it does not map resources after the connection is made. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable logging

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable logging**

1. Open Network Connections.
2. On the **Advanced** menu, click **Remote Access Preferences**.
3. On the **Diagnostics** tab, do one or more of the following:
   - To enable logging for all remote access connections, select the **Enable logging** check box.
   - To clear logs created during a previous connection, click **Clear Log**.
   - To generate a report, click **Generate Report**.
4. If you clicked **Generate Report** in the previous step, do one of the following:
   - To view the diagnostic report, click **View report**.
   - To save the report to a file, click **Save report to this file**, and specify the location and the name of the file you want to create. Specify the location by typing it or by clicking **Browse** and browsing to the location you want.
   - To send the report to an e-mail address, click **Send report to this e-mail address**, and type the e-mail address to which you want to send the report.
   - To quickly generate a more concise report, select the **Generate summary report** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Creating a diagnostic report in HTML can take several minutes. If you need only configuration and installation information, you can create a summary report.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable multiple device dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable multiple device dialing**

1. Open Network Connections.
2. Right-click the connection on which you want to enable the dialing of multiple devices, and then click **Properties**.
3. On the **Options** tab, in **Multiple devices**, do one of the following:
   - If you want to dial only the first available device, click **Dial only first available device**.
   - If you want to use all of your devices, click **Dial all devices**.
   - If you want to dynamically dial and hang up devices as needed, click **Dial devices only as needed**, and then click **Configure**.

     In **Automatic dialing**, click the **Activity at least** percentage and **Duration at least** time you want to set. Another line is dialed when connection activity reaches this level for the amount of time that you specify.

     In **Automatic hangup**, click the **Activity no more than** percentage and **Duration at least** time you want to set. A device is disconnected when connection activity decreases to this level for at least the amount of time that you specify.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you selected **Dial devices only as needed**, the last multilinked device ignores the **Automatic hangup** setting, and a twenty-minute time-out is used for the last device.
- If you use multiple devices to dial a server that requires callback, then only one of your multilinked devices is called back. This is because only one number is stored in a user account. Therefore, only one device connects and all other devices fail to complete the connection, and your connection loses Multilink functionality.

  You can avoid this problem if the multilinked phonebook entry is an ISDN with two channels that have the same phone number.
- Multiple device dialing is available only if multiple adapters are available on the computer.
- If you select **Dial all devices**, dropped links in the multilinked bundle are not automatically reinitialized. You can force links to reinitialize by selecting **Dial devices only as needed**, then **Configure**, and then setting easily achieved **Automatic dialing** conditions which cause another line to be dialed. For example, set **Activity at least** to 1% and **Duration at least** to 3 seconds.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Using ISDN lines

# Configure phone number modifiers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure phone number modifiers**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **General** tab, modify the phone number by using one or more characters from the following list.

| Character | Function |
|---|---|
| , (comma) | Pauses briefly (two seconds for most modems) before continuing. |
| P | Switches from touch-tone to pulse/rotary dialing. |
| T | Switches from pulse/rotary to touch-tone dialing. |
| $ | Waits for a calling card prompt tone. |

For example, when you dial in from a hotel room, you may have to add 9 to the number you are calling to get an outside line. Your number may look similar to the following:

9,555-0100

The comma after the 9 gives a pause long enough to get an outside line before continuing to dial the full number.

**Notes**

- To configure phone number modifiers, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- By selecting the **Use dialing rules** check box, and then clicking **Dialing Rules**, you can create a **Location** for which specific dialing rules automatically apply. For example, if you frequently connect from home and need to disable call waiting, you can create a location for use from home that automatically dials the code to disable call waiting before the connection call is placed.
- If you see unfamiliar characters being dialed before your number, check to make sure the **Use dialing rules** check box is not selected. If it is selected, a location may be enforcing a dialing rule that you do not need. For example, a location may be selected that always dials 1 to accommodate long distance dialing.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure redial options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure redial options**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **Options** tab, in **Redialing options**, click the arrows to set the number of times the dial-up connection is automatically redialed if the first attempt to connect fails.
4. In **Time between redial attempts**, click the down arrow to set the amount of time to pause between the end of one attempt and the beginning of another.
5. In **Idle time before hanging up**, click the down arrow to set the amount of idle time before a client hangs up a connection.
6. If you want the connection to automatically redial if the line is dropped, select the **Redial if line is dropped** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The **Time between redial attempts** pause lets the device reset itself before redialing. The default is one minute. If that is not enough time, increase this setting. You can also experiment with shorter times, but if you make the pause too short, the device does not have time to reset itself.
- Keep in mind that the remote access server also has a disconnect timer. If **Idle time before hanging up** is set to a high time-out number, there is no guarantee that the connection will not disconnect before the time passes. This is because the server may choose to disconnect you before the time set here.
- If you are using Internet Explorer, the browser's own settings for dial-up connections may conflict with these redial options.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign multiple phone numbers to a connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign multiple phone numbers to a connection**

1. Open Network Connections.
2. Right-click the dial-up connection to which you want to assign multiple phone numbers, and then click **Properties**.
3. On the **General** tab, click **Alternates**.
4. If you want the connection to attempt a different phone number if the first number in the list is not successful, select the **If number fails, try next number** check box.
5. If you want the connection to move the first successful phone number to the top of the list under **Phone numbers** and use it on the next connection attempt, click **Move successful number to top of list**.
6. To add a new phone number to the list, click **Add**, and in **Phone number**, type the phone number.
7. If you want the connection to use established area code and dialing rules, select the **Use dialing rules** check box.
8. When you are finished adding the new phone number, click **OK**.
9. If you want to change the order of phone numbers under **Phone numbers**, click a phone number, and then click the **Up** button or **Down** button until the phone number is in the correct order.
10. If you want to remove a phone number under **Phone numbers**, click the phone number, and then click **Delete**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you have alternate phone numbers defined for a connection, you can specify a particular phone number at the time you initiate your connection.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable operator-assisted calls or manual dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable operator-assisted calls or manual dialing**

1. Open Network Connections.
2. On the **Advanced** menu, click **Operator-Assisted Dialing**.
3. Double-click the connection you want to dial.
4. Pick up the telephone handset, and then dial the number or ask the operator to dial it for you.

   The number assigned to the entry is displayed in the dialog box for easy reference.
5. Immediately after you have finished dialing, click **Dial**.
6. Hang up the handset only after the modem takes control of the line, which is typically signaled with a click followed by silence.

   It is always safe to replace the handset once Network Connections begins verifying your user name and password. The status message will remind you of this.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If operator-assisted dialing is enabled, a check mark appears next to **Operator-Assisted Dialing** on the **Advanced** menu.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make Internet Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make Internet connections**

- Make an Internet connection
- Make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE)

# Make an Internet connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make an Internet connection**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Connect to the Internet**, and then click **Next**.
4. Click **Connect using a dial-up modem**, and click **Next**.
5. If prompted, select the check box for the modem you want to use for this connection, and click **Next**.
6. Type the name of your ISP in **ISP Name**, and click **Next**.
7. Type the phone number of your ISP, including the area code, in **Phone number**, and click **Next**.
8. Make the connection available to any user or only to yourself by selecting **Anyone's use** or **My use only**.
9. In **User name**, type the account name your ISP assigned to you. In **Password** and **Confirm password**, type the password for your account name, and click **Next**.
10. If you want to create a shortcut for this connection on your desktop, select the **Add a shortcut to this connection to my desktop** check box.
11. Click **Finish.**

## Notes

- To make a connection available to any user, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- To enable automatic dialing for all users, create a connection, save your user name and password for all users, and then enable Internet Connection Sharing for the new connection.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE)**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Connect to the Internet**, and then click **Next**.
4. To create a high-speed connection that requires you to sign in, click **Connect using a broadband connection that requires a user name and password**, and click **Next**.
5. Type the name of your ISP in **ISP Name**, and click **Next**.
6. Do one of the following:
   - If you want this connection to be made available to all users on your network, click **Anyone's use**, and then click **Next**.
   - If you want to reserve the connection for your own use, click **My use only**, and then click **Next**.
7. In **User name**, type the account name your ISP assigned to you. In **Password** and **Confirm password**, type the password for your account name, and click **Next**.
8. To create a shortcut for this connection on your desktop, select the **Add a shortcut to this connection to my desktop** check box.
9. Click **Finish**.

## Notes

- To make a connection available to any user, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make Direct Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Make direct network connections**

- Make a direct network connection
- Make a direct network connection by using a DirectParallel cable

# Make a direct network connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a direct network connection**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Set up an advanced connection**, and then click **Next**.
4. Click **Connect directly to another computer**, click **Next**, and then follow the instructions in the New Connection Wizard.

## Notes

- To create a direct network connection that acts as a host, you must be logged on as Administrator or be a member of the Administrators group. Guest direct network connections do not require administrator credentials.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you specify your connection as a host when you create it, the connection appears as **Incoming Connections** in the Network Connections folder.
- You can create multiple direct connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple ports, host computers, and so on.
- Direct connections can bypass authentication requirements. This is useful for devices such as handheld PCs. You must configure this setting in the host incoming connection. For more information, see Related Topics.
- If you create a direct connection by using a serial (RS-232C) cable, the port that you select in the New Connection Wizard is enabled for connections that use a null modem.
- If you are logged on to your computer as Administrator or a member of the Administrators group when you create a direct connection, you are presented with a list of connection devices to choose from that includes all of the parallel ports for the computer, infrared ports that are installed and enabled, and COM ports. If you need to use a COM port for a direct connection, ask your system administrator to configure one of the COM ports on your computer with a null modem by using Phone and Modem Options in Control Panel.
- Users do not need to use direct connections to allow access to shared resources, such as files and printers, over a local area network. In order to enable shared access to resources on the local computer, you must enable file and print sharing, share the resources, and then set up the appropriate permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Make a direct network connection by using a DirectParallel cable

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To make a direct network connection by using a DirectParallel cable**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Set up an advanced connection**, and then click **Next**.
4. Click **Connect directly to another computer**, click **Next**, and then do one of the following:
   - If you want your computer to act as the host, click **Host**, and click **Next**. Click **Direct Parallel (LPT1)** in the **Device for this connection**, and click **Next**.
   - If you want your computer to act as the guest, click **Guest**, and click **Next**. Type the name of the other computer in **Computer Name**, and click **Next**.
5. Follow the remaining instructions in the New Connection Wizard.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- For information about contacting Parallel Technologies or their local dealers to order DirectParallel cables, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up Incoming Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up incoming connections**

- Accept incoming network connections
- Grant incoming connection access rights to your computer
- Configure an incoming connection to use TCP/IP
- Configure callback for incoming connections

# Accept incoming network connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To accept incoming network connections**

1. Open Network Connections.
2. Double-click **New Connection Wizard**, and then click **Next**.
3. Click **Set up an advanced connection**, and then click **Next**.
4. Click **Accept incoming connections**, click **Next**, and then follow the instructions in the New Connection Wizard.

## Notes

- To create an incoming network connection, you must be a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you make another incoming network connection, and you use the New Connection Wizard again, the existing incoming network connection is reconfigured.
- For large numbers of incoming connections on a server that operates as part of a distributed network or as a domain controller, use Routing and Remote Access to create a remote access server.
- If your incoming connection and Fax Service have problems working together (for example, you cannot receive incoming connection calls on a device enabled for Fax receive), the modem may not support adaptive answer. Check your modem documentation to verify that you need to disable Fax receive for that device to accept incoming connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**See Also**
**Concepts**
Incoming connections

Grant incoming connection access rights to your computer

# Grant incoming connection access rights to your computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To grant incoming connection access rights to your computer**

1. Open Network Connections.
2. Right-click **Incoming Connections**, and then click **Properties**.
3. On the **General** tab, do one or more of the following:
   - In **Devices**, click the check boxes next to the devices through which incoming connections can connect.
   - If you have more than one device selected, and you want to enable Multilink dialing, select the **Enable multilink** check box.
   - If you want to enable others to make private connections to your computer by tunneling through the Internet or other network, select the **Allow others to make private connections to my computer by tunneling through the Internet or other network** check box.
   - If you want to show icons on the taskbar when incoming connections are connected, select the **Show icon in notification area when connected** check box.
4. On the **Users** tab, do one or more of the following:
   - If you want to allow a user to connect, select the check box next to the user's name.
   - If you want to revoke a user's right to connect, clear the check box next to a user's name.
   - To create a new user and grant them access to connect, click **New**.
   - To remove a user, click **Delete**.
   - To modify a user's name, password, and callback options, click **Properties**.
   - If you want directly connected devices to connect without providing a password, select the **Always allow directly connected devices such as palmtop computers to connect without providing a password** check box.
5. On the **Networking** tab, do one or more of the following:
   - If you want to enable a network component, in **Network components**, select the check box next to the component name.
   - If you want to disable a network component, in **Network components**, clear the check box next to the component name.
   - To add a network component, click **Install**.
   - To remove a network component, click **Uninstall**.

- To configure a network component, click **Properties**.

**Notes**

- To modify an incoming connection, you must be logged on as a member of the Administrators group.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you enable or disable TCP/IP for incoming connections, the settings affect only incoming connections. Other protocols, such as AppleTalk, are enabled or disabled for all connection types.

# Configure an incoming connection to use TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure an incoming connection to use TCP/IP**

1. Open Network Connections.
2. Right-click **Incoming Connections**, and then click **Properties**.
3. On the **Networking** tab, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. If you want incoming users to be able to access the local area network on which the dial-up computer resides, select the **Allow callers to access my local area network** check box.
5. Do one of the following:

   - If you want to automatically assign TCP/IP addresses, select the **Assign TCP/IP addresses automatically using DHCP** check box.
   - If you want to specify TCP/IP addresses, click **Specify TCP/IP addresses**, and do the following:

     In **From**, type the starting IP address.

     In **To**, type the ending IP address.

     Based on the addresses you type in **From** and **To**, the number of addresses that are allocated is displayed in **Total**. The starting and ending IP addresses that you choose depend on the originating address space and the number of addresses needed. For more information on defining IP addresses for incoming connections, see Related Topics.

6. If you want incoming connections to be able to use a specific TCP/IP address, select the **Allow calling computer to specify its own IP address** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Most TCP/IP networks use subnets in order to effectively manage routed IP addresses. The closest matching subnet is calculated for the range that you specified in **From** and **To**. The range of addresses in the closest matching subnet may exceed the range that you specified. Unless the addresses specified in **From** and **To** are subnet boundaries, the range based on the calculated subnet will be larger than the range that you specified. To avoid this, specify a range that falls on subnet boundaries. For example, if you are using the 10.0.0.0 private network ID for your intranet, a range that falls on subnet boundaries is 10.0.1.168 to 10.0.1.175. Or, if you are using the 192.168.0.0 private network ID for your intranet, a range that falls on subnet boundaries is 192.168.1.0 to 192.168.1.255.
- If you select **Allow callers to access my local area network** or **Allow calling computer to specify its own IP address**, these changes take effect immediately.
- If you select **Assign TCP/IP addresses automatically using DHCP**, but there is no DHCP server available, random addresses from the range 169.254.0.1 to 169.254.255.254 are assigned.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure callback for incoming connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure callback for incoming connections**

1. Open Network Connections.
2. Right-click **Incoming Connections**, and then click **Properties**.
3. On the **Users** tab, click the user for which you want to configure callback, and then click **Properties**.
4. On the **Callback** tab, do one of the following:
   - If you do not want to use callback for incoming connections, click **Do not allow callback**.
   - If you want to give incoming connections the option of setting a specific callback number, click **Allow the caller to set the callback number**.
   - If you want to consistently use the same callback number, click **Always use the following callback number**, and type the number.

**Note**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure Network and Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configure network and dial-up connections**

- Configure a connection to a remote network
- Set up Network Components
- Secure Network or Dial-up Connections

# Configure a connection to a remote network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a connection to a remote network**

1. Open Network Connections.
2. Right-click the dial-up connection that you want to configure, and then click **Properties**.
3. Do one or more of the following:
   - To configure dialing devices, phone numbers, host address, country/region codes, or dialing rules, click the **General** tab.
   - To configure dialing and redialing options, multilink configuration, or X.25 parameters, click the **Options** tab.
   - To configure identity authentication, data encryption, or terminal window and scripting options, click the **Security** tab.
   - To configure the remote access server and protocols used for this connection, click the **Networking** tab.
   - To enable or disable Internet Connection Firewall, Windows Firewall, Internet Connection Sharing, and on-demand dialing, click the **Advanced** tab. For more information, see Related Topics.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Depending on the type of connection you are configuring, different options appear in the properties dialog box.
- For more information about a specific item on a tab, right-click the item, and then click **What's This?**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure TCP/IP settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure TCP/IP settings**

1. Open Network Connections.
2. Right-click the connection you want to configure, and then click **Properties**.
3. Do one of the following:
   - If the connection is a local area connection, on the **General** tab, in **This connection uses the following items**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
   - If the connection is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
   - If the connection is an incoming connection, on the **Networking** tab, in **Network components**, click **Internet Protocol (TCP/IP)**, and then click **Properties**.
4. Do one of the following:
   - If you want IP settings to be assigned automatically, click **Obtain an IP address automatically**, and then click **OK**.
   - If you want to specify an IP address or a DNS server address, do the following:

     Click **Use the following IP address**, and in **IP address**, type the IP address.

     Click **Use the following DNS server addresses**, and in **Preferred DNS server** and **Alternate DNS server**, type the addresses of the primary and secondary DNS servers.
5. To configure DNS, WINS, and IP settings, click **Advanced**.
6. In a local area connection, selecting the **Obtain an IP address automatically** option enables the **Alternate Configuration** tab. Use this to enter alternate IP settings if your computer is used on more than one network. To configure DNS, WINS, and IP settings, click **User configured** on the **Alternate Configuration** tab.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should use automated IP settings (DHCP) whenever possible for all connections because they eliminate the need to configure settings such as IP address, DNS server address, and WINS server address.
- The **Alternate Configuration** settings specify a second set of IP settings that are used when a DHCP server is not available. This is very useful for laptop users who often switch between two different network environments such as DHCP and static IP network environments.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your

account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a network component**

1. Open Network Connections.
2. Right-click the connection to which you want to add a network component, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, click **Install**.
   - If this is a dial-up, VPN, or incoming connection, on the **Networking** tab, click **Install**.
4. In the **Select Network Component Type** dialog box, click either **Client**, **Service**, or **Protocol**, and then click **Add**.
5. Do one of the following:
   - If you do not have an installation disk for the component, click the appropriate client, service, or protocol, and then click **OK**.
   - If you have an installation disk for the component, click the appropriate client, service, or protocol, click **Have Disk**, insert the installation disk into the selected drive, and then click **OK**.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should only install the network components that you need, for the following reasons:
  - Network performance is enhanced and network traffic is reduced when only the required protocols and clients are installed.
  - If a problem with a network or dial-up connection occurs, your computer attempts to establish connectivity by using every network protocol that is installed and enabled. By only installing and enabling the protocols that your system can use, the operating system does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.
  - Excessive services can hinder performance on your local computer.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove a network component**

1. Open Network Connections.
2. Right-click the connection on which you want to remove a network component, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, click the client, service, or protocol you want to remove, and then click **Uninstall**.
   - If this is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, click the client, service, or protocol you want to remove, and then click **Uninstall**.
   - If this is an incoming connection, on the **Networking** tab, in **Network components**, click the client, service, or protocol you want to remove, and then click **Uninstall**.
4. In the **Uninstall***component name* dialog box, click **Yes**.

**Note**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable a network component

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable a network component**

1. Open Network Connections.
2. Right-click a connection, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, select the check box next to the client, service, or protocol you want to enable.
   - If this is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, select the check box next to the client, service, or protocol you want to enable.
   - If this is an incoming connection, on the **Networking** tab, in **Network components**, select the check box next to the client, service, or protocol you want to enable.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You should only enable the network components that you need, for the following reasons:
  - Network performance is enhanced and network traffic is reduced when only the required protocols and clients are enabled.
  - If your computer encounters a problem with a network or dial-up connection, it attempts to establish connectivity by using every network protocol that is installed and enabled. By only enabling the protocols that your system can use, the operating system does not attempt to connect with protocols it cannot use, and returns status information to you more efficiently.
  - Excessive services can hinder performance on your local computer.

# Configure File and Printer Sharing for Microsoft Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure File and Printer Sharing for Microsoft Networks**

1. Open Network Connections.
2. Right-click a connection, and then click **Properties**.
3. Do one of the following:
   - If this is a local area connection, on the **General** tab, in **This connection uses the following items**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
   - If the connection is a dial-up or VPN connection, on the **Networking** tab, in **This connection uses the following items**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
   - If the connection is a incoming connection, on the **Networking** tab, in **Network components**, click **File and Printer Sharing for Microsoft Networks**, and then click **Properties**.
4. Do one of the following:
   - To optimize the server for a small number of clients, click **Minimize memory used**.
   - To optimize the server for a mixed usage of file and printer sharing in addition to other services, such as serving as an interactive workstation, click **Balance**.
   - To dedicate as many resources as possible to file and print server services, click **Maximize data throughput for file sharing**.
   - To optimize server memory for distributed applications that perform their own memory caching, such as Microsoft SQL Server, click **Maximize data throughput for network applications**.
5. To specify that LAN Manager 2.*x* clients on your network can browse for shared resources on this computer, select the **Make browser broadcasts to LAN Manager 2.x clients** check box.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can only configure File and Printer Sharing for Microsoft Networks on a server.
- To share local folders, you must enable File and Printer Sharing for Microsoft Networks. For more information, see Related Topics.
- The File and Printer Sharing for Microsoft Networks component is the equivalent of the Server service in Windows NT 4.0.
- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

**Information about functional differences**

# Secure Network or Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Secure network or dial-up connections**

- Configure identity authentication and data encryption settings
- Enable smart card or other certificate authentication
- Terminal and Scripting Options

For information on security considerations for routing, remote access and VPN, see Security information for routing, Security information for remote access and Security issues for VPN.

# Configure identity authentication and data encryption settings

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure identity authentication and data encryption settings**

1. Open Network Connections.
2. Right-click the dial-up connection you want to configure, and then click **Properties**.
3. On the **Security** tab, do one of the following:

   - To select preconfigured combinations of identity authentication methods and data encryption requirements, click **Typical (recommended settings)**, and in **Validate my identity as follows**, click a method to use for validation.

     Depending on your **Validate my identity as follows** selection, you can select (enable) or clear (disable) the **Automatically use my Windows logon name and password (and domain if any)** or **Require data encryption (disconnect if none)** check boxes. The following table shows which selections are available.

     If **Require data encryption (disconnect if none)** is not enabled, encryption is optional. To prevent encryption, click **Advanced (custom settings)**, and then click **Settings**. In **Data encryption**, click **No encryption allowed (server will disconnect if it requires encryption)**.

     For dial-up connections:

     | Validate my identity as follows | Automatically use my Windows logon name and password (and domain if any) | Require data encryption (disconnect if none) |
     |---|---|---|
     | Allow unsecured password | Unavailable | Unavailable |
     | Require secured password | Available | Available |
     | Use smart card | Unavailable | Available |

     For VPN connections:

     | Validate my identity as follows | Automatically use my Windows logon name and password (and domain if any) | Require data encryption (disconnect if none) |
     |---|---|---|
     | Require secured password | Available | Available (enabled by default) |
     | Use smart card | Unavailable | Available (enabled by default) |

   - To individually enable, configure, and disable authentication methods and encryption requirements, click **Advanced (custom settings)**, and then click **Settings**.

**Important**

- Modifying **Advanced (custom settings)** requires a knowledge of security protocols.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

- Among the advanced custom settings is the **Allow older MS-CHAP version for Windows 95 servers** check box. You must select this check box to configure a connection to a server running Windows 95.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable smart card or other certificate authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable smart card or other certificate authentication**

1. Open Network Connections.
2. Right-click the dial-up, VPN, or incoming connection on which you want to use smart card or other certificate authentication, and then click **Properties**.
3. If you are using typical settings for your smart card, on the **Security** tab, click **Typical (recommended settings)**, and in the **Validate my identity as follows** list, click **Use smart card**, and then click **OK**.
4. If you are individually enabling, configuring, and disabling authentication methods and encryption requirements, on the **Security** tab, click **Advanced (custom settings)**, and click **Settings**. In **Logon security**, click **Use Extensible Authentication Protocol (EAP)**, click **Smart card or other certificate (encryption enabled)**, click **Properties**, and then do the following:
   - If you want to use the certificate that resides on your smart card, click **Use my smart card**.
   - If you want to use the certificate that resides in the certificate store on your computer, click **Use a certificate on this computer**.
   - If you want to verify that the server certificate presented to your computer has not expired, has the correct signature, and has a trusted root certification authority, select the **Validate server certificate** check box.
   - If you only want to connect to servers within a particular domain, select the **Connect only if server name ends with** check box, and then type the name of the domain.
   - To specify that the root certification authority for your server certificate must be in a particular root certification authority, in **Trusted root certification authority**, click the appropriate certification authority.
   - To use a different user name when the user name in the smart card or certificate is not the same as the user name in the domain that you are logging on to, select the **Use a different user name for the connection** check box.

**Notes**

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If, for example, you only want to connect to servers that reside in Microsoft.com, you type **Microsoft.com** in **Connect only if server name ends in**.
- If, for example, you are working for a consulting company where you need to log on to the domain of the company to which you are assigned, but your smart card contains a user name specific to your home company, select the **Use a different user name for the connection** check box.
- If you select the **Use a different user name for the connection** check box, your certificate is exported without private keys and submitted to your system administrator to be explicitly mapped to your domain user account. For more information, see Related Topics.
- If you select the **Connect only if server name ends with** check box, and do not type a domain name, at the time you connect you are prompted to use the domain name in the server certificate.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Terminal and Scripting Options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Terminal and scripting options**

- Use the Terminal feature to log on to a remote computer
- Activate a logon script
- Log and view modem commands

# Use the Terminal feature to log on to a remote computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To use the Terminal feature to log on to a remote computer**

1. Open Network Connections.
2. Right-click the dial-up connection on which you want to use Terminal, and then click **Properties**.
3. On the **Security** tab, select the **Show terminal window** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- After you connect, the After Dial Terminal window appears and prompts you from the remote computer display. You then use this window to log on to the remote computer. After you have completed all interactions with the remote computer, click **Done**. At this point, authentication on the remote access server begins.
- If the logon sequence does not vary, you can write a script that automatically passes information to the remote computer during the logon sequence, which enables completely automatic connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Activate a logon script

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To activate a logon script**

1. Open Network Connections.
2. Right-click the dial-up connection on which you want to run a script, and then click **Properties**.
3. On the **Security** tab, select the **Run script** check box.
4. To use an existing script file, click **Browse**.

   Or, to use Switch.inf, click **Edit**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- In addition to Switch.inf, the Windows 95 scripting language is supported for computers running the Windows Server 2003 family that connect to computers running operating systems other than Windows. You may find the Windows 95 scripting language easier to use than Switch.inf. For more information, see Related Topics.
- If you click **Edit** and load Switch.inf into Notepad, immediately resave the file with a different name to preserve the default Switch.inf file.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Log and view modem commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To log and view modem commands**

1. Open Phone and Modem Options in Control Panel.
2. On the **Modems** tab, click the modem whose commands you want to log.
3. Click **Properties**, then click the **Diagnostics** tab.
4. In **Logging**, select the **Append to Log** check box if you are working on a computer running Windows XP or **Record a Log** check box if you are working on a computer running a member of the Windows Server 2003 family.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
- Click **View Log** to display the log file. This file identifies the modem and displays information about how it is functioning.
- Commands sent to the modem are captured in the file:

  *systemroot*\System32\ModemLog_*Model*.txt.

  The path is usually C:\Windows\System32\. *Model* is the name of the modem as it appears in the list of installed modems on the **Modems** tab of **Phone and Modem Options**.
- In Windows XP, logging is always turned on, and the log is overwritten at the beginning of every session unless you select the **Append to Log** check box. In the Windows Server 2003 family, logging is turned off unless you select the **Record a Log** check box.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Monitor Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitor network connections**

- Monitor a connection
- View the status of a local area connection

# Monitor a connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To monitor a connection**

1. Open Network Connections.
2. Do one of the following:
   - To monitor activity for the current session, right-click the connection you want to monitor, and then click **Status**.
   - To automatically enable the status monitor each time the connection is active, right-click the connection, click **Properties**, and then select the **Show icon in taskbar when connected** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If your computer is set up to accept incoming connections, a connection with a user name assigned to it appears in the Network Connections folder as each user connects. You can view the progress of incoming connections by right-clicking a named connection, and then clicking **Status**.
- You can also monitor a connection by clicking **Status** on the **File** menu or by clicking the status icon in the taskbar. You can also right-click the taskbar icon and click **Status**.
- If you want to view the general status (**Disconnected**, **Connected**) of all of your connections, on the **View** menu, click **Details**.
- You also can disconnect an active connection by clicking **Disconnect** in the **Status** dialog box.
- By default, the status monitor is disabled for local area connections, but enabled for all other types of connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the status of a local area connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the status of a local area connection**

1. Open Network Connections.
2. Do one of the following:
   - To monitor activity for the current session, right-click the local area connection, and then click **Status**.
   - To automatically enable the status monitor each time the connection is active, right-click the local area connection, click **Properties**, and then select the **Show icon in taskbar when connected** check box.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You can view and modify the network components of a local area connection, such as network protocol settings, by clicking **Properties**.
- By default, the status monitor is disabled for local area connections, but enabled for all other types of connections.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up and Manage Home and Small Office Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage home and small office networking**

- Set up and Manage Internet Connection Firewall (ICF)
- Set up and Manage Network Bridge
- Set up and Manage Internet Connection Sharing (ICS)
- Manage service definitions for ICF or ICS

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Set up and Manage Internet Connection Firewall (ICF)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage Internet Connection Firewall (ICF)**

- Enable or disable ICF
- Enable or disable Internet Control Message Protocol requests for ICF
- Enable or disable ICF security log options
- View the ICF security log
- Change the file size of the ICF security log
- Change the path and file name of the ICF security log
- Restore the default settings to the ICF security log

# Enable or disable ICF

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable ICF**

1. Open Network Connections.
2. Under **Dial-up** or **LAN or High-Speed Internet**, right-click the connection that you want to protect, and then click **Properties**.
3. On the **Advanced** tab, under **Internet Connection Firewall**, do one of the following:
   - To enable Internet Connection Firewall (ICF), select the **Protect my computer and network by limiting or preventing access to this computer from the Internet** check box.
   - To disable ICF, clear the **Protect my computer and network by limiting or preventing access to this computer from the Internet** check box.

**Caution**

- If you clear the **Protect my computer and network by limiting or preventing access to this computer from the Internet** check box, the firewall on this connection is disabled. When the firewall is disabled, your computer is exposed to possible external attacks through the unprotected connection.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- You need to enable ICF only on connections that connect to the Internet. You should not enable ICF on virtual private network (VPN) connections or on network client computers because ICF interferes with network activities such as file and printer sharing.
- If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.
- ICF cannot be enabled on the private connections of the Internet Connection Sharing host computer, on Network Bridge, or on the adapters that are included in Network Bridge.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable Internet Control Message Protocol requests for ICF

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable Internet Control Message Protocol requests for ICF**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **ICMP** tab, do one of the following:
   - To enable Internet Control Message Protocol (ICMP) options, select the check box next to each type of request for information to which you would like your computer to respond.
   - To disable ICMP options, clear any or all of the ICMP check boxes.

### Caution

- All ICMP options are disabled by default. If you enable ICMP options on a computer running ICF, that computer may become visible to the Internet and vulnerable to attacks.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable ICF security log options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable ICF security log options**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Logging Options**, select from the following:

   To enable ICF security log options:

   - To enable the logging of all dropped packets that originate from either the home or small office network or the Internet, select the **Log dropped packets** check box.
   - To enable the logging of all successful connections that originate from either the home or small office network or the Internet, select the **Log successful connections** check box.

   Or, to disable ICF security log options:

   - To disable the logging of all dropped packets that originate from either the home or small office network or the Internet, clear the **Log dropped packets** check box.
   - To disable the logging of all successful connections that originate from either the home or small office network or the Internet, clear the **Log successful connections** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Security logging is not enabled by default when ICF is enabled.
- ICF functions whether security logging is enabled or disabled.
- If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Log file options**, in **Name**, click **Browse**.
5. Scroll to the ICF security log, right-click the file, and then click **Open**.

## Notes

- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- The default name for the ICF security log is pfirewall.log, and the default location is in the Windows directory.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

# Change the file size of the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the file size of the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Log file options**, in **Size limit**, use the arrow buttons to adjust the size limit.

### Caution

- If the maximum allowable size for pfirewall.log is exceeded, the information that pfirewall.log contains is saved as pfirewall.log.old, and new information is saved as pfirewall.log. If the maximum allowable size for pfirewall.log is exceeded again, the information that pfirewall.log contains is saved as pfirewall.log.old, and the information that had been in pfirewall.log.old is overwritten. New information is always saved in pfirewall.log.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.
- The default size limit of the ICF security log is 4,096 kilobytes.
- You must enable ICF before you can adjust the size limit of the ICF security log.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

# Change the path and file name of the ICF security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the path and file name of the ICF security log**

1. Open Network Connections.
2. Right-click the connection on which Internet Connection Firewall (ICF) has been enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Security Logging** tab, under **Log file options**, click **Browse**, and then do the following:
   - To change the path of the ICF security log, navigate to the location where you want the ICF security log to be saved. (If you do not want to change the path, do not navigate to a new location.)
   - To change the file name of the ICF security log, in **File name**, type a new name, and then click **Open**. (If you do not want to change the default file name, in **File name**, type **pfirewall**, and then click **Open**.)

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.

# Set up and Manage Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage Network Bridge**

- Set up Network Bridge
- Add a connection to or remove a connection from Network Bridge
- Enable or disable Network Bridge
- Remove Network Bridge

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Set up Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up Network Bridge**

1. Open Network Connections.
2. Under **LAN or High-Speed Internet**, hold down the CTRL key, and then click each of the adapters that you want to include in the bridge.
3. Right-click one of the connections that you have selected, and then click **Bridge Connections**.

**Caution**

- If Internet Connection Firewall (ICF), Windows Firewall, or Internet Connection Sharing (ICS) are not enabled on your network, do not set up Network Bridge between the public Internet connection and the private network connection. Setting up Network Bridge between the public Internet connection and the private network connection creates an unprotected link between your network and the Internet, leaving your network vulnerable to external attacks. When ICF, Windows Firewall, or ICS are enabled, this risk is mitigated.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Connections that run ICF, Windows Firewall, or adapters that provide shared Internet connections cannot be a part of the Network Bridge and do not appear under **LAN or High-Speed Internet**. Similarly, the **Bridge Connections** menu command is available only for adapters that you can add as connections to Network Bridge.
- You must select at least two private network connections in order for **Bridge Connections** to create a bridge.
- You can create only one Network Bridge on a computer, but the bridge can accommodate numerous network connections.
- Network adapters that previously appeared under **LAN or High-Speed Internet**, appear under **Network Bridge** when you add them as connections to the bridge. Network adapters that provide Internet connectivity, such as DSL and cable modems, cannot be bridged and always appear under **LAN or High-Speed Internet**.
- Only Ethernet, IEEE-1394 adapters, or Ethernet-compatible adapters, such as wireless and Home Phoneline Network adapters, can be a part of Network Bridge.
- Network Bridge with a wireless or IEEE-1394 connection supports traffic using Internet Protocol version 4 (IPv4) only.
- You cannot create Network Bridge on a computer running Windows 2000 or earlier versions of Windows.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add a connection to or remove a connection from Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add a connection to or remove a connection from Network Bridge**

1. Open Network Connections.
2. Under **Network Bridge**, right-click **Network Bridge**, and then click **Properties**.
3. On the **General** tab, under **Adapters**, do one of the following.
   - To add a connection to Network Bridge, select the check box next to each adapter you want to add to the bridge, and then click **OK**.
   - To remove a connection from Network Bridge, clear the check box next to each adapter you want to remove from the bridge, and then click **OK**.

**Caution**

- If Internet Connection Firewall (ICF), Windows Firewall, or Internet Connection Sharing (ICS) are not enabled on your network, do not set up Network Bridge between the public Internet connection and the private network connection. Setting up Network Bridge between the public Internet connection and the private network connection creates an unprotected link between your network and the Internet, leaving your network vulnerable to external attacks. When ICF, Windows Firewall, or ICS are enabled, this risk is mitigated.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you remove network adapters from Network Bridge and less than two adapters remain, Network Bridge does not perform its intended function but continues to use system resources.
- You must set up Network Bridge before you can add connections to it. For more information, see Related Topics.
- Connections that run ICF, Windows Firewall, or adapters that provide shared Internet connections cannot be a part of Network Bridge and do not appear under **Adapters**. Similarly, the **Add to Bridge** menu command is available only for adapters that you can add as connections to Network Bridge.
- Network adapters that previously appeared under **LAN or High-Speed Internet**, appear under **Network Bridge** when you add them as connections to the bridge. Network adapters that provide Internet connectivity, such as DSL and cable modems, cannot be bridged and always appear under **LAN or High-Speed Internet**.
- Only Ethernet, IEEE-1394 adapters, or Ethernet-compatible adapters, such as wireless and Home Phoneline Network adapters, can be a part of Network Bridge.
- Network Bridge with a wireless or IEEE-1394 connection supports traffic using Internet Protocol version 4 (IPv4) only.

- You can also add a connection to or remove a connection from Network Bridge by opening Network Connections, right-clicking the adapter that you want to add, and then clicking **Add to Bridge**.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable or disable Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable or disable Network Bridge**

1. Open Network Connections.
2. Under **Network Bridge**, right-click **Network Bridge**, and do one of the following:
   - To enable Network Bridge, click **Enable**.
   - To disable Network Bridge, click **Disable**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you remove or disable Network Bridge, computers on your network are unable to communicate with computers that are on different network segments. Some of the computers on your network may lose Internet connectivity.
- You must set up Network Bridge before you can enable or disable it. For more information, see Related Topics.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Remove Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To remove Network Bridge**

1. Open Network Connections.
2. Under **Network Bridge**, right-click **Network Bridge**, and then click **Delete**.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- If you remove or disable Network Bridge, computers on your network are unable to communicate with computers that are on different network segments. Some of the computers on your network may lose Internet connectivity.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up and Manage Internet Connection Sharing (ICS)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Set up and manage Internet Connection Sharing (ICS)**

- Enable ICS
- Enable ICS on-demand dialing
- Configure client computers for ICS

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Enable ICS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable ICS**

1. Open Network Connections.
2. Under **Dial-up** or **LAN or High-Speed Internet**, right-click the connection on which you want to enable (ICS), and then click **Properties**.
3. On the **Advanced** tab, under **Internet Connection Sharing**, select the **Allow other network users to connect through this computer's Internet connection** check box.
4. If present, under **Home networking connection**, in the **Select a private network connection** drop-down box, select the connection that connects directly to your network. For more information, see Notes.

**Important**

- You can enable ICS only when two or more network adapters are installed.
- If your computer has multiple private connections that connect to private LAN segments, you should bridge the private connections before you enable ICS. For information about how to set up Network Bridge, see Related Topics.
- When ICS is enabled, it automatically provides an IP address for the private connection of the ICS host.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- **Home networking connection** and the **Select a private network connection** drop-down box are present only when two or more adapters that can connect to the private network are installed.
- For information about the protocols, services, interfaces, and routes that are automatically configured by ICS when you connect to the Internet in a home or small office network, see Related Topics.
- If you are having difficulty connecting the ICS host to the Internet, you can use **Repair** to obtain refreshed IP address configurations from your Internet service provider (ISP).
- If a computer on your network is unable to communicate with other network computers, you can use **Repair** to force the connection to refresh its IP address configuration from the ICS host.
- Before using **Repair**, ensure that the client computers are plugged into the network and that the ICS host is running, configured, and connected to the network and the Internet.
- For information about how to configure client computers for ICS, see Related Topics.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Enable ICS on-demand dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To enable ICS on-demand dialing**

1. Open Network Connections.
2. Right-click the dial-up connection on which you want to enable ICS on-demand dialing, and then click **Properties**.
3. On the **Advanced** tab, under **Internet Connection Sharing**, do one of the following:
   - To enable ICS on-demand dialing, select the **Establish a dial-up connection whenever a computer on my network attempts to access the Internet** check box.
   - To disable ICS on-demand dialing, clear the **Establish a dial-up connection whenever a computer on my network attempts to access the Internet** check box.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- In order for ICS on-demand dialing to work correctly, the shared Internet connection must be available for all ICS clients, and the dial-up credentials must be saved for all users. For more information, see Related Topics.
- **Establish a dial-up connection whenever a computer on my network attempts to access the Internet** is selected by default. Unless you clear the check box, clients can activate the shared Internet connection from their computers by starting their Internet browsers or mail programs.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure client computers for ICS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure client computers for ICS**

1. Insert the Windows Server 2003, Standard Edition or Windows Server 2003, Enterprise Edition CD into the CD-ROM drive of your computer running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition.

2. When the Welcome screen appears, click **Perform additional tasks**, and then click **Browse this CD**.

3. Double-click **Support**, and then double-click **Netsetup**.

4. Follow the instructions that appear on your screen.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.

- Enable Internet Connection Sharing (ICS) on your ICS host computer before you attempt to configure client computers for your home or small office network. For more information, see Related Topics.

- You can run Netsetup.exe only on computers running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Manage service definitions for ICF or ICS

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To manage service definitions for ICF or ICS**

1. Open Network Connections.
2. Right-click the shared Internet connection or the Internet connection on which Internet Connection Firewall (ICF) or Internet Connection Sharing (ICS) is enabled, and then click **Properties**.
3. On the **Advanced** tab, click **Settings**.
4. On the **Services** tab, do one of the following:
   - If you want to enable a service, under **Services** select the check box next to service that you want to enable, and then enter the required information.
   - If you want to add a service definition, click **Add**, and then enter the required information.
   - If you want to edit a service definition, click the service that you want to edit, click **Edit**, and then change the appropriate information.
   - If you want to delete a service definition, click the service that you want to delete, and then click **Delete**.

**Caution**

- This feature is intended for advanced users. When you add or edit a service definition, you create a port mapping that can expose your network to the Internet. For more information about service definitions, see Related Topics.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure.
- To open Network Connections, click **Start**, click **Control Panel**, and then double-click **Network Connections**.
- Before you can add, edit, or delete service definitions, you must enable ICF, ICS, or both.
- You can obtain the correct configuration values for the TCP or UDP port number from the service's documentation or Web site.
- No two service definitions can use the same port numbers simultaneously.
- For service definitions that are preconfigured, you can edit only the field that is labeled **Name or IP address of the computer hosting this service on your network**.
- For service definitions that you have added, you can edit only the fields that are labeled **Name or IP address of the computer hosting this service on your network**, **External Port number for this service**, and **Internal Port number for this service**.
- You can delete only the service definitions that you have added. You cannot delete service definitions that are preconfigured.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

- This topic applies only to product features available in the original release of Windows Server 2003.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# About Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**About Network Connections**

Network Connections provides connectivity between your computer and the Internet, a network, or another computer. With Network Connections, you can gain access to network resources and functionality, whether you are physically located at the location of the network or in a remote location. Connections are created, configured, stored, and monitored from within the Network Connections folder. For information about creating connections, see Make Network and Dial-up Connections. For a list of network connection icons, see Network connection icons.

Each connection in the Network Connections folder contains a set of features that you can use to create a link between your computer and another computer or network. Outgoing connections contact a remote access server by using a configured access method (LAN, modem, ISDN line, cable modem, DSL line, X.25 line, and so on) to establish a connection with a remote network. Conversely, an incoming connection enables a computer running Microsoft® Windows® XP or a stand-alone computer running a member of the Windows Server 2003 family to be contacted by other computers. This means your computer can operate as a remote access server. Whether you are connected locally (LAN), remotely (dial-up, VPN, and so on), or both, you can configure any connection so that it can perform any needed network function. For example, you can print to network printers, access network drives and files, browse other networks, or access the Internet.

Because all services and communication methods are configured within the connection, you do not need to use external management tools to configure connection settings. For example, the settings for a dial-up connection include features to be used before, during, and after connecting. These include the modem you use to dial, the type of password encryption you want to use upon connecting, and the network protocols you use after you connect. Connection status, which includes the duration and speed of a connection, is viewed from the connection itself; you do not need to use an external status tool. For information about configuring a connection, see Configure a connection to a remote network.

Logon and domain security, support for security hosts, data encryption, authentication, and callback provide secure network access for network and dial-up connections. For more information about security features, see Security Features of Network Connections.

# Hardware requirements for network and dial-up connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Hardware requirements for network and dial-up connections**
Depending on your configuration, you may need some or all of the following hardware:

- One or more network adapters with a Network Driver Interface Specification (NDIS) driver for LAN connectivity
- One or more compatible modems and an available COM port
- ISDN adapter (if you are using an ISDN line)
- DSL adapter
- X.25 adapter or PAD (if you are using X.25)
- Analog telephone line, ISDN line, X.25 line, or DSL line
- Smart card reader
- Wireless adapter

To verify the compatibility of all hardware, see the compatibility information at Support resources.

For information about configuring a connection, see Configure a connection to a remote network. For a list of network connection icons, see Network connection icons.

# Network connection types

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network connection types**

You can use Network Connections to create several types of connections between computers. The following table shows each type of connection you can create, the communication methods you can use to create each type of connection, and an example of each connection type. For more information, click the appropriate connection type in the table.

| Connection type | Communication method | Example |
|---|---|---|
| Dial-up connections | Modem, ISDN, X.25 | Connect to a private network or the Internet by using remote access |
| Virtual Private Network (VPN) Connections | VPN connections to organization networks over the Internet using PPTP or L2TP | Connect securely to a private network over the Internet |
| Connection Manager Administration Kit | See dial-up or VPN connections | Connect to a private network using a collection of dial-up or VPN settings provided by your network administrator in a self-installing profile |
| Using local area connections | Ethernet, token ring, cable modem, DSL, FDDI, IP over ATM, IrDA, wireless, WAN technologies (T1, Frame Relay), PPPoE | Connect directly to a local area network, to your cable modem, or to your DSL modem through an Ethernet adapter or a similar device |
| Using direct connections | Serial cabling, infrared link, DirectParallel cable | Connect a handheld computer running Microsoft® Windows® CE to a desktop computer so you can synchronize information |
| Incoming connections | See dial-up, VPN, or direct connections | Accept dial-up, VPN, or direct connections from other computers |

For a list of icons that appear in the Network Connections folder, see Network connection icons.

# Dial-up connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up connections**

A dial-up connection connects you to a network or the Internet by using a device that utilizes the telephone network. This device can be a modem that uses a standard phone line, an ISDN adapter with a high-speed ISDN line, DSL, broadband, a cable modem, or an X.25 network.

If you are a typical user, you may have one or two dial-up connections, perhaps to the Internet and to your corporate network.

You can create multiple dial-up connections by copying them in the Network Connections folder. You can then rename the connections and modify connection settings. By doing so, you can easily create different connections to accommodate multiple modems, dialing profiles, and different destinations.

For more information about creating dial-up connections, see Set up Dial-up Connections.

# Network connection icons

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network connection icons**

The following table displays the different icons that appear in the Network Connections folder.

| Icon | Description | Location |
|---|---|---|
| | The local area connection is active | Network Connections folder |
| | The local area connection is disabled | Network Connections folder |
| | The default remote access connection | Network Connections folder |
| | An incoming connection | Network Connections folder |
| | The media is disconnected | Network Connections folder |
| | The media is disconnected | Taskbar |
| | The driver is disabled | Network Connections folder |
| | The adapter in this connection has an invalid IP address | Network Connections folder |
| | The adapter in this connection has an invalid IP address | Taskbar |
| | A connection on which Internet Connection Sharing (ICS) has been enabled. | Network Connections folder |
| | A connection on which Internet Connection Firewall (ICF) has been enabled. | Network Connections folder |
| | A connection on which Network Bridge has been enabled. | Network Connections folder |

**Notes**

- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Protocols and Access Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protocols and access methods**
This section covers:

- Network communications
- TCP/IP
- IPX
- AppleTalk
- ISDN access
- Serial (RS-232) cable access
- DirectParallel cable access
- SLIP
- Point-to-Point Protocol (PPP)

**Note**

- The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

# Network communications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network communications**
Network protocols, access methods, and server protocols help create a communications link between your computer and a network.

Whether information is transported from your computer to a server by using a direct serial cable, or across a secure VPN from your Internet service provider (ISP) to the corporate network, different combinations of access methods and protocols are used to send information. These access methods and protocols are listed as follows:

**Network protocols**

- TCP/IP
- IPX
- AppleTalk

**Access methods**

- Using phone lines and modems
- ISDN access
- Serial (RS-232) cable access
- DirectParallel cable access

**Server protocols**

- Point-to-Point Protocol (PPP)
- SLIP
- Layer Two Tunneling Protocol (L2TP)
- Point-to-Point Tunneling Protocol (PPTP)

The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

# TCP/IP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**TCP/IP**
Transmission Control Protocol/Internet Protocol (TCP/IP) is the most popular protocol, and the basis for the Internet. Its routing capabilities provide maximum flexibility in an enterprise-wide network.

On a TCP/IP network, you must provide IP addresses to clients. Clients may also require a naming service or a method for name resolution. This section explains IP addressing and name resolution for Network Connections on TCP/IP networks. It also describes the FTP and Telnet tools that are provided by the Microsoft® Windows Server 2003 family.

**Assigning IP addresses to remote access connections**
Each remote computer that connects to a remote access server on a Windows TCP/IP network is provided an IP address by the server. This IP address is either automatically provided through the server by DHCP on the target network or selected from the static range that is assigned to the remote access server. For more information see Incoming connections and IP addresses.

If you use a specific IP address, the remote access server must be configured to permit users to request a specific address.

**Name resolution for network and dial-up connections**
In addition to requiring an IP address, network and dial-up connections for a NetBT gateway on a TCP/IP network may require a mechanism to resolve computer names to IP addresses. You can use any one of the following mechanisms for name resolution: DNS, WINS, broadcast name resolution, and the Hosts and Lmhosts files.

Incoming connections clients are assigned the same WINS and DNS servers that are assigned to the incoming connections computer. The TCP/IP settings of a network or dial-up connection can override these automatic assignments.

Incoming connections that do not have a DNS or WINS server rely completely on broadcast name resolution, which occurs by using broadcasts to locate network resources that match a computer name.

**Internet tools**
The Windows Server 2003 family provides File Transfer Protocol (FTP) and Telnet. FTP is a character-based utility that permits you to connect to FTP servers and transfer files. Telnet is a command-line application that lets you log on to remote computers and issue commands as if you were at the keyboard of the remote computer. Multiple variations of FTP, Telnet, and other services based on earlier Internet standards are also available on the Internet or commercially.

For information about configuring a connection, see Configure a connection to a remote network. For information about configuring TCP/IP, see Configure TCP/IP settings.

### Note

- FTP and Telnet tools run on top of TCP/IP networks.

# IPX

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IPX**
Internetwork Packet Exchange (IPX) is the protocol that is used on many Novell NetWare networks. This section explains how to integrate Network Connections into an IPX network.

**Support for NetWare and IPX**
Network Connections supports NetWare and IPX networks by including:

- NWLink IPX/SPX/NetBIOS Compatible Transport Protocol, also known as NWLink, which is the Microsoft® Windows Server 2003 family implementation of the IPX protocol.
- Client Service for NetWare client component, which provides access to NetWare shared file and printer resources.
- Point-to-Point Protocol (PPP) IPX Configuration Protocol (IPXCP), which supports IPX over PPP for dial-up, virtual private network (VPN), and incoming connections. PPP connections use IPXCP, as defined in RFC 1552, "The PPP Internetwork Packet Exchange Control Protocol (IPXCP)," to configure PPP connections for IPX.

For information about configuring a connection, see Configure a connection to a remote network. For information about configuring NWLink IPX/SPX/NetBIOS Compatible Transport Protocol, see Configure NWLink.

**Notes**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.
- IPX routing is not supported in the Windows Server 2003 family.
- IPX cannot be configured for incoming or dial-up connections in the Windows Server 2003 family.

# AppleTalk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**AppleTalk**

Networking on an Apple Macintosh computer is implemented through the AppleTalk protocol. Applications and processes can communicate across a single AppleTalk network or an AppleTalk internet, which is a number of interconnected AppleTalk networks. By using AppleTalk, applications and processes can transfer and exchange data and share resources, such as printers and file servers. AppleTalk remote access is supported by the AppleTalk Control Protocol (ATCP).

With ATCP, Macintosh clients can run the AppleTalk network protocol over the Point-to-Point Protocol (PPP). With ATCP support, a remote user can access a Web server over TCP/IP, print a document to an AppleTalk printer, and connect to a Macintosh file server (over TCP/IP or AppleTalk), all with the same dial-up connection over PPP.

For more information, see AppleTalk over PPP.

For information about configuring a connection, see Configure a connection to a remote network.

# ISDN access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ISDN access**

To enhance your network connection speed, you can use an Integrated Services Digital Network (ISDN) line. Whereas standard phone lines typically transmit at up to 56 kilobits per second (Kbps), ISDN lines can transmit at speeds of 64 or 128 Kbps.

An ISDN line must be installed by the phone company at both the server and at the remote site. ISDN also requires that you install an ISDN adapter on the server and your computer. Costs for ISDN equipment and lines may be higher than standard modems and phone lines. However, the speed of communication reduces the duration of the connection, possibly saving toll charges.

An ISDN line comes with two B channels that transmit data at 64 Kbps, and one D channel for signaling that transmits data at 16 Kbps. You can configure each B channel to operate as a port. With some ISDN drivers, you can aggregate the channels. This means you can statically assign a higher bandwidth by configuring both B channels to act as a single port. With this configuration, line speed increases to 128 Kbps. For information about configuring a connection to use ISDN, see Make a dial-up connection by using an ISDN line or Configure ISDN settings.

The Multilink feature performs channel aggregation for ISDN. Multilink combines multiple physical links into a logical bundle. This aggregate link increases the bandwidth of a connection. In addition, you can allocate multiple links dynamically, which means ISDN lines are used only as they are required. This eliminates excess bandwidth, representing a significant efficiency advantage to users. You can configure the conditions under which extra lines are dialed, and underused lines are disconnected, through Network Connections settings. For more information, see Configuring multiple device dialing.

# Serial (RS-232) cable access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Serial (RS-232) cable access**

Suppose you have two networks in the same location that are not physically connected. To use resources on both networks from one computer, you can use RS-232 cables and COM ports to create null modems. You connect an RS-232 cable from a COM port to a COM port on each remote access server. To the servers, the COM ports then appear to be modems. You can use server remote access, a part of the integrated Routing and Remote Access service, to create network access.

For information about creating a direct connection by using serial access, see Make a direct network connection.

# DirectParallel cable access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**DirectParallel cable access**

The DirectParallel feature supports computer-to-computer connections by using standard and enhanced (ECP) parallel ports, which use Parallel Technologies' Basic or Fast parallel cables. For information about configuring a direct network connection to use a DirectParallel cable, see Make a direct network connection by using a DirectParallel cable. Direct cable connection cables are available from several sources. You can obtain DirectParallel cables from Parallel Technologies or from their local dealers. For more information, see To contact Parallel Technologies.

# SLIP

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SLIP**
Serial Line Internet Protocol (SLIP) is an older remote access standard typically used by UNIX remote access servers. Network Connections supports SLIP for dial-up connections.

When you connect to a SLIP server, a **Windows Terminal** dialog box appears for an interactive logon session with the UNIX SLIP server. The UNIX logon overrides and prevents the remote access logon session from appearing. After a connection is established, remote network access becomes transparent to the user.

The RFCs supported in remote access are:

- RFC 1055, "A Nonstandard for Transmission of IP Datagrams Over Serial Lines: SLIP"
- RFC 1144, "Compressing TCP/IP Headers for Low-Speed Serial Links"

For information about configuring a network or dial-up connection, see Configure a connection to a remote network.

**Notes**

- Microsoft® Windows® XP does not support SLIP for incoming connections.
- You must use the TCP/IP protocol and a serial COM port to connect to a SLIP server.

# Point-to-Point Protocol (PPP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Point-to-Point Protocol (PPP)**
The Point-to-Point Protocol (PPP) is a set of standard protocols that allow remote access software from different vendors to interoperate. A PPP-enabled connection can dial into remote networks through any industry-standard PPP server. PPP also permits a remote access server to receive calls from, and provide network access to, other vendors' remote access software that complies with the PPP standards.

The PPP standards also permit advanced features that are not available with older standards such as SLIP. PPP supports several authentication methods, as well as data compression and encryption. With most PPP implementations, you can automate the entire logon sequence.

PPP also supports multiple LAN protocols. You can use TCP/IP or IPX as your network protocol.

The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

PPP is the basis for the Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP) protocols, which are used in secure virtual private network (VPN) connections.

PPP is the primary standard for most remote access computing.

This section covers:

- PPP operation and protocols
- Point-to-Point Protocol over Ethernet (PPPoE) Protocols

# PPP operation and protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**PPP operation and protocols**

Connections made using Point-to-Point Protocol (PPP) must adhere to standards established in PPP RFCs. For information on PPP RFCs, see "Introduction to TCP/IP" at the Microsoft Windows Resource Kits Web site. This topic gives an overview of PPP operations and the protocols used in a PPP connection. For information about how to configure PPP settings, see PPP Settings.

**PPP connection process**

After a physical or logical connection is made to a PPP-based remote access server, the following negotiations establish a PPP connection:

1. Negotiate the use of the link

   PPP uses Link Control Protocol (LCP) to negotiate link parameters such as the maximum PPP frame size, the use of Multilink, and the use of a specific PPP authentication protocol.

2. Authenticate the remote access computer

   The remote access client and the remote access server exchange messages according to the negotiated authentication protocol. If EAP is being used, the client and the server negotiate a specific EAP method, known as an EAP type, and then exchange the messages of that EAP type.

3. Use callback

   If callback for the dial-up connection is configured, the physical connection is terminated, and the remote access server calls the remote access client back.

4. Negotiate the use of network protocols

   This process involves using a series of network control protocols (NCPs) to configure the network protocols the remote access client uses. For example, the NCP for TCP/IP is Internet Protocol Control Protocol (IPCP). If the remote access client is configured to use TCP/IP, IPCP is used to assign an IP address to the client and to configure the client with the IP addresses of DNS and WINS servers.

The resulting connection remains active until the line is disconnected for any of the following reasons:

- The user or the administrator explicitly hangs up the line.
- The line is disconnected due to idle time-out.
- An unrecoverable link error occurs.

**Link Control Protocols**

Link Control Protocol (LCP) establishes and configures PPP framing. PPP framing defines how data is encapsulated before it is transmitted on the wide area network. The PPP standard framing format ensures that remote access software from any vendor can communicate and recognize data packets from any remote access software that adheres to the PPP standards.

PPP and the Microsoft® Windows Server 2003 family use variants of High-level Data Link Control (HDLC) framing for serial or ISDN connections.

**Authentication protocols**

Authentication protocols are negotiated immediately after link quality is determined and before the network layer is negotiated. For more information about available authentication protocols, see Authentication Protocols and Methods.

**Network control protocols**

Network control protocols establish and configure different network protocol settings for TCP/IP, IPX, and AppleTalk. The following table describes network control protocols used with a PPP connection.

The IPX/SPX protocol is not available on the Itanium-based versions of the Windows operating systems.

| Network control protocol | Description |
|---|---|
| Internet Protocol Control Protocol (IPCP) | IPCP is used to configure TCP/IP on the remote access client. Configuration parameters include an IP address and the IP addresses of DNS and WINS servers. |
| Internetwork Packet Exchange Control Protocol (IPXCP) | IPXCP is used to configure IPX on the remote access client. IPXCP is widely implemented by PPP vendors. Configuration parameters include the IPX network and node numbers. |
| AppleTalk Control Protocol (ATCP) | ATCP is used to configure AppleTalk on the remote access client. Configuration parameters include an AppleTalk address. |

**Note**

- The **PPP settings** dialog box includes the option **Negotiate multi-link for single-link connections**. This option enables separation of high and low-priority channels over a single link connection. If your remote access server supports this feature, you might notice improved audio quality. However, because this feature is incompatible with many remote access servers, you should leave it disabled unless instructed otherwise. For more information on PPP settings, see PPP Settings.

# Point-to-Point Protocol over Ethernet (PPPoE) Protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Point-to-Point Protocol over Ethernet (PPPoE) Protocols**
Using Point-to-Point Protocol over Ethernet (PPPoE) and a broadband modem, LAN clients can gain individual authenticated access to high-speed data networks. By combining Ethernet and Point-to-Point Protocol (PPP), PPPoE provides an efficient way to create a separate connection to a remote server for each user. Access, billing, and choice of service are managed on a per-user basis, rather than a per-site basis. Clients can create both dial-up and dial-on-demand connections using PPPoE.

**PPPoE RFCs**
Requests for Comments (RFCs) are an evolving series of technical reports, proposals for protocols, and protocol standards used by the Internet community. PPPoE is defined in RFCs published by the Internet Engineering Task Force (IETF) and other working groups. The following is an example of a PPPoE RFC:

**RFC number** - 2516A

**Title** - Method for Transmitting PPP Over Ethernet (PPPoE)

**Obtaining RFCs**
You can obtain RFCs from the RFC Editor Web site. This Web site is currently maintained by members of the Information Sciences Institute (ISI) who publish a classified listing of all RFCs. RFCs are classified as one of the following: approved Internet standards, proposed Internet standards (circulated in draft form for review), Internet best practices, or For Your Information (FYI) documents.

### Notes

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.
- PPPoE is supported on clients running Microsoft® Windows® XP. All members of the Windows Server 2003 family can connect to and route PPPoE traffic. However, they cannot accept an incoming PPPoE connection.

For more information, see Make a broadband connection using Point-to-Point Protocol over Ethernet (PPPoE).

# Home and Small Office Networking Overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking overview**
With home and small office networking, even if you do not have the resources, time, or experience of a network administrator, you can build a small network in your home or small office. Home and small office networking is a group of features that limits hardware requirements and automates configurations for routing and private IP addressing. This reduces the work that is typically required to connect and configure a network. It also reduces the associated costs.

Home and small office networking provides many of the benefits of traditional networks and offers benefits that are uniquely suited for a home or small office network. With home and small office networking you can:

- Share one Internet connection with all of the computers on your network.
- Provide local private network services, such as name resolution and addressing, automatically.
- Share printers or other hardware devices, such as cameras and scanners, from any computer on your network.
- Share folders and files with other computers on your network.
- Use one computer to secure your entire network and protect your Internet connection.
- Easily establish network connections across two or more types of network media, such as IEEE 1394, Ethernet, wireless, and Home Phoneline Network adapters.

This section covers:

- Home and small office networking features
- Home and small office networking compared to Routing and Remote Access

# Home and small office networking features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking features**
Home and small office networking uses the following features to simplify the implementation and administration of small networks.

**Internet Connection Firewall (ICF) and Windows Firewall**
Home and small office networking offers computers that are directly connected to the Internet the added security of firewall protection. The firewall checks all communications that cross the connection between your network and the Internet and is selective about which responses from the Internet it allows. ICF and Windows Firewall protect only the computer on which they are enabled. However, if ICF or Windows Firewall are enabled on the Internet Connection Sharing (ICS) host computer, ICS clients that use the shared Internet connection for Internet connectivity are protected because they cannot be seen from outside your network. For this reason, you should always enable ICF or Windows Firewall on the ICS host computer. In addition, if there are clients on your network with direct Internet connections, or if you have a stand-alone computer that is connected to the Internet, then it is recommended that you enable ICF or Windows Firewall on those Internet connections as well.

For more information about ICF, see Internet Connection Firewall. For more information about Windows Firewall, see Help: Windows Firewall.

**Network Bridge**
Network Bridge removes the need for routing and bridging hardware in a home or small office network that consists of multiple LAN segments. With Network Bridge, multiple LAN segments become a single IP subnet, even if the LAN segments are of mixed network media types. Network Bridge automates the configuration and management of the address allocation, routing, and name resolution that is typically required in a network that consists of multiple LAN segments.

For more information see Network Bridge.

**Internet Connection Sharing (ICS)**
ICS allows you to provide Internet access for a home or small office network by using one common connection as the Internet gateway. The ICS host is the only computer that is directly attached to the Internet. Multiple ICS clients simultaneously use the common Internet connection and benefit from Internet services as if the clients were directly connected to the Internet service provider (ISP) (for more information, see Dial-up credentials). Security is enhanced when ICS is enabled because only the ICS host computer is visible to the Internet. The addresses of ICS clients are hidden from the Internet rendering ICS clients invisible to the Internet. In addition, ICS simplifies the configuration of small networks by providing local private network services, such as name resolution and addressing.

For more information about ICS, see Connecting to the Internet in a home or small office network.

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Home and small office networking compared to Routing and Remote Access

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking compared to Routing and Remote Access**
Home and small office networking and the Routing and Remote Access service are both included in Microsoft® Windows® XP and the Windows Server 2003 family to provide the following networking capabilities:

- Network address translation (NAT)
- Packet filtering
- Dial-up access
- Virtual private network (VPN) access
- Automated IP addressing for network clients
- Name resolution
- Internet connections

Because home and small office networking features and Routing and Remote Access share common drivers, they cannot coexist, and you need to decide which to implement in order to meet the needs of your networking environment.

**Home and small office networking**
You can use home and small office networking features--Internet Connection Firewall (ICF), Windows Firewall, Network Bridge, and Internet Connection Sharing (ICS)--to simplify the configuration of your home or small office network. These features are intended for networks that consist of two to 10 computers when you want to:

- Protect computers that are connected to the Internet using an easily configured firewall. For more information, see Internet Connection Firewall.
- Connect LAN segments simply, by using the **Bridge Connections** menu command. For more information, see Network Bridge.
- Provide simultaneous Internet access for up to 10 computers using a single dial-up or high-speed Internet connection. For more information, see Connecting to the Internet in a home or small office network.
- Support up to 10 simultaneous dial-up or VPN connections to provide remote computers with access to network resources. For more information, see Incoming connections.

**Routing and Remote Access**
You can use Routing and Remote Access in combination with Internet Security and Acceleration (ISA) server to meet the needs of your small business with high security needs, your medium-sized private business, or your enterprise network that spans multiple subnets and supports up to 1,000 computers running Windows Server 2003, Standard Edition or up to 5,000 computers running Windows Server 2003, Enterprise Edition. Internet connectivity for branch offices is routed through the corporate routing and firewall infrastructure. Use Routing and Remote Access when you want to:

- Provide local and branch office computers with high-security Internet access.
- Connect branch offices with corporate intranets, and share resources as if all computers are connected to the same LAN.

- Protect network interfaces with static packet filters or dynamic packet filters.
- Support up to 1,000 simultaneous dial-up or VPN connections to provide remote computers with access to corporate network resources.

**Comparisons**

The following table summarizes the differences between the way that home and small office networking features (and incoming connections) and Routing and Remote Access (with ISA server) implement basic networking services.

| Service | Description | Home and small office networking features (and incoming connections) | Routing and Remote Access (with ISA server) |
|---|---|---|---|
| **NAT** | Hides internally managed IP addresses from external networks by translating private internal addresses to public external addresses. This reduces IP address registration costs by letting you use unregistered IP addresses internally, with translation to a small number of registered IP addresses externally. It also hides the internal network structure, reducing the risk of attacks against internal systems. | ICS | Routing and Remote Access NAT |
| **Dynamic packet filtering** | Provides protection from unsolicited traffic for the private network. Permits only traffic that is sent in response to an internal request. | ICF, Windows Firewall | Basic Firewall |
| **VPN and dial-up access** | Allows clients on a remote computer to connect to a private network and to access network resources as if the computer was physically attached to the network. | Incoming connections | Routing and Remote Access |
| **Address assignment** | Automates the assignment of client IP addresses on the private network in order to configure clients to allow client-access to network resources. | ICS DHCP allocator | Routing and Remote Access NAT, with a DHCP allocator or a DHCP server |
| **DNS name resolution** | Converts the names of computers and other network devices, such as printers, to IP addresses. | ICS DNS Proxy | NAT, with a DNS proxy or a DNS server |
| **Internet connections** | Provides a high-speed or dial-up connection for the computer that is connected to the Internet to use to publish its services to the private network. | Configured through Network Connections | Configured through Routing and Remote Access |

The following table summarizes which components, features, and connection types are best suited to provide networking services in a given networking scenario.

| Service | Scenario: Small office, non-domain network | Scenario: Small office, domain network | Scenario: Medium office network with NAT traversal | Scenario: Medium office network without NAT traversal | Scenario: Enterprise network | Scenario: Branch office network |
|---|---|---|---|---|---|---|
| **NAT** | ICS | ICS | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access with ISA (on the corporate network) |

| | | | | | | |
|---|---|---|---|---|---|---|
| **Packet filtering** | ICF, Windows Firewall | ICF, Windows Firewall | Basic Firewall or ISA | Basic Firewall or ISA | ISA | ISA (on the corporate network) |
| **VPN/remote access** | Incoming connections | Incoming connections | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access | Routing and Remote Access with ISA (on the corporate network) |
| **Address assignment** | ICS DHCP allocator | DHCP server | DHCP server | DHCP server | DHCP server | DHCP server |
| **Internet connection** | Dial-up, ISDN, broadband, DSL, or LAN | Dial-up, ISDN, broadband, DSL, or LAN (with ISA) | Any combination of T1 or T3, dial-up, ISDN, broadband, DSL, and LAN | Any combination of dial on demand (DoD) routing, T1 or T3, dial-up, ISDN, broadband, DSL, or LAN | Any combination of dial on demand (DoD) routing, T1 or T3, dial-up, ISDN, broadband, DSL, or LAN | Any combination of dial on demand (DoD) routing, T1 or T3, dial-up, ISDN, broadband, DSL, or LAN |
| **NAT traversal** | Not available | Not available | ISA | Does not apply | ISA | ISA (on the corporate network) |
| **DNS** | DNS proxy | DNS server | DNS server | DNS server | DNS server | DNS server |

**Notes**

- In the case of ICS with a DNS or DHCP server, ICS discovers the DHCP service or DNS service and, if present, disables the DNS proxy, DHCP allocator, or both.
- Because ICS, ICF, and Windows Firewall are not compatible with Routing and Remote Access, you cannot enable ICS or ICF if Routing and Remote Access is configured. Likewise, if ICS or ICF are enabled, they must first be disabled in order to configure Routing and Remote Access.
- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Understanding Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding Network Connections**
This section covers:

- Security for Network Connections
- Tunneling Protocols
- Home and Small Office Networking

# Security for Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security for network connections**

This section covers:

- Security Features of Network Connections
- Intermediary Devices

# Security Features of Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security features of Network Connections**

You can configure your dial-up, virtual private network (VPN), broadband, and direct connections to enforce various levels of password authentication and data encryption. Authentication methods range from unencrypted to custom, using Extensible Authentication Protocol (EAP). EAP provides an infrastructure to support a wide range of authentication methods, including smart cards, certificates, one-time passwords, and public keys. You can also specify the type of data encryption, depending on the level of password authentication (MS-CHAP, MS-CHAP v2, or EAP-TLS) that you select. Finally, you can configure callback options to increase dial-up security.

User accounts and domains provide security with encrypted authentication and encrypted data. For more information about security, see Security.

This section covers:

- Callback
- How security works at connection
- Group Policy for Network Connections
- Group Policy settings that prohibit home and small office networking on your domain
- Dial-up credentials
- Data Encryption and Encryption Methods
- Network Authentication

# Callback

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Callback**
The callback feature instructs the remote access server to disconnect after authentication and then to call you back. Callback provides cost advantages to you and security advantages to your network. By immediately hanging up and then dialing you back, callback reduces phone charges. Required callback enhances network security by ensuring that only users from specific locations can access the server. By dropping the call, and then calling back a moment later to the preassigned callback number, most impersonators can be thwarted.

If callback has been required by your administrator, the following steps occur when your call reaches the remote access server:

1. The server determines whether your user name and password are correct.

2. If they are correct, the server disconnects and then returns the call.

If your administrator has configured callback for your connection through the **Remote Access Preferences** menu option, the following steps occur when your call reaches the remote access server:

1. The server determines whether your user name and password are correct.

2. If they are correct, the **Callback** dialog box appears on your computer.

3. You then type the current callback number in the dialog box and wait for the server to disconnect and return the call.

   Optionally, you can press ESC to cancel the callback process and remain connected.

For more information about configuring your callback options, see Configure client callback options.

**Notes**

- Your callback options are determined by your system administrator. The administrator may deny the use of callback, allow user-defined callback, or require callback to a particular number. You can contact your system administrator to determine your callback options.

- If your computer is configured to accept incoming connections, you can enforce callback options on that computer. For more information, see Configure callback for incoming connections.

# How security works at connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How security works at connection**

The following steps describe what happens during a call to a remote access server:

1. The remote access client computer calls a remote access server.

2. Depending on the authentication methods that have been negotiated, one of the following happens:

   - If you are using PAP or SPAP:

     The client sends its user name and password to the server.

     The server checks the account credentials against the user database.

   - If you are using CHAP or MS-CHAP:

     The server sends a challenge to the client.

     The client sends an encrypted response to the server.

     The server checks the response against the user database.

   - If you are using MS-CHAP v2:

     The server sends a challenge to the client.

     The client sends an encrypted response and a challenge to the server.

     The server checks the encrypted response of the client against the user database and sends the client its own encrypted response.

     The client verifies the encrypted response of the server.

   - If you are using certificate-based authentication:

     The server sends its computer certificate to the client.

     If the client is configured for certificate-based authentication, the client validates the server certificate.

     The client sends its user certificate to the server.

     The server verifies that the user certificate is valid and has not been revoked.

3. If the connection attempt is both authenticated (the user credentials are valid, the user account is enabled and not locked out, and the connection is occurring within the allowed logon hours) and authorized (for incoming connections, the user account has remote access permission), the server accepts the remote access connection.

   If callback is enabled, the server calls your computer back and repeats steps 2 through 3.

**Notes**

- For the Routing and Remote Access service, authorization of the connection is determined by the dial-in properties of the

user account and remote access policies. Remote access policies are a set of conditions and connection settings that give network administrators more flexibility in granting remote access permissions and usage. If the settings of the connection do not match at least one of the remote access policies that apply to your connection, the connection attempt is rejected, regardless of the dial-in properties of the user account.

- Network Connections authentication methods control access to your network, not to resources on the network. Once you are connected to a network, resource access control is managed through access control lists (ACLs) in various ways: Local Users and Groups, Active Directory, Group Policy, file and printer sharing, and so on.

- Authentication methods are designed for remote computing environments where the computer that is dialing in does not have access to the network until credentials, such as user name and password, are validated.

- For information about configuring security options for your connections, such as identity authentication protocols and data encryption settings, see Secure Network or Dial-up Connections.

# Group Policy for Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy for Network Connections**
By using the Group Policy snap-in, an administrator can configure the desktop settings of many computers at once. Some Group Policy settings apply specifically to Network Connections, such as user access to connections and the ability to change the properties of connections. These settings can be found in the Administrative Templates of the Group Policy snap-in.

### Where?

- *Group_Policy_object_name*/Computer Configuration (or User Configuration)/Administrative Templates/Network/Network Connections

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.

- If you do not have write access to a Group Policy object, you cannot see the settings contained in that object.

For an overview of Group Policy, Group Policy objects, and administrative templates, see Group Policy overview. For more information on how to use Group Policy to define policy settings that are applied to computers or users, see Group Policy (pre-GPMC).

# Group Policy settings that prohibit home and small office networking on your domain

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Group Policy settings that prohibit home and small office networking on your domain**

Group Policy settings define the various components of the user's environment that a system administrator can manage. The following Group Policy settings are available to prohibit home and small office networking on your domain:

- **prohibit use of Internet Connection Sharing on your DNS domain network** determines whether computer users with administrator accounts can enable and configure Internet Connection Sharing (ICS) on network connections on your domain.

- **prohibit use of Internet Connection Firewall on your DNS domain network** determines whether computer users with administrator accounts can enable and configure Internet Connection Firewall (ICF) on network connections on your domain.

- **prohibit installation and configuration of Network Bridge on your DNS domain network** determines whether computer users with administrator accounts can enable Network Bridge on your domain.

**Group Policy for ICS**

ICS allows a user with an administrator account to provide Internet access for a home or small office network, using one common connection as the Internet gateway, and to provide local private network services, such as name resolution and addressing. The ICS host is the only computer that is directly connected to the Internet. Multiple ICS clients simultaneously use the common (shared) Internet connection. ICS is available only on computers that have two or more network connections. Users with administrator accounts enable ICS by accessing the **Advanced** tab on network connections. For more information about ICS, see Connecting to the Internet in a home or small office network.

If you do not want users on your domain to be able to enable or configure ICS, apply the **prohibit use of Internet Connection Sharing on your DNS domain network** Group Policy setting. When you apply the **prohibit use of Internet Connection Sharing on your DNS domain network** Group Policy setting, users with administrator accounts cannot enable or configure ICS because the **Advanced** tab on network connections becomes unavailable, and the related wizard options on computers running Windows XP Professional are blocked.

Computer users with user rights are prohibited from configuring ICS, regardless of this Group Policy setting.

**Group Policy for ICF**

ICF allows a user with an administrator account to activate a firewall to protect the public connection of a small network or a single computer that is connected to the Internet. ICF is enabled by default only on dial-up connections. Users with administrator accounts can enable ICF on other types of connections, such as LAN and wireless connections, by accessing the **Advanced** tab on network connections. For more information about ICF, see Internet Connection Firewall.

If you do not want users to be able to enable or configure ICF, apply the **prohibit use of Internet Connection Firewall on your DNS domain network** Group Policy setting. When you apply the **prohibit use of Internet Connection Firewall on your DNS domain network** Group Policy setting, users with administrator accounts cannot enable or configure ICF because the **Advanced** tab becomes unavailable, and the related wizard options on computers running Windows XP Professional are blocked.

Computer users with user rights are prohibited from configuring ICF, regardless of this Group Policy setting.

**Group Policy for Network Bridge**

Network Bridge automates the configuration that is required to route traffic between multi-segment networks comprised of a single type of media or mixed media. With Network Bridge, no configuration is required, and you do not need purchase additional hardware such as routers or bridges. The Network Bridge menu command **Bridge Connections** is available only when two or more network adapters are present. By default, Network Bridge is disabled, but users with administrator accounts can use **Bridge Connections** to enable Network Bridge. For more information about Network Bridge, see Network Bridge.

If you do not want users on your domain to be able to enable or configure Network Bridge, apply the **prohibit installation and configuration of Network Bridge on your DNS domain network** Group Policy setting. When you apply the **prohibit**

**installation and configuration of Network Bridge on your DNS domain network** Group Policy setting, users with administrator accounts cannot enable or configure Network Bridge because the **Bridge Connections** command is removed from the menu on network connection icons, and the related wizard options on computers running Windows XP Professional are blocked.

Computer users with user rights are prohibited from configuring Network Bridge, regardless of this Group Policy setting.

**Important**

The Group Policy settings for ICS and ICF are location-aware. A location-aware Group Policy setting applies only when a computer is connected to the domain that it was connected to when the setting was last refreshed. If a computer, such as a laptop computer, is connected to your domain, but the setting on the computer was last refreshed on another domain, then the Group Policy setting on your network do not apply to that computer.

For example, if ICS is enabled on a computer that is on your network, and then you apply the Group Policy setting for ICS, ICS continues to run as normal until you restart the computer or log off of the network and then log on again. The same is true if the Group Policy setting for ICS is set on your network, and then a computer on which ICS is enabled joins your network. In this case also, ICS continues to run as normal until you restart the new computer or log off of the network and then log on again. This example applies to ICF as well.

The Group Policy setting for Network Bridge works somewhat differently. If Network Bridge is enabled on a computer that is on your network, and then you apply the Group Policy setting for Network Bridge, or if the Group Policy setting for Network Bridge is set on your network, and then a computer on which Network Bridge is enabled joins your network, Network Bridge continues to exist in the Network Connections folder and to use system resources, but the functionality of Network Bridge changes. In these cases, Network Bridge continues to receive and send data over the network connections that are included in the bridge but, for security reasons, no longer forwards traffic from one network connection to another. This change is immediate; it does not require that you restart the computer or log off of the network and then log on again.

For an overview of Group Policy, see Group Policy (pre-GPMC).

**Note**

- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Dial-up credentials

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up credentials**

Credentials are required to successfully connect to the Internet using dial-up connections. Your credentials are the combination of your ISP account name and password. Your computer user profile identifies your account as either an administrator account or a user account. If you log on using user credentials, you will have two options for how your credentials are saved when you create a dial-up connection. If you log on with administrative credentials, you will have three options for how your credentials are saved when you create a dial-up connection. If you have account profiles with both administrator and user credentials, only the credentials for the account that you have logged on with will apply.

If you log on with user account credentials, you can create only dial-up connections for **My use only**. These connections will be successful only when you are logged on to the computer, and they will not be accessible to any other users. When creating user account dial-up connections, you can either save your credentials as **Me only** (for your use only) or not save your credentials. If you save your credentials as **Me only**, and you are logged on to the computer using the account you used when you created the connection, your credentials will be automatically supplied when using the connection. If you do not save your credentials, a dialog box will be provided for you to enter your credentials each time you are logged on to the computer using the account you used when creating the connection and you attempt to connect to the Internet.

If you log on with administrative credentials, you can create connections for either **Anyone's use** or **My use only**. If you create a connection for **My use only**, the connection options are the same as those created by anyone with a user account. Connections created for **Anyone's use** can be seen by any user who logs on to that computer, but connection success to the Internet is affected by how credentials were saved. When creating a connection for **Anyone's use**, you can save your credentials so that they will be supplied automatically for **Anyone who logs on to this computer** or **Me only**. You can also choose not to save your credentials.

If you save your credentials for **Anyone who logs on to this computer**, your saved credentials will automatically be supplied for any user who has logged on to the computer and attempts to connect to the Internet using that connection or on-demand dialing. If you save your credentials but do not make them available for **Anyone who logs on to this computer**, then your saved credentials will be automatically supplied only if you are logged on to the computer. Other users will see a dialog box that prompts them for your user name and password; they will be unable to connect to the Internet using this connection unless they can provide your credentials. If you do not save your credentials, a dialog box will appear and prompt you or any other user to enter your credentials before the connection to the Internet can be completed.

The following summarizes the experience of a user logging on with user credentials and experience of a user logging on with administrative credentials:

**Logging on with user credentials**

| Connection type created | Credential save options | Local computer access |
|---|---|---|
| • **My use only** | • **Me only**<br>• Not saved | This connection will work only when you are logged on with the account that you used when you created the connection. If you did not save your credentials, you will be prompted to supply them every time you use the connection. You cannot configure Internet Connection Sharing (ICS), Internet Connection Firewall (ICF), or Windows Firewall on this connection. If you want to enable ICS or configure ICF or Windows Firewall, you should log on with administrative credentials before you create the dial-up connection because only administrators can access the **Advanced** tab. If you want to enable ICS, ICF, or Windows Firewall on a dial-up connection that was created with user credentials, the user who created the connection must be promoted to an administrator. |

| ICS client Internet access through My use only ICS connections |
|---|

| |
|---|
| Users of ICS client computers can connect to the Internet through connections on the ICS host computer that are saved for **My use only** if:<br>• The user who created the connection saved credentials and is logged on to the ICS host computer.<br>• The user who created the connection did not save credentials but that user or another user can supply those credentials when prompted by the ICS host computer to do so. |

**Logging on with administrative credentials**

| Connection type created | Credential save options | Local computer access |
|---|---|---|
| • **My use only** | • **Me only**<br>• Not saved | This connection will work only when you are logged on with the account that you used when you created the connection. If you did not save your credentials, you will be prompted to supply them every time you use the connection. You cannot configure Internet Connection Sharing (ICS), Internet Connection Firewall (ICF), or Windows Firewall on this connection. If you want to enable ICS or configure ICF or Windows Firewall, you should log on with administrative credentials before you create the dial-up connection because only administrators can access the **Advanced** tab. If you want to enable ICS, ICF, or Windows Firewall on a dial-up connection that was created with user credentials, the user who created the connection must be promoted to an administrator. |
| • **Anyone's use** | • **Anyone who uses this computer**<br>• **Me only**<br>• Not saved | All users can see the Internet connection. If you saved your credentials for all users, any user who is logged on to the computer can connect to the Internet. If you saved your credentials as **Me only**, the connection is automatically completed only if you log on to the computer as the administrator who saved the credentials when you created the connection. If you did not save your credentials, when you or another user attempts to connect to the Internet, your credentials must be supplied when prompted in order to complete the connection. You can access the **Advanced** tab to enable ICS or configure ICF or Windows Firewall because you logged on as an administrator when you created the dial-up connection. |

| **ICS client Internet access through Anyone's use connections** |
|---|
| Users of ICS client computers can connect to the Internet through connections on the ICS host computer that are saved for **Anyone's use** only if:<br>• The administrator who created the connection saved credentials for use by anyone who uses the computer. (This attempt will succeed whether a user is logged on to the ICS host computer or the ICS client computer.)<br>• The administrator who created the connection saved credentials as **User only** and is now logged on to the ICS host computer with the same credentials.<br>• The administrator who created the connection did not save credentials, but a user can supply those credentials when prompted by the ICS host computer. |

You must enable on-demand dialing in order for programs to automatically initiate dial-up connections to your Internet service provider. For more information, see Enable ICS on-demand dialing.

You must enable ICS in order for computers on your network to share a common Internet connection. For more information, see Connecting to the Internet in a home or small office network.

**Notes**

- As a security measure, you should log on using user credentials rather than administrative credentials.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Windows Firewall is not included in the original release of the Windows Server 2003 operating systems.

# Data Encryption and Encryption Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data encryption and encryption methods**

This section covers:

- Data encryption
- Microsoft Point-to-Point Encryption (MPPE)
- Internet Protocol Security (IPSec) Encryption

# Data encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Data encryption**

You can think of encryption as locking something valuable into a strong box with a key. Sensitive data is encrypted by using an encryption algorithm and a key, which renders it unreadable without the knowledge of the key. Data encryption keys are determined at connect time between the connecting computers. The use of data encryption can be initiated by your computer or by the server you are connecting to.

Network Connections supports two types of encryption:

- Microsoft MPPE, which uses RSA RC4 encryption.
- An implementation of Internet Protocol security (IPSec) that uses Data Encryption Standard (DES) encryption.

Both MPPE and IPSec support multiple levels of encryption, as shown in the following table.

| Encryption type | Level of encryption supported |
|---|---|
| MPPE Standard | 40-bit, 56-bit |
| MPPE Strong | 128-bit |
| IPSec DES | 56-bit |
| IPSec Triple DES | 3DES |

For more information, see the following:

- Microsoft Point-to-Point Encryption (MPPE)
- Internet Protocol Security (IPSec) Encryption

**Notes**

- Server controls are flexible and can be set to deny the use of encryption, require a specific encryption strength, or allow your computer to select an encryption strength. By default, most servers allow encryption and allow clients to select their encryption methods. This works for most computers. A system administrator sets encryption requirements. To determine your options, contact your system administrator.
- To enable MPPE-based data encryption for dial-up or virtual private network (VPN) connections, you must select the MS-CHAP, MS-CHAP v2, or EAP-TLS authentication methods. These authentication methods generate the keys used in the encryption process.
- Virtual Private Networks (VPNs) use encryption depending on the type of server they are connecting to. If the VPN connection is configured to connect to a PPTP server, then MPPE encryption is used. If the VPN is configured to connect to an L2TP server, then IPSec encryption methods are used. If the VPN is configured for an Automatic server type, which is the default selection, then L2TP, and its associated IPSec encryption, will be attempted first, then PPTP, and its associated MPPE encryption.

# Microsoft Point-to-Point Encryption (MPPE)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Point-to-Point Encryption (MPPE)**
Microsoft Point-to-Point Encryption (MPPE) encrypts data in Point-to-Point Protocol (PPP)-based dial-up connections or Point-to-Point Tunneling Protocol (PPTP) virtual private network (VPN) connections. 128-bit key (strong), 56-bit key, and 40-bit key (standard) MPPE encryption schemes are supported. MPPE provides data security for the PPTP connection that is between the VPN client and the VPN server.

For more information about configuring connections, see Configure a connection to a remote network.

**Note**

- MPPE requires encryption keys as generated by Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2), or Extensible Authentication Protocol-Transport Level Security (EAP-TLS) authentication process.

# Internet Protocol Security (IPSec) Encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Protocol security (IPSec)**
The long-term direction for secure networking, IPSec is a suite of cryptography-based protection services and security protocols. Because it requires no changes to applications or protocols, you can easily deploy IPSec for existing networks.

IPSec provides computer-level authentication, as well as data encryption, for VPN connections that use the L2TP protocol. IPSec is negotiated between your computer and an L2TP-based VPN server before an L2TP connection is established. This negotiation secures both passwords and data.

L2TP uses standard PPP-based authentication protocols, such as EAP, MS-CHAP, MS-CHAP v2, CHAP, SPAP, and PAP with IPSec.

Encryption is determined by the IPSec Security Association, or SA. A security association is a combination of a destination address, a security protocol, and a unique identification value, called a Security Parameters Index (SPI). The available encryptions include:

- Data Encryption Standard (DES), which uses a 56-bit key.
- Triple DES (3DES), which uses three 56-bit keys and is designed for high-security environments.

For more information about IPSec, see Internet Protocol Security (IPSec).

For more information about configuring connections, see Configure a connection to a remote network.

# Network Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication**
This section covers:

- Authentication process
- Authentication Protocols and Methods

# Authentication process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication process**
Authentication in the Windows Server 2003 family consists of two parts: an interactive logon process and a network authentication process. Successful user authentication depends on both of these processes.

**Interactive logon process**
The interactive logon process confirms the user's identification to either a domain account or a local computer. Depending on the type of user account, the interactive logon process is different:

- With a domain account, a user logs on to the network with a password or smart card by using single sign-on credentials stored in Active Directory. By logging on with a domain account, an authorized user can access resources in the domain and any trusting domains. Kerberos V5 is used for authentication if a password is used to log on to a domain account. Kerberos V5 authentication with certificates is used if a smart card is used instead.

- With a local computer account, a user logs on to a local computer by using credentials stored in the Security Accounts Manager (SAM), which is the local security account database. Any workstation or member server can store local user accounts.

**Network authentication process**
Network authentication confirms the user's identification to any network service that the user is attempting to access. To provide this type of authentication, many mechanisms are supported, including Kerberos V5, Secure Socket Layer/Transport Layer Security (SSL/TLS), and, for compatibility with Windows NT 4.0, LAN Manager.

Users who use a domain account do not see network authentication. Users who use a local computer account must provide credentials (such as a user name and password) every time they access a network resource. By using the domain account, the user has credentials that are automatically used for single sign-on.

For information about authentication methods and protocols used by Network Connections, see Authentication Protocols and Methods.

# Authentication Protocols and Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication protocols and methods**

With Network Connections, you can use the following authentication protocols and methods:

- Password Authentication Protocol (PAP)
- Challenge Handshake Authentication Protocol (CHAP)
- Shiva Password Authentication Protocol (SPAP)
- Microsoft Challenge Handshake Authentication Protocol (MS-CHAP)
- Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2)
- Extensible Authentication Protocol (EAP)
- Smart card and other certificate authentication

# Password Authentication Protocol (PAP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Password Authentication Protocol (PAP)**
Password Authentication Protocol (PAP) is a simple authentication protocol in which the user name and password is sent to the remote access server in a plaintext (unencrypted) form. Using PAP is strongly discouraged because your passwords are easily readable from the Point-to-Point Protocol (PPP) packets exchanged during the authentication process. PAP is typically used only when connecting to older UNIX-based remote access servers that do not support more secure authentication protocols.

To configure a connection for PAP, see Configure identity authentication and data encryption settings.

### Notes

- You cannot use Microsoft Point-to-Point Encryption (MPPE) if PAP is used to authenticate the connection.
- If the connection is configured to require a secured password and you attempt to connect to a server that is configured only for PAP, the Windows XP remote access client terminates the connection.

# Challenge Handshake Authentication Protocol (CHAP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Challenge Handshake Authentication Protocol (CHAP)**
Challenge Handshake Authentication Protocol (CHAP) is a widely supported authentication method in which a representation of the user's password, rather than the password itself, is sent during the authentication process. With CHAP, the remote access server sends a challenge to the remote access client. The remote access client uses a hash algorithm (also known as a hash function) to compute a Message Digest-5 (MD5) hash result based on the challenge and a hash result computed from the user's password. The remote access client sends the MD5 hash result to the remote access server. The remote access server, which also has access to the hash result of the user's password, performs the same calculation using the hash algorithm and compares the result to the one sent by the client. If the results match, the credentials of the remote access client are considered authentic. A hash algorithm provides one-way encryption, which means that calculating the hash result for a data block is easy, but determining the original data block from the hash result is mathematically infeasible.

To configure a connection for CHAP, see Configure identity authentication and data encryption settings.

### Notes

- You cannot use Microsoft Point-to-Point Encryption (MPPE) if CHAP is used to authenticate the connection.

- If you are using CHAP to authenticate a connection to a remote access server running Windows 2000 and Routing and Remote Access, the user account of the connecting client must be configured to allow the storage of the password in a reversibly encrypted form. For more information on configuring user accounts for storing a reversibly encrypted form of a password, see Enable reversibly encrypted passwords in a domain.

# Shiva Password Authentication Protocol (SPAP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Shiva Password Authentication Protocol (SPAP)**
Shiva Password Authentication Protocol (SPAP) is a simple encrypted password authentication protocol supported by Shiva remote access servers. With SPAP, the remote access client sends an encrypted password to the remote access server. SPAP uses a two-way encryption algorithm. The remote access server decrypts the password and uses the plaintext form to authenticate the remote access client.

To configure a connection for SPAP, see Configure identity authentication and data encryption settings.

**Note**

- You cannot use Microsoft Point-to-Point Encryption (MPPE) if SPAP is used to authenticate the connection.

# Microsoft Challenge Handshake Authentication Protocol (MS-CHAP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Challenge Handshake Authentication Protocol (MS-CHAP)**
Microsoft created MS-CHAP to authenticate remote Windows-based workstations, integrating the functionality to which LAN-based users are accustomed with the hashing algorithms used on Windows networks. Like CHAP, MS-CHAP uses a challenge-response mechanism to authenticate connections without sending any passwords.

MS-CHAP uses the Message Digest 4 (MD4) hashing algorithm and the Data Encryption Standard (DES) encryption algorithm to generate the challenge and the response. MS-CHAP also provides mechanisms for reporting connection errors and for changing the user's password. The response packet is in a format designed to work with networking products in Windows 95, Windows 98, Windows Millennium Edition, Windows NT, Windows 2000, Windows XP, and the Windows Server 2003 family.

To configure a connection for MS-CHAP, see Configure identity authentication and data encryption settings.

**Notes**

- If you are configuring a connection to a server running Windows 95, you must use a specific version of MS-CHAP. To enable this older version of MS-CHAP, see Configure identity authentication and data encryption settings.
- Unlike CHAP, MS-CHAP does not require that the user's password be stored in a reversibly encrypted form.
- During the MS-CHAP authentication process, shared secret encryption keys for Microsoft Point-to-Point Encryption (MPPE) are generated.

# Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2)**
The Windows Server 2003 family supports MS-CHAP v2, which provides mutual authentication, the generation of stronger initial data encryption keys for Microsoft Point-to-Point Encryption (MPPE), and different encryption keys for sent and received data. To minimize the risk of password compromise during a password change, support for older methods of the MS-CHAP password change are not supported.

Because MS-CHAP v2 is more secure than MS-CHAP, it is offered before MS-CHAP (if enabled) for all connections.

MS-CHAP v2 is supported by computers running Windows XP, Windows 2000, Windows 98, Windows Millennium Edition, and Windows NT version 4.0. Computers running Windows 95 support MS-CHAP v2 only for VPN connections, not for dial-up connections.

To configure a connection for MS-CHAP v2, see Configure identity authentication and data encryption settings.

**Note**

- MS-CHAP v2 is a mutual authentication protocol, which means that both the client and the server prove that they have knowledge of the user's password. First, the remote access server asks the remote access client for proof by sending a challenge to the client. Then the remote access client asks the remote access server for proof by sending a challenge back to the server. If the server cannot prove that it has knowledge of the user's password by correctly answering the challenge from the client, the client terminates the connection. Without mutual authentication, a remote access client cannot establish a connection to an unauthorized remote access server.

# Extensible Authentication Protocol (EAP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Extensible Authentication Protocol (EAP)**
Extensible Authentication Protocol (EAP) extends Point-to-Point Protocol (PPP) by allowing arbitrary authentication methods that use credential and information exchanges of arbitrary lengths. EAP was developed in response to an increasing demand for authentication methods that use security devices, such as smart cards, token cards, and crypto calculators. EAP provides an industry-standard architecture for supporting additional authentication methods within PPP.

By using EAP, you can support additional authentication schemes, known as EAP types. These schemes include token cards, one-time passwords, public key authentication using smart cards, and certificates. EAP, in conjunction with strong EAP types, is a critical technology component for secure virtual private network (VPN) connections. Strong EAP types, such as those based on certificates, offer better security against brute-force or dictionary attacks and password guessing than password-based authentication protocols, such as CHAP or MS-CHAP.

To find out if an EAP type is being used in your organization, contact your network administrator.

To configure a connection for EAP, see Configure identity authentication and data encryption settings.

The Windows Server 2003 family supports two EAP types:

- EAP-MD5 CHAP (equivalent to the CHAP authentication protocol)
- EAP-TLS (used for user certificate-based authentication).

EAP-TLS is a mutual authentication method, which means that both the client and the server prove their identities to each other. During the authentication process, the remote access client sends its user certificate and the remote access server sends its computer certificate. If either certificate is not sent or is invalid, the connection is terminated.

**Note**

- During the EAP-TLS authentication process, shared secret encryption keys for Microsoft Point-to-Point Encryption (MPPE) are generated.

# Smart card and other certificate authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Smart card and other certificate authentication**

If a user certificate is installed, either in the certificate store on your computer or on a smart card, Extensible Authentication Protocol (EAP) is enabled, and **Smart Card or other Certificate EAP type (EAP-TLS)** is selected, you can use certificate-based authentication in a single network logon process, which provides tamper-resistant storage of authentication information.

A certificate is an encrypted set of authentication credentials. A certificate includes a digital signature from the certification authority that issued the certificate. In the EAP-TLS certificate authentication process, your computer presents its user certificate to the remote access server, and the remote access server presents its computer certificate to your computer, providing mutual authentication. Certificates are authenticated by using a public key to verify the included digital signature. The digital signature is contained in a trusted root certification authority certificate that is stored on your computer. These trusted root certificates are the basis for certificate verification. The Windows Server 2003 family provides many trusted root certificates. You should add or remove trusted root certificates only if your system administrator advises.

Certificates can reside either in the certificate store on your computer or on a smart card. A smart card is a credit-card-sized device that is inserted into a smart card reader, which is either installed internally in your computer or connected externally to your computer.

If you configure the advanced security settings for a connection, you can choose to use a smart card or other certificate, and you can specify particular certificate requirements. For example, you can specify that the computer certificate for the server must be validated, that the server name must end in a particular value, and that the computer certificate must be issued by a specific trusted root certification authority for the server.

When you double-click **New Connection Wizard** in the Network Connections folder and a smart card reader is installed, Windows detects it and prompts you to use it as the authentication method for the connection. If you decide not to use the smart card at the time you create a connection, you can modify the connection to use the smart card or other certificate at a later time. For more information, see Enable smart card or other certificate authentication.

If you are a member of an Active Directory domain, and need to request a certificate, see Request a certificate. If you are not a member of an Active Directory domain, or you need to request a certificate from the Internet, see Submit a user certificate request via the Web. For information about mobile users and certificates, see Mobile users and certificates.

# Intermediary Devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Intermediary devices**
This section covers:

- Using an intermediary device
- Security hosts
- Writing scripts for intermediary devices

# Using an intermediary device

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using an intermediary device**

Network Connections supports various kinds of intermediary devices (security hosts and switches) between the remote access client and the remote access server. These devices include:

- Modem-pool switches
- Security hosts
- X.25 networks

Before you connect to the remote access server, you can have one of two possible dialog boxes (user input and computer response screens) with each intermediary device:

- Static (a dialog box that never changes and requires no input from you)
- Interactive (a dialog box that always changes and requires input from you)

You must configure your connection to work with each intermediary device.

If you require both static and interactive dialog boxes, you must take the following steps:

- Write a script for the static dialog box. For more information, see Writing scripts for intermediary devices.
- Activate Terminal mode for the interactive dialog boxes. For more information, see Use the Terminal feature to log on to a remote computer.

If you require only one kind of dialog box, take only one of the preceding steps. For example:

- If your clients connect through only one intermediary device with a static dialog box (such as an X.25 network), skip step 2.
- If your clients connect through a security host with an interactive dialog box, skip step 1.

# Security hosts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security hosts**
A security host is an authentication device that verifies whether a connection is authorized to connect to a remote access server. This verification supplements security already supplied by Network Connections and by the Windows Server 2003 family. There are two kinds of security hosts:

- Those which perform authentication checks during a modem call

  This type of security host sits between you and the remote access server and performs an authentication check before remote access server authentication. This type of security host generally provides an extra layer of security by requiring a hardware key of some sort in order to provide authentication. Verification that you are in physical possession of the key takes place before access to the remote access server is granted. With this open architecture, your system administrator can select from a variety of security hosts to augment the security in Network Connections, but the authentication check is restricted to modem calls.

  For example, one such security system consists of two hardware devices: the security host and the security card. The security host is installed between the remote access server and its modem. The security card is a small unit the size of a credit card that resembles a pocket calculator without keys. The security card displays a different access number every minute. This number is synchronized with a similar number calculated in the security host every minute. When connecting, you send a PIN number and the number on the security card to the host. If these match the number calculated on the host, the security host connects you with the remote access server.

  Another security host of the same type prompts you to type in a user name (which may or may not be the same as the remote access user name) and a password (which differs from the remote access password). The security host must be configured to allow the remote access server to initialize the modem before the security functions take effect. The remote access server must also be able to directly initialize the modem connected to the security host without security checks from the security host.

- Those which are called during the authentication process of the connection

  This type of security host provides custom authentication during the remote access authentication process. This authentication may augment or replace the standard verification of your network credentials by Routing and Remote Access in the Windows Server 2003 family. RADIUS servers are examples of this type of security host in that they perform user authentication on behalf of Routing and Remote Access. With the introduction of the Extensible Authentication Protocol (EAP), other vendors can create interfaces between remote access authentication and their own proprietary servers. Servers of this type are used to verify smart cards and other forms of extended authentication.

**Note**

- To make other security devices work with your connection, you must activate Terminal mode to interact with the security host. For more information, see Use the Terminal feature to log on to a remote computer.

# Writing scripts for intermediary devices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Writing scripts for intermediary devices**

Each script for a static dialog box is a section of the Switch.inf file. You add a script for each intermediary device to the Switch.inf file. For an example of X.25 network scripts, see the Pad.inf file, located in the *systemroot*\System32\Ras folder.

When you connect by using modem pools or security hosts, you must have a dialog with that device. The dialog occurs either before dialing or after dialing. Although preconnect and postconnect dialogs can be either static or interactive, the preconnect dialog box is normally static and the postconnect is normally interactive.

The included Switch.inf file provides a generic script that will probably work with little or no modification when you are connecting to PPP servers. You should try to connect by using the generic Switch.inf script. If that does not work, you can copy--and then modify--the generic script to match the logon sequence of the remote computer to which you want to connect.

For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts. For information about configuring a connection to use a Switch.inf script, see Activate a logon script.

# Tunneling Protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Tunneling protocols**
This section covers:

- Point-to-Point Tunneling Protocol (PPTP)
- Layer Two Tunneling Protocol (L2TP)

# Point-to-Point Tunneling Protocol (PPTP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Point-to-Point Tunneling Protocol (PPTP)**

You can access a private network through the Internet or other public network by using a virtual private network (VPN) connection with the Point-to-Point Tunneling Protocol (PPTP).

PPTP enables the secure transfer of data from a remote computer to a private server by creating a VPN connection across IP-based data networks. PPTP supports on-demand, multiprotocol, virtual private networking over public networks, such as the Internet.

Developed as an extension of the Point-to-Point Protocol (PPP), PPTP adds a new level of enhanced security and multiprotocol communications over the Internet. By using the new Extensible Authentication Protocol (EAP) with strong authentication methods such as certificates, data transfer through a PPTP-enabled VPN connection is as secure as within a single LAN at a corporate site. For more information on EAP, see Extensible Authentication Protocol (EAP).

PPTP encapsulates IP or IPX protocols inside of PPP datagrams. This means that you can remotely run applications that are dependent upon particular network protocols. The tunnel server performs all security checks and validations, and enables data encryption, which makes it much safer to send information over nonsecure networks. You can also use PPTP in private LAN-to-LAN networking.

The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

PPTP requires IP connectivity between your computer and the server. If you are directly attached to an IP LAN and can reach a server, then you can establish a PPTP tunnel across the LAN. If you are creating a tunnel over the Internet, and your normal Internet access is a dial-up connection to an ISP, you must dial up your Internet connection before you can establish the tunnel.

For more information about VPNs, see Virtual Private Network (VPN) Connections. For information about creating a VPN, see Make a virtual private network (VPN) connection.

# Layer Two Tunneling Protocol (L2TP)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Layer Two Tunneling Protocol (L2TP)**

You can access a private network through the Internet or other public network by using a virtual private network (VPN) connection with the Layer Two Tunneling Protocol (L2TP). L2TP is an industry-standard Internet tunneling protocol with roughly the same functionality as the Point-to-Point Tunneling Protocol (PPTP). The Windows Server 2003 family implementation of L2TP is designed to run natively over IP networks. This implementation of L2TP does not support native tunneling over X.25 or Frame Relay networks.

Based on the Layer Two Forwarding (L2F) and Point-to-Point Tunneling Protocol (PPTP) specifications, you can use L2TP to set up tunnels across intervening networks. Like PPTP, L2TP encapsulates Point-to-Point Protocol (PPP) frames, which in turn encapsulate IP or IPX protocols, thereby allowing users to remotely run applications that are dependent upon specific network protocols.

The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

With L2TP, the computer running a member of the Windows Server 2003 family that you are logging on to performs all security checks and validations, and enables data encryption, which makes it much safer to send information over nonsecure networks. By using Internet Protocol security (IPSec) authentication and encryption, data transfer through an L2TP-enabled VPN is as secure as within a single LAN at a corporate site. For more information about IPSec, see Internet Protocol Security (IPSec) Encryption.

For more information about VPNs, see Virtual Private Network (VPN) Connections. For information about creating a VPN connection, see Make a virtual private network (VPN) connection.

# Home and Small Office Networking

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Home and small office networking**
This section covers:

- Internet Connection Firewall
- Internet Connection Firewall security log
- Network Bridge
- Service definitions for Internet Connection Firewall and Internet Connection Sharing

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Internet Connection Firewall

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Connection Firewall**

A firewall is a security system that acts as a protective boundary between a network and the outside world. Internet Connection Firewall (ICF) is firewall software that is used to set restrictions on what traffic is allowed to enter your network from the Internet. ICF protects your network against external threats by allowing safe network traffic to pass through the firewall into your network, while denying the entrance of unsafe traffic.

If your network uses Internet Connection Sharing (ICS) to provide shared Internet access to multiple computers, ICF should be enabled on the shared Internet connection.

Additionally, you should enable ICF on the Internet connection of any computer that is connected directly to the Internet. ICF can provide protection to a single computer connected to the Internet with a cable modem, a DSL adapter or modem, or a dial-up modem. You should not enable ICF on VPN connections because it will interfere with the operation of file sharing and other VPN functions.

When ICF has been enabled on a network connection, the following network connection icon appears in Network Connections: . To check to see whether ICF is enabled, or to enable ICF, see Enable or disable ICF. For information about using ICF, see Protecting your home or small office network using Internet Connection Firewall.

**How ICF works**

ICF is considered a "stateful" firewall. A stateful firewall is one that monitors all aspects of the communications that cross its path and inspects the source and destination address of each message that it handles. To prevent unsolicited traffic from the public side of the connection from entering the private side, ICF keeps a table of all communications that have originated from the ICF computer. When used in conjunction with ICS, ICF tracks all traffic that has originated from the ICF/ICS computer and all traffic that has originated from private network computers. All inbound traffic from the Internet is compared against entries in the table. Inbound Internet traffic is allowed to reach the computers in your network only when there is a matching entry in the table that shows that the communication exchange originated from your computer or private network.

To thwart common hacking attempts, such as port scanning, communications that originate from the Internet are dropped by the firewall. Rather than sending you notifications about firewall activity, ICF silently discards unsolicited communications, because such notifications could be sent frequently enough to become a distraction. Instead, ICF creates a security log to track this activity. For more information, see Internet Connection Firewall security log.

Services can be configured to allow unsolicited traffic from the Internet to be forwarded by the ICF computer to the private network. For example, if you are hosting an HTTP Web server service, and the HTTP service is enabled on your ICF computer, unsolicited HTTP traffic will be forwarded by the ICF computer. A set of operational information, known as a service definition, is required by ICF to allow the unsolicited Internet traffic to be forwarded to the Web server on your private network. Service definitions for ICF work on a per connection basis. If your network has multiple firewall connections, you should configure service definitions on all firewall connections. For information about service definitions, see Service definitions for Internet Connection Firewall and Internet Connection Sharing. For information about adding and editing service definitions, see Manage service definitions for ICF or ICS.

**Note**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and

Windows Server 2003, Enterprise Edition.

- This topic applies only to product features available in the original release of Windows Server 2003.

# Internet Connection Firewall security log

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet Connection Firewall security log**

The Internet Connection Firewall (ICF) security log allows advanced users to choose which information to log. With ICF security logging you can:

- **Log dropped packets**. Log all dropped packets that originate from either the home or small office network or the Internet.
- **Log successful connections**. Log all successful connections that originate from either the home or small office network or the Internet.

When you select the **Log dropped packets** check box, information is collected each time ICF detects and denies traffic attempts. For example, if your Internet Control Message Protocol (ICMP) settings are not set to allow incoming echo requests, such as those sent by the **ping** and **tracert** commands, and an echo request from outside your network is received, the echo request is dropped, and an entry is made in the log.

When you select the **Log successful connections** check box, information is collected each time ICF detects and permits traffic attempts. For example, when a computer on your network successfully connects to a Web site, an entry is produced in the log.

The ICF security log is produced using the W3C Extended Log File Format, a format similar to the format that is used in common log analysis tools. For information about how to view an ICF security log, see View the ICF security log. To save the ICF security log using your choice of name and location, see Change the path and file name of the ICF security log.

ICF security logging is considered an advanced option and is not enabled by default. In order for the ICF security log to accept new data, you must select one or both of the logging options. For more information, see Enable or disable ICF security log options.

The ICF security log has two sections:

- The *header* provides information about the version of the ICF security log and the fields that are available for data entry. The header information is presented as a static list.
- The *body* contains compiled data that is entered as a result of traffic attempting to cross the firewall. The fields in the body of the ICF security log are entered from left to right across the page. The body of the ICF security log is a dynamic list--new data entries are entered at the bottom of the log.

The following tables define the information that the ICF security log contains:

**Header items**

| Item | Description | Example |
|---|---|---|
| #Version | Displays which edition of the ICF security log is installed. | 1.0 |
| #Software | Provides the name of the ICF security log. | Microsoft Internet Connection Firewall |
| #Time | Indicates that all of the timestamps in the log are in local time. | Local |
| #Fields | Displays a static list of the fields that are available for ICF security log entries, if data is available. Fields include: date, time, action, protocol, src-ip, dst-ip, src-port, dst-port, size, tcpflags, tcpsyn, tcpack, tcpwin, icmptype, icmpcode, and info. | Src-port, dst-port, size |

**Body data**

| Field | Description | Example |
|---|---|---|
| Date | Specifies the year, month, and day on which the recorded transactions occurred. Dates are recorded in the format:<br><br>`YY-MM-DD`<br><br>where YY is the year, MM is the month, and DD is the day. | 2001-01-27 |
| Time | Specifies the hour, minute, and seconds at which the recorded transaction occurred. Times are recorded in the format:<br><br>`HH:MM:SS`<br><br>where HH is the hour in 24 hour format, MM is minutes, and SS is seconds. | 21:36:59 |
| Action | Specifies which operation was observed by the firewall. The options available to the firewall are OPEN, CLOSE, DROP, and INFO-EVENTS-LOST. An INFO-EVENTS-LOST action indicates the number of events that happened but were not recorded in the log. | DROP |
| Protocol | Specifies which protocol was used for the communication. A protocol entry can be TCP, UDP, ICMP, or, if the protocol that was used was not TCP, UDP, or ICMP, a number. | ICMP |
| Src-ip | Specifies the source IP address (the IP address of the computer attempting to establish communications). The source IP is recorded in the dotted decimal format:<br><br>`(number).(number).(number).(number)` | 192.168.0.0 |
| Dst-ip | Specifies the destination IP address (the IP address of the destination for a communication attempt). The destination IP is recorded in the dotted decimal format:<br><br>`(number).(number).(number).(number)` | 192.168.0.1 |
| Src-port | Specifies the port number of the source (sending) computer. A src-port entry is recorded as a whole number, ranging from 1 to 65,535. Only TCP and UDP return a valid src-port entry. All other protocols are invalid for src-port and result in an entry of **-**. | 4039 |
| Dst-port | Specifies the port number of the destination computer. A dst-port entry is recorded as a whole number, ranging from 1 to 65,535. Only TCP and UDP return a valid dst-port entry. All other protocols are invalid for dst-port and result in an entry of **-**. | 53 |
| Size | Specifies the packet size in bytes. | 60 |
| Tcpflags | Specifies the TCP control flags found in the TCP header of an IP packet:<br><br>• **A**ck-Acknowledgment field significant<br><br>• **F**in-No more data from sender<br><br>• **P**sh-Push function<br><br>• **R**st-Reset the connection<br><br>• **S**yn-Synchronize sequence numbers<br><br>• **U**rg-Urgent pointer field significant<br><br>Flags are written as uppercase letters. The entry information for tcpflags is provided for users with an in-depth knowledge of Transmission Control Protocol (TCP). Additional information about TCP can be found in RFC 793. | AFP |
| Tcpsyn | Specifies the TCP sequence number in the packet. The entry information for tcpsyn is provided for users with an in-depth knowledge of TCP. | 1315819770 |

| | | |
|---|---|---|
| Tcpack | Specifies the TCP acknowledgement number in the packet. The entry information for tcpack is provided for users with an in-depth knowledge of TCP. | 0 |
| Tcpwin | Specifies the TCP window size in the packet. The size is specified in bytes. The entry information for tcpack is provided for users with an in-depth knowledge of TCP. | 64240 |
| Icmptype | Specifies a number that represents the type field of the ICMP message. | 8 |
| Icmpcode | Specifies a number that represents the code field of the ICMP message. | 0 |
| Info | Specifies an information entry that depends on the type of action that occurred. For example, an INFO-EVENTS-LOST action displays the number of events that occurred but were not placed in the log since the last occurrence of this event type. | 23 |

The character (**-**) is entered when no information is available for a field.

If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer.

**Notes**

- If the maximum allowable size for pfirewall.log is exceeded, the information that pfirewall.log contains is saved as pfirewall.log.old, and new information is saved as pfirewall.log. If the maximum allowable size for pfirewall.log is exceeded again, the information that pfirewall.log contains is saved as pfirewall.log.old, and the information that had been in pfirewall.log.old is overwritten. New information is always saved in pfirewall.log.

- You can obtain RFCs from the RFC Editor Web site. This Web site is currently maintained by members of the Information Sciences Institute (ISI) who publish a classified listing of all RFCs. RFCs are classified as one of the following: approved Internet standards, proposed Internet standards (circulated in draft form for review), Internet best practices, or For Your Information (FYI) documents.

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

- This topic applies only to product features available in the original release of Windows Server 2003.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

# Network Bridge

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network Bridge**
Network Bridge makes it inexpensive and easy to connect LAN segments. A LAN segment is a section of network media that connects computers. Frequently, a network has more than one LAN segment. Prior to Windows XP; Windows Server 2003, Standard Edition; and Windows Server 2003, Enterprise Edition, if you wanted to have a network with more than one LAN segment, then you had two options: IP routing and hardware bridging. IP routing required you to buy hardware routers or configure computers to act like routers, configure IP addressing for each computer on each network segment, and configure each network segment as a separate subnet. Hardware bridging did not require difficult configurations, but it did require you to purchase hardware bridges. Additionally, if you were using different types of network media, you needed to create a separate subnet for each type of media.

In contrast, the Network Bridge feature that is available with Windows XP; Windows Server 2003, Standard Edition; and Windows Server 2003, Enterprise Edition allows you to connect LAN segments simply by clicking the **Bridge Connections** menu command. No configuration is required, and you do not need to purchase additional hardware, such as routers or bridges. Network Bridge automates the configuration that is required to route traffic between multi-segment networks that consist of a single type of media or mixed media.

**Network Bridge example**
Suppose you have a small office network with four computers (PC1, PC2, PC3, and PC4) and one Ethernet hub. The four computers are running Windows XP; Windows Server 2003, Standard Edition; or Windows Server 2003, Enterprise Edition and have the following hardware installed:

- PC1 has an adapter connecting it to the Internet, an Ethernet network adapter, an HPNA network adapter, and a wireless adapter.
- PC2 has an Ethernet network adapter.
- PC3 has an HPNA network adapter.
- PC4 has a wireless network adapter.

The Ethernet adapters on PC1 and PC2 are connected to a common Ethernet hub to form the first LAN segment. PC1 is connected to PC3 with the HPNA adapter to form a second LAN segment, and PC1 is connected to PC4 with the wireless adapter to form a third LAN segment.

You can use Network Bridge to connect the Ethernet network adapter, the HPNA network adapter, and the wireless network adapter on PC1. Network Bridge can forward traffic from one LAN segment to another and enable all of your computers to communicate with each other.

Without Network Bridge (or additional routing configurations or bridging hardware), only PC1 can communicate with each of the other computers because PC1 is the only computer that has connections to all three LAN segments. Because PC2, PC3, and PC4 use different types of network media, they are on different LAN segments, and they are unable to communicate with any computer other than PC1 (without Network Bridge or additional routing configurations or bridging hardware).

**Network Bridge considerations**

Only one bridge can exist on a computer, but it can be used to bridge as many different network connections as the computer can physically accommodate. For information about creating Network Bridge, see Set up Network Bridge.

In order to include the ICS private connection as part of a Network Bridge, you must temporarily disable ICS. Be careful not to include the ICS public connection as part of a Network Bridge. To do so creates an unprotected link between your network and the Internet, leaving your network vulnerable to intrusions, and prevents you from enabling ICF or ICS. For more information about using ICS, see Connecting to the Internet in a home or small office network.

Only Ethernet, IEEE-1394 adapters, or Ethernet-compatible adapters, such as wireless and Home Phoneline Network adapters, can be a part of Network Bridge. Network Bridge with a wireless or IEEE-1394 connection supports traffic using Internet Protocol version 4 (IPv4) only.

**Spanning tree algorithm**

Network Bridge uses the IEEE spanning tree algorithm (STA) to establish a loop-free forwarding topology. When there are multiple paths in a bridged network, loops can form, and the simple forwarding rules of a bridge can cause forwarding storms--a condition in which the same frame is relayed endlessly from one network segment, across the bridge, to another segment. STA provides an automated mechanism to selectively disable bridge forwarding on individual ports as is necessary, in order to ensure that the network topology is loop-free. There is no configuration needed to configure Network Bridge for STA.

### Note

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Service definitions for Internet Connection Firewall and Internet Connection Sharing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Service definitions for Internet Connection Firewall and Internet Connection Sharing**

Services run transparently to support other programs. An example of a service is an HTTP Web server that supports hosting Web pages from your home or small office network. If the HTTP Web server service is enabled for your network, you can use that service to supply your own Web pages to the Internet. In addition to having a Web server on your network, you can have an FTP service that permits users to upload or download files through the Internet, an Internet mail server for storing and forwarding mail, and a variety of other services.

In order to permit traffic to flow from the Internet to the computer hosting the service, you must use a preconfigured service or add the service to the **Services** list by entering information about the operational settings of the services on the **Services** tab of the Internet Connection Firewall (ICF) or Internet Connection Sharing (ICS) host computer. The operational settings are known as a "service definition," because they define the environment that the service requires in order to operate. Service definitions for ICF and ICS provide the port mappings that are required in order for ICF to allow unsolicited traffic to travel from the Internet to the network.

Some service definitions are preconfigured for ICF and ICS. FTP server, Internet Mail server, Secure Web server, Telnet server, and Web server are examples of preconfigured (built-in) services. These services can run on ICS client computers or on your ICF or ICS host computer. You can add a new service to your network by installing the service software on one of your network computers and then adding the service definition so that ICF and ICS, if one or both are enabled, will allow the service to be accessed from the Internet.

Services for ICF and ICS can run on an ICS client computer or an ICS host computer. When you add a service definition to an ICS host computer, it is made available to ICS clients. For information about how to add or edit a service definition, see Manage service definitions for ICF or ICS.

**Notes**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.
- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.

# Using Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Network Connections**

Network Connections is automatically installed. This section covers:

- Monitoring network and dial-up connections
- Making Network Connections
- Using Home and Small Office Networking Features

# Monitoring network and dial-up connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Monitoring network and dial-up connections**
You can obtain information about an active connection by using the **Status** menu command on the **File** menu.

By using **Status**, you can view:

- The duration of a connection.
- The speed at which you initially connected.

  For a single-link connection and for individual links in a multilink connection, this speed is negotiated (and fixed) at the time the connection or link is established. For multilink connections, this speed is equal to the sum of the speeds of the individual links. For multilink connections, this speed varies as links are added or deleted.
- For local area connections, the number of bytes transmitted and received during a connection. For other types of connections, the number of bytes transmitted and received during a connection, and the associated compression and error statistics.
- The diagnostic tools that you can use for a connection, if any. For example, the Windows Network Troubleshooter, TCP/IP, Autoping, and TCP/IP Windows IP Configuration. These tools are explicitly registered in the Windows Server 2003 family by their providers, whether the provider is Microsoft or another organization.

You can also generate diagnostic reports for remote access connections. For more information on remote access preferences and generating diagnostic reports, see Logging remote access connections and Enable logging.

For more information on monitoring connections, see Monitor a connection.

**Note**

- If your computer is set up to accept incoming connections, a connection icon with a user name assigned to it appears in the Network Connections folder as each user connects. You can view the progress of incoming connections by right-clicking a named connection, and then clicking **Status**.

# Making Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Making network connections**

This section covers:

- Using local area connections
- Using direct connections
- Using Remote Access Methods
- Using Incoming Connections
- Using Internet Connections
- Virtual Private Network (VPN) Connections

# Using local area connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using local area connections**

Typically, computers running Windows are connected to a local area network (LAN). When you install Windows, your network adapter is detected, and a local area connection is created. It appears, like all other connection types, in the Network Connections folder. By default, a local area connection is always activated. A local area connection is the only type of connection that is automatically created and activated.

If you disable your local area connection, the connection is no longer automatically activated. Because your hardware profile remembers this, it accommodates your location-based needs as a mobile user. For example, if you travel to a remote sales office and use a separate hardware profile for that location that does not enable your local area connection, you do not waste time waiting for your network adapter to time out. The adapter does not even try to connect.

If your computer has more than one network adapter, a local area connection icon for each adapter is displayed in the Network Connections folder.

Examples of LAN connections include Ethernet, token ring, cable modems, DSL, FDDI, IP over ATM, IrDA (Infrared), wireless, and ATM-emulated LANs. Emulated LANs are based on virtual adapter drivers such as the LAN Emulation Protocol.

If changes are made to your network, you can modify the settings of an existing local area connection to reflect those changes. The **General** tab of the *Local Area Connection***Status** dialog box allows you to view connection information such as connection status, duration, speed, signal strength, amounts of data transmitted and received, and any diagnostic tools available for a particular connection. The **Support** tab contains information on:

- The address type which indicates how the address was assigned. For example the TCP/IP address is assigned by DHCP.
- The IP address currently assigned for the session.
- The IP subnet mask for the IP address currently assigned for the session.
- The default gateway address of the IP device that allows access to other protocols.

The **Support** tab also has a **Details** button that displays detailed information about the properties of the network connection. This includes the addresses of dependent external devices. For information about using the **Status** menu option, see View the status of a local area connection.

If you install a new LAN adapter in your computer, the next time you start your computer, a new local area connection icon appears in the Network Connections folder. Plug and Play functionality finds the network adapter and creates a local area connection for it. If you are using a laptop computer, you can add a PC card while the computer is on. Plug and Play will identify the new card without you having to restart your laptop computer. The local area connection icon is immediately added to the folder. You cannot manually add local area connections to the Network Connections folder.

You can configure multiple LAN adapters through the **Advanced Settings** menu option. You can modify the order of adapters that are used by a connection, and the associated clients, services, and protocols for the adapter. You can modify the provider order in which this connection gains access to information on the network, such as networks and printers.

You configure the device a connection uses, and all of the associated clients, services, and protocols for the connection, through the **Properties** menu option. Clients define the access of the connection to computers and files on your network. Services provide features such as file and printer sharing. Protocols, such as TCP/IP, define the language your computer uses to communicate with other computers.

Depending on the status of your local area connection, the icon changes appearance in the Network Connections folder, or a separate icon appears in the taskbar. If a LAN adapter is not detected by your computer, a local area connection icon does not appear in the Network Connections folder. For a list of connection icons, see Network connection icons.

# Using direct connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using direct connections**

With Network Connections, you can create a physical connection to another computer by using a serial cable, a DirectParallel cable, a modem, infrared devices or other methods. For example, you might want to connect a handheld PC running Windows CE to your network. Or, you may have two or more networks in the same location that are not physically connected. If you want to use resources on both networks from one computer, you can use a serial cable connection with an RS-232C null modem cable. You connect an RS-232C cable from a COM port on the computer to a COM port on your remote access server, which is used to create network access. You can also use an RS-232C null modem as a substitute for a network adapter if your computer is located physically near (less than 50 feet of cable) a remote access server.

The DirectParallel driver supports computer-to-computer connections by using standard and enhanced (ECP) parallel ports, which use Parallel Technologies' Basic or Fast parallel cables. For more information about using a DirectParallel cable for a direct connection, see DirectParallel cable access.

Remote access authentication methods control access to your network, not resources on the network. Having a Windows CE device directly attached to a computer on your network is analogous to having a computer attached to your network, but not logged on. In that instance, you attached and accessed the network without using authentication of any kind.

Once you are present on a network, resource control is managed in various ways: Local Users and Groups, Active Directory, Group Policy, file and printer sharing, and so on.

Therefore, if you have set up a direct network connection using, for example, a Windows CE device, you need to ensure that resource control is in place that enforces access to restricted folders, printers, and so on.

Authentication methods are designed for remote computing, where the computer dialing in does not have access to the network until credentials such as user name and password are exchanged.

For information about creating a direct network connection, see Make a direct network connection.

**Note**

- To create or modify a direct network connection, you must be a member of the Administrators group.

# Using Remote Access Methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using remote access methods**

This section covers:

- Using phone lines and modems
- Using ISDN lines
- Using X.25

# Using phone lines and modems

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using phone lines and modems**

The most common dial-up connection is made by using DSL, a cable modem, or a standard analog telephone line and a modem. Standard analog phone lines are available worldwide and meet most requirements of a mobile user. Standard analog phone lines are also called PSTN (public switched telephone network) or POTS (plain old telephone service).

Hundreds of modems are compatible with Windows XP and all members of the Windows Server 2003 family. Most modems that comply with industry standards should interoperate. However, many difficult-to-detect problems are the result of incompatible modems. To verify the compatibility of a modem, see the compatibility information at Support resources.

Modems are automatically detected. This is especially useful for users who are not sure what modem is installed (for example, an internal modem). You can use shared modem pools for dial-up connections. Modem data compression and error control are available on most modems. However, built-in software compression offers enhanced performance over modem data compression.

For information about connecting to a network by using a phone line, see Make a dial-up connection by using a phone line.

# Using ISDN lines

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using ISDN lines**

To enhance connection speeds, you can use an Integrated Services Digital Network (ISDN) line. Whereas standard phone lines typically transmit from 28.8 to 56 kilobits per second (Kbps), typical ISDN devices are capable of 64 or 128 Kbps. This is slower than local area networks supported by high-speed data communications technology, but faster than analog telephone lines. ISDN provides end-to-end digital connectivity between your computer and a remote computer or network by using a local telephone line for network connection.

An ISDN line must be installed by the phone company at your site and at the remote access server. Also, an ISDN adapter must be installed in place of a modem in both your computer and the remote access server. For information about installing an ISDN adapter, see Install an ISDN adapter. Costs for ISDN equipment and lines may be higher than standard modems and phone lines. However, the speed of communication reduces the duration of the connection time, thereby possibly saving toll charges.

An ISDN line comes with two B channels that transmit data at 64 Kbps, and one D channel for signaling that transmits data at 16 Kbps. You can configure each B channel to operate as a port. With this configuration, line speed increases to 128 Kbps. Channel aggregation schemes are specific to each driver, so you must use the same driver and equipment on the client and server.

Multilink dialing over ISDN combines multiple physical links into a logical bundle. This aggregate link increases your bandwidth. To use Multilink, both your connection and the remote access server must have Multilink enabled. For more information about the Multilink feature, see Configuring multiple device dialing.

For information about creating an ISDN network connection, see Make a dial-up connection by using an ISDN line. For information about configuring ISDN network connection settings, see Configure ISDN settings.

# Using X.25

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using X.25**

An X.25 network transmits data with a packet-switching protocol, bypassing noisy telephone lines. This protocol relies on an elaborate worldwide network of packet-forwarding nodes that can participate in delivering an X.25 packet to its designated address.

Network Connections supports X.25 by using packet assemblers/disassemblers (PADs) and X.25 cards. You can also use a modem and special dial-up X.25 carriers in place of a PAD or X.25 smart card on your computer.

Remote access clients running Windows XP or a member of the Windows Server 2003 family can either use an X.25 card or dial in to an X.25 PAD to create connections. To accept incoming connections on a computer using X.25 running Windows XP or a member of the Windows Server 2003 family, you must use an X.25 card.

For information about creating an X.25 connection, see Make a dial-up connection by using X.25.

# Using Incoming Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using incoming connections**

This section covers:

- Incoming connections
- Incoming connections and IP addresses
- Incoming connection clients

# Incoming connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incoming connections**
With the Windows Server 2003 family, you can create incoming connections and allow even computers that are members of a domain to run incoming connections.

You can configure an incoming connection to accept the following connection types: Dial-up connections (modem, ISDN, X.25), Virtual Private Network (VPN) Connections (PPTP, L2TP), or Using direct connections (serial, infrared, DirectParallel). On a computer running Windows 2000 professional or Windows XP Professional, an incoming connection can accept up to three incoming calls, up to one of each of these types. On a computer running Windows 2000 Server, the number of inbound calls is only limited by the computer and its hardware configuration. For information about Windows NT Server (and other operating systems) that can accept an incoming connection, see Incoming connection clients.

You can use the Multilink feature to configure multiple modems or ISDN adapters for use with incoming dial-up connections. For more information on Multilink, see Configuring multiple device dialing.

When you create a connection, the users that can connect to your incoming connection and their network protocols are selected. Each user that connects to an incoming connection must have established a local user account. For more information about user settings such as name, password, and callback rights, see Grant incoming connection access rights to your computer. For more information about configuring your connection for the TCP/IP network protocol, see Configure an incoming connection to use TCP/IP.

For information about creating an incoming connection, see Accept incoming network connections.

**Notes**

- For large numbers of incoming connections on a computer that is running Windows 2000 Server or a member of the Windows Server 2003 family and that operates as part of a distributed network or as a domain controller, you can use Routing and Remote Access to create a remote access server.

- To create an incoming connection, you must be a member of the Administrators group.

- Users do not need to use incoming connections to allow access to shared resources, such as files and printers, over a local area network. In order to enable shared access to resources on the local computer, you must enable file and print sharing, share the resources, and then set the appropriate permissions. For information about sharing a folder, see Share a folder or drive.

- The Guest account is disabled by default for both incoming connections and in the Computer Management snap-in. Guests can connect only after you enable the Guest account in the Computer Management snap-in and in the **Users** tab of the properties dialog box of the connection.

# Incoming connections and IP addresses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incoming connections and IP addresses**
The incoming connections computer will assign IP addresses to the remote computers that connect to it. These addresses can be allocated in one of two ways:

- They are automatically allocated by DHCP.
- They are assigned based on a range of addresses that is defined in the TCP/IP properties for the incoming connection.

If you want to specify a range of IP addresses, you must provide a starting IP address and an ending IP address for the range. Network Connections calculates the number of addresses that can be used within the starting and ending addresses of the range. For more information about specifying the range, and the effects of a subnet on the address range, see Configure an incoming connection to use TCP/IP.

If the incoming connections computer is attached to another network, and the specified address range consists of a subset of IP addresses for the network to which the computer is attached, you must ensure that the addresses in the range are not already assigned to other TCP/IP nodes within the attached network. This is recommended because using a subset of the larger network's addresses requires less manual configuration of the intranet nodes.

If you must use a range of addresses that is not a subset of the network to which the incoming connections computer is attached, then steps must be taken to ensure that computers on the network attached to the incoming connections computer can reach the incoming connection clients. To do this, on each of the computers on the network you can create a route to the incoming client computers with the IP address of the incoming connections computer as the associated gateway.

For more information, see To configure a default gateway.

**Notes**

- If Internet Connection Sharing (ICS) is already enabled on the dial-up, virtual private network (VPN), or local area connection of an incoming connections computer, you do not need to configure the default gateway setting. ICS automatically makes the ICS host computer the default gateway for all of the computers on the intranet.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Incoming connection clients

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Incoming connection clients**
The Windows Server 2003 family supports incoming connections from clients running Windows XP, Windows 2000, and the following operating systems:

- Windows NT version 4.0 clients

  Windows NT version 4.0 clients can take full advantage of all incoming connection features except dynamic allocation of multilinked lines, Extensible Authentication Protocol (EAP), IPSec client to server data security, and L2TP for tunneling across intervening networks.

- Windows NT version 3.1, 3.5, and 3.51 clients

  Windows NT version 3.5*x* clients can take full advantage of incoming connection features, except for Multilink functionality. Windows NT 3.5*x* clients negotiate the logon process and authentication with the incoming connection. You can also configure these clients to use scripts that completely automate the logon process.

  Windows NT version 3.1 clients do not support the implementation of Point-to-Point Protocol (PPP) that was introduced in Windows NT 3.5. Only Windows NT 3.5*x* or other PPP clients provide the support necessary to run TCP/IP or IPX applications on clients that directly communicate with servers on the LAN by using TCP/IP or IPX.

- Windows 98 clients

  Windows 98 clients can take full advantage of incoming connection features, except dynamic allocation of multilinked lines and the Extensible Authentication Protocol. Windows 98 clients negotiate the logon process and authentication with the server. You can also configure these clients to use scripts that completely automate the logon process.

- Windows 95 clients

  Windows 95 clients can take full advantage of incoming connection features, except the use of Multilink, dynamic allocation of multilinked lines, and Extensible Authentication Protocol. Windows 95 clients negotiate the logon process and authentication with the server. You can also configure these clients to use scripts that completely automate the logon process.

- Macintosh clients

  Macintosh users can connect to a computer running Services for Macintosh and access Macintosh file volumes and AppleTalk printers by using the AppleTalk Control Protocol (ATCP).

- PPP clients

  PPP clients that other companies offer and that use TCP/IP can access an incoming connection. The incoming connection automatically negotiates authentication with PPP clients; special configuration for these PPP clients is not required.

  For more information about your PPP client, see the software documentation for your PPP client.

For information about creating and configuring incoming connections, see Set up Incoming Connections.

**Notes**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

- IPX cannot be configured for incoming or dial-up connections in the Windows Server 2003 family.

# Using Internet Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Internet connections**
With Network Connections, connecting to the Internet is easy. You can use the following components to gain access to the Internet:

- The TCP/IP protocol that is enabled for your network connection.
- If you are part of a corporate domain, a user account with remote access permissions.
- A modem or other connection to an Internet service provider (ISP).
- An account with an ISP.

This section covers:

- ISP access methods
- Internet service providers

# ISP access methods

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**ISP access methods**
You can create a connection to an Internet service provider (ISP) through a modem and telephone line, a Point-to-Point Protocol over Ethernet (PPPoE) broadband connection, an ISDN adapter and ISDN line, or an X.25 network.

If you are using a modem, you will want the fastest possible speed to reduce downloading time while on the Internet. A modem of 28.8 Kbps or above is recommended. For more information about modems, see Installing and configuring Modems.

Your Internet connection dials the ISP and logs you on. The logon sequence varies based on the requirements of the ISP that you are calling. Point-to-Point Protocol (PPP) connections are often entirely automatic. Serial Line Internet Protocol (SLIP) connections may require that you log on using the terminal window, which may or may not permit you to automate the logon process with Switch.inf file scripts. You can set the terminal window to appear during the logon process by selecting **Show terminal window** on the **Security tab** of the **Dial-up Connection Properties** dialog box.

For more information, see:

- TCP/IP
- Internet service providers
- Make an Internet connection

**Note**

- Before you create an Internet connection, check with your ISP to verify the required connection settings. A connection to your ISP may require one or more of the following settings:
    - A specific IP address.
    - IP header compression (for PPP).
    - DNS addresses and domain names.
    - Optional settings, such as Internet Protocol security (IPSec).

For information about creating an Internet connection, see Make an Internet connection

# Internet service providers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Internet service providers**

There are Internet service providers (ISPs) around the world. Similar to other online services or bulletin boards, you dial the service number and log on to the remote system. Once connected, you have access to the Internet and any other services, such as electronic mail, that are provided by the ISP. Fees usually apply for commercial ISPs.

For information about creating an Internet connection, see Make an Internet connection.

# Virtual Private Network (VPN) Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Virtual private network (VPN) connections**

A virtual private network (VPN) extends the capabilities of a private network to encompass links across shared or public networks such as the Internet. With a VPN, you can send data between two computers across a shared or public network in a manner that emulates a point-to-point link on a private network. Virtual private networking is the act of creating and using a virtual private network.

To emulate a point-to-point link, data is encapsulated, or wrapped, with a header that provides routing information, which allows the data to traverse the shared or public network to reach its endpoint. To emulate a private link, the data is encrypted for confidentiality. Packets that are intercepted on the shared or public network cannot be read without the encryption keys. The link in which the private data is encapsulated and encrypted is a VPN connection.

The following table describes the advantages of using VPN connections. For more information, click an advantage.

| Advantage | Example |
|---|---|
| Cost advantages | The Internet is used as a connection instead of a long-distance telephone number or 1-800 service. Because an Internet service provider (ISP) maintains communications hardware, such as modems and ISDN adapters, to access the Internet, your network requires less hardware to purchase and manage. |
| Outsourcing dial-up networks | You can make a local call to the telephone company or ISP, which then connects you to a remote access server and your corporate network. The telephone company or ISP manages the modems and telephone lines required for dial-up access. Because the ISP supports complex configurations of communication hardware, a network administrator is free to centrally manage user accounts at the remote access server. |
| Enhanced security through VPN | The connection over the Internet is encrypted and secure. Authentication and encryption are enforced by the VPN server. Sensitive data is hidden from unauthorized users, but it is accessible to users authorized through the connection. |
| Network protocol support | You can remotely run any application that depends on the most common network protocols, including TCP/IP and IPX. The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family. |
| IP address security | Because information sent over a VPN is encrypted, the addresses you specify are protected, and the Internet sees only the external IP address. For organizations with private addresses, this advantage is substantial, because no administrative costs are incurred from having to change IP addresses for remote access over the Internet. |

You can create a VPN connection by dialing an ISP or by connecting directly to the Internet, as shown in the following examples.

**Example 1**

- In the first example, the VPN user makes a call to an ISP. After a connection is established with the ISP, the ISP server then makes a call to the remote access server that establishes the Point-to-Point Tunneling Protocol (PPTP) or Layer Two Tunneling Protocol (L2TP) tunnel. These protocols are automatically installed on your computer. After the VPN connection is made, you can access the corporate network, as shown in the following illustration.

**Example 2**

- In the second example, a user who is already connected to the Internet uses a VPN connection to connect to the VPN server. Examples of this type of user include a person whose computer is connected to a local area network, a cable

modem user, or a subscriber of a service such as ADSL, where IP connectivity is established immediately after the user's computer is turned on. The VPN client makes a tunnel through the Internet and connects to the PPTP-enabled or L2TP-enabled VPN server. After the VPN connection is made, the user can access the corporate network, achieving the same functionality as the user in the preceding example.

For information about creating a VPN connection, see Make a virtual private network (VPN) connection. For information about the ways Active Directory can tighten security measures for VPNs, see VPN administration.

**Note**

- Connecting directly to the Internet means direct IP access without going through an ISP. (For example, some hotels allow you to use an Ethernet cable to connect to the Internet.)

# Cost advantages

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Cost advantages**

By using virtual private networks (VPNs), mobile professionals and telecommuters can access their corporate local area network (LAN) over the Internet for a fraction of the cost of traditional remote access solutions. Just as it is more cost effective to make use of the phone company's massive switching system, rather than to string up your own telephone lines and invest in your own switch, a connection to the IP address or DNS name of your Point-to-Point Tunneling Protocol (PPTP)-enabled VPN server makes use of the physical base of routers that are available on the Internet, asynchronous transfer mode (ATM) switches, and digital and analog lines, without sacrificing security.

You can use a network adapter to dial in to a virtual private network, as you would dial a modem to connect to a traditional remote server. VPNs offer corporations a release from the cost and maintenance obligations of components such as modem banks and dedicated analog (1-800) phone lines. The modems and their associated infrastructure remain centralized at the Internet service provider's locations, without sacrificing security or the ability to control remote connections. At the same time, the benefits of secure access to private data are ensured by additional VPN-required authenticated access, encryption, and user data compression.

For information about creating a VPN connection, see Make a virtual private network (VPN) connection.

# Outsourcing dial-up networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Outsourcing dial-up networks**

The communications hardware that is available for supporting dial-up needs can be complicated and not well-integrated. For a large organization, putting together a remote access server requires modems, serial controllers, and many cables. Furthermore, many solutions do not provide a single integrated way to efficiently support V.34 and ISDN dial-up lines.

Many corporations like to outsource dial-up access to their corporate backbone networks in a manner that is cost-effective, hassle-free, protocol-independent, secure, and that requires no changes to the existing network addressing. Virtual WAN support by using Virtual Private Network (VPN) Connections is one way an Internet service provider (ISP) can meet the needs of corporations. In this way, the outsourcing company maintains and manages remote access modems and lines, leaving a system administrator free to manage users and their authentication needs.

This type of solution takes advantage of proven PPP authentication, encryption, and compression technologies. For information about creating a VPN connection, see Make a virtual private network (VPN) connection.

The following illustration shows an example of outsourcing.

The connection does not need to have a PPTP driver; the client simply makes a PPP connection to the modem pool or communications server. The communication server or modem pool must implement PPTP for communication with the remote access server.

# Enhanced security through VPN

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enhanced security through VPN**

Virtual private network (VPN) connections that are enabled with Point-to-Point Tunneling Protocol (PPTP) and Layer Two Tunneling Protocol (L2TP) are authenticated by using Point-to-Point Protocol (PPP) user-level authentication methods. For PPTP connections, you can use only the Microsoft Challenge Authentication Protocol (MS-CHAP), MS-CHAP version 2 (MS-CHAP v2) or Extensible Authentication Protocol-Transport Level Security (EAP-TLS). For L2TP connections, you can use any PPP authentication protocol because the PPP authentication message exchange is encrypted with Internet Protocol Security (IPSec); however, MS-CHAP, MS-CHAP v2, or EAP-TLS is recommended.

For the most secure PPTP VPN connections, do the following:

- Use EAP-TLS with user certificates or smart cards.
- Require the use of the strongest possible encryption.
- Use a remote access policy to define who can make a PPTP connection based on group membership (if you are using the Routing and Remote Access service).
- Configure PPTP packet filters on your firewall interfaces and VPN server interfaces.

For security reasons, you should use PPTP with either MSCHAPv2 or EAP-TLS with PPTP connections. If using EAP-TLS is not feasible, use MSCHAP v2 for secure connections.

For the most secure L2TP VPN connections, do the following:

- Use EAP-TLS with user certificates or smart cards.
- Require the use of the strongest possible encryption.
- Use a remote access policy to define who can make a L2TP connection based on group membership (if you are using the Routing and Remote Access service).
- Configure IPSec or L2TP packet filters on your firewall interfaces and VPN server interfaces.

In some environments, data is so sensitive that it needs to be hidden from the majority of corporate users. Finance data or human resources data are examples of this type of data. Corporations can store extremely sensitive data servers on a separate network segment that is connected to the corporate network by a VPN server. Authorized users use a VPN connection to connect to the VPN server, and then they can access the protected resources. All communication across the VPN connection is encrypted in order to ensure data confidentiality. Users who do not have authorization to establish a VPN connection with the VPN server cannot see the hidden server or its resources.

For information about creating a VPN connection, see Make a virtual private network (VPN) connection.

# Network protocol support

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Network protocol support**
Because virtual private networks (VPNs) support the most common network protocols, it is easy for clients on Ethernet and TCP/IP networks to use VPNs. Any network protocol supported by remote access is inherently supported in a VPN. This means that you can remotely run applications that are dependent upon particular network protocols. In turn, this translates to reduced costs in setting up and maintaining VPN connections.

For information about creating a VPN connection, see Make a virtual private network (VPN) connection.

**Notes**

- The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.
- IPX cannot be configured for incoming or dial-up connections in the Windows Server 2003 family.
- IPX cannot be configured on a computer running a member of the Windows Server 2003 family that is being used as a VPN server.

# IP address security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**IP address security**
If you are using a private IP address range (for example, 10.0.0.0-8, 172.16.0.0-12, 192.168.0.0-16), you can find a path through the Internet by providing valid, public IP addresses for the virtual private network (VPN) client and the VPN server. The original IP packets, those with the private addresses of your source and destination, are encapsulated using Point-to-Point Tunneling Protocol (PPTP) or Layer Two Tunneling Protocol (L2TP) during data transfer over non-secure networks. Because the IP packets are also encrypted, the private addresses are protected. Internet users see only the public IP addresses of the VPN client and the VPN server. In this case, and whenever you use private IP addresses, there are no administrative costs associated with changing IP addresses for remote access.

**Note**

- It is possible to use a nonregistered IP address range (a range of private IP addresses that overlaps with the valid, public IP addresses that are used on the Internet), but it is not recommended.

For information about creating a VPN connection, see Make a virtual private network (VPN) connection.

# VPN administration

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VPN administration**

By using access policies in the remote access server infrastructure, your system administrator can configure virtual private network (VPN) user settings that significantly tighten security measures, such as required levels of data and password encryption and authentication. These requirements can be applied to individual users, or to a group (or profile) of similar users. For example, a system administrator can configure remote access dial-in settings to define a group profile such that all users who are assigned to that profile are required to authenticate by using the Extensible Authentication Protocol (EAP) and encrypt their data by using strong (128-bit) data encryption. By assigning a user to the group profile, these security measures are automatically required when anyone in that group profile connects to the remote access server.

You should configure your VPN connection to match the policies that your network administrator established. For information about configuring connections, see Configure a connection to a remote network.

# Using Home and Small Office Networking Features

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using home and small office networking features**

This section covers:

- Protecting your home or small office network using Internet Connection Firewall
- Connecting to the Internet in a home or small office network

# Protecting your home or small office network using Internet Connection Firewall

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Protecting your home or small office network using Internet Connection Firewall**

Home and small office networking offers computers that are directly connected to the Internet the added security of firewall protection. Internet Connection Firewall (ICF) checks all communications that cross the connection between your network and the Internet and is selective about which responses from the Internet it allows.

**Recommended topologies**

You can enable Internet Connection Sharing (ICS) on only one Internet connection on your network, and you should protect this connection by enabling ICF. ICF can check only the communications that cross the Internet connection on which it is enabled. These types of network topologies are safe and the most recommended.

**Topologies that are not recommended**

You should avoid topologies with multiple Internet connections. If you must have multiple direct Internet connections on your network, you should ensure that ICF is enabled on each direct Internet connection in order to protect your network, as shown in the following illustration. However, because ICF works on a per-connection basis, this topology is still not a recommended topology because there is no central point of administration through which you can ensure the continuous protection of all Internet connections.

Likewise, providing Internet connectivity to your network by connecting your network hub directly to the Internet causes similar vulnerabilities and is not a recommended topology.

Enabling ICF on this type of network topology disrupts some network communications and provides protection only for the computer on which it is enabled. The other computers have direct connections to the Internet through the hub and are not protected.

**Connection icons**

When ICF has been enabled on a network connection, the following network connection icon appears in Network Connections: . To check to see if ICF is enabled, or to enable ICF, see Enable or disable ICF. When ICS is enabled on a network connection, it appears in Network Connections as the shared Internet connection icon. To check to see if ICS is enabled, or to enable ICS, see Enable ICS.

**Recommendations for using ICF**
You should enable ICF on every Internet connection. You should not enable ICF on virtual private network (VPN) connections or on network client computers because ICF interferes with some types of network activities such as file and printer sharing. For a similar reason, ICS prohibits you from enabling ICF on the ICS host computer's private connection, the connection that connects the ICS host to the ICS client computers. A firewall on this location would completely obstruct network communications. You should not enable ICF on any connection that does not directly connect to the Internet. ICF is not needed if an Internet connection already has a firewall or proxy server running.

**ICF and notification messages**
Because ICF inspects all incoming communications, some programs, especially e-mail programs, may behave differently when ICF is enabled. Some e-mail programs periodically poll their e-mail server for new mail, and some e-mail programs wait for notification from their e-mail server. Outlook Express, for example, automatically checks for new e-mail when its timer tells it to do so. When new e-mail is present, Outlook Express prompts the user with a notification about the new e-mail. ICF does not affect the behavior of this program, because the request for new e-mail notification originates from inside the firewall. The firewall makes an entry in a table noting the outbound communication to the mail server. When the mail server returns the response for new e-mail, the firewall finds an associated entry in the table and allows the communication to pass, then the user receives notification that a new e-mail has arrived.

Outlook 2000, however, is connected to a Microsoft Exchange server that uses a remote procedure call (RPC) to send new e-mail notifications to client computers. Outlook 2000 does not automatically check for new e-mail when it is connected to an Exchange server. The Exchange server notifies Outlook 2000 when new e-mail arrives. Because the RPC notification is initiated from the Exchange server that is outside the firewall, and not by Outlook 2000, which is inside the firewall, ICF cannot find the corresponding entry in the table, and the RPC messages are not allowed to cross from the Internet into the home or small office network. The RPC notification message is dropped. Users can send and receive e-mail but need to manually check the inbox for new e-mail.

**Advanced ICF settings**
The ICF security logging feature provides a way to create a security log of firewall activity. ICF is capable of logging both traffic that is permitted and traffic that is rejected. For example, incoming echo requests from the Internet, by default, are not allowed by the firewall. If the Internet Control Message Protocol (ICMP) **Allow incoming echo request** is not enabled, then the inbound request fails, and a log entry that records the failed inbound attempt is generated.

ICMP allows you to modify the behavior of the firewall by enabling various ICMP options, such as **Allow incoming echo request**, **Allow incoming timestamp request**, **Allow incoming router request** and **Allow redirect**. Brief descriptions of these options are provided on the **ICMP** tab. For information about ICMP, see Internet Control Message Protocol (ICMP).

If ICF is enabled on two or more connections on a single computer, the settings for the ICMP options are per connection. If you make a setting or change a setting in the ICMP options on any connection on which ICF is enabled, that setting is not applied to the other ICF firewalls on that computer. For more information, see Enable or disable Internet Control Message Protocol requests for ICF.

You can set the allowable size of the ICF security log to prevent the potential overflow that could be caused by denial-of-service attacks. Event logging is generated in the Extended Log File Format as established by the World Wide Web Consortium (W3C). For more information about ICF security logging, see Internet Connection Firewall security log.

If ICF is enabled on two or more connections on a single computer, the ICF settings are global. If you select a setting or change a setting in **Logging Options** or **Services** on any one of the connections on which ICF is enabled, that setting is applied to all of the ICF firewalls on that computer. For more information, see Internet Connection Firewall security log.

### Note

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.
- This topic applies only to product features available in the original release of Windows Server 2003.
- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Connecting to the Internet in a home or small office network

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connecting to the Internet in a home or small office network**

With the Internet Connection Sharing (ICS) feature of Network Connections, you can connect your home or small office network to the Internet. For example, you might have a home network that connects to the Internet by using a dial-up connection. By enabling ICS on the computer that uses the dial-up connection, you provide network address translation (NAT), addressing (DHCP Allocator), and name resolution (DNS Proxy) services for all of the computers on your network.

For more information, see Enable ICS, Internet Connection Sharing and network address translation, and Incoming connections.

After ICS is enabled, and users verify that they are all joined to the same networking workgroup as the ICS host, home or small office network users can use programs such as Internet Explorer and Outlook Express as if they were directly connected to the Internet service provider (ISP). The ICS host computer connects to the ISP and creates the connection so that the user can reach the specified Web address or resource.

ICS is intended for use in a home or small office where network configuration and the Internet connection are managed by the computer where the shared connection resides. It is assumed that this computer is the only Internet connection on the network, the only gateway to the Internet, and that ICS sets up all internal network addresses.

You might need to configure services on the ICS host computer to work properly across the Internet. The Web services that you provide must be configured so that Internet users can access them. For example, if you are hosting a Web server on your home network, and you want Internet users to be able to connect to it, you must configure the ICS host computer to permit traffic from the Web on to your network. For information, see Manage service definitions for ICF or ICS.

ICS requires two connections in order to work: one public and one private. The private connection, typically a LAN adapter, connects the ICS host computer to the computers on your home or small office network. The public connection, typically a DSL, cable, or dial-up modem, connects your network to the Internet.

Enable ICS on the public connection of your home or small office network, and before doing so, ensure that the network connection that ICS will use as the private connection connects only to your home or small office network. If you have only one connection to your network, that connection is automatically selected as the private side of your shared Internet connection when you enable ICS. If you have two or more connections to your network, you must do one of the following in order to enable ICS:

- Select one connection to be the private side of your shared Internet connection. For information about how to select the private connection, see Enable ICS.

- Set up Network Bridge to include all of the private connections to your network, so that Network Bridge serves as the private side of your shared Internet connection. If you set up Network Bridge to include all of the connections to your network, Network Bridge is automatically selected as your private connection when you enable ICS. If you do not set up Network Bridge to include all of the connections to your network, you can still select Network Bridge as your private connection.

For information about how to select the private connection, see Enable ICS. For more information about how to bridge connections, see Set up Network Bridge.

**Adding ICS client computers to a home or small office network**

When ICS is enabled on the Internet connection of a computer running Windows XP; Windows Server 2003, Standard Edition;

or Windows Server 2003, Enterprise Edition, you can add a client running Windows 98; Windows 98 Second Edition; Windows Millennium Edition; Windows XP; Windows Server 2003, Standard Edition; or Windows Server 2003, Enterprise Edition to your home or small office network in the following ways:

- Add a computer running Windows Server 2003, Standard Edition or Windows Server 2003, Enterprise Edition to your home or small office network by adding it to the home or small office network workgroup. For more information, see Join a workgroup.

- Add a computer running Windows XP to your home or small office network by running the Windows XP Network Setup Wizard on it.

- Add a computer running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition to your home or small office network by running a Windows Server 2003, Standard Edition or Windows Server 2003, Enterprise Edition installation CD on it, and then running the setup program Netsetup.exe. For more information, see Configure client computers for ICS.

You can also add a computer running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition to your home or small office network if you have a Windows XP installation CD. Run Network Setup Wizard on the computer running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition. The wizard provides an opportunity to create a setup disk that can be run on computers running Windows 98, Windows 98 Second Edition, or Windows Millennium Edition.

Network Setup Wizard cannot be run on computers running Windows 2000. You can provide ICS addressing and name resolution services to a computer running Windows 2000 by adding it to your home and small office network workgroup.

**Notes**

- When you enable ICS, the adapter connected to the home or small office network is given a new static IP address configuration. Consequently, when you enable ICS, TCP/IP connections that are established between any small office or home office computer and the ICS host computer are lost and need to be reestablished.

- If your home or small office users need to access a corporate network that is connected to the Internet by a tunnel server from a home or small office network on which ICS is enabled, they need to create a virtual private network (VPN) connection to tunnel from the computer on the home or small office network on which ICS is enabled to the corporate tunnel server on the Internet. The VPN connection is authenticated and secure, and creating the tunneled connection allocates proper IP addresses, DNS server addresses, and WINS server addresses for the corporate network. For more information about creating a VPN connection, see Make a virtual private network (VPN) connection.

**Items configured by ICS**

When you enable ICS, certain protocols, services, interfaces, and routes are configured automatically. One important configuration is that the ICS host computer automatically becomes a Dynamic Host Configuration Protocol (DHCP) allocator for the home or small office network. DHCP distributes IP addresses to users when they start up.

**Caution**

- If you enable ICS on any of your private network adapters, the home or small office network DHCP allocator might grant IP addresses to users outside of your network, causing problems on their networks. Additionally, if you enable ICS on a private network adapter on a computer that is directly attached to the Internet, you might expose your network to computers outside your network, potentially allowing external attacks.

- Transmissions may be disrupted if you enable ICS on an existing network with other domain controllers running Windows Server 2003, Standard Edition, DNS servers, gateways, DHCP servers, or systems configured for static IP addresses. If you are running Windows Server 2003, Standard Edition and one or more of these components exist, you must use NAT to achieve the same results and to protect your network against data loss. For more information, see Deploying network address translation.

The following table describes each of the protocols, services, interfaces, and routes are configured automatically when you enable ICS.

| Configured item | Action |
| --- | --- |
| IP address 192.168.0.1 | Configured with a subnet mask of 255.255.255.0 on the LAN adapter that is connected to the home or small office network |
| Autodial feature | Enabled |
| Static default IP route | Created when the dial-up connection is established |
| ICS service | Started |
| DHCP allocator | Enabled with the default range of 192.168.0.0 and a subnet mask of 255.255.255.0. Unique addresses in the range of 192.168.0.2 to 192.168.0.254 are allocated to private network clients |
| DNS proxy | Enabled |

**Notes**

- You cannot modify the default configuration of ICS. This means you cannot configure items such as disabling the DHCP allocator or modifying the range of private IP addresses that are distributed, disabling the DNS proxy, configuring a range of public IP addresses, or configuring inbound mappings. If you want to modify any of these items, you must use NAT.

- For information about how to enable ICS, see Enable ICS.

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

# Administering Network Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administering Network Connections**

This section covers:

- Managing network connections from the command line
- Logging remote access connections
- Configuring Network and Dial-up Connections

# Managing network connections from the command line

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing network connections from the command line**

You can display or change settings for the Server service or the Workstation service while the service is running with Net config. **Net config** allows you to display the configurable services that are running, or to display and change settings for a service. Additional Net services commands are available.

Netsh overview allows you to, either locally or remotely, display or modify the network configuration of a computer that is currently running. Netsh also provides a scripting feature that allows you to run a group of commands in batch mode against a specified computer. Netsh can also save a configuration script in a text file for archival purposes or to help you configure other servers.

For information about other command-line utilities, see Command-line reference A-Z. For more information about manageability, see Management Strategies and Tools.

# Logging remote access connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logging remote access connections**

You can enable logging to automatically record configuration and activity details of remote access connections. If you enable logging, you can review connection errors and pertinent connection information in a log file. This option is especially helpful when you need to determine why a remote access connection failed. If a connection fails, you can generate a diagnostic report based on the log file and send the report to a support engineer.

If you enable logging, you can view a diagnostic report, save the report to a file, or send the report to an e-mail address that you specify. You can also clear previous logs so that the report contains details of the most recent connection only. If you do not need detailed connection information but want to run the report more quickly, you can generate a summary report that contains configuration and installation information only. You can use this information to troubleshoot configurations.

If you do not enable logging and a connection fails, you are prompted to enable logging. After you enable logging, you can dial the remote access connection again to log errors for the failed connection.

For more information, see Enable logging.

# Configuring Network and Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring network and dial-up connections**
This section covers:

- Configuring a network or dial-up connection
- Optional networking components
- Client for Microsoft Networks
- File and Printer Sharing for Microsoft Networks
- Mobile users and certificates
- Configuring Dial-up Connections
- Using Terminal and Scripting
- Configuring Authentication and Data Encryption
- Automating a Network or Dial-up Connection

# Configuring a network or dial-up connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring a network or dial-up connection**

You can change a network or dial-up connection by modifying its settings. Dial-up settings, such as the phone number of the connection, the number of redial attempts, and so on, are defined for each connection. These pre-connection and post-connection settings do not modify or affect the settings of other connections. For example, you may have a dial-up connection that makes 10 attempts to redial a server that is frequently busy. You may have a second dial-up connection that makes 3 attempts to redial another server that is more readily available. The redial setting of the first connection never causes the second connection to redial more than its own established attempts of 3. There is no need to make changes to any settings outside of the settings of the dial-up connection.

Changes to some networking settings of a connection can affect other connections. For example, if you add the IPX protocol to the list of available network components for one connection, the IPX protocol also is available to other connections on the same computer.

You can modify connection settings when you are connected. You can also rename a connection when it is connected. However, the connection may need to be reconnected in order to save the changes. In a dial-up connection, modifying settings displays the message **Since this connection is currently active, some settings will not take affect until the next time you dial it**. In a local area connection, changed settings are stored automatically.

Each connection is configured with general settings that represent the basic information needed to connect successfully. These options are found on the **General** tab. For example, a local area connection only needs to list its network adapter. For a dial-up connection, the **General** tab includes required information, such as the device used to dial, the area code, the phone number, and the country/region code to dial.

For outgoing connections, you can set additional configuration options on the **Options**, **Security**, **Networking**, and **Advanced** tabs. You can set additional configuration options for an incoming connection on the **Users** and **Networking** tabs. Local area connections have additional configuration options in the **Authentication** and **Advanced** tabs.

You can configure advanced settings from **Advanced Settings** on the **Advanced** menu of the Network Connections folder. By modifying these settings, you can improve performance. For example, network providers and protocols are accessed in the order specified in **Advanced Settings**. If your LAN connection is enabled to access NetWare and Microsoft Windows networks that use TCP/IP and IPX, but your primary connection is to a Microsoft Windows network that uses TCP/IP, you can move **Microsoft Windows Network** to the top of the **Network Providers** list on the **Provider Order** tab, and move **Internet Protocol (TCP/IP)** to the top of the **File and Printer Sharing for Microsoft Networks** binding on the **Adapters and Bindings** tab. By changing your provider order, and by changing the order of protocols bound to those providers, you can improve performance. For more information about modifying the order of network providers, see Modify the network provider order. For more information about modifying the protocol binding order, see Modify the protocol bindings order.

The IPX/SPX protocol is not available on Windows XP 64-bit Edition (Itanium) and the 64-bit versions of the Windows Server 2003 family.

For more information about configuring connections, see Configure a connection to a remote network.

# Optional networking components

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Optional networking components**

You can add or remove optional networking components. Optional networking components support network operations and are not automatically installed. Some of these components include the Route Listening Service, Simple TCP/IP Services, SNMP Services, and Print Services for UNIX.

For information about installing optional networking components, see Add optional networking components.

# Client for Microsoft Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Client for Microsoft Networks**
The Client for Microsoft Networks component allows a computer to access resources on a Microsoft network.

This component is installed and enabled by default for all VPN connections. However, this component needs to be enabled for PPPoE connections. You should not need to configure the component unless you are running software from The Open Group, such as Distributed Computing Environment (DCE) server or client kits. If you are, contact your system administrator for the correct DCE Cell Directory Service network address.

The Client for Microsoft Networks component is the equivalent of the Workstation service in Windows NT 4.0.

For information about configuring the Client for Microsoft Networks component, see Configure Client for Microsoft Networks.

# File and Printer Sharing for Microsoft Networks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**File and Printer Sharing for Microsoft Networks**
The File and Printer Sharing for Microsoft Networks component allows other computers on a network to access resources on your computer by using a Microsoft network.

This component is installed and enabled by default for all VPN connections. However, this component needs to be enabled for PPPoE and dial-up connections. It is enabled per connection and is necessary to share local folders.

The File and Printer Sharing for Microsoft Networks component is the equivalent of the Server service in Windows NT 4.0.

For information about configuring the File and Printer Sharing for Microsoft Networks component, see Configure File and Printer Sharing for Microsoft Networks. For information about sharing folders, see Share a folder or drive.

**Note**

- This feature is not included on computers running the Microsoft® Windows Server® 2003, Web Edition, operating system. For more information, see Overview of Windows Server 2003, Web Edition.

# Mobile users and certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Mobile users and certificates**

If you are a mobile user, you need to enable the use of certificates on your computer. Unless your system administrator preconfigures your computer with machine and user certificates before you receive it, you must connect to your corporate network by using conventional, password-based authentication methods to get your machine and user certificates. At the time you connect, you join your computer to the corporate domain, obtain certificates, and set certificates policy. The next time you connect to the corporate network, you can use certificate-based authentication methods such as EAP.

To enable the use of certificates on a computer, do the following:

- Connect to the corporate network by using a dial-up or PPTP network connection, and authentication protocols such as MS-CHAP, or MS-CHAP v2. When you connect, your computer name joins the corporate domain and receives machine certificates.

- Request a user certificate. For more information about requesting certificates, see Request a certificate, Submit a user certificate request via the Web, and Requesting certificates.

- Create another connection that uses certificate-based authentication, and then connect again by using certificate-based authentication methods such as EAP or IPSec. For more information about enabling a connection to use a smart card or other certificate, see Enable smart card or other certificate authentication.

You can avoid these steps by having your system administrator load machine and user certificates before you take your laptop out onto the road.

**Note**

- For machine certificates to be received automatically, you must implement public key policies (by using Group Policy) that autoenroll computers to receive certificates. If the machine certificate process is not automated, you must log on to your computer with administrative credentials, install Certificate Services, and request a computer certificate. For more information, see Manage certificates for a computer and Manage certificates for your user account.

# Configuring Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring dial-up connections**
This section covers:

- Configuring dial-up options
- Configuring redial options
- Configuring multiple device dialing

# Configuring dial-up options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring dial-up options**

There are many dialing features that you can use to streamline the dial-up connection process. For instructions about configuring a dialing feature, click the feature in the following table.

| Dialing feature | Function |
|---|---|
| Configure client callback options | Reduces phone charges by having the remote access server dial back to your location after you initially connect. |
| Configure autodial | Remembers network addresses to connection destinations, which allows them to be automatically dialed when referenced from an application or from the command prompt. |
| Enable multiple device dialing | Combines multiple physical links, which increases the aggregate bandwidth of your connection, and dynamically dials and drops multilinked lines as needed. |
| Configure phone number modifiers | Manually inserts characters to force dialing behaviors (pause, suspend dialing until input provided, and so on). |
| Configure redial options | Specifies the number of times your connection automatically redials when you fail to connect to your remote access server. You can also set this feature to reconnect automatically when an inactive link is dropped. |
| Assign multiple phone numbers to a connection | Assigns more than one destination phone number to your dial-up connection. This is useful if you have a pool of phone numbers to connect to. |
| Enable operator-assisted calls or manual dialing | Overrides automatic dial-up situations where intervention is required. For example, when you call through a manually operated switchboard. |

**Note**

- You can configure dial-up options that apply to all connections within a location (for example, dialing 9 for an outside line, disabling call waiting, using pulse dialing instead of tone dialing, and so on) in Phone and Modem Options. For more information, see Create a new location.

# Configuring redial options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring redial options**

With redial options, you can determine the number of times your connection automatically redials when you fail to connect to a remote access server. You can also reconnect automatically when a link is dropped.

By default, a dial-up connection is set up to redial 3 times (at 1 minute intervals) if it cannot reach its remote access server. Also, by default the **Idle time before hanging up** is set to **Never**.

For information about configuring redial options, see Configure redial options.

# Configuring multiple device dialing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring multiple device dialing**

The Multilink Control Protocol allows dialing over multiple ISDN, X.25, or modem lines. The feature combines multiple physical links into a logical bundle and the resulting aggregate link increases your connection bandwidth. To dial multiple devices, both your connection and your remote access server must have Multilink enabled.

Network Connections can dynamically control the use of multilinked lines. By allocating lines only as they are required, thereby eliminating excess bandwidth, you can realize a significant efficiency advantage. You can configure the conditions under which extra lines are dialed, and underused lines are disconnected, through Network Connections settings.

For more information, see Enable multiple device dialing.

**Note**

- If you use Multilink to dial a server that requires callback, then only one of your multilinked devices is called back. This is because you can only store one number in a user account. Therefore, only one device connects and all other devices fail to complete the connection, and your connection loses Multilink functionality. You can avoid this problem:
    - If the multilinked phonebook entry uses a standard modem configuration, and the remote access server that your connection is calling uses more than one line for the same number.
    - If the multilinked phonebook entry is ISDN with two channels that have the same phone number.

# Using Terminal and Scripting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Terminal and scripting**

If you are connecting to a remote access server that is not running Windows, you may need to provide logon information in a separate logon Terminal window. Your connection must be configured to accommodate this requirement.

You can use one of two possible scripting methods to automate the remote Terminal logon process: Switch.inf scripts or Windows scripting. Switch.inf is an older scripting method that was developed for earlier versions of Windows NT. You may find the Windows 95 scripting language easier to use than Switch.inf.

This section covers:

- Using the Terminal feature for the remote logon process
- Automating the Dial-up Logon Process by Using Switch.inf Scripts

For information on automating the dial-up logon process by using Windows scripting, see "Using Windows Scripting with Network Connections" at the Microsoft Windows Resource Kits Web site.

# Using the Terminal feature for the remote logon process

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using the Terminal feature for the remote logon process**

For a PPP or SLIP server, if the remote computer you connect to requires that you log on with a terminal-emulation screen, you must configure the script settings for that network connection to use a Terminal logon window. With this logon process, after your connection connects to the remote system, a character-based window displays the logon sequence from the remote computer. You can use this window for logging on to the remote computer. For more information, see Use the Terminal feature to log on to a remote computer. Alternatively, you can automate this manual logon process as described in Automating the Dial-up Logon Process by Using Switch.inf Scripts.

Some commercial networks present a large menu of available services before you log on. On SLIP servers, typically running on UNIX, you may go through an extensive sequence of commands that updates files, collects data about you, or configures your SLIP connection during your logon process. On a newer PPP server, you may be prompted for only your user name and password before you are given a connection.

**Note**

- If the remote computer is a remote access server running Windows, you do not need to use a Terminal logon window. Instead, the logon process is completely automated for you.

# Automating the Dial-up Logon Process by Using Switch.inf Scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automating the dial-up logon process by using Switch.inf scripts**
To automate the logon process, you can use the Switch.inf file (or Pad.inf on X.25 networks) instead of the manual Terminal window described in Using the Terminal feature for the remote logon process.

Automated scripts are especially useful when a constant connection to a remote computer is needed. If your network connection is configured to use a script, and a remote connection fails, your connection automatically redials the number and reestablishes the connection. Scripts also save time if you frequently log on to a remote system and do not want to manually log on each time.

The Switch.inf file provides a generic script that you can use with little or no modification. You can try Switch.inf without modification and if it does not work, then copy and modify the generic script to match the logon sequence of the remote computer to which you want to connect.

The script language is also designed to communicate with other devices, including modems. If you are unfamiliar with modem scripts, scripting can be difficult to understand. You may find it easier to copy, then modify, one of the generic sample scripts.

This section covers:

- Using device command (.inf) files
- Creating Switch.inf Scripts for Network and Dial-up Connections
- Stepping through an example Switch.inf script
- Getting through two-second gaps and large blocks of text in Switch.inf
- Using commands and carriage returns in Switch.inf
- Troubleshooting logon scripts

# Using device command (.inf) files

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using device command (.inf) files**
Network Connections uses the Switch.inf and Pad.inf files to automate the interactive logon process with servers and to initialize X.25 packet assemblers/disassemblers (PADs). These device command (.inf) files, located in the *systemroot*\System32\Ras folder, use the same commands and syntax to communicate with devices or computers automatically.

**Switch.inf**
You can use the commands in this file when you connect to the network through a security host or a remote server that requires you to log on interactively (for example, a UNIX server). You can create a script by typing the name of the device in brackets and then adding one or more commands following the device name. After you create the script, activate the script (on the **Security** tab) for each connection that will use the script. You can use the scripts before you dial (for example, modem pools) or after you dial (for example, using security hosts or actually logging on to a remote server). For more information, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

**Pad.inf**
You can use the commands in this file when you connect to the network through an X.25 PAD. Most supported PADs have scripts that are provided in Pad.inf. If necessary, you can create a script by typing the name of the device within brackets and then adding one or more commands following the device name. After you create the script, activate the script (on the **Security** tab) for each connection that will use the script.

### Caution

- You should not edit Switch.inf or Pad.inf without a basic understanding of system configuration files.

# Creating Switch.inf Scripts for Network and Dial-up Connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Creating Switch.inf scripts for network and dial-up connections**
The Switch.inf file, located in the *systemroot*\System32\Ras folder, is like a set of small batch files (scripts) contained in one file. The Switch.inf file contains a different script for each intermediary device or online service that a connection calls.

A Switch.inf script has six elements:

- Section headers
- Comment lines
- Commands
- Responses
- Response keywords
- Macros

# Section headers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Section headers**

Section headers divide the Switch.inf file into individual scripts. A section header marks the beginning of a script for a particular remote computer and must not exceed 31 characters. The text of a section header appears in Network Connections when you activate the script. The section header is enclosed in square brackets. For example:

```
[Route 66 Logon Process]
```

For information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Comment lines

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Comment lines**

Comment lines must have a semicolon (;) in column one and can appear anywhere in the file. Comment lines contain information for people who maintain the Switch.inf file. For example:

```
; This script was created by Martha on September 29, 1996.
```

For more information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Commands

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Commands**

Each line in a script is a command from your local computer to a remote computer or a response from a remote computer to your local computer. Each command or response is a stream of data or text. For example, the following command sends a user name (Martha) and a carriage return (the macro <cr>) to the remote computer:

```
COMMAND=Martha<cr>
```

The commands and responses must be in the exact order the remote computer expects them. Branching statements, such as GOTO or IF, are not supported.

The required sequence of commands and responses for a specific remote device should be in the documentation for that device or, if you are connecting to a commercial service, from the support staff of that service. If the exact sequence is not available, you can activate the generic script provided with Network Connections and modify it to match the logon sequence of the remote computer as described in Troubleshooting logon scripts.

You can use the COMMAND= statement in two additional ways:

- `COMMAND= NoResponse`

  This is the default behavior and causes an approximate two-second delay. This is useful when an intermediate device requires a delay.

- `COMMAND=` *string*

  In this case, *string* is not followed by a carriage return (<cr>). This is useful when a device requires slow input. Instead of receiving the whole command string, the device requires characters to be sent one-by-one.

The following example shows a script for an intermediary device that is so slow, it is able to receive and process only one character of the command PPP at a time:

```
COMMAND=P
NoResponse

COMMAND=P
NoResponse

COMMAND=P
NoResponse
```

**Note**

- To activate a script.inf file, see Activate a logon script.

# Responses

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Responses**

A response is sent from the remote device or computer. To write an automatic script, you must know the responses you will receive from the remote device. If a gap of two or more seconds occurs between characters, the received text is sent as a response. This gap is the only cue that a response is over. For more information, see Getting through two-second gaps and large blocks of text in Switch.inf.

For information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Response keywords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Response keywords**

The keyword in a response line specifies what to do with the responses you receive from the remote computer, as follows:

- `OK=` *remote computer response<macro>*

  The script continues to the next line if the response or macro is encountered.

- `LOOP=` *remote computer response<macro>*

  The script returns to the previous line if the response or macro is encountered.

- CONNECT=remote computer response<macro>

  Used at the end of a successful modem script. Not generally useful with the Switch.inf file.

- `ERROR=` *remote computer response<macro>*

  Causes Network Connections to display a generic error message if the response is encountered. Useful for notifying you when the remote computer reports a specific error.

- `ERROR_DIAGNOSTICS=` *remote computer response<diagnostics>*

  Causes Network Connections to display the specific cause for an error returned by the device. Not all devices report specific errors. Use **ERROR=** if your device does not return specific errors that can be identified with Network Connections diagnostics.

- `NoResponse`

  Used when no response comes from the remote device.

A connection always expects a response from the remote device and waits until a response is received unless a NoResponse statement follows the COMMAND= line. If there is no statement for a response following a COMMAND= line, the COMMAND= line executes and stops the script at that point.

For information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Macros

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Macros**

Macros are enclosed in angle brackets (<>) and perform a variety of special functions, as follows:

- `<cr>`

  Inserts a carriage return.

- `<lf>`

  Inserts a line feed.

- `<match>` " *string* "

  Reports a match if the string enclosed in quotation marks is found in the device response. Each character in the string is matched according to upper and lower case. For example, <match> "Smith" matches Denise Smith and Jeff Smith, but not SMITH.

- `<?>`

  Inserts a wildcard character, for example, CO<?><?>2 matches COOL2 or COAT2, but not COOL3.

- `<hXX>`

  (XX are hexadecimal digits)

  Allows any hexadecimal character to appear in a string--including the zero byte, <h00>.

- `<ignore>`

  Ignores the rest of a response from the macro on.

- `<diagnostics>`

  Passes specific error information from a device to remote access, which displays the specific error to you. Otherwise, a nonspecific error message appears.

For information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Stepping through an example Switch.inf script

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Stepping through an example Switch.inf script**

This section describes each part of the generic script provided in the Switch.inf file.

Every script must start with a command to the remote computer, followed by one or more response lines. This initial command might be simply to wait for the remote computer to initialize and send its logon banner. The default initial command is to wait two seconds for the logon banner. It appears as follows in the Switch.inf file:

```
COMMAND=
```

If the response (the logon banner from the remote computer) is the following:

```
Welcome to A. Datum Corporation. Please enter your login:
```

then the corresponding response line in the Switch.inf file should be:

```
OK=<match>"Please enter your login:"
```

If the remote computer sends the "Please enter your login:" string, then this indicates that everything is correct. You respond by sending a command with the characters in your user name and the carriage return, as follows:

```
COMMAND=Martha<cr>
```

If the response from the remote computer is the following:

```
Please enter your password:
```

then the corresponding response line in the Switch.inf file should be:

```
OK=<match>"Please enter your password:"
```

To send your password, you send the following command:

```
COMMAND=mUs3naB<cr>
```

On many PPP computers, this script automatically logs you on.

For information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Getting through two-second gaps and large blocks of text in Switch.inf

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Getting through two-second gaps and large blocks of text in Switch.inf**

If the computer you are connecting to has a two-second gap in the data stream response to your computer, the remote access server assumes that the gap is the end of the response. These gaps can occur anywhere, even between words, and are detected by using modem diagnostics. For more information, see Log and view modem commands.

If you write a script that fails for no apparent reason, you can use modem diagnostics, and then consult *systemroot*\ModemLog_*model*.txt to see if a response ends in the middle of a word. *Model* is the name of the modem as it appears in the list of installed modems in **Modem Properties**. If a response ends in the middle of a word, your script must account for the two-second gap. A simple way to do this is to include the following command:

```
COMMAND=<cr>
```

You can skip to the end of large blocks of text that contain multiple gaps by using the LOOP= keyword and by matching text at the end of a block. For example:

```
COMMAND=<cr>
OK=<match>"Enter the service to start:"
LOOP=<ignore>
```

In this example, the network connection sends a null command (waits two seconds). The network connection then waits for the "Enter the service to start:" message. If this is a long block of text, the connection does not find the string. The connection then moves to the **LOOP** command. The **LOOP** command causes Network Connections to return to the line above, and the connection waits for the words "Enter the service to start:" in the second response. In this manner, you can loop though long blocks of text until you reach the text of the desired prompt.

For information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Using commands and carriage returns in Switch.inf

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using commands and carriage returns in Switch.inf**

In Switch.inf scripts, you usually must include <cr>, which indicates a carriage return, at the end of a command. The carriage return causes the remote computer to process the command immediately. If you do not include <cr>, the remote computer may not recognize the command.

In other situations, you cannot use <cr> because the remote computer accepts a command without a carriage return and requires time to process the command. This situation mainly applies when you are sending a series of commands without expecting a response.

For more information about activating a Switch.inf script, see Activate a logon script. For more information about Switch.inf scripts, see Automating the Dial-up Logon Process by Using Switch.inf Scripts.

# Troubleshooting logon scripts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting logon scripts**

You can log all information passed between your network connection, the modem, and the remote device, including errors reported by the remote device.

You can view modem commands by enabling logging. After you enable logging, commands sent to the modem are captured in the file *systemroot*\ModemLog_*model*.txt. *Model* is the name of the modem as it appears in the list of installed modems. For instructions about logging modem commands, see Log and view modem commands.

# Configuring Authentication and Data Encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Configuring authentication and data encryption**
This section covers:

- Dial-up connection authentication and data encryption
- VPN connection authentication and data encryption

# Dial-up connection authentication and data encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Dial-up connection authentication and data encryption**

The **Typical (recommended settings)** security options that you select on the **Security** tab result in a predefined set of authentication methods and encryption requirements that are negotiated with the server during a PPP exchange.

The following table shows the authentication and data encryption methods that you can use with each combination of **Validate my identity as follows** and **Require data encryption (disconnect if none)** selections. You can also view these settings by making your identity validation and data encryption requirement selections in **Typical (recommended) settings**, and then clicking **Settings** in **Advanced (custom) settings**.

You may individually enable, configure, and disable these combinations of security settings by using **Advanced (custom settings)**, but this requires a knowledge of security protocols.

For more information about a specific authentication or data encryption method, click the method in the table. For information about configuring a connection, see Configure a connection to a remote network.

| Validate my identity as follows | Require data encryption | Authentication methods negotiated | Encryption enforcement |
|---|---|---|---|
| Allow unsecured password | No | Password Authentication Protocol (PAP), Challenge Handshake Authentication Protocol (CHAP), Shiva Password Authentication Protocol (SPAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Optional encryption (connect even if no encryption) |
| Require secured password | No | Challenge Handshake Authentication Protocol (CHAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Optional encryption (connect even if no encryption) |
| Require secured password | Yes | Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Require encryption (disconnect if server declines) |
| Smart card | No | Extensible Authentication Protocol (EAP) | Optional encryption (connect even if no encryption) |
| Smart card | Yes | Extensible Authentication Protocol (EAP) | Require encryption (disconnect if server declines) |

**Notes**

- Data is only encrypted if MS-CHAP, MS-CHAP v2, or EAP-TLS authentication is negotiated. These are the only authentication protocols that generate their own initial encryption keys, which are required for encryption.
- Microsoft Point-to-Point Encryption (MPPE) encrypts data in PPP-based dial-up connections. Strong (128-bit key) and

standard (40-bit key) MPPE encryption schemes are supported.

- MS-CHAP v2 and EAP are mutual authentication protocols, which means that both the client and the server prove their identities. If your connection is configured to use either MS-CHAP v2 or EAP as its only authentication method, and the server that you are connecting to does not provide proof of its identity, your connection disconnects. Previously, servers could skip authentication and simply accept the call. This change ensures that you can configure a connection to connect to the expected server.

# VPN connection authentication and data encryption

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**VPN connection authentication and data encryption**

The **Typical (recommended settings)** security options that you select on the **Security** tab result in a predefined set of authentication methods and encryption requirements that are negotiated with the server during a PPP exchange.

The following tables show the authentication and data encryption methods that you can use with each combination of **Validate my identity as follows** and **Require data encryption (disconnect if none)** selections. You can also view these settings by making your identity validation and data encryption requirement selections in **Typical (recommended settings)**, and then clicking **Settings** in **Advanced (custom settings)**.

You may individually enable, configure, and disable these combinations of security settings, by using **Advanced (details for all possible settings)**, but this requires a knowledge of security protocols.

For more information about a specific authentication or data encryption method, click the method in the table. For information about configuring a connection, see Configure a connection to a remote network.

**Point-to-Point Tunneling Protocol (PPTP) remote access server**

| Validate my identity as follows | Require data encryption | Authentication methods negotiated | Encryption enforcement |
|---|---|---|---|
| Require secured password | No | Challenge Handshake Authentication Protocol (CHAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Optional encryption (connect even if no encryption) |
| Require secured password | Yes | Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Require encryption (disconnect if server declines) |
| Smart card | No | Extensible Authentication Protocol (EAP) | Optional encryption (connect even if no encryption) |
| Smart card | Yes | Extensible Authentication Protocol (EAP) | Require encryption (disconnect if server declines) |

**Layer Two Tunneling Protocol (L2TP) remote access server**

| Validate my identity as follows | Require data encryption | Authentication methods negotiated | Encryption enforcement |
|---|---|---|---|
| Require secured password | No | Challenge Handshake Authentication Protocol (CHAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Optional encryption (connect even if no encryption) |
| Require secured password | Yes | Challenge Handshake Authentication Protocol (CHAP), Microsoft Challenge Handshake Authentication Protocol (MS-CHAP), Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAP v2) | Require encryption (disconnect if server declines) |
| Smart card | No | Extensible Authentication Protocol (EAP) | Optional encryption (connect even if no encryption) |

| | | | |
|---|---|---|---|
| Smart card | Yes | Extensible Authentication Protocol (EAP) | Require encryption (disconnect if server declines) |

**Notes**

- In L2TP VPN connections, data is encrypted by using Internet Protocol Security (IPSec) Encryption.
- Microsoft Point-to-Point Encryption (MPPE) encrypts data in PPTP VPN connections. Strong (128-bit key) and standard (40-bit key) MPPE encryption schemes are supported.
- Data is only encrypted by MPPE if MS-CHAP, MS-CHAP v2, or EAP-TLS authentication is negotiated. These are the only authentication protocols that generate their own initial encryption keys. MPPE requires common client and server keys as generated by these types of authentication.
- MS-CHAP v2 and EAP-TLS are mutual authentication protocols, which means that both the client and the server prove their identities. If your connection is configured to use either MS-CHAP v2 or EAP-TLS as its only authentication method, and the server that you are connecting to does not provide proof of its identity, your connection disconnects. Previously, servers could skip authenticating themselves to clients and simply accept the call. This change ensures that you can configure a connection to connect to the expected server.

# Automating a Network or Dial-up Connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Automating a network or dial-up connection**
You can automate the connection process for a network or dial-up connection by using the autodial feature. With autodial enabled, network addresses are mapped to connection destinations, which allows a destination connection to be automatically dialed when a remote resource is referenced.

You can also automate the connection process for any Microsoft client by using a simple batch file and the **rasdial** command or by using a custom application that recognizes remote access.

This section covers:

- Autodial
- Using rasdial

# Autodial

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Autodial**
Autodial maps and maintains network addresses to connection destinations, which allows the destinations to be automatically dialed when referenced, whether from an application or from the command prompt. A network address can be an Internet host name, an IP address, or a NetBIOS server name. When a more specific mapping is not available in the database, autodial dials the default Internet connection.

The following example describes how autodial works:

1. You are not connected to your ISP, and you click an Internet address that is embedded in a word processing document.

2. If you have a connection that is set as the default Internet connection, autodial dials this connection, and then you can access the Internet address that you are trying to reach.

3. If you do not have a connection that is set as the default Internet connection, you are prompted to select a connection to use to reach your ISP. Autodial dials with this connection, and then you can access the Internet address that you are trying to reach.

4. The next time that you are not connected to your ISP and click the Internet address in a word processing document, a similar process occurs. If you selected a specific connection, that connection is automatically dialed. Otherwise, the default connection is dialed.

Autodial maps the resources that are required to initially make a connection but does not map resources once the connection is made.

There are two possibilities when autodial attempts to make a connection:

- If you are not connected to a network, autodial attempts to create a connection whenever an application references a remote address.

- If you are connected to a network, autodial attempts to create a connection only for those addresses that it has previously learned. Incorrectly typed server or Internet host names do *not* cause an autodial attempt.

For more information, see Configure autodial.

**Note**

- Autodial is disabled by default in all members of the Windows Server 2003 family. To enable autodial, the Remote Access Auto Connection Manager service needs to be started. For more information, see Start Remote Access Auto Connection Manager.

# Using rasdial

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using rasdial**

You can create a simple batch file that connects to a dial-up network connection by using the **rasdial** command. You can also use **rasdial** to connect to or disconnect from a network connection from a command line. Unlike autodial, the **rasdial** command does not automatically detect your network connection status before dialing a connection and is not dependent on the Remote Access Auto Connection Manager service.

For example, you might want to automatically connect to a dial-up connection during off-peak hours in order to transfer large data files. You can create a batch file or a series of batch files to automate this process. You would use the **rasdial** command to start and end the dial-up connection. There are additional configurable parameters that are associated with **Rasdial**, such as what phone number to use, the callback number, the phone book file, prefix and suffix.

For more information about using the **rasdial** command, see Rasdial. For more information about batch files, see Using batch files.

# Network Connections Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
This section covers:

- Troubleshooting network and dial-up connections
- Error messages in Network Connections (Windows Server 2003)

# Troubleshooting network and dial-up connections

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting network and dial-up connections**
What problem are you having?

- The modem does not work.
- Unable to connect to a remote access server.
- When trying to connect, a message is received that says the remote access server is not responding.
- The modem always connects at a lower bits-per-second (bps) rate than specified.
- The sessions with a remote access server on the network keep getting dropped.
- Connections are disconnecting abnormally.
- When trying to connect, a hardware error is received.
- Conflicts between serial ports are causing connection problems.
- When trying to connect by using ISDN, a "No Answer" message is received.
- Connections made by using X.25 fail.
- Connections through PPTP fail.
- Connections configured by using PPP or TCP/IP are failing.
- Connections made by using Internet Connection Sharing (ICS) are failing.
- When using a local area network connection, there is no response.
- When using a laptop to connect to an ISP, some or all of the applications do not run properly.
- Incoming connection clients cannot see resources beyond the incoming connection computer.
- The smart card reader does not work.
- The smart card does not work.
- When you try to establish a remote access connection using a smart card, you receive an error.

**The modem does not work.**
**Cause:** The modem is incompatible.

**Solution:** If you have access to another computer with an Internet connection, check the list of compatible modems at Support resources.

**Cause:** The modem is not connected properly or is turned off.

**Solution:** Verify that the modem is connected properly to the correct port on your computer. If the modem is external, verify that the power is on.

**See Also:** Modems Troubleshooting.

**Unable to connect to a remote access server.**
**Cause:** The remote access server is not running.

**Solution:** Ask your system administrator to verify that the remote access server is running. If the server is down, the administrator needs to check the error and audit logs to see why the service stopped. After the problem is fixed, restart the service. If the service is running, the administrator needs to check whether other remote access clients can connect properly. If other clients can connect, the problem may be specific to your workstation.

**Cause:** You do not have a valid user account, or you do not have remote access permission.

**Solution:** Verify with your system administrator that your user account has been created, and that you have remote access permission.

**Cause:** You dialed the wrong number, or you dialed the correct number but forgot to dial an external line-access number, such as 9.

**Solution:** Verify that the dialed number is correct.

**Cause:** Your modem cannot negotiate with the modem of the server.

**Solution:** Try using the same type of modem as the server.

**Cause:** The modem cabling is faulty.

**Solution:** Do not use the 9-to-25-pin converters that are included with most mouse hardware because some of them do not carry modem signals. To be safe, you should use a converter made especially for this purpose.

**Cause:** The telephone line (for example, in your hotel room) does not accommodate your modem speed.

**Solution:** Select a lower bits-per-second (bps) rate (or call the hotel manager to request a direct line).

**See also:** Change the maximum modem port speed.

**Cause:** The line you are trying to use is digital.

**Solution:** Most modems work only with analog phone lines. Verify that you have analog phone lines installed or, if you have digital phone lines installed, verify that the servers and clients have digital modems.

**Cause:** Your modem settings need to be changed because of a remote access server change.

**Solution:** Verify the modem settings with your system administrator.

**When trying to connect, a message is received that says the remote access server is not responding.**
**Cause:**

- At higher bits-per-second (bps) rates, your modem is incompatible with the modem of the server.
- There is a lot of static on the phone line, which prevents a modem from connecting at a higher bps rate.
- Switch equipment between the client and server that prevents the two modems from negotiating at a higher bps rate.

**Solution:** Adjust the speed of your modem to a lower bit-per-seconds (bps) rate.

**See also:** Change the maximum modem port speed.

**Cause:** The remote access server is not running.

**Solution:** Ask your system administrator to verify that the server is running.

**The modem always connects at a lower bits-per-second (bps) rate than specified.**
**Cause:** The modem and telephone line are not operating correctly. Excessive static on the telephone line causes sessions to be dropped.

**Solution:** You can use modem diagnostics to confirm correct modem operation.

**See also:** Log and view modem commands.

**Cause:** The remote access server is not functioning properly.

**Solution:** Ask your system administrator to verify that the destination server is running properly. Try connecting to the same server from another workstation. If other workstations are having the same problem, there may be problems with server applications or hardware. If not, the problem is specific to your workstation.

**Cause:** The quality of your line is insufficient.

**Solution:** Contact your telephone company to verify the quality of your line.

**Cause:** The line you are dialing is affecting the speed.

**Solution:** If you can connect to your remote access server by using more than one number, try another number and see if the speed improves.

**Cause:** Your modem software needs to be updated.

**Solution:** Check with your modem manufacturer for modem software updates.

**The sessions with a remote access server on the network keep getting dropped.**
**Cause:** Call waiting is disrupting your connection.

**Solution:** Verify that the phone has call waiting. If so, disable call waiting and try calling again.

**See also:** Change dialing properties for a location.

**Cause:** The remote access server disconnected you because of inactivity.

**Solution:** Reattempt dial-up connection again.

**Cause:** Someone picked up the phone. Picking up the phone automatically disconnects you.

**Solution:** Reattempt dial-up connection again.

**Cause:** Your modem cable is loose.

**Solution:** Verify that the modem cable is connected properly.

**Cause:** Your modem software needs to be updated.

**Solution:** Check with your modem manufacturer for modem software updates.

**Connections are disconnecting abnormally.**
**Cause:** The remote access server is not performing optimally.

**Solution:** Ask your system administrator to verify that the remote access server is running properly.

**Cause:**

- Your modem is unable to negotiate correctly with the modem of the remote access server.
- The serial port of the computer cannot keep up with the speed you have selected.

**Solution:** Try to connect at a lower initial port speed.

**See also:** Change the maximum modem port speed.

**Cause:** Your modem software needs to be updated.

**Solution:** Check with your modem manufacturer for modem software updates.

**When trying to connect, a hardware error is received.**
**Cause:** The modem is turned off.

**Solution:** Verify that the modem is turned on. If the modem is turned off, turn it on and redial.

**Cause:** Your modem is not functioning properly.

**Solution:** Enable modem logging to test the modem.

**See also:** Log and view modem commands.

**Cause:** Your cable is incompatible.

**Solution:** If your modem does not communicate through Network Connections, the cable that attaches your modem to the computer is probably incompatible. You need to install a compatible cable.

**Conflicts between serial ports are causing connection problems.**
**Cause:** The serial ports are conflicting.

**Solution:** Com1 and Com3 share interrupt request (IRQ) 4. Com2 and Com4 share IRQ 3. As a result, for serial communications, you cannot use COM1 and COM3 simultaneously, or COM2 and COM4 simultaneously. For example, you cannot use Network Connections on COM1 and Terminal on COM3.

This rule applies if you are using the mouse in addition to other serial communications programs such as Network Connections or the Terminal program. The rule does not apply if you are using an intelligent serial adapter.

**See Also:** Configure a connection to a remote network; Change the COM port for a modem.

**When trying to connect by using ISDN, a "No Answer" message is received.**
**Cause:** The remote access server did not answer because it is turned off or the modem is not connected.

**Solution:** Contact your system administrator.

**Cause:** The line is busy.

**Solution:** Try calling later, or contact your system administrator.

**Cause:** There is a problem with the ISDN hardware.

**Solution:** Verify that the ISDN adapters are installed and configured correctly.

**Cause:** Your phone number is not configured correctly.

**Solution:** In some cases, each B channel on an ISDN line has its own number, while in other cases both B channels share a single number. Your telephone company can tell you how many numbers your ISDN line has.

**Cause:** If you are located in the United States or Canada, your Service Profile Identifier (SPID) is configured incorrectly. The SPID normally consists of the phone number with additional digits added to the beginning, the end, or both. The SPID helps the switch understand what type of equipment is attached to the line and routes calls to appropriate devices on the line. If an ISDN channel requires a SPID, but it is not entered correctly, then the device cannot place or accept calls.

**Solution:** Verify that the SPID is entered correctly.

**Cause:** A poor line condition (for example, too much static) interrupted your connection.

**Solution:** Wait a few minutes and try dialing again.

**Cause:** You did not enable line-type negotiation, or a connection cannot be made with the line type you selected.

**Solution:** Enable line-type negotiation.

**Cause:** Your ISDN switching facility is busy.

**Solution:** Try again later.

**Cause:** Your DigiBoard card is too old.

**Solution:** If you do not have the latest PCIMAC-ISA DigiBoard card, serial number A14308 or greater, contact DigiBoard for a replacement.

**Connections made by using X.25 fail.**
**Cause:** The dial-up PAD is configured with the wrong X.3 parameters or serial settings.

**Solution:** If the remote access server is running and you cannot connect to it directly through an X.25 smart card or an external PAD, modify the dial-up PAD X.3 parameters or serial settings. Ask your system administrator for the correct settings.

**See also:** Configure a connection to a remote network.

**Cause:** New Pad.inf entries are incorrect.

**Solution:** You can check other Pad.inf entries for direct connections and external PADs, and view the comments that go with them. You may need a line analyzer or a terminal program to see the response for the PAD. For dial-up PAD entries, you can use an entry in Pad.inf as an example, paying attention to the comments that go with the example.

**Cause:** Your modem is incompatible.

**Solution:** If the modem that connects to a dial-up PAD connects at a lower speed than it should, replace the modem with a compatible one.

**See also:** The modem does not work with Network Connections.

**Cause:** The line for the remote access server is congested. If a connection has been established, but the network drives are disconnecting, and you are dropping sessions or getting network errors, the cause may be congestion on the leased line for the remote access server.

For example, four clients connecting at 9600 bps (through dial-up PADs) require a 38,400-bps (four times 9600) leased line on the server end. If the leased line does not have adequate bandwidth, it can cause time-outs and degrade performance for connected clients. This example assumes that Routing and Remote Access is using all the bandwidth. If Routing and Remote Access is sharing the bandwidth, fewer connections can be made.

**Solution:** Your system administrator needs to verify that the speed of the leased line can support all the COM ports at all speeds clients use to dial in.

**Connections through PPTP fail.**
**Cause:** TCP/IP connectivity problems are keeping you from connecting to the PPTP server.

**Solution:** You or your system administrator can use the **ipconfig** and **ping** commands to verify a connection to your server.

**Cause:** A Winsock Proxy client is active.

**Solution:** A VPN connection cannot operate with an active Winsock Proxy client. Winsock Proxy immediately redirects packets to the proxy server before they can be processed by a virtual network connection for encapsulation. To fix this, you need to disable the Winsock Proxy client.

**Cause:** You do not have the appropriate remote access permissions and domain rights on the remote access server.

**Solution:** Contact your system administrator.

**Cause:** If you are using the TCP/IP protocol, you do not have a unique TCP/IP address.

**Solution:** Contact your system administrator.

**Cause:** Name resolution problems are keeping you from resolving names to IP addresses.

**Solution:** Specify a valid IP address for your connection.

**See Also:** Configure TCP/IP settings.

**Connections configured by using PPP or TCP/IP are failing.**
**Cause:** The server does not support LCP extensions.

**Solution:** If you cannot connect to a server by using PPP, or the remote computer terminates your connection, the server may not support LCP extensions. In Network Connections, clear the **Enable LCP extensions** check box.

**Cause:** IP header compression is keeping TCP/IP from running. If you successfully connect to a remote server by using PPP, but TCP/IP does not work, the problem may be IP header compression.

**Solution:** Try to reconnect after turning off IP header compression.

**See Also:** Stop requesting LCP extensions in PPP; Turn off IP header compression in PPP.

**Connections made by using Internet Connection Sharing (ICS) are failing.**
**Cause:** The wrong LAN network adapter is shared.

**Solution:** A computer with ICS needs two connections. One connection, typically a LAN adapter, connects to the computers on the home or small office network and the other connection connects the home or small office network to the Internet. You need to ensure that ICS is enabled on the connection that connects your home or small office network to the Internet.

**Cause:** TCP/IP is not installed on home network computers.

**Solution:** By default, the TCP/IP protocol is installed on computers running Windows NT version 4.0, Windows 98, Windows 2000, Windows XP, and Windows Server 2003 operating systems. If users on your home or small office network are running operating systems other than these, verify that TCP/IP is installed on their computers.

**Cause:** If users on your home or small office network cannot reach the Internet, TCP/IP is incorrectly configured on their home or small office network computers.

**Solution:** Verify that the following TCP/IP settings are established on home or small office network local area connections:

- IP Address: Obtain an IP address automatically (through DHCP)
- DNS server: Obtain DNS server address automatically
- Default gateways: None specified

For computers running Windows 9*x* or Windows NT version 4.0, you can find the TCP/IP settings in Network in Control Panel.

**Cause:** The Internet Connection Sharing (ICS) service is not started.

**Solution:** Use Event Viewer to verify that the ICS service is started.

**See also:** Event Viewer.

**Cause:** The Internet Connection Sharing (ICS) host computer is not properly configured for name resolution.

**Solution:** You may need to configure the WINS or DNS name resolution services on the computer. If computers on the home or small office network cannot resolve names to IP addresses, you can check the name resolution configuration of the ICS host computer by using the **ipconfig** command. There are two ways that your ISP can configure name resolution:

- Statically assigned name servers

  You must manually configure the TCP/IP protocol with the IP address (or addresses) of the name servers provided by the ISP. If you have statically assigned name servers, you can use the **ipconfig** command at any time to get the IP addresses of your configured name servers.

- Dynamically assigned name servers

  Manual configuration is not required. The IP addresses of the name servers provided by the ISP are dynamically assigned whenever you dial the ISP. If you have dynamically assigned name servers, you must run the **ipconfig** command *after* a connection to the ISP has been made.

**Cause:** If you cannot play a game across the Internet, the protocol used by the application is not translatable.

**Solution:** Try running the application from the Internet Connection Sharing host computer. If the application works there but not at a workstation on the home or small office network, then the application may not be translatable.

**Cause:** If you cannot play a game across the Internet, the application is not configured on the Internet Connection Sharing host computer.

**Solution:** Verify that the application, including port numbers, is configured correctly.

**See also:** Manage service definitions for ICF or ICS.

**Cause:** If Internet users cannot see services on your home or small office network, such as a Web server, the service is not configured correctly.

**Solution:** Verify that the service, including port numbers and TCP/IP addresses, is configured correctly.

**Cause:** If users on your home or small office network cannot reach Internet sites by using friendly names, there is a DNS resolution problem.

**Solution:** Have users on your home or small office network use fully qualified domain names or IP addresses when accessing Internet resources.

**See Also:** Manage service definitions for ICF or ICS; Connecting to the Internet in a home or small office network; Configure TCP/IP to use WINS; Configure TCP/IP to use DNS; Test a TCP/IP configuration by using the ping command.

**Notes**

- Internet Connection Sharing and Network Bridge are not included in Windows Server 2003, Web Edition; Windows Server 2003, Datacenter Edition; and the Itanium-based versions of the original release of the Windows Server 2003 operating systems.

- Internet Connection Firewall is included only in the original releases of Windows Server 2003, Standard Edition, and Windows Server 2003, Enterprise Edition.

**When using a local area network connection, there is no response.**
**Cause:** There may be problems with your network adapter.

**Solution:** Try the following:

- Check the appearance of the local area connection icon. Depending on the status of the local area connection, the icon appears in different ways in the Network Connections folder. Also, if the local area connection media is disconnected (for example, the cable is unplugged), a status icon is displayed in the taskbar.

- Use Device Manager to verify that your network adapter is working correctly.

**See also:** Using local area connections

**Cause:** The LAN cable may not be plugged into the network adapter.

**Solution:** Check to make sure the LAN cable is inserted into the network adapter.

**When using a laptop to connect to an ISP, some or all of the applications do not run properly.**
**Cause:** The WinSock Proxy Client may be preventing your applications from running properly when you use the ISP connection.

**Solution:** If you are a mobile user and use your laptop in your corporate environment, you may need to disable the Microsoft WinSock Proxy Client (WSP Client in Control Panel) when you use the same computer to dial to an ISP or other network. For example, if you use a laptop in your office and use the same computer to connect to an ISP or other network from your home, you may have problems running all of your applications when you use the ISP connection. (For example, your applications may not be able to find the resources or servers they need.) If this is the case, you should disable the Microsoft WinSock Proxy Client (WSP Client in Control Panel) to run the applications that you typically run when you use your laptop in the corporate office.

**Incoming connection clients cannot see resources beyond the incoming connection computer.**
**Cause:** If the addresses that are being allocated to incoming clients are not a subset of the network to which the incoming connection computer is attached, you must create a route to the incoming client computers on the intranet computers.

**Solution:** Reconfigure your range of IP addresses that are being allocated to incoming clients so that it is a subset of the network to which the incoming connections computer is attached. If you cannot do this, then configure your intranet hosts with the IP address of the incoming connections computer as a default gateway.

- If your intranet hosts are configured to obtain an IP address automatically and a Dynamic Host Configuration Protocol (DHCP) server is present, you can configure your DHCP server to assign the default gateway.

- If your intranet hosts are configured to obtain an IP address automatically and a DHCP server is not present (you are using the Automatic Private IP Addressing feature), then you must manually configure all of your intranet hosts with an IP address, subnet mask, and default gateway.

**See Also:** To configure a default gateway, Incoming connections and IP addresses.

**Cause:** The calculated range of addresses allocated to connecting clients is larger than the range that you configured.

**Solution:** Most TCP/IP networks use subnets in order to effectively manage routed IP addresses. The closest matching subnet is calculated for the range that you specified in **From** and **To**. The range of addresses in the closest matching subnet may

exceed the range that you specified. Unless the addresses specified in **From** and **To** are subnet boundaries, the range based on the calculated subnet will be larger than the range that you specified. To avoid this, specify a range that falls on subnet boundaries. For example, if you are using the 10.0.0.0 private network ID for your intranet, a range that falls on subnet boundaries is 10.0.1.168 to 10.0.1.175. Or, if you are using the 192.168.0.0 private network ID for your intranet, a range that falls on subnet boundaries is 192.168.1.0 to 192.168.1.255.

**See Also:** Configure an incoming connection to use TCP/IP.

**The smart card reader does not work.**
**Cause:** The smart card reader is not installed.

**Solution:** Install the smart card reader and make sure that it is properly attached to the port.

**Cause:** The smart card reader is not installed properly.

**Solution:** Try the following:

- Make sure that the smart card reader appears in Device Manager.
- Ensure that you have the latest drivers installed for your smart card reader. To do so, right-click the smart card reader in Device Manager and click **Update driver**. If this does not work, check Windows Update to verify whether you are using the most recent drivers.
- If the drivers for your smart card reader are not loaded correctly or have become corrupted, you can reinstall them. To do this, right-click the smart card reader in Device Manager, and click **Uninstall**. Right-click any device and then click **Scan for hardware changes**.
- If the solutions given above do not work, uninstall the smart card reader drivers using Device Manager and then unplug the smart card reader from its port. Next, plug the smart card reader back into its appropriate port. Windows will automatically reinstall the drivers for the newly detected hardware.
- If Windows Update does not offer drivers for your smart card reader, contact the supplier for your smart card reader to verify whether you have the appropriate drivers.
- Try a different smart card reader.

**Notes**

- The above-mentioned causes can generate the following errors:
    - 0x80090022: Provider could not perform the action since the context was acquired as silent.
    - Error 0x80090019: The keyset is not defined.
    - Error 764: No smart card reader is installed.
    - An internal error has been detected, but the source is unknown.
    - Error 0x8010002e: Cannot find a smart card reader. For customized troubleshooting information for this connection, click Help.
- If you are using cryptographic service provider (CSP) software from a supplier other than Microsoft, the software might not be installed properly or might be corrupted. If this happens, you may see the following error messages:
    - 0x80090022: Provider could not perform the action since the context was acquired as silent.
    - Error 0x80090019: The keyset is not defined.
    - An internal error has been detected, but the source is unknown.

**Cause:** The smart card reader might be physically damaged.

**Solution:** Try the following:

- Check whether the smart card reader has an LED or a display that tells you whether the device is functioning properly. Verify using the manual supplied by your vendor.

- Try a different smart card reader.

**The smart card does not work.**
**Cause:** The smart card might be inserted incorrectly.

**Solution:** Try the following:

- The smart card might be inserted upside down in the smart card reader. Make sure you insert it with the correct side up.

- If this does not work, see the solutions for "The smart card reader does not work."

**Cause:** The smart card might be physically damaged.

**Solution:** Try the following:

- See the solutions for "The smart card reader does not work."

- If the smart card reader is working properly and the smart card is inserted correctly, then the smart card itself could be damaged. Try a different smart card.

- Contact your system administrator for additional support.

**When you try to establish a remote access connection using a smart card, you receive an error.**
**Cause:** Multiple users might be logged on to the same computer.

**Solution:** Try the following:

- Log off any additional users that are logged on at the same time using Fast User Switching.

- If more than one user is logged on with administrative credentials, the following error message appears: "Local Security Authority cannot be contacted." Log off additional users that have logged on with administrative credentials.

- If more than one user is logged on using local user credentials, the following error message appears: "Cannot find a smart card reader (Error 0x8010002e). For customized troubleshooting information for this connection, click Help." Log off additional users that have logged on using local user credentials.

# Error messages in Network Connections (Windows Server 2003)

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Error messages**

You may receive one or more of the following errors when you use Network Connections. To see more information about an error, click the error.

- 600 An operation is pending.
- 601 An invalid port handle was detected.
- 602 The specified port is already open.
- 603 The caller's buffer is too small.
- 604 Incorrect information was specified.
- 605 The port information cannot be set.
- 606 The specified port is not connected.
- 607 An invalid event was detected.
- 608 A device was specified that does not exist.
- 609 The device type does not exist.
- 610 The buffer is invalid.
- 611 The route is not available.
- 612 The route is not allocated.
- 613 Invalid compression specified.
- 614 Out of buffers.
- 615 The port was not found.
- 616 An asynchronous request is pending.
- 617 The port or device is already disconnecting.
- 618 The port is not open.
- 619 A connection to the remote computer could not be established, so the port used for this connection was closed.
- 620 There are no endpoints.
- 621 Cannot open the phone book file.
- 622 Cannot load the phone book file.

- 623 Cannot find the phone book entry.
- 624 Cannot write the phone book file.
- 625 Invalid information found in the phone book.
- 626 Cannot load a string.
- 627 Cannot find key.
- 628 The connection was terminated by the remote computer before it could be completed.
- 629 The data link was terminated by the remote machine.
- 630 The port was disconnected due to hardware failure.
- 631 The port was disconnected by the user.
- 632 The structure size is incorrect.
- 633 The port is already in use or is not configured for Remote Access dialout.
- 634 Cannot register your computer on the remote network.
- 635 Unknown error.
- 636 The wrong device is attached to the port.
- 637 The string could not be converted.
- 638 The request has timed out.
- 639 No asynchronous net available.
- 640 A NetBIOS error has occurred.
- 641 The server cannot allocate NetBIOS resources needed to support the client.
- 642 One of your NetBIOS names is already registered on the remote network.
- 643 A network adapter at the server failed.
- 644 You will not receive network message popups.
- 645 Internal authentication error.
- 646 The account is not permitted to log on at this time of day.
- 647 The account is disabled.
- 648 The password has expired.
- 649 The account does not have Remote Access permission.
- 650 The Remote Access server is not responding.

- 651 Your modem (or other device) has reported an error.
- 652 Unrecognized response from the device.
- 653 A macro required by the device was not found in the device .INF file section.
- 654 A command or response in the device .INF file section refers to an undefined macro.
- 655 The <message> macro was not found in the device .INF file section.
- 656 The <defaultoff> macro in the device .INF file section contains an undefined macro.
- 657 The device .INF file could not be opened.
- 658 The device name in the device .INF or media .INI file is too long.
- 659 The media .INI file refers to an unknown device name.
- 660 The device .INF file contains no responses for the command.
- 661 The device .INF file is missing a command.
- 662 Attempted to set a macro not listed in the device .INF file section.
- 663 The media .INI file refers to an unknown device type.
- 664 Cannot allocate memory.
- 665 The port is not configured for Remote Access.
- 666 Your modem (or other device) is not functioning.
- 667 Cannot read the media .INI file.
- 668 The connection dropped.
- 669 The usage parameter in the media .INI file is invalid.
- 670 Cannot read the section name from the media .INI file.
- 671 Cannot read the device type from the media .INI file.
- 672 Cannot read the device name from the media .INI file.
- 673 Cannot read the usage from the media .INI file.
- 674 Cannot read the maximum connection BPS rate from the media .INI file.
- 675 Cannot read the maximum carrier BPS rate from the media .INI file.
- 676 The line is busy.
- 677 A person answered instead of a modem.

- 678 The remote computer did not respond.
- 679 Cannot detect carrier.
- 680 There is no dial tone.
- 681 General error reported by device.
- 691 Access denied because user name and/or password is invalid on the domain.
- 692 Hardware failure in port or attached device.
- 695 The state machines are not started.
- 696 The state machines are already started.
- 697 The response looping did not complete.
- 699 The device response caused buffer overflow.
- 700 The expanded command in the device .INF file is too long.
- 701 The device moved to a BPS rate not supported by the COM driver.
- 703 The connection needs information from you, but the application does not allow user interaction.
- 704 The callback number is invalid.
- 705 The authorization state is invalid.
- 707 There was an error related to the X.25 protocol.
- 708 The account has expired.
- 709 Error changing password on domain.
- 710 Serial overrun errors were detected while communicating with your modem.
- 711 A configuration error on this computer is preventing this connection.
- 712 Biplex port is initializing. Wait a few seconds and redial.
- 713 No active ISDN lines are available.
- 714 Not enough ISDN channels are available to make the call.
- 715 Too many errors occurred because of poor phone line quality.
- 716 The Remote Access IP configuration is unusable.
- 717 No IP addresses are available in the static pool of Remote Access IP addresses.
- 718 The connection was terminated because the remote computer did not respond in a timely manner.
- 719 PPP was terminated by remote machine.

- 720 A connection to the remote computer could not be established. You might need to change the network settings for this connection.
- 721 The remote computer did not respond.
- 722 The PPP packet is invalid.
- 723 The phone number, including prefix and suffix, is too long.
- 726 The IPX protocol cannot be used for dial-out on more than one port at a time.
- 728 Cannot find an IP adapter bound to Remote Access.
- 729 SLIP cannot be used unless the IP protocol is installed.
- 731 The protocol is not configured.
- 732 The PPP negotiation is not converging.
- 733 A connection to the remote computer could not be completed.
- 734 The PPP link control protocol was terminated.
- 735 The requested address was rejected by the server.
- 736 The remote computer terminated the control protocol.
- 737 Loopback detected.
- 738 The server did not assign an address.
- 739 The remote server cannot use the encrypted password.
- 740 The TAPI devices configured for Remote Access failed to initialize or were not installed correctly.
- 741 The local computer does not support encryption.
- 742 The remote server does not support encryption.
- 743 The remote server requires encryption.
- 752 A syntax error was encountered while processing a script.
- 753 The connection could not be disconnected because it was created by the multi-protocol router.
- 754 The system could not find the multi-link bundle.
- 755 The system cannot perform automated dial because this entry has a custom dialer specified.
- 756 This connection is already being dialed.
- 757 Remote access services could not be started automatically. Additional information is provided in the event log.
- 758 Internet Connection Sharing is already enabled on the connection.

- 760 An error occurred while routing capabilities were being enabled.
- 761 An error occurred while Internet Connection Sharing was being enabled for the connection.
- 763 Internet Connection Sharing cannot be enabled. There are two or more LAN connections in addition to the connection to be shared.
- 764 No smart card reader is installed.
- 765 Internet Connection Sharing cannot be enabled. A LAN connection is already configured with the IP address required for automatic IP addressing.
- 766 A certificate could not be found. Connections that use the L2TP protocol over IPSec require the installation of a machine certificate, also known as a computer certificate.
- 767 Internet Connection Sharing (ICS) cannot be enabled. The LAN connection selected on the private network has more than one IP address configured. Reconfigure the LAN connection with a single IP address before enabling ICS.
- 768 The connection attempt failed because of failure to encrypt data.
- 769 The specified destination is not reachable.
- 770 The remote computer rejected the connection attempt.
- 771 The connection attempt failed because the network is busy.
- 772 The remote computer's network hardware is incompatible with the type of call requested.
- 773 The connection attempt failed because the destination number has changed.
- 774 The connection attempt failed because of a temporary failure. Try connecting again.
- 775 The call was blocked by the remote computer.
- 776 The call could not be connected because the destination has invoked the Do Not Disturb feature.
- 777 The connection attempt failed because the modem (or other connecting device) on the remote computer is out of order.
- 778 It was not possible to verify the identity of the server.
- 779 To dial out using this connection you must use a smart card.
- 780 An attempted function is not valid for this connection.
- 781 The encryption attempt failed because no valid certificate was found.
- 782 Network address translation (NAT) is currently installed as a routing protocol and must be removed before enabling Internet Connection Sharing.
- 783 Internet Connection Sharing (ICS) cannot be enabled. The LAN connection selected as the private network is either not present, or it is disconnected from the network. Please ensure that the LAN adapter is connected before enabling ICS.
- 784 You cannot dial using this connection at logon time, because it is configured to use a user name different than the one on the smart card. If you want to use it at logon time, you must configure it to use the user name on the smart card.

- 785 You cannot dial using this connection at logon time, because it is not configured to use a smart card. If you want to use it at logon time, you must edit the properties of this connection so that it uses a smart card.
- 786 The L2TP connection attempt failed because there is no valid machine certificate on your computer for security authentication.
- 787 The L2TP connection attempt failed because the security layer could not authenticate the remote computer.
- 788 The L2TP connection attempt failed because the security layer could not negotiate compatible parameters with the remote computer.
- 789 The L2TP connection attempt failed because the security layer encountered a processing error during initial negotiations with the remote computer.
- 790 The L2TP connection attempt failed because certificate validation on the remote computer failed.
- 791 The L2TP connection attempt failed because security policy for the connection was not found.
- 792 The L2TP connection attempt failed because security negotiation timed out.
- 793 The L2TP connection attempt failed because an error occurred while negotiating security.
- 794 The Framed Protocol RADIUS attribute for this user is not PPP.
- 795 The Tunnel Type RADIUS attribute for this user is not correct.
- 796 The Service Type RADIUS attribute for this user is neither Framed nor Callback Framed.
- 797 A connection to the remote computer could not be established because the modem was not found or was busy.
- 798 A certificate could not be found that can be used with this Extensible Authentication Protocol.
- 799 Internet Connection Sharing (ICS) cannot be enabled due to an IP address conflict on the network. ICS requires that the host be configured to use 192.168.0.1. Ensure that no other client on the network is configured to use 192.168.0.1.
- 800 Unable to establish the VPN connection. The VPN server may be unreachable, or security parameters may not be configured properly for this connection.
- 801 This connection is configured to validate the identity of the access server, but Windows cannot verify the digital certificate sent by the server.
- 802 The card supplied was not recognized. Please check that the card is inserted correctly, and fits tightly.

**600**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**601**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**602**
The COM port that the network connection attempted to use is already in use by another active network connection or another process (for example, a phone line monitoring program, such as a fax program). Close the application that is blocking the use of the COM port.

**603**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**604**
The remote access phonebook file and the current Network Connections configuration are probably inconsistent. If you changed your communications equipment (such as your serial port or modem), make sure you reconfigure Network Connections. See Configure a connection to a remote network.

**605**
The remote access phonebook file and the current Network Connections configuration are probably inconsistent. If you changed your communications equipment (such as your serial port or modem), make sure you reconfigure Network Connections. See Configure a connection to a remote network.

If the error persists, delete and re-create the connection in Network Connections.

**606**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**607**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**608**
The remote access phonebook file and the current Network Connections configuration are probably inconsistent. If you changed your communications equipment (such as your serial port or modem), make sure you reconfigure Network Connections. See Configure a connection to a remote network.

If the error persists, delete and re-create the connection in Network Connections.

**609**
The remote access phonebook file and the current Network Connections configuration are probably inconsistent. If you changed your communications equipment (such as your serial port or modem), make sure you reconfigure Network

Connections. See Configure a connection to a remote network.

If the error persists, delete and re-create the connection in Network Connections.

**610**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**611**
Your network configuration is probably incorrect. Restart your computer to make sure that all recent configuration changes have taken effect. If the error persists, check Event Viewer for detailed warnings or errors.

**612**
Your network configuration is probably incorrect. Restart your computer to make sure that all recent configuration changes have taken effect. This error may also occur if your computer is running low on resources. If the error persists, check Event Viewer for detailed warnings or errors.

**613**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**614**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

If the error persists, check Event Viewer for detailed warnings or errors.

**615**
The remote access phonebook file and the current Network Connections configuration are probably inconsistent. If you changed your communications equipment (such as your serial port or modem), make sure you reconfigure Network Connections. See Configure a connection to a remote network.

If the error persists, delete and re-create the connection in Network Connections.

**616**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**617**
Wait for Network Connections to finish disconnecting.

**618**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**619**
There are several possible reasons why a connection to the remote computer could not be established:

- The remote computer might have been too busy. Wait a few minutes and try the connection again.
- If you are trying to establish a dial-up connection, you might have tried to redial before the modem fully disconnected. Wait a short time and try your call again.
- If you are trying to establish a connection by using a modem, the modem might not be functioning properly. For more information, see Troubleshooting modems.
- If you are using a device such as a router, a hub, or a network adapter for network address translation (NAT), the device might not be functioning properly. If the device provides firewall capabilities, the device might be blocking the connection. Consult the documentation for the device.

**620**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

If the error persists, check Event Viewer for detailed warnings or errors.

**621**
Network Connections uses the Rasphone.pbk file located in the systemroot\System32\Ras folder. Make sure the file is in this folder, and then restart Network Connections.

**622**
Network Connections uses the Rasphone.pbk file located in the systemroot\System32\Ras folder. Make sure the file is in this folder, and then restart Network Connections.

**623**
Network Connections located the phone book but cannot find the specified connection entry. This error should not occur unless another application is using the Network Connections phone book and has specified an incorrect connection entry.

**624**
Network Connections uses the Rasphone.pbk file located in the systemroot\System32\Ras folder. Make sure your disk is not full and that you have permission to change this file.

**625**
The phonebook file, Rasphone.pbk, may be corrupt. Delete this file from the systemroot\System32\Ras folder, and then restart Network Connections to create a new one.

**626**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.

- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

If the error persists, check Event Viewer for detailed warnings or errors.

**627**
One of the Network Connections configuration files probably contains invalid information. If you are using a modem that is not supported, install a supported modem.

**628**
The connection could not be completed because the connection attempt was terminated by the remote computer. Try the following:

- If you are trying to establish a dial-up connection, make sure that the phone number you are dialing is correct. Try dialing this phone number from your telephone. For more information, see Configure a connection to a remote network.

- If you are trying to establish a connection by using a modem, you might need to change the modem settings. For more information, see Troubleshooting modems.

- If you are trying to establish a connection to a virtual private network (VPN), you might need to change the security settings for this type of connection. For more information, see VPN connection authentication and data encryption, or contact the system administrator for the VPN to which you are trying to connect.

**629**
The connection link disconnected for one of the following reasons:

- An unrecoverable phone line error.

- A noisy line.

- Disconnection by the system administrator.

- Failure to negotiate correctly with the modem on the remote computer at the selected speed.

To reestablish the connection, click **Redial**. You can also enable automatic redialing on the **Options** tab for the connection. If this error persists, reduce the modem speed for the connection to 9600 bps, and then try to redial. See Change the maximum modem port speed.

You can try to connect to another computer to determine if the problem is related to the particular computer you are calling. Also, you can try connecting to the original computer from another phone line.

If the problem persists, contact the system administrator of the remote computer.

**630**
The link disconnected for one of the following reasons:

- An unrecoverable error occurred in your modem (or other communication device).

- An unrecoverable error occurred on your communications port.

- Your modem cable is unplugged.

To diagnose and correct the problem, do the following:

- Make sure your modem is on and your cable is securely attached.

- Make sure your modem is functioning properly. For instructions on testing your modem, see Test a modem.

**631**
An action on your computer disconnected the line. Redial.

**632**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

If the error persists, check Event Viewer for detailed warnings or errors.

**633**
If this is a dial-up connection, the COM port that the network connection attempted to use is already in use by another active network connection or another process (for example, a phone line monitoring program, such as a fax program). Close the application that is blocking the use of the COM port. For more information about troubleshooting modem problems, see Troubleshooting modems.

If this is a virtual private network (VPN) connection, the VPN device that the network connection attempted to use cannot be opened. If the problem persists, contact your system administrator.

If this is a broadband connection, the broadband device that the network connection attempted to use cannot be opened. Make sure that the required hardware, such as a cable modem, is functioning properly. For more information about required hardware, contact your broadband service provider.

**634**
The remote access server cannot register the name of your computer on the network. This generally occurs with the NetBIOS protocol, but it may also occur with TCP/IP or IPX protocols. Typically, the error occurs when an address is already in use on the network. Contact your system administrator.

**635**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click Start, and then click Help and Support.

If the error persists, check Event Viewer for detailed warnings or errors.

**636**
Your hardware configuration and the configuration settings for your connection are probably inconsistent with each other. If you changed your communications equipment (such as a serial port or modem), make sure you reconfigure the connection. See To configure a connection to a remote network.

**637**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**638**
An internal error occurred.

- Check the networking configurations for your computer.

- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**639**
Your NetBIOS network configuration is probably incorrect. Restart your computer to make sure that all recent configuration changes have taken effect. If the error persists, check Event Viewer for detailed warnings or errors.

If you call for help, record the Fail Code (a NetBIOS error code) and give it to the technical support staff.

**640**
The modem cannot negotiate a connection at the speed that is set. Set the modem to a lower initial speed, and then redial. See Change the maximum modem port speed. Also, try disabling modem compression and software compression. See Configure a modem for a dial-up connection or Disable software compression.

If you still cannot make a connection, try adding the **NWLink IPX/SPX/NetBIOS Compatible Transport Protocol** to the connection. See Add a network component.

**641**
Ask your system administrator to increase the resource capacity of the remote access server, or use **Services** in **Computer Management** to stop nonessential services on your computer, such as messenger services and Network DDE.

**642**
Another computer with the same computer name is already logged on to the remote network. Each computer on the network must be registered with a unique name. Verify the following:

- A computer with the same computer name as yours is not located on the network you are attempting to connect to.
- Your computer is not already physically attached to the network that you are attempting to connect to.

**643**
Report this error to your system administrator.

**644**
Another computer that is already connected to the network is using your messaging name. Messages addressed to you are sent to that computer. If you want to receive messages at your remote workstation, you must log off your office computer before you dial in to the network the next time.

This error does not affect messaging through Microsoft Outlook, Microsoft Outlook Express, or Microsoft Exchange.

**645**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**646**
Your account is configured for limited access to the network. If you need to access the network at a different time of day than what is presently configured, ask your system administrator to change the configuration.

**647**
The user account is disabled. This may be due to repeated failed logon attempts or because the system administrator disabled the account for security reasons. Ask your system administrator to enable your account in **Local Users and Groups**.

**648**
If you connect through Network Connections, you are automatically prompted to change your password. If you connect by using the **rasdial** command, you can change your password by doing the following:

- Press CTRL+ALT+DEL.

- Click **Change Password**, and then follow the instructions on the screen.

If you belong to an administrators group and your password expires, another administrator must change your password. You cannot change the password yourself.

**649**
The account does not have permission to connect for one of the following reasons:

- You have a valid account on the domain you selected, but your account does not have permission to access the network remotely. Ask your system administrator to enable dial-up permission for your user account or to enable dial-up permission in Routing and Remote Access.

- Your account has expired, been disabled, or is locked out, or your dial-up access has been locked out.

- You are either attempting to connect outside of allowable server logon hours or attempting to connect outside of the times allowed for dial-up access, or the policy that applies to your account may not allow dial-up access.

- A caller ID rule may prevent you from connecting. For example, your account may be required to dial in from a specific number.

- The remote computer may allow only local accounts to connect.

- An authentication protocol may be required that your computer cannot negotiate, or your computer may be attempting to use a protocol that is not authorized by the policy on the remote computer.

If you have an account with dial-in permission on another domain, do the following to use your account on that domain:

1. Right-click the connection, and then click **Properties**.

2. On the **Options** tab, select the **Prompt for name and password, certificate, etc.** and **Include Windows logon domain** check boxes.

3. On the **Security** tab, clear the **Automatically use my Windows logon name and password (and domain if any)** check box, and then click **OK**.

4. Double-click the connection, and then click **Dial**.

5. Specify the appropriate user name, password, and domain.

**650**
One of the following may have caused this error:

- The remote access server is not running. Contact your system administrator to make sure the server is running.

- The line may be too noisy, or your modem may have failed to negotiate correctly with the modem of the remote access server at the selected speed. For either of these possibilities, lower the initial speed (bps) of the modem, and then redial. See Change the maximum modem port speed.

- The serial cable of your modem may need replacing.

- The authentication settings for the connection may be incorrect. Contact your system administrator to make sure that your authentication settings meet those required by the remote access server.

- The software compression and modem hardware compression for the remote access server may be enabled at the same time. Generally, the remote access server software compression is enabled and hardware compression is disabled.

**651**
Your modem (or other device) reported an error.

If this is a dial-up connection and you are using a supported external modem, turn off and then restart the modem. Close and restart Network Connections, and then redial. If your modem is not supported by Network Connections, switch to a supported modem. Make sure you correctly configured your modem for remote access. To check your configuration, see Configure a connection to a remote network.

If this is a virtual private network (VPN) connection, you may have specified an incorrect TCP/IP address in the connection configuration, or the server that you are trying to reach may not be available. To determine if the server is available, contact your system administrator.

**652**
Your modem (or other device) returned a message that is not listed in one or more of your script files (Pad.inf, Switch.inf, or FileName.scp).

If you are using a supported external modem, turn off and restart the modem, and then redial.

If the problem persists, try connecting at a lower initial speed. See Change the maximum modem port speed.

**653**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**654**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**655**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**656**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**657**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**658**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**659**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**660**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**661**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**662**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**663**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**664**
The system is out of memory. Close some programs, and then redial.

**665**
If the device is already being used for another connection, hang up that connection.

Modify the connection to use another device. See Configure a connection to a remote network.

**666**
Your modem (or other device) is not responding for one of the following reasons:

- The external modem is turned off.
- The modem is not securely connected to your computer. Make sure the cable is securely fastened to both the modem and the computer.
- The serial cable does not meet the specifications required by Network Connections.
- The modem has experienced a hardware problem. Turn off the modem, wait for 20 seconds, and then restart the modem.

**667**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**668**
Redial the connection. If you continue to receive this message, reduce the initial speed of the modem and turn off advanced modem features, such as software compression. See Change the maximum modem port speed or Disable software compression.

Also, you should confirm that the modem is compatible.

If you are dialing manually, make sure you are connected before you click **Done**. You are dialing manually if you selected **Operator-Assisted Dialing** on the **Advanced** menu in the Network Connections folder.

**669**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**670**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**671**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**672**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**673**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**674**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**675**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**676**
Redial the number. You can automate redialing on the **Options** tab in the properties of the connection. See Configuring redial options. If this is a virtual private network (VPN) connection, check the host name or IP address of your destination server, and try to connect again. Also, contact your system administrator to verify that the remote server is running.

**677**
A modem or other device did not pick up the phone. Check the number and dial again. If this is a virtual private network (VPN) connection, check the host name or IP address of your destination server, and try to connect again.

**678**
The connection could not be completed because the remote computer did not answer the connection request. Try the following:

- If you are trying to establish a dial-up connection, make sure that the phone number you are dialing is correct. Try dialing this phone number from your telephone. For more information, see Configure a connection to a remote network.
- If you are trying to establish a connection by using a modem, make sure the modem is functioning properly. For more information, see Troubleshooting modems.
- If you are trying to establish a connection to a virtual private network (VPN), make sure that the host name or the IP address of your destination server is correct, and try again to establish the connection. To view the properties of a connection, right-click the connection, click **Properties**, and review the information on the **General** tab. For more information, contact the system administrator for the VPN to which you are trying to connect.
- If you are trying to establish a connection to a VPN, network congestion or a network device (such as a firewall) might be blocking your attempt to make a connection. For more information, contact the system administrator for the VPN to which you are trying to connect.
- If you are trying to establish a broadband connection, make sure the service name is correct and try again to establish the connection. To view the properties of a connection, right-click the connection, click **Properties**, and review the information on the **General** tab. For more information, contact your broadband service provider.
- If you are trying to establish a broadband connection, make sure that the necessary hardware (such as a cable modem) is installed and functioning properly. For more information, contact your broadband service provider.

**679**
A modem or other device did not pick up the phone. Many modems return this error if the remote modem does not pick up the phone. Check the number and dial again. If this is a virtual private network (VPN) connection, check the host name or IP address of your destination server, and try to connect again. You can automate redialing on the **Options** tab in the properties of the connection. See Configuring redial options.

**680**
A phone line may be incorrectly connected to your modem or disconnected from your modem. The number may require a prefix, such as 9, to access external lines, or the number may be too long.

Make sure that the phone line is plugged into the correct socket in the modem. Also, make sure you added any special access numbers, such as the prefix 9 followed by a comma, to connect to an outside line (for example: 9,555-0100). For more information, see Configure phone number modifiers.

Check that there is no stutter tone, which indicates voicemail messages, on your phone line.

Many modems cannot dial more than 34 digits. When longer numbers are encountered, these modems split them into two or more parts, of which only the first part is dialed. This occurs with USRobotics and Multitech modems. The only known solution for this problem is to use another brand of modem.

For more information, see Technical support options.

**681**
One of the Network Connections configuration files probably contains information that is not valid.

If your modem is not supported by Network Connections, switch to a supported modem.

**691**
Either your user account is not registered with the domain listed, your password is expired, or you mistyped the information. If you do not specify a domain, the remote access server attempts to verify your user name and password on the domain of which it is a member.

Carefully retype your user name, password, and domain. If you are unsure of this information, contact your system administrator.

**692**
Your modem (or other device) is not responding because of the following:

- The modem is turned off, malfunctioning, or is not securely connected to your computer.

To resolve this problem, do the following:

- Reset your modem. For more information, consult your modem documentation.
- If you are using an external modem, ensure that you are using a proper serial cable and that it is connected securely. You may want to try replacing the modem cable. Also, if you are using an adapter to connect your external modem to your serial port, ensure that the adapter is wired properly for modem communication. For example, a 9-to-25 pin adapter for a mouse does not work properly with a serial network connection.
- Test the serial port or multiport adapter, and replace it if necessary.
- Ensure that the handshaking options for the modem are configured properly. Consult your modem documentation for information about different handshaking options available for your modem.
- If your modem is not supported by Network Connections, switch to a supported modem.
- Verify that another application, such as HyperTerminal, is not using the communications port. If the port is being used, subsequently starting Network Connections may cause this message to appear.
- For more information, see Technical support options.

**695**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**696**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**697**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**699**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**700**
Commands in script files cannot exceed 256 characters. Break up the command into multiple commands. See Automating the Dial-up Logon Process by Using Switch.inf Scripts.

**701**
Your modem tried to connect at a speed that the serial port cannot interpret. Reset your initial speed to the next lowest standard bps rate. See Change the maximum modem port speed.

**703**
The server you are attempting to connect to requires user interaction. The rasdial command, or the application you are using that is attempting to dial, does not support user interaction.

If possible, try to connect by using an existing connection in the Network Connections folder.

If you are using scripting to connect, try using a dial-up connection that is configured with the Terminal feature. The Terminal window may enable the user interaction that is required. See Use the Terminal feature to log on to a remote computer.

**704**
The callback number that you specified for the client is not valid. Check to make sure the callback number has been typed correctly, including area code.

**705**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**707**
The X.25 connection returned an error. Ask your X.25 provider to interpret the diagnostic information that is provided.

**708**
Ask your system administrator to reactivate your account.

**709**
Try changing your password again. If you continue to receive this message, report it to your system administrator.

**710**
Lower the modem's initial speed (bits per second), and then redial. See Change the maximum modem port speed.

**711**
A connection could not be established because a required service was not started on your computer. Make sure the following services are started on your computer and try again to establish the connection:

- Plug and Play

- Remote Access Auto Connection Manager

For information about how to start a service, see Start, stop, pause, resume, or restart a service.

**712**
This error can occur on a connection that is configured to receive calls (biplex connection). It happens when you dial out at the same time the server is initializing the connection for receiving calls. Network Connections redials in a few seconds.

**713**
Make sure that your ISDN line is plugged in correctly and that the terminating resistors are installed correctly (see the documentation for your ISDN card), and then redial. If you still receive this error, contact customer service for the ISDN card vendor or your ISDN telephone company.

**714**
All of the available ISDN channels are busy. Typically, ISDN provided in the BRI (Basic Rate Interface) level of service offers two channels on which voice or data calls can be made. If both channels are in use, Network Connections is not able to dial out. Hang up one channel and then redial.

**715**
Too many asynchronous errors occurred on your phone line during authentication. Try again. If the problem persists, lower your baud rate and disable any modem features that are set. See Change the maximum modem port speed and Configure an installed modem.

**716**
There is a problem with the TCP/IP configuration on the remote access server. For example, your connection is requesting a TCP/IP address from the server that is not usable.

Contact your system administrator to verify the TCP/IP settings on your server.

**717**
Try to use an IP address that does not cause a conflict on the remote network. If possible, use DHCP to avoid addressing conflicts. See Configure TCP/IP settings.

**718**
A Point to Point Protocol (PPP) connection was initiated but could not be completed because the remote computer did not respond in a timely manner or it did not give a valid response. This can occur for any of several reasons:

- If you are trying to establish a connection to a virtual private network (VPN), try entering your domain name and your user name in **User name** as follows: DOMAIN\username, and try again to establish the connection.

- If you are trying to establish a connection to a remote network, network congestion or a network device (such as a firewall) might be blocking your attempt to make a connection. Try your connection later, or contact the administrator of the remote network for more information.

- You might need to install updated drivers for your modem, your network card, or another connection device. For more information, contact your hardware manufacturer.

**719**
A PPP conversation started, but it was terminated at the request of the remote computer. An error probably occurred on the server.

**720**
A connection could not be established because the Point to Point Protocol (PPP) settings on your computer and on the remote computer do not match. Try the following:

- Make sure that TCP/IP is installed and enabled for this type of connection. For more information, see Enable a network component.

- Make sure that all protocols needed to establish this type of connection are installed. For more information, see PPP operation and protocols.

- Contact the administrator of the remote computer for more information about establishing this type of connection.

**721**
The connection could not be established because the remote computer did not respond to the connection request. Try the following:

- Make sure that your modem is functioning properly. For more information, see Troubleshooting modems.
- Make sure that TCP/IP is installed and configured correctly for this connection. For more information, see Connect to the Internet by using PPPoE.
- This connection might require a Terminal window. For more information on enabling a Terminal window, see Use the Terminal feature to log on to a remote computer.
- If you are trying to establish a virtual private network (VPN) connection, make sure that the host name or the IP address of your destination server is correct and try the connection again. To check this information, right-click the connection, click **Properties**, and review the information on the **General** tab.

**722**
A PPP packet was received that was not in a valid format. Your system administrator may need to log PPP events to a file to solve the problem. For more information, see Support resources.

**723**
The maximum length of the phone number, including prefix and suffix, is 128 characters.

**726**
Only one connection can be used to dial out by using the IPX protocol.

**728**
There is a problem with the TCP/IP configuration. Restart your computer to ensure that all recent configuration changes have taken effect.

**729**
Verify that TCP/IP is installed. For more information, see Add a network component.

**731**
Specific information was requested on a PPP control protocol that is not configured. To identify the PPP negotiation problem, ask your system administrator to enable PPP logging by using the Netsh.exe utility.

**732**
PPP parameter negotiation did not succeed because the local and remote computers did not agree on a common set of parameters. Contact your system administrator to verify the configuration of network protocols such as TCP/IP or IPX. Also, your system administrator can enable PPP logging by using the Netsh.exe utility, which may help identify the PPP negotiation problem.

**733**
The connection could not be completed because your computer and the remote computer could not negotiate PPP control protocols. Try the following:

- Make sure that all network components necessary for the connection are installed and configured for the connection type. For more information, see Add a network component and Configure a connection to a remote network.
- Enable or disable multi-link negotiation for the connection. To configure multi-link, open the **Network Connections** folder, right-click the icon for the connection, click **Properties**, click the **Networking** tab, and click **Settings**.

**734**
The PPP link control protocol was terminated. There are several possible causes. Try the following:

- Your Internet service provider might have experienced a problem. Contact your Internet service provider.
- The security protocols on the server to which you are trying to connect are incompatible with your security settings. In **Network Connections**, right-click the connection you are using. Click **Properties**, and click the **Security** tab. In **Validate my identity as follows**, select **Allow unsecured password**.

- LCP extensions are not supported. In **Network Connections**, right-click the connection you are using. Click **Properties**, and click the **Networking** tab. Click **Settings**, and clear the **Enable LCP extension** check box.

**735**
Your connection is configured to request a specific IP address. Either the server is not configured to permit clients that request specific IP addresses, or the specific IP address may already be in use by another client. If possible, use DHCP to avoid addressing conflicts. See Configure TCP/IP settings.

**736**
A PPP network control protocol conversation started, but it was terminated at the request of the remote computer. An error probably occurred on the server. See your system administrator. Also, your system administrator can enable PPP logging by using the Netsh.exe utility, which may help to identify the PPP negotiation problem.

**737**
The local and remote computers that are involved in the PPP conversation are the same computer. This usually means that a device (for example, a modem) on the link is echoing characters back. Try resetting these devices.

For other servers from other vendors, it may indicate that the remote computer is attempting a teletypewriter (TTY) logon before connecting. You can configure the connection for a post-connect terminal on the **Security** tab.

**738**
The server cannot assign an IP address to your computer from the pool of allocated addresses. Ask your system administrator to configure the connection to use a specific IP address on the client that does not cause a conflict on the remote network. Or, if possible, use DHCP to avoid addressing conflicts. See Configure TCP/IP settings.

**739**
This error occurs only when making a PPP connection to a server that is not running Windows. The standard PPP authentication protocols, used for interoperating with other servers, require that the password is available in plaintext form. Servers that are running Windows store only the encrypted form for security.

**740**
The TAPI devices configured for Network Connections failed to initialize or are not installed correctly. Restart your computer to make sure that all recent configuration changes have taken effect. If the error persists, check Event Viewer for detailed warnings or errors.

**741**
This error may be resolved by either selecting or clearing the **Require data encryption (disconnect if none)** check box located on the **Security** tab. Check with your system administrator regarding client-side security settings.

This error may also occur if your password is longer than 14 characters, you selected the **Require data encryption (disconnect if none)** check box on the **Security** tab, and you selected the **Require secured password** check box in **Validate my identity as follows**. Use a password less than 14 characters, clear the Require data encryption (disconnect if none) check box, and clear the **Allow unsecured password** check box in **Validate my identity as follows**.

See Configure a connection to a remote network and VPN connection authentication and data encryption.

**742**
The required level of encryption is not available on the remote computer. One computer is probably using 128-bit encryption technology while the other is using 40-bit or 56-bit encryption. Contact your system administrator to determine your level of encryption and to verify that the server is using the same level of encryption. For more information, see Data encryption.

**743**
The remote access server requires encryption, but your connection is not enabled for encryption. See Configure identity authentication and data encryption settings.

**751**
An invalid callback number has been specified. Only the characters 0 to 9, T, P, W, (, ), -, @, and space are allowed in the number. Enter the correct number and redial.

**752**
A syntax error was encountered while processing a script. See Automating the Dial-up Logon Process by Using Switch.inf Scripts and Troubleshooting logon scripts.

**753**
This connection is being used by Routing and Remote Access. Use the Routing and Remote Access service to terminate the connection. The connection appears in either the list of routing interfaces or the list of remote access clients.

**754**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.

For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

**755**
Contact your system administrator.

**756**
Wait and try again later.

**757**
An internal error occurred.

- Check the networking configurations for your computer.
- Make sure all devices are functional.
- For more information about diagnosing a problem, click **Start**, and then click **Help and Support**.

If the error persists, check the Event Viewer for detailed warnings or errors.

**758**
This error may occur if an application enables Internet Connection Sharing while the properties of the connection are open, and then you try to enable the feature. Close and then reopen the properties of the connection. The **Enable Internet Connection Sharing** check box on the **Advanced** tab should be selected.

**760**
An internal error occurred while attempting to enable routing. Contact your system administrator.

**761**
An internal error occurred while Internet Connection Sharing was being enabled. Contact your system administrator.

**763**
Close and reopen the properties of the connection. The **Enable Internet Connection Sharing** check box on the **Advanced** tab should be selected. Select a LAN connection from the list.

**764**
Install a smart card reader.

**765**
Internet Connection Sharing configures the LAN connection of the home network or small office network with a static address. Another network adapter in the system is configured with the same address. Change the static address of the network adapter before enabling Internet Connection Sharing.

**766**
Contact your system administrator. If you are a member of an Active Directory domain and need to request a certificate, see Request a certificate. If you are not a member of an Active Directory domain or you need to request a certificate from the Internet, see Submit a user certificate request via the Web.

**767**
Remove the additional static IP addresses, or reconfigure the LAN connection for DHCP. See Configure TCP/IP settings.

**768**
If encryption is not necessary, disable encryption and try again. See Configure identity authentication and data encryption settings.

**769**
Either you specified a destination address that is not valid, or your remote access server is down. Check the destination address and try again.

**770**
The remote computer may be rejecting your connection because of a caller ID rule or another hardware setting.

**771**
Wait and try again later.

**772**
Contact your system administrator.

**773**
Enter the correct number and try again.

**774**
Wait and try again later. This error may indicate a timing issue or a problem with the remote computer.

**775**
The remote computer may be blocking your connection because of a caller ID rule, a scheduling policy that allows access only during specific times, or another setting.

**776**
Contact your system administrator.

**777**
Contact your system administrator.

**778**
In the authentication process, the server identifies itself to your computer, and your computer identifies itself to the server. When this error occurs, your computer is not recognizing the server.

**779**
Install a smart card reader. See Install a smart card reader on a computer.

**780**
An internal error occurred. Contact your system administrator. You may need to configure the connection for EAP.

**781**
This L2TP/IPSec connection requires a valid certificate to be installed on your computer, and no such certificate was found. Try the following:

- If you are a member of an Active Directory domain, request a certificate from the appropriate certification authority. For more information, see Request a certificate.
- If you want to request a certificate from the Internet, see Submit a user certificate request via the Web.
- If you want more information about certificates, see Smart card and other certificate authentication.
- If this connection requires a preshared key, contact your network administrator.

**782**
Remove the Network Address Translation (NAT) routing protocol. See Delete an IP routing protocol.

**783**
Before you enable Internet Connection Sharing, verify that the LAN adapter and its associated cabling are securely connected.

**784**
Configure the connection to use the same name as the smart card. Open the properties of the connection. On the **Security** tab, click **Advanced (custom settings)** and **Settings**. Click **Smart Card or other Certificate (encryption enabled)**, click **Properties**, and then clear the **Use a different user name for the connection** check box.

**785**
Configure the connection to use a smart card. See Enable smart card or other certificate authentication.

**786**
Contact the administrator of the remote network. Your connection may be failing for one or more of the following reasons:

- Your computer's certificate is invalid, is expired, or lacks the preshared key that it needs.

- None of your computer's certificates are trusted by the server.
- Your computer is using a preshared key that is not valid. Try using another pre-shared key.

If you are a member of an Active Directory domain and need to request a certificate, see Request a certificate. If you are not a member of an Active Directory domain or you need to request a certificate from the Internet, see Submit a user certificate request via the Web. For more information about remote access security, see How security works at connection.

**787**
Contact your system administrator. Your connection may be failing for one or more of the following reasons:

- Your user name and password credentials are incorrect.
- The certificate your computer is using expired.
- The certificate the server is using expired.

If you are a member of an Active Directory domain and need to request a certificate, see Request a certificate. If you are not a member of an Active Directory domain or you need to request a certificate from the Internet, see Submit a user certificate request via the Web.

**788**
Contact your system administrator. The current configuration of L2TP parameters is not compatible with the Microsoft implementation of L2TP.

**789**
Contact your system administrator.

**790**
Contact your system administrator. Your connection may be failing for one or more of the following reasons:

- The server you are reaching does not have a certificate.
- The server you are reaching does not have the correct certificate.
- Your connection is not configured to use the correct certificate.

If you are a member of an Active Directory domain and need to request a certificate, see Request a certificate. If you are not a member of an Active Directory domain or you need to request a certificate from the Internet, see Submit a user certificate request via the Web. For more information about remote access security, see How security works at connection.

**791**
Contact your system administrator. Your connection may be failing for one or more of the following reasons:

- The remote server may be offline.
- The server you are reaching does not have the correct credentials.
- Your connection is not configured with the correct credentials.

**792**
Check your connection for connectivity to the Internet. If the connection is working, contact your system administrator. Your connection may be failing for one or more of the following reasons:

- The remote server may be offline.
- The server you are reaching does not have the correct credentials.
- Your connection is not configured with the correct credentials.

- Your connection is configured to use a different security method than the remote computer. Try changing the type of VPN connection. To change the type of VPN connection, right-click the connection, click **Properties**, and review the information on the **Networking** tab.

**793**
Contact your system administrator. Your connection may be failing for one or more of the following reasons:

- The remote server may be offline.
- The server you are reaching does not have the correct credentials.
- Your connection is not configured with the correct credentials.
- Your computer is using a preshared key that is not valid. Try using another pre-shared key.

For more information about remote access security, see How security works at connection.

**794**
An attribute on the remote network must be configured to allow this connection. Contact the system administrator of the remote network.

**795**
An attribute on the remote network must be configured to allow this connection. Contact the system administrator of the remote network.

**796**
An attribute on the remote network must be configured to allow this connection. Contact the system administrator of the remote network.

**797**
This connection requires a modem. Try the following:

- Close all other programs and try again to establish the connection. Another program might be using the modem or the communication port to which the modem is attached.
- Make sure that a modem has been installed on your computer. For more information, see Install a modem.
- Make sure that the modem is functioning correctly. For more information, see Troubleshooting modems.

**798**
Contact your system administrator. If you are a member of an Active Directory domain and need to request a certificate, see To request a certificate. If you are not a member of an Active Directory domain or you need to request a certificate from the Internet, see Submit a user certificate request via the Web.

**799**
Check the IP address settings on all computers connected to the local network, and reconfigure them if necessary. See Configure TCP/IP settings.

**800**
The connection to the VPN server could not be established using either PPTP or L2TP. One or more of the following circumstances might have caused this error:

- The PPTP server is not reachable. The server name you supplied might not exist, or a network component (such as a firewall) might be blocking PPTP traffic.
- Verify whether the PPTP server name for this connection is correct. To check your configuration, see Configure a connection to a remote network.
- Check whether Internet Connection Firewall has been enabled for this connection. For more information, see Set up and

Manage Internet Connection Firewall (ICF).

- Contact your system administrator for additional support.

The L2TP/IPSec server is not reachable. The server name you supplied might not exist. Your connection configuration might prevent IPSec from establishing a secure channel with the server. A network component such as Network Address Translation (NAT) or a firewall might be blocking IPSec traffic.

- Verify whether the L2TP server name is correct and that the connection you are trying to use has been configured correctly for your computer. To check your configuration, see Configure a connection to a remote network.
- Verify whether you have a current machine certificate or that the preshared key is correct. For more information, see Enable smart card or other certificate authentication.
- Check whether Internet Connection Firewall has been enabled for this connection. For more information, see Set up and Manage Internet Connection Firewall (ICF).
- Contact your system administrator for additional support.

**801**
However, the digital certificate the server sent cannot be verified. One or more of the following circumstances might have caused this error.

- The root of the certificate chain that sent by the server is not available for the local system to verify.
- You have specified the server and the trusted root certification authority for your local system. The client computer cannot find or authenticate the root certification authority, which is probably missing and thus generating an error.
- If the server is not part of a domain, it might not have a root certification authority.

To resolve this problem:

- Ensure that you obtain the root certificate and distribute it to any user and computer that needs to establish trust in the root authority.
- Using Group Policy, verify whether the policy settings for your trusted root certification authority are appropriate. For more information, see Policies to establish trust of root certification authorities.
- Contact your system administrator for additional support.

**802**
The smart card that you are using could not be recognized. One or more of the following circumstances might have caused this error.

- The smart card is not inserted properly. For example, it might be inserted upside down.
- The smart card reader is not installed properly.
- If you are using cryptographic service provider (CSP) software, it might be corrupted or not installed properly.

To resolve this problem:

- Insert the smart card properly so that it fits tightly in the smart card reader.
- Insert that the smart card with the correct side up. See instructions on the smart card reader to ensure that the smart card is inserted with the correct side facing up.

- Verify that the smart card reader is installed properly. For more information, see Install a smart card reader on a computer.
- Ensure that you are using the correct CSP and that it is installed properly. For more information, see Set up a smart card for user logon or Key type and cryptographic service provider type.
- Contact your system administrator for additional support.

# Connect clients to a printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Connect clients to a printer**

- Connect to a printer published in Active Directory
- Connect to a printer on a network
- Connect to a printer with a browser
- Connect Windows NT 4.0, Windows 95, and Windows 98 clients
- Connect MS-DOS, Windows 3.x, and OS/2 clients
- Connect Macintosh clients to a printer
- Print from an LPR client to a printer
- Connect to a printer on a NetWare server
- Connect to a printer on a Macintosh server

# User and Group Accounts

Updated: January 21, 2005

- Manage Local Users
- Manage Local Groups

# Local Users and Groups overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Local Users and Groups overview**

Local Users and Groups is located in Computer Management, a collection of administrative tools that you can use to manage a single local or remote computer. You can use Local Users and Groups to secure and manage user accounts and groups stored locally on your computer. A local user or group account can be assigned permissions and rights on a particular computer and that computer only. Local Users and Groups is available on the following client and server operating systems:

- Client computers running Microsoft® Windows® 2000 Professional or Windows XP Professional
- Member servers running a product in the Microsoft Windows 2000 Server family or the Windows Server 2003 family
- Stand-alone servers running a product in the Microsoft Windows 2000 Server family or the Windows Server 2003 family

Using Local Users and Groups you can limit the ability of users and groups to perform certain actions by assigning them rights and permissions. A right authorizes a user to perform certain actions on a computer, such as backing up files and folders or shutting down a computer. A permission is a rule associated with an object (usually a file, folder, or printer), and it regulates which users can have access to the object and in what manner.

You cannot use Local Users and Groups to view local user and group accounts once a member server has been promoted to a domain controller. However, you can use Local Users and Groups on a domain controller to target remote computers (that are not domain controllers) on the network. Use Active Directory Users and Computers to manage users and groups in Active Directory.

For more information, see:

- Local user accounts
- Default local groups
- Default security settings for groups
- Active Directory Users and Computers (Windows Server 2003)

# Manage Local Users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage local users**

- Create a local user account
- Reset the password for a local user account
- Disable or activate a local user account
- Delete a local user account
- Rename a local user account
- Assign a logon script to a local user account
- Assign a home folder to a local user account

# Manage Local Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage local groups**

- Create a local group
- Add a member to a local group
- Identify members of a local group
- Delete a local group
- Allow members of the Anonymous Logon group to be members of the Everyone group on a local computer

# Managing Domain Users and Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Managing domain users and groups**
This section covers:

- User and computer accounts
- Manage Users
- Manage Groups
- Manage Computers

# User and computer accounts

Updated: July 26, 2013

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User and computer accounts**

Active Directory user accounts and computer accounts represent a physical entity such as a computer or person. User accounts can also be used as dedicated service accounts for some applications.

User accounts and computer accounts (as well as groups) are also referred to as security principals. Security principals are directory objects that are automatically assigned security IDs (SIDs), which can be used to access domain resources. A user or computer account is used to:

- Authenticate the identity of a user or computer.

  A user account enables a user to log on to computers and domains with an identity that can be authenticated by the domain. For information about authentication, see Access control in Active Directory. Each user who logs on to the network should have his or her own unique user account and password. To maximize security, you should avoid multiple users sharing one account.

- Authorize or deny access to domain resources.

  Once the user has been authenticated, the user is authorized or denied access to domain resources based on the explicit permissions assigned to that user on the resource. For more information, see Security information for Active Directory.

- Administer other security principals.

  Active Directory creates a foreign security principal object in the local domain to represent each security principal from a trusted external domain. For more information about foreign security principals, see When to create an external trust.

- Audit actions performed using the user or computer account.

  Auditing can help you monitor account security. For more information about auditing, see Auditing overview.

**User accounts**

The Users container located in Active Directory Users and Computers displays the three built-in user accounts: Administrator, Guest, and HelpAssistant. These built-in user accounts are created automatically when you create the domain.

Each built-in account has a different combination of rights and permissions. The Administrator account has the most extensive rights and permissions over the domain, while the Guest account has limited rights and permissions. The table below describes each default user account on domain controllers running Windows Server 2003.

| Default user account | Description |
|---|---|

| | |
|---|---|
| Administrator account | The Administrator account has full control of the domain and can assign user rights and access control permissions to domain users as necessary. This account must be used only for tasks that require administrative credentials. It is recommended that you set up this account with a strong password. For more information, see Strong passwords. For additional security considerations for accounts with administrative credentials, see Active Directory Best practices.<br><br>The Administrator account is a default member of the Administrators, Domain Admins, Enterprise Admins, Group Policy Creator Owners, and Schema Admins groups in Active Directory. The Administrator account can never be deleted or removed from the Administrators group, but it can be renamed or disabled. Because the Administrator account is known to exist on many versions of Windows, renaming or disabling this account will make it more difficult for malicious users to try and gain access to it. For more information about how to rename or disable a user account, see Rename a local user account or Disable or enable a user account.<br><br>The Administrator account is the first account created when you set up a new domain using the Active Directory Installation Wizard.<br><br>• **Important** When the Administrator account is disabled, it can still be used to gain access to a domain controller using Safe Mode. |
| Guest account | The Guest account is used by people who do not have an actual account in the domain. A user whose account is disabled (but not deleted) can also use the Guest account. The Guest account does not require a password.<br><br>You can set rights and permissions for the Guest account just like any user account. By default, the Guest account is a member of the built-in Guests group and the Domain Guests global group, which allows a user to log on to a domain. The Guest account is disabled by default, and it is recommended that it stay disabled. |
| HelpAssistant account (installed with a Remote Assistance session) | The primary account used to establish a Remote Assistance session. This account is created automatically when you request a Remote Assistance session and has limited access to the computer. The HelpAssistant account is managed by the Remote Desktop Help Session Manager service and will be automatically deleted if no Remote Assistance requests are pending. For more information about Remote Assistance, see Administering Remote Assistance. |

**Securing user accounts**

If built-in account rights and permissions are not modified or disabled by a network administrator, they could be used by a malicious user (or service) to illegally log on to a domain using the Administrator or Guest identity. A good security practice for protecting these accounts is to rename or disable them. Because it retains its security ID (SID), a renamed user account retains all its other properties, such as its description, password, group memberships, user profile, account information, and any assigned permissions and user rights.

To obtain the security of user authentication and authorization, create an individual user account for each user who will participate on your network by using Active Directory Users and Computers. Each user account (including the Administrator and Guest account) can then be added to a group to control the rights and permissions assigned to the account. Using accounts and groups that are appropriate for your network ensures that users logging on to a network can be identified and can access only the permitted resources.

You can help defend your domain from attackers by requiring strong passwords and implementing an account lockout policy. Strong passwords reduce the risk of intelligent guessing and dictionary attacks on passwords. For more information, see Strong passwords and Password Best practices for passwords.

An account lockout policy decreases the possibility of an attacker compromising your domain through repeated logon attempts. This is because an account lockout policy determines how many failed logon attempts a user account can have before it is disabled. For more information, see Apply or modify account lockout policy.

For more information about securing user accounts, see Securing Active Directory.

**Account options**

Each Active Directory user account has a number of account options that determine how someone logging on with that particular user account is authenticated on the network. You can use the following options to configure password settings and security-specific information for user accounts:

| Account option | Description |
| --- | --- |
| User must change password at next logon | Forces a user to change their password the next time the user logs on to the network. Use this option when you want to ensure that the user will be the only person to know their password. |
| User cannot change password | Prevents a user from changing their password. Use this option when you want to maintain control over a user account, such as for a guest or temporary account. |
| Password never expires | Prevents a user password from expiring. It is recommended that Service accounts should have this option enabled and should use strong passwords. For more information about strong passwords, see Strong passwords. |
| Store passwords using reversible encryption | Allows a user to log on to a Windows network from Apple computers. If a user is not logging on from an Apple computer, this option should not be used. For more information, see Store passwords using reversible encryption. |
| Account is disabled | Prevents a user from logging on with the selected account. Many administrators use disabled accounts as templates for common user accounts. For more information, see Disable or enable a user account. |
| Smart card is required for interactive logon | Requires that a user possess a smart card to log on to the network interactively. The user must also have a smart card reader attached to their computer and a valid personal identification number (PIN) for the smart card. When this option is selected, the password for the user account is automatically set to a random and complex value. For more information about smart cards, see Logging on to a computer with a smart card and Authentication process. |
| Account is trusted for delegation | Allows a service running under this account to perform operations on behalf of other user accounts on the network. A service running under a user account (otherwise known as a service account) that is trusted for delegation can impersonate a client to gain access to resources on the computer where the service is running or on other computers. In a forest set to the Windows Server 2003 functional level, this setting is found on the **Delegation** tab, and is only available for accounts that have been assigned service principal names (SPNs), as set using the **setspn** command from the Windows Support Tools. This is a security-sensitive capability and should be cautiously assigned. For more information, see Allow a user to be trusted for delegation and Delegating authentication.<br><br>This option is only available on domain controllers running Windows Server 2003 where the domain functionality is set to Windows 2000 mixed or Windows 2000 native. On domain controllers running Windows Server 2003 where the domain functional level is set to Windows Server 2003, the **Delegation** tab is used to configure delegation settings. The **Delegation** tab only appears for accounts which have an assigned SPN. For more information about domain functionality, see Domain and forest functionality. For more information about configuring delegation in a Windows Server 2003 domain, see Allow a user to be trusted for delegation. |
| Account is sensitive and cannot be delegated | Allows control over a user account, such as for a guest or temporary account. This option can be used if this account cannot be assigned for delegation by another account. |
| Use DES encryption types for this account | Provides support for the Data Encryption Standard (DES). DES supports multiple levels of encryption, including MPPE Standard (40-bit), MPPE Standard (56-bit), MPPE Strong (128-bit), IPSec DES (40-bit), IPSec 56-bit DES, and IPSec Triple DES (3DES). For more information about DES encryption, see Data encryption. |
| Do not require Kerberos preauthentication | Provides support for alternate implementations of the Kerberos protocol. Domain controllers running Windows 2000 or Windows Server 2003 can use other mechanisms to synchronize time. Because preauthentication provides additional security, use caution when enabling this option. For more information about Kerberos, see Kerberos V5 authentication. |

**InetOrgPerson accounts**

Active Directory provides support for the InetOrgPerson object class and its associated attributes defined in RFC 2798. The InetOrgPerson object class is used in several non-Microsoft LDAP and X.500 directory services to represent people within an organization.

Support for InetOrgPerson makes migrations from other LDAP directories to Active Directory more efficient. The InetOrgPerson object is derived from the user class and can be used as a security principal just like the user class. For

information about creating an inetOrgPerson user account, see Create a new user account.

When the domain functional level has been set to Windows Server 2003, you can set the userPassword attribute on InetOrgPerson and user objects as being the effective password just like you can with the *unicodePwd* attribute.

**Computer accounts**

Every computer running Windows NT, Windows 2000, Windows XP, or a server running Windows Server 2003 that joins a domain has a computer account. Similar to user accounts, computer accounts provide a means for authenticating and auditing computer access to the network and to domain resources. Each computer account must be unique.

**Note** Computers running Windows 95 and Windows 98 do not have advanced security features and are not assigned computer accounts.

User and computer accounts can be added, disabled, reset, and deleted using Active Directory Users and Computers. A computer account can also be created when you join a computer to a domain. For more information about user and computer accounts, see Active Directory naming and Object names.

When the domain functional level has been set to Windows Server 2003, a new lastLogonTimestamp attribute is used to track the last logon time of a user or computer account. This attribute is replicated within the domain and can provide you with important information regarding the history of a user or computer.

# Manage Users

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage users**

- Create a new user account
- Reset a user password
- Copy a user account
- Move a user account
- Set logon hours
- Disable or enable a user account
- Map a certificate to a user account
- Change a user's primary group
- Delete a user account
- Rename a user account

# Rename a user account

Updated: August 9, 2010

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To rename a user account**
**To rename a user account using the Windows interface**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.
3. **Where?**
   - Active Directory Users and Computers/*domain node*/Users

   Or, click the folder that contains the user account.
4. In the details pane, right-click the user account that you want to rename, and then click **Rename**.
5. Type the new full name for the user account, and then press ENTER. The **Rename User** dialog box appears.
6. The name that you type appears as the full name. You may edit the name, if necessary. When you are satisfied with the new full name, press the Tab key to go to the next box, or click the appropriate box.
7. In **First name**, type the user's first name.
8. In **Last name**, type the user's last name.
9. In **Display name**, type the name for the user to be displayed in Active Directory.
10. In **User logon name**, type the user's logon name, click the user principal name (UPN) suffix in the drop-down list, and then click **Next**.
11. In **User logon name (pre-Windows 2000)**, type a name for the user that is unique for the Active Directory forest.
12. Click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

**To rename a user account using a command line**

1. Open a command prompt.
2. Type the following command, and then press ENTER:

**Dsmod user** *UserDN* **[-upn** *UPN* **] [-fn** *FirstName* **] [-mi** *Initial* **] [-ln** *LastName* **] [-dn** *DisplayName* **] [-email** *EmailAddress* **]**

| Parameter | Description |
| --- | --- |
| *UserDN* | Specifies the distinguished names of the users that you want to modify. A user distinguished name **(UserDN**) is required. If values are omitted, they are optained through standard input (**stdin**) to support piping of output from another command to input of this command. An example of a user distinguished name is CN=CGreen,OU=IT,DC=Contoso,DC=Com. |
| **-upn** *UPN* | Specifies the new user principal names for the user objects that you want to modify, for example, cgreen@contoso.com. |
| **-fn** *FirstName* | Specifies the first names of the user names that you want to modify. |
| **-mi** *Initial* | Specifies the middle initials of the user objects that you want to modify. |
| **-ln** *LastName* | Specifies the last names of the user objects that you want to modify. |
| **-dn** *DisplayName* | Specifies the display names for the user objects that you want to modify. The display name of a user object is the name that you want to see when the user communicates using the account. The display name is also the name that other users search for when they look up this user object in Active Directory Domain Services (AD DS), Exchange, or any directory search tool. |
| **-email** *EmailAddress* | Specifies the e-mail addresses of the user object that you want to modify, which is often the same as the UPN. |

Notes

- To perform this procedure, you must be a member of the Account Operators group, Domain Admins group, or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

- If a value that you supply contains spaces, use quotation marks around the text, for example, "CN=Mike Danseglio,CN=Users,DC=Microsoft,DC=Com".

- If you supply multiple values for a parameter, use spaces to separate the values, for example, a list of distinguished names.

- To view the complete syntax for this command and for information about entering more user account information, at a command prompt, type the following command, and then press ENTER:

  **dsmod /?**

**See Also**

Install the Active Directory Schema snap-in

# Manage Groups

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage groups**

- Create a new group
- Add a member to a group
- Allow anonymous users to be members of the Everyone security group on a domain controller
- Convert a group to another group type
- Change group scope
- Delete a group
- Find groups in which a user is a member
- Assign user rights to a group in Active Directory

# Manage Computers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Manage computers**

- Create a new computer account
- Add a computer account to a group
- Delete a computer account
- Manage a remote computer
- Move a computer account
- Reset a computer account
- Disable or enable a computer account

# Security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security**
This section discusses Microsoft® Windows Server 2003 family security; how you can ensure that data access, storage, and exchange complies with your security needs.

This section covers:

- New features in security
- New ways to do familiar Security tasks
- Best practices for security
- Security overview
- Authentication
- Access Control
- Authorization Manager
- Security Configuration Manager
- Software Restriction Policies
- Auditing Security Events
- Encrypting File System
- Public Key Infrastructure
- Internet Protocol Security (IPSec)
- Windows Time Service
- Security Resources
- Security Troubleshooting

# New features in security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New features in security**

| New features | More information |
|---|---|
| **Authorization Manager**. Authorization Manager gives application developers a flexible framework for integrating role-based access control into their applications, and it lets administrators who use those applications provide access in a natural, intuitive way: through assigned user roles relating to job function. | Authorization Manager |
| **Stored user names and passwords**. This utility provides secure storage for user names and credentials that are needed to access network or Internet resources. | Stored User Names and Passwords |
| **Software restriction policies**. This new security policy enables administrators to prevent software applications from running based on a hash algorithm of the software, the software's associated file path, the software publisher's certificate, or the Internet zone that hosts the software. | Software Restriction Policies |
| **Changes to existing technologies** | |
| **Certification authoritities**. Numerous improvements and added features are included for certification authorities. | New features in Certificate Services |
| **Constrained delegation**. With this new security feature, you can specify what services you want to trust for delegation for a server. | Delegating authentication |
| **Effective permissions tool**. This tool calculates the permissions that are granted to a specified user or group. | Effective Permissions tool |
| **Encrypting File System (EFS)** no longer requires a recovery agent. | Encrypting File System |
| **Everyone membership**. The built-in Everyone group includes Authenticated Users and Guests, but no longer includes members of the Anonymous group. | Differences in default security settings |
| **Operation-based auditing**. Operation based auditing offers more descriptive auditing events and provides you with the opportunity to choose what operations you want to audit when auditing object accesses. | Operation-based auditing on files or folders |
| **Reapplying security defaults**. This procedure enables you to easily reapply the default security settings for the Windows Server 2003 family. | Reapply default security settings |

# New ways to do familiar Security tasks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**New ways to do familiar tasks**
The following table lists common tasks for managing domain security. For most tasks, the user interface is different in Windows Server 2003 family than in Windows NT 4.0.

### Note

- There are no significant user interface differences between Windows 2000, Windows XP, and the Windows Server 2003 family for this component.

| If you want to | In Windows NT 4.0, use | In this version of Windows, use |
|---|---|---|
| Edit user rights for domain groups and users that apply to domain controllers | User Manager for Domains | Active Directory Users and Computers. For more information, see Define a security template. |
| Edit account policies for users in a domain | User Manager for Domains | Active Directory Users and Computers. For more information, see Define a security template. |
| Edit audit policies for groups and users that apply to domain controllers or specific computers | User Manager for Domains | Active Directory Users and Computers. For more information, see Define or modify auditing policy settings for an event category. |
| Establish domain trust relationships | User Manager for Domains | Active Directory Domains and Trusts. |
| Promote member server to a domain controller | Not available | Active Directory Installation Wizard |
| Assign permissions to files, folders, and registry keys | Appropriate object manager and **Properties** page | Appropriate object manager and **Properties** page. For more information, see the Access Control How To... page for Access Control. |
| Audit security events | User Manager for Domains | Appropriate object manager and **Properties** page. For more information, see Apply or modify auditing policy settings for a local file or folder. |
| View security log | Event Viewer | Event Viewer. For more information, see View the security log. |
| Create users and groups | User Manager for Domains | Active Directory Users and Computers. For more information, see Create a new user account and Create a new group. |
| Manage a Windows NT 4.0 domain | User Manager for Domains | User Manager for Domains |

# Best practices for security

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Restrict physical access to computers, especially domain controllers, to trusted personnel**

- Physical access to a server is a high security risk. Physical access to a server by an intruder could result in unauthorized data access or modification as well as installation of hardware or software designed to circumvent security. To maintain a secure environment, you must restrict physical access to all servers and network hardware.

**For administrative tasks, use the principle of least privilege**

- Using the principle of least privilege, Administrators should use an account with restrictive permissions to perform routine, nonadministrative tasks and use an account with broader permissions only when performing specific administrative tasks.

- To accomplish this without logging off and back on, log on with a regular user account and use the Runas command to run the tools that require the broader permissions.

  For more information, see Run a program with administrative credentials and Runas.

**Define groups and their membership**

- When deciding on the default level of computer access that end users will have, the determining factor is the installed base of applications that need to be supported. If your organization uses only applications that belong to the Windows Logo for Software program, then you can make all your end users members of the Users group. If not, you may have to make your end users part of the Power Users group or relax the Users group's permissions security settings. Both are less secure options.

  Running legacy programs on Windows 2000 or Windows XP Professional often requires you to modify access to certain system settings. The same default permissions that allow Power Users to run legacy programs also make it possible for a Power User to gain additional privileges on the system, even complete administrative control. Therefore, it is important to deploy Windows 2000 or Windows XP Professional programs in the Windows Logo program for Software in order to achieve maximum security without sacrificing program functionality.

  For more information, see the Windows Logo program for Software page at the Microsoft Web site.

- All domain administrators (including child domain administrators) who can modify the system software on domain controllers in a forest must be equally trusted.

- Domain administrators and enterprise administrators should be the only users allowed to link a Group Policy object to an organizational unit. This is the default setting.

  Authenticated users only need Read and Apply Group Policy object permissions.

**Secure data on computers**

- Ensure that the system files and the registry are protected using strong access control lists.

  For more information, see Access Control.

- Use Syskey to provide additional protection of the security account manager (SAM), especially on your domain controllers.

For more information, see The system key utility.

**Use strong passwords throughout your organization**

- Most authentication methods require the user to provide a password to prove their identity. These passwords are normally chosen by the user, who may want a simple password that is easily remembered. In most cases, these passwords are weak and may be easily guessed or determined by an intruder. Weak passwords can circumvent this security element and become the weak point of an otherwise strong security environment. Strong passwords tend to be more difficult for an intruder to discern and, as a result, help provide an effective defense of your organization's resources.

  For more information, see Strong passwords.

**Do not download or run programs that come from untrusted sources**

- programs can contain instructions to violate security in a number of ways including data theft, denial of service and data destruction. These malicious programs often masquerade as legitimate software and can be difficult to identify. To avoid these programs, you should only download and run software that is guaranteed authentic and obtained from a trusted source. You should also ensure a current virus scanner is installed and functioning in case this type of software does inadvertently wind up on your computer.

**Keep virus scanners up to date**

- Virus scanners frequently identify infected files by scanning for a signature, which is a known component of a previously identified virus. The scanners keep these virus signatures in a signature file, which is usually stored on the local hard disk. Because new viruses are discovered frequently, this file should also be updated frequently for the virus scanner to easily identify all current viruses.

**Keep all software patches up to date**

- Software patches provide solutions to known security issues. Check software provider Web sites periodically to see if there are new patches available for software used in your organization.

  For more information and for the latest recommendations on security, see Security.

In order to subscribe to the product Security Notification Service, see "product Security Notification" at the Microsoft Web site

For more information, see:

- Best practices for permissions and user rights
- Auditing Security Events Best practices
- Encrypting File System best practices

- Best practices for Security Templates
- Best practices for Security Settings

# Security overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security overview**
The primary features of the Microsoft® Windows Server 2003 family security model are user authentication and access control. The Active Directory® directory service ensures that administrators can manage these features easily and efficiently. The following sections describe these features of the security model.

**Authentication**

- *Interactive logon* confirms the user's identification to the user's local computer or Active Directory account.

- *Network authentication* confirms the user's identification to any network service that the user is attempting to access. To provide this type of authentication, the security system includes these authentication mechanisms: Kerberos V5, public key certificates, Secure Sockets Layer/Transport Layer Security (SSL/TLS), Digest, and NTLM (for compatibility with Windows NT® 4.0 systems).

  Single sign-on makes it possible for users to access resources over the network without having to repeatedly supply their credentials. For the Windows Server 2003 family, users need to only authenticate once to access network resources; subsequent authentication is transparent to the user.

Authentication in the Windows Server 2003 family also includes two-factor authentication, such as smart cards. For more information, see Smart Cards.

For more information, see Authentication protocols overview.

**Object-based access control**
Along with user authentication, administrators are allowed to control access to resources or objects on the network. To do this, administrators assign security descriptors to objects that are stored in Active Directory. A security descriptor lists the users and groups that are granted access to an object and the specific permissions assigned to those users and groups. A security descriptor also specifies the various access events to be audited for an object. Examples of objects include files, printers, and services. By managing properties on objects, administrators can set permissions, assign ownership, and monitor user access.

Not only can administrators control access to a specific object, they can also control access to a specific attribute of that object. For example, through proper configuration of an object's security descriptor, a user could be allowed to access a subset of information, such as employees' names and phone numbers but not their home addresses. For more information, see Access Control.

For more information, see "Authorization and access control" at the Microsoft Windows Resource Kits Web site.

**Security policy**
You can control security on your local computer or on multiple computers by controlling password policies, account lockout policies, Kerberos policies, auditing policies, user rights, and other policies. To create a systemwide policy, you can use security templates, apply templates using Security Configuration and Analysis or edit policies on the local computer, organizational unit, or domain. For more information, see Security Configuration Manager.

**Auditing**
Monitoring the creation or modification of objects gives you a way to track potential security problems, helps to ensure user accountability, and provides evidence in the event of a security breach. For more information, see Auditing overview.

**Active Directory and security**
Active Directory provides protected storage of user account and group information by using access control on objects and user credentials. Because Active Directory stores not only user credentials but also access control information, users who log on to the network obtain both authentication and authorization to access system resources. For example, when a user logs on to the network, the security system authenticates the user with information stored in Active Directory. Then, when the user attempts to access a service on the network, the system checks the properties defined in the discretionary access control list (DACL) for that service.

Because Active Directory allows administrators to create group accounts, administrators can manage system security more

efficiently. For example, by adjusting a file's properties, an administrator can permit all users in a group to read that file. In this way, access to objects in Active Directory is based on group membership.

**Data protection**
Stored data (online or offline) can be protected using:

- **Encrypting File System (EFS)**. EFS uses public key encryption to encrypt local NTFS data. For more information, see Storing Data Securely.

- **Digital signatures**. Digital signatures sign software components, ensuring their validity. For more information, see Digital signatures.

**Network data protection**
Network data within your site (local network and subnets) is secured by the authentication protocol. For an additional level of security, you can also choose to encrypt network data within a site. Using Internet Protocol security, you can encrypt all network communication for specific clients, or for all clients in a domain.

Network data passing in and out of your site (across intranets, extranets, or an Internet gateway) can be secured using the following utilities:

- Internet Protocol Security (IPSec) Encryption. A suite of cryptography-based protection services and security protocols.

- **Routing and Remote Access**. Configures remote access protocols and routing. For more information, see Routing Overview.

- **Internet Authentication Service (IAS)**. Provides security and authentication for dial-in users. For more information, see Internet Authentication Service.

**Public key infrastructure**
Public key encryption is an important aspect of security. For more information, see Deploying a Public Key Infrastructure.

**Trusts**
The Windows Server 2003 family supports domain trusts and forest trusts.

Domain trust allows a user to authenticate to resources in another domain. For more information on establishing and managing domain trust relationships, see Trust direction.

In a Windows Server 2003 forest, administrators can create a forest to extend two-way transitivity beyond the scope of a single forest to a second Windows Server 2003 forest. For more information, see Forest trusts.

For more information about authorization and access control, see "Domain Trust" at the Microsoft Windows Resource Kits Web site.

# Authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication**

- Authentication protocols
- Smart Cards
- Stored User Names and Passwords
- Passwords

# Authentication protocols

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication protocols**

This section covers the authentication protocols.

- For help with specific tasks, see Authentication Protocol How To....
- For general background information, see Authentication Protocol Concepts.

# Authentication Protocol How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Configure Kerberos policy
- Allow a computer to be trusted for delegation for specific services
- Allow a user to be trusted for delegation for specific services
- Allow a computer to be trusted for delegation
- Allow a user to be trusted for delegation
- Map an account from a trusted non-Windows kerberos realm to a user account

# Configure Kerberos policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure Kerberos policy**

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit for which you want to set Group Policy.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Do one of the following:
   - To edit an existing Group Policy object (GPO), in **Group Policy Object Links**, click the GPO that you want to edit, then click **Edit**.
   - To create a new GPO, click **New**, type the name of the new GPO, and then click **Edit**.
5. In the console tree, click **Kerberos Policy**.

   **Where?**

   - Computer Configuration/Windows Settings/Security Settings/Account Policies/Kerberos Policy
6. In the details pane, double-click the Kerberos policy you want to modify.
7. Modify the policy, and then click **OK**.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- Any modifications to Kerberos policy will affect all the computers in the domain.
- The Kerberos policies in the Windows Server 2003 family refer to the ticket-granting ticket as a **user ticket**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow a computer to be trusted for delegation for specific services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow a computer to be trusted for delegation for specific services**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Computers**.

   **Where?**

   - *DomainName*/Computers

3. In the details pane, right-click the computer you want to trust for delegation and then click **Properties**.
4. On the **Delegation** tab, click **Trust this computer for delegation to specified services only**.
5. Do one of the following:

   - Confirm that **Use Kerberos only** is selected.
   - Click **Use any authentication protocol**.

6. Click **Add** and, in **Add Services**, click **Users and Computers**.
7. In **Enter the object names to select (examples)**, type the name of the user or computer that the computer will be trusted to delegate for, and then click **OK**.
8. In **Add Services**, click the service or services that will be trusted for delegation and click **OK**. Repeat this step as necessary.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- If you cannot see the **Delegation** tab, do one or both of the following:

  - Register a Service Principal Name (SPN) for the computer account using the **Setspn** utility in the support tools that are on your CD. Delegation is only intended to be used by service accounts, which should have registered SPNs, as opposed to a regular user account which typically does not have SPNs.
  - Raise the functional level of your domain to Windows Server 2003 . For more information, see Related Topics.

- Constrained delegation, delegation of authentication for only specified services, can only be enabled on a member of the

Windows Server 2003 family.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Allow a user to be trusted for delegation for specific services

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To allow a user to be trusted for delegation for specific services**

1. Open Active Directory Users and Computers.
2. In the console tree, click **Users**.
3. Right-click the user you want to be trusted for delegation, and click **Properties**.
4. Click the **Delegation** tab and click **Trust this user for delegation to specified services only**.
5. Select **Use Kerberos only** (default) or select **Use any authentication protocol**, where the initial client-to-server authentication protocol can be any protocol supported by the Windows Server 2003 local security authority. Typically, this could be NTLM, SSL client certificate mapping or Digest.
6. Click **Add** and, in **Add Services** click **Users and Computers**.
7. In **Select Users or Computers**, enter the name of the user or computer that the user will be trusted to delegate for.
8. In **Add Services**, select the service or services that will be trusted for delegation and click **OK**. Repeat as necessary.

## Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- If you cannot see the **Delegation** tab, do one or both of the following:
    - Register a Service Principal Name (SPN) for the user account with the **Setspn** utility in the support tools on your CD. Delegation is only intended to be used by service accounts, which should have registered SPNs, as opposed to a regular user account which typically does not have SPNs.
    - Raise the functional level of your domain to Windows Server 2003 . For more information, see Related Topics.
- Constrained delegation, which is trusting a computer for delegation of specified services, can only be enabled for a computer in a Windows Server 2003 domain.

# Authentication Protocol Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

For more information on authentication protocols, see the following:

- Authentication protocols overview
- Introduction to authentication
- Kerberos V5 authentication
- Enabling Kerberos V5 authentication
- Delegating authentication
- Interoperability with RFC-1510 Kerberos implementations
- SSL/TLS authentication
- NTLM authentication
- Passport authentication

# Authentication protocols overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authentication protocols overview**

Authentication is a fundamental aspect of system security. It confirms the identity of any user trying to log on to a domain or access network resources. Windows Server 2003 family authentication enables single sign-on to all network resources. With single sign-on, a user can log on to the domain once, using a single password or smart card, and authenticate to any computer in the domain.

**Authentication types**

When attempting to authenticate a user, several industry-standard types of authentication may be used, depending on a variety of factors. The following table lists the types of authentication that the Windows Server 2003 family supports.

| Authentication protocols | Description |
|---|---|
| Kerberos V5 authentication | A protocol that is used with either a password or a smart card for interactive logon. It is also the default method of network authentication for services. |
| SSL/TLS authentication | A protocol that is used when a user attempts to access a secure Web server. |
| NTLM authentication | A protocol that is used when either the client or server uses a previous version of Windows. |
| Digest authentication | Digest authentication transmits credentials across the network as an MD5 hash or message digest. |
| Passport authentication | Passport authentication is a user-authentication service which offers single sign-in service. |

For more information on authentication types, see "Logon and Authentication" at the Microsoft Windows Resource Kits Web site.

# Introduction to authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Introduction to authentication**
A key feature of authentication in the Windows Server 2003 family is its support of single sign-on. Single sign-on allows a user to log on to the domain once, using a single password, and authenticate to any computer in the domain.

Single sign-on provides two main security benefits:

- For a user, the use of a single password or smart card reduces confusion and improves work efficiency.
- For administrators, the amount of administrative support required for domain users is reduced, because the administrator only needs to manage one account per user.

Authentication, including single sign-on, is implemented as a two-part process: interactive logon and network authentication. Successful user authentication depends on both of these processes.

**Interactive logon**
Interactive logon confirms the user's identification to either a domain account or a local computer. This process is different, depending on the type of user account:

- With a domain account, a user logs on to the network with a password or smart card, using single sign-on credentials stored in the Active Directory directory service. By logging in with a domain account, an authorized user can access resources in the domain and any trusting domains. If a password is used to log on to a domain account, Kerberos V5 is used for authentication. If a smart card is used instead, Kerberos V5 authentication is used with certificates.
- With a local computer account, a user logs on to a local computer, using credentials stored in Security Account Manager (SAM), which is the local security account database. Any workstation or member server can store local user accounts, but those accounts can only be used for access to that local computer.

**Network authentication**
Network authentication confirms the user's identification to any network service that the user is attempting to access. To provide this type of authentication, the security system supports many different authentication mechanisms, including Kerberos V5, Secure Socket Layer/Transport Layer Security (SSL/TLS), and, for compatibility with Windows NT 4.0, NTLM.

Users who use a domain account do not see network authentication. Users who use a local computer account must provide credentials (such as a user name and password) every time they access a network resource. By using the domain account, the user has credentials that can be used for single sign-on.

For more information about authentication, see "Logon and Authentication" at the Microsoft Windows Resource Kits Web site.

# Kerberos V5 authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Kerberos V5 authentication**
Kerberos V5 is the primary security protocol for authentication within a domain. The Kerberos V5 protocol verifies both the identity of the user that is requesting authentication as well as server providing the requested authentication. This dual verification is also known as *mutual authentication*.

**An overview of how Kerberos V5 works**
The Kerberos V5 authentication mechanism issues tickets for accessing network services. These tickets contain encrypted data, including an encrypted password, that confirms the user's identity to the requested service. Except for entering a password or smart card credentials, the entire authentication process is invisible to the user.

An important service within Kerberos V5 is the Key Distribution Center (KDC). The KDC runs on each domain controller as part of the Active Directory directory service, which stores all client passwords and other account information.

The Kerberos V5 authentication process works as follows:

1. The user on a client system, using a password or a smart card, authenticates to the KDC.

2. The KDC issues a special ticket-granting ticket to the client. The client system uses this TGT to access the ticket-granting service (TGS), which is part of the Kerberos V5 authentication mechanism on the domain controller.

3. The TGS then issues a service ticket to the client.

4. The client presents this service ticket to the requested network service. The service ticket proves both the user's identity to the service and the service's identity to the user.

The Kerberos V5 services are installed on each domain controller, and a Kerberos client is installed on each workstation and server.

Every domain controller acts as a KDC. A client uses a Domain Name Service (DNS) lookup to locate the nearest available domain controller. That domain controller then functions as the preferred KDC for that user during the user's logon session. If the preferred KDC becomes unavailable, the system locates an alternate KDC to provide authentication.

For more information on how Kerberos V5 provides authentication, see Kerberos Authentication Technical Reference in the Windows Server 2003 Technical Reference.

For more information about Kerberos, see "Logon and Authentication" at the Microsoft Windows Resource Kits Web site.

# Enabling Kerberos V5 authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enabling Kerberos V5 authentication**

The Kerberos V5 authentication protocol is enabled by default for all computers joined to a Windows Server 2003 or Windows 2000 domain during installation. Kerberos provides single sign-on to resources within a domain, and to resources residing in trusted domains.

You can control certain aspects of Kerberos configuration through Kerberos security settings which are part of the account policies. For example, you can set the lifetime of users' Kerberos V5 tickets. As an administrator, you can use the default Kerberos policy or you can change it to suit the needs of your environment.

Successful authentication using Kerberos V5 requires that both the client and server computers must run the Windows 2000, Windows Server 2003 family, or Windows XP Professional operating system.

If a client system tries to authenticate to a server running another version of the Windows operating system, the NTLM protocol will be used as the authentication mechanism.

**Note**

- Computers using Kerberos for authentication must have their time settings synchronized with a common time service within five minutes or authentication fails. Computers running members of the Windows Server 2003 family, Windows XP Professional, or Windows 2000 automatically update the current time, using the domain controller as a network time service.

For more information about configuring Kerberos policy, see Kerberos Policy and Account Policies.

For more information about Kerberos, see "Logon and Authentication" at the Microsoft Windows Resource Kits Web site.

# Delegating authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Delegating authentication**

*Delegation* is the act of allowing a service to impersonate a user account or computer account in order to access resources throughout the network. When a service is *trusted for delegation*, that service can impersonate a user to use other network services.

For more information about delegation, see "Designing an Authentication Strategy" at the Microsoft Windows Resource Kits Web site.

To set up delegation on a computer, the following conditions must be met:

- The account doing the delegation must be set to **Trusted for delegation to any service** or **Trusted for delegation to specified services only**.
- The account that the service is delegating for must not have the **Account is sensitive and cannot be delegated** option chosen.
- An administrator must have the Enable computer and user accounts to be trusted for delegation privilege on the computer in order to enable delegation.

For more information about how to allow users or computers to be trusted for delegation, see Authentication Protocol How To....

**Differences in Windows Server 2003 family delegation**

| Windows 2000 | Members of the Windows Server 2003 family |
|---|---|
| Delegation requires the Kerberos authentication protocol. | Delegation can be used when the client authenticates to the service using protocols other then Kerberos because of a new feature of the Windows Server 2003 family, Protocol Transition. |
| The Key Distribution Center (KDC) embeds a copy of the user's ticket-granting ticket (TGT) inside the service ticket that is sent to the server. With this TGT, the server that has been trusted for delegation can request service tickets for the user to any other service on the network. | A ticket-granting ticket (TGT) is not needed. With protocol transition, a service can use a service ticket for delegation. |
| Delegation allows the server to connect to any resource in the domain on behalf of the client. | An administrator can specify which Service Principal Names (SPNs) an account is able to delegate to with constrained delegation. |

**Constrained delegation**

Constrained delegation is a new option and can only be used on members of the Windows Server 2003 family. With this option, the administrator can specify which Service Principal Names (SPNs) an account is able to delegate to. A service can be trusted for delegation, but that trust can be limited to a select group of services explicitly specified by a domain administrator.

In a Windows Server 2003 domain, there are three options to consider in trusting a computer for delegation:

- **Do not trust this computer for delegation**. This option was available in Windows 2000 and is the default setting for members of the Windows Server 2003 family.
- **Trust this computer for delegation to any service (Kerberos only)**. This option was available in Windows 2000. This setting is only as secure as the service and the actions of all its administrators. When this option is selected on a computer, all services under the Local System account on the computer will be trusted for delegation. This means an administrator on that computer may install any service and then that service will have the ability to access any network resource by impersonating a user.

- **Trust this computer for delegation to specified services only**. This is a new feature for the Windows Server 2003 family, and it is commonly referred to as constrained delegation. With constrained delegation, the administrator can specify which Service Principal Names (SPNs) this account is able to delegate to. If an application requires delegation for best functionality, this is the most secure option. Delegation for specified services allows an administrator to choose what services on the network can be delegated to by choosing a specific service or computer account. By only allowing delegation to specific services, an administrator can control what network resources the service or computer can use.

For more information on functional levels, see Domain and forest functionality.

For information on about configuring constrained delegation, see

- Allow a computer to be trusted for delegation for specific services
- Allow a user to be trusted for delegation for specific services

For information on about configuring delegation, see

- Allow a computer to be trusted for delegation
- Allow a user to be trusted for delegation

# Interoperability with RFC-1510 Kerberos implementations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Interoperability with RFC-1510 Kerberos implementations**
Kerberos V5 is designed for interoperability with other security services that are based on the RFC-1510 Kerberos reference implementation.

Windows Server 2003 family supports two types of Kerberos V5 interoperability:

- A trust relationship can be established between a domain and an MIT-based Kerberos realm. This means that a client in a Kerberos realm can authenticate to an Active Directory directory service domain to access network resources in that domain.

- Within a domain, UNIX clients and servers can have Active Directory accounts and therefore obtain authentication from a domain controller.

Kerberos V5 interoperates with other RFC-1510 implementations of the Kerberos protocol in the following ways:

- A domain controller can provide authentication for client systems running implementations of RFC-1510 Kerberos, including clients running an operating system other than Windows XP Professional or Windows 2000.

- Windows XP Professional systems can authenticate to a Kerberos V5 server within a realm, with single sign-on to both the server and a local Windows XP Professional account.

- Client applications for Win32 and operating systems other than Windows XP Professional that are based on the General Security Service Application program Interface (GSS API) can obtain session tickets for services within a domain.

For more information, see the Step-by-Step Guide to Kerberos 5 (krb5 1.0) Interoperability on the Microsoft Web site and the Kerberos Network Authentication Service (V5).

**Note**

- Web addresses can change, so you might be unable to connect to the Web site or sites mentioned here.

# SSL/TLS authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**SSL/TLS authentication**

For conceptual information about certificates and Transport Layer Security (TLS)/Secure Socket Layer (SSL) connections and authentication, see Certificates Technical Reference and TLS/SSL Technical Reference in the Windows Server 2003 Technical Reference.

With Secure Socket Layer/Transport Layer Security (TLS/SSL), you have the ability to control what ciphers or cryptographic algorithms are allowed. By default, all ciphers can be used; however, you can control what ciphers your computer can use. For more information, see article Q216482, "How to Control the Ciphers for SSL and TLS," in the Microsoft Knowledge Base (http://www.microsoft.com/).

For instructions on how to map certificates to user accounts in Internet Information Services (IIS), see "Mapping Client Certificates to User Accounts" in the Internet Information Services (IIS) 6.0 documentation.

**Note**

- You must have IIS installed to have access to the documentation.

# NTLM authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**NTLM authentication**

In a networking environment, NTLM is used as the authentication protocol for transactions between two computers where one or both computers are running Windows NT 4.0 or earlier. Networks with this configuration are referred to as mixed-mode, the default setting in the Windows Server 2003 family.

As examples, the following configurations would use NTLM as the authentication mechanism:

- A Windows 2000 or Windows XP Professional client authenticating to a Windows NT 4.0 domain controller.
- A Windows NT 4.0 Workstation client authenticating to a Windows 2000 or Windows Server 2003 domain controller.
- A Windows NT 4.0 Workstation client authenticating to a Windows NT 4.0 domain controller.
- Users in a Windows NT 4.0 domain authenticating to a Windows 2000 or a domain running Windows Server 2003 family.
- A client running Windows 95, Windows 98, or Windows Millennium Edition that is authenticating to any domain controller.

In addition, NTLM is the authentication protocol for computers that are not participating in a domain, such as stand-alone servers and workgroups.

For more information about NTLM and NTLMv2, see "Logon and Authentication" at the Microsoft Windows Resource Kits Web site. (http://www.microsoft.com/)

# Passport authentication

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Passport authentication**
Passport authentication is a centralized service provided by Microsoft that offers single logon and core profile services for member Web sites. This benefits Web site users by making it unnecessary to log on again to access additional protected resources or Web sites. You can make your business Web site compatible with Passport authentication and authorization by using the Passport authentication provider.

The Microsoft .NET Passport Home Web page provides information for:

- Consumers, who want to manage their .NET Passports and change their passwords.
- Businesses, which can license and use .NET Passport on their Web sites.

For more information, see the Microsoft .NET Passport Home Web page at the Microsoft Web site.

Web site administrators can use the Microsoft Passport Manager Administration utility to change registry settings that affect the default behavior of the Passport Manager object. For information about the Passport Manager Administration utility, see the MSDN Web site. For information about the Microsoft .NET Passport Software Development Kit, see the MSDN Web site.

**Note**

- To start the Passport Manager Administration utility, click **Start**, click **Run**, type **msppcnfg.exe**, and then click **OK**.

# Smart Cards

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Smart cards**
Smart cards are a tamper-resistant and portable way to provide security solutions for tasks such as client authentication, logging on to a Microsoft® Windows Server 2003 family domain, code signing and securing e-mail.

- Before deploying smart cards, see Checklist: Deploying smart cards for logging on to Windows.
- For help with specific tasks, see Smart Card How To....
- For general background information, see Smart Card Concepts.

# Checklist: Deploying smart cards for logging on to Windows

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Deploying smart cards for logging on to Windows**

| Step | Reference |
|---|---|

# Smart Card How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to ...**

- Install a smart card reader on a computer
- Log on to a computer with a smart card
- Administer Smart Cards

# Install a smart card reader on a computer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To install a smart card reader on a computer**

1. Depending on the type of reader you have purchased, attach your reader to an available serial or USB port or insert the PC card reader into an available PCMCIA slot.

2. If you connected a serial port reader, restart the computer to detect it and then log on to the computer.

3. Do one of the following:

   - If the device driver for the smart card reader is available as part of Windows Server 2003 family, the installation of the driver takes place without any prompting by the user. This may take a few minutes.

   - If the device driver for the smart card reader is not available as part of Windows Server 2003 family, the Add Hardware Wizard starts. Follow the directions for installing the device driver software.

### Important

- Smart card readers generally come with setup instructions from the manufacturer. If your reader comes with instructions, you should use those. If not, then use these general procedures.

### Notes

- You can confirm that the installation was successful by confirming that the reader appears in the **Device Manager** tree.

- If the smart card reader is not installed automatically or the Add Hardware Wizard does not start automatically, then your smart card reader may not be compliant with Plug and Play specifications. You should contact the smart card reader manufacturer for the device driver and the instructions on how to install and configure the device.

- When using the Add Hardware Wizard to install a smart card reader, you need the device driver. Contact the manufacturer of the smart card reader. Alternatively, your administrator may provide the driver.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Log on to a computer with a smart card

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To log on to a computer with a smart card**

1. At the Windows Server 2003 family logon screen, insert your smart card in the smart card reader.
2. Type the personal identification number (PIN) for the smart card when prompted by your computer.

## Notes

- You must prepare the smart card by creating the appropriate credentials before using it to log on to the computer. For more information on preparing a smart card, see Related Topics.
- If the PIN you enter is recognized as legitimate, this logs you on to the computer and to the Windows Server 2003 family domain, based on the permissions assigned to your user account by the domain administrator.
- If you enter the incorrect PIN for a smart card several times in a row, you will be unable to log on to the computer using that smart card. The number of allowable invalid logon attempts before lockout occurs varies according to the smart card manufacturer. Contact your administrator for assistance.
- If you insert the smart card backwards or upside down, the smart card reader will not work. However, you may be prompted for a PIN which will not work. Follow the directions for your specific model of card reader to understand which way to insert the smart card.
- Smart card logon only works for computers that are joined to a domain.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Administer Smart Cards

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Administer smart cards**

- Prepare a certification authority to issue smart card certificates
- Prepare a smart card certificate enrollment station
- Set up a smart card for user logon
- Configure a smart card user to temporarily log on to the network without a smart card

# Prepare a certification authority to issue smart card certificates

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prepare a certification authority to issue smart card certificates**

1. Confirm that the proper security permissions are set on the Smart Card Logon, Smart Card User, and Enrollment Agent certificate templates.

2. Log on with administrator rights to the certification authority (CA) you will use to issue smart card certificates.

3. Open Certification Authority.

4. In the console tree, click **Certificate Template**.

   **Where?**

   - Certification Authority (*Computer*)/*CA_Name*/Certificate Templates

5. Do one of the following:

   - If the CA will issue certificates that are only for logging on to Windows with smart cards, click the **Smart Card Logon** certificate template, and then click **OK**.

   - If the CA will issue certificates that can be used to log on to Windows with smart cards and other uses, click the **Smart Card User** certificate template, and then click **OK**.

6. On the **Action** menu, point to **New**, and then click **Certificate to Issue**.

7. Click the **Enrollment Agent** certificate template, and then click **OK**.

## Notes

- To open Certification Authority, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Certification Authority**.

- The security permission setting of a certificate template indicates who is allowed to request a certificate of that type.

- The Enrollment Agent certificate does not have to be issued from the same certification authority (CA) that will issue certificates for smart cards, as takes place in this procedure, but the issuing CA for the Enrollment Agent certificate must be a trusted enterprise CA in the domain. In that case, make sure that there is an enterprise CA in your domain that is capable of issuing Enrollment Agent certificates. To do this, follow the above steps for the CA that will issue certificates that will be used for logging on to Windows with a smart card and other uses. Then follow the above steps to issue an enrollment agent certificate.

- This procedure only applies to enterprise CAs.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Prepare a smart card certificate enrollment station

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To prepare a smart card certificate enrollment station**

1. On the computer that you will use to set up smart cards, install a smart card reader, following the manufacturer's instructions.
2. Log on as the user or administrator who will be installing certificates on smart cards.
3. On the taskbar, click the **Start** button, click **Run**, type **mmc**, and then click **OK**.
4. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
5. In **Snap-in**, double-click **Certificates**. If you are logged on as a user, the Certificates snap-in automatically loads.
   - If you are logged on as an Administrator, click **My user account**, and then click **Finish**.
6. Click **Close** and then click **OK**.
7. Double-click **Certificates - Current User**.
8. In the console tree, click **Personal**.

   **Where?**

   - Certificates - Current User/Personal
9. On the **Action** menu, point to **All Tasks**, and then click **Request New Certificate**.
10. In the Certificate Request Wizard, click the **Enrollment Agent** certificate template and type a friendly name and a description for the certificate.
11. When prompted by the Certificate Request Wizard, click **Install Certificate**.

**Notes**

- The Web enrollment station can also be used instead of the method described in this procedure. For more information, see Related Topics.
- Before requesting smart card logon certificates for users, a smart card administrator must have an Enrollment Agent certificate available to generate smart card certificate requests on the behalf of others. That is the purpose of this procedure.
- To perform this procedure, you must have the appropriate security permissions to administer the Enrollment Agent certificate template. See Related Topics for more information about Enrollment Agent certificates and enrolling for a smart card certificate.
- The Enrollment Agent certificate can be installed on a smart card, if you want. In that case, you must use the smart card manufacturer's cryptographic service provider (CSP) when requesting the certificate. (Click the **Advanced Options** button in the Certificate Request Wizard to select a smart card CSP for the Enrollment Agent certificate.)

- These tasks can be performed on any computer running Windows XP or a member of the Windows Server 2003 family that you want to use as a smart card certificate enrollment station.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set up a smart card for user logon

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set up a smart card for user logon**

1. Log on as an enrollment agent for the domain where the user's account is located.
2. Open Internet Explorer.
3. In **Address**, type the address of the certification authority (CA) that issues smart card certificates, and then press ENTER.
4. Click **Request a certificate** and then click **advanced certificate request**.
5. Click **Request a certificate for a smart card on behalf of another user using the smart card certificate enrollment station**. If you are prompted to accept the smart card signing certificate, click **Yes**.
6. On the **Smart Card Certificate Enrollment Station** Web page, in **Certificate Template**, do one of the following:
   - Click **Smart Card Logon** if you want to use the smart card for logging on to Windows only.
   - Click **Smart Card User** if you want to use the smart card for secure e-mail as well as logging on to Windows.
7. In **Certification Authority**, click the name of the CA you want to issue the smart card certificate.
8. In **Cryptographic Service Provider**, select the cryptographic service provider (CSP) of the smart card's manufacturer.
9. In **Administrator Signing Certificate**, click the Enrollment Agent certificate that will sign the enrollment request.
10. In **User To Enroll**, click **Select User**, select the appropriate user account, and then click **Enroll**.
11. When prompted by the system, insert the smart card into the smart card reader on your computer, click **OK**, and then, when prompted by the system, enter the personal identification number (PIN) for the smart card.
12. (Optional) If the smart card you are setting up has a previously installed certificate on it, a message appears, asking whether you want to replace the existing credentials on the card. Click **Yes**.
13. After the certificate is installed on the smart card, the CA Web page will give you the option of viewing the certificate you just installed or beginning a new smart card certificate request.

**Notes**

- To open Internet Explorer, click **Start**, point to **All programs**, and then click **Internet Explorer**.
- In the first step, anyone in the domain who has an Enrollment Agent certificate and has security permissions to issue smart card certificates is considered an enrollment agent.
- The address of the certification server is the name of the server followed by **/Certsrv**. For example, in order to connect to the CA on a server named SmartcardCA, you would connect to: http://SmartcardCA/Certsrv

  Be sure to use the name of the server that the CA is installed on, not the CA name itself. In many cases, these names will be different.

- If you have no Enrollment Agent certificate available, see Related Topics.

- Users that will be logging on to computers running the Windows 2000 operating system must have a smart card enrolled from a computer running Windows 2000. Users that will log on to computers running Windows XP or Windows Server 2003, Standard Edition can have a smart card enrolled from a computer running any of these operating systems.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Configure a smart card user to temporarily log on to the network without a smart card

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To configure a smart card user to temporarily log on to the network without a smart card**

1. Open Active Directory Users and Computers.
2. In the console tree, do one of the following.
   - Click **Users**.

     **Where?**

   - Active Directory Users and Computers/*Domain Node*/Users
   - Click the folder that contains the user account that you want.
3. Right-click the user account, and then click **Properties**.
4. Click the **Account** tab.
5. In the **Account options** list, do the following:
   - Clear the **Smart card is required for interactive logon** check box.
   - Select the **User must change password at next logon** check box.
6. Right-click the user account, and then click **Reset Password**.
7. Provide a new password for this user.
8. Inform the user of the new password and that the password must be changed the next time he or she logs on to the network.

## Notes

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.
- The **User must change password at next logon** option is not required for this procedure to work, but it ensures that only the user has the correct password.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Smart cards overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Smart cards overview**
Smart cards are a tamper-resistant and portable way to provide security solutions for tasks such as logging on to a Microsoft® Windows Server 2003 family domain, client authentication, code signing, and securing e-mail.

Support for cryptographic smart cards is a key feature of the public key infrastructure (PKI) that Microsoft has integrated into Microsoft® Windows® XP and the Windows Server 2003 family.

Smart cards provide:

- Tamper-resistant storage for protecting private keys and other forms of personal information.
- Isolation of security-critical computations involving authentication, digital signatures, and key exchange from other parts of the computer that do not have a "need to know." These operations are all performed on the smart card.
- Portability of credentials and other private information between computers at work, home, or on the road.

For more information, see Understanding smart cards and Using Smart Cards.

For smart card administrative and user procedures, see Smart Card How To....

For the smart card deployment checklist, see Checklist: Deploying smart cards for logging on to Windows.

# Understanding smart cards

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding smart cards**

Logging on to a network with a smart card provides a strong form of authentication because it uses cryptography-based identification and proof of possession when authenticating a user to a domain.

For example, if a malicious person obtains a user's password, that person can assume the user's identity on the network simply through use of the password. Many people choose passwords they can remember easily, which makes passwords inherently weak and open to attack.

In the case of smart cards, that same malicious person would have to obtain both the user's smart card and the personal identification number (PIN) to impersonate the user. This combination is obviously more difficult to attack because an additional layer of information is needed to impersonate a user. An additional benefit is that, after a small number of unsuccessful PIN inputs occur consecutively, a smart card is locked, making a dictionary attack against a smart card extremely difficult. (Note that a PIN does not have to be a series of numbers; it can also use other alphanumeric characters.) Smart cards are also resistant to undetected attacks because the card needs to be obtained by the malicious person, which is relatively easy for a user to know about.

For more conceptual information, see Using Smart Cards.

For smart card administrative and user procedures, see Smart Card How To....

# Using Smart Cards

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using smart cards**

This section provides general information about using smart cards:

- Smart card readers
- Supported smart cards
- Enrolling for a smart card certificate
- Logging on to a computer with a smart card
- Using smart cards with system tools

# Smart card readers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Smart card readers**

It is strongly recommended that only smart card readers that have been tested by the Microsoft Windows Hardware Quality Labs and have obtained the Windows-compatible logo be installed on Windows XP and Windows Server 2003 family computers.

Smart card readers that are not Plug and Play-compliant are not recommended on computers running Windows XP or the Windows Server 2003 family. If you are using such a reader, then you must obtain installation instructions (including associated device driver software) directly from the manufacturer of the smart card reader. Microsoft neither supports nor recommends the use of non-Plug and Play smart card readers.

For instructions on installing smart card readers, refer to the manufacturer's materials that are provided with the reader, or see Install a smart card reader on a computer.

The following smart card readers are supported by Windows XP and Windows Server 2003 family. Their drivers are installed only upon detection of the corresponding Plug and Play smart card reader hardware.

| Brand | Smart card reader | Interface | Device driver |
|---|---|---|---|
| American Express | GCR435 | USB | Grclass.sys |
| Bull | SmarTLP3 | Serial | Bulltlp3.sys |
| Compaq | Serial reader | Serial | grserial.sys |
| Gemplus | GCR410P | Serial | Grserial.sys |
| Gemplus | GPR400 | PCMCIA | Gpr400.sys |
| Gemplus | GemPC430 | USB | Grclass.sys |
| Hewlett Packard | ProtectTools | Serial | Scr111.sys |
| Litronic | 220P | Serial | Lit220p.sys |
| Schlumberger | Reflex 20 | PCMCIA | Pscr.sys |
| Schlumberger | Reflex 72 | Serial | Scmstcs.sys |
| Schlumberger | Reflex Lite | Serial | Scr111.sys |
| SCM Microsystems | SCR111 | Serial | Scr111.sys |
| SCM Microsystems | SCR200 | Serial | Scmstcs.sys |
| SCM Microsystems | SCR120 | PCMCIA | Pscr.sys |
| SCM Microsystems | SCR300 | USB | Stcusb.sys |
| Systemneeds | External | Serial | Scr111.sys |
| Omnikey AG | 2010 | Serial | Sccmn50m.sys |
| Omnikey AG | 2020 | USB | Sccmusbm.sys |
| Omnikey AG | 4000 | PCMCIA | Cmbp0wdm.sys |

# Supported smart cards

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Supported smart cards**

When you install Windows XP or the Windows Server 2003 family, support for the following smart cards is included in the default installation.

| Manufacturer | Model |
|---|---|
| Gemplus | GemSAFE 4k |
| Gemplus | GemSAFE 8k |
| Infineon | SICRYPT v2 |
| Schlumberger | Cryptoflex 4k |
| Schlumberger | Cryptoflex 8k |
| Schlumberger | Cyberflex Access 16k |

You do not need to configure anything on the client or server to use either of these cards. Cryptographic smart cards can only be obtained directly from the respective companies and not from Microsoft Corporation.

While support for these cards is included in Windows XP and the Windows Server 2003 family, other RSA-based cryptographic smart cards will also work with Windows XP and the Windows Server 2003 family, provided the card vendor has developed a cryptographic service provider (CSP) for the card using CryptoAPI and the Smart Card Software Developer's Kit, which is available through Microsoft Developer's Network (MSDN).

Smart card personal identification numbers (PINs) can be changed anytime the CSP displays the private key PIN dialog box. PIN management is the responsibility of the card CSP and the user. Windows XP and the Windows Server 2003 family do not manage PINs. For PIN management tools and instructions, contact the smart card vendor.

# Enrolling for a smart card certificate

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Enrolling for a smart card certificate**

A domain user cannot enroll for a Smart Card Logon certificate (which provides authentication) or a Smart Card User certificate (which provides authentication plus other uses of the smart card cryptography) unless a system administrator has granted the user access rights to the certificate template that is stored in Active Directory. Enrollment for a smart card certificate must be a controlled procedure, in the same manner that employee badges are controlled for purposes of identification and physical access.

The recommended method for enrolling users for smart card-based certificates and keys is through the smart card enrollment station that is integrated with Certificate Services in Windows Server 2003, Standard Edition and Windows Server 2003, Enterprise Edition.

When an enterprise certification authority (CA) is installed, the installation includes the Smart Card Enrollment station. This allows an administrator to act on behalf of a user to request and install a Smart Card Logon certificate or Smart Card User certificate on the user's smart card. Prior to using the Smart Card Enrollment station, the smart card issuer must have obtained a signing certificate based on the Enrollment Agent certificate template. The signing certificate signs the certificate request that is generated on behalf of the smart card recipient.

By default, only domain administrators are granted permission to request a certificate based on the Enrollment Agent template. A user other than a domain administrator can be granted permission to enroll for an Enrollment Agent certificate by means of Active Directory Sites and Services.

**Important**

- Once someone has an Enrollment Agent certificate, they can enroll for a certificate and generate a smart card on behalf of anyone in the organization. The resulting smart card could then be used to log on to the network and impersonate the real user.

Because of the powerful capability of the Enrollment Agent certificate, it is strongly recommended that your organization maintain very strong security policies over who has one. A scenario to minimize risk of Enrollment Agent certificate misuse would be to have one subordinate CA with very tight administrative controls in your organization that is only used to issue Enrollment Agent certificates. Once the initial Enrollment Agent certificates have been issued, the administrator of the CA can disable the issuance of Enrollment Agent certificates until they are needed again. By restricting the administrators who can operate the CA service on the subordinate CA, the service can be kept online for the generation and distribution of certificate revocation lists (CRLs) if necessary. Other CAs in the hierarchy can still issue Enrollment Agent certificates if their policy settings are changed, but you can determine whether inappropriate Enrollment Agent certificates are issued by checking the Issued Certificates log for each CA regularly.

For information on how to change the security permissions for a certificate template, see Allow subjects to request a certificate that is based on the template.

The enrollment station does not provide any card personalization functions, such as creating a file structure or setting the personal identification number (PIN), because those are card-specific functions and can only be done using specialized software provided by the smart card manufacturer.

For instructions on enrolling users for smart card certificates, see Set up a smart card for user logon. Note that users that log on to computers running a Windows 2000 operating system must have a smart card enrolled from a computer running Windows 2000. Users that log on to computers running Windows XP or Windows Server 2003, Standard Edition can have a smart card enrolled from a computer running any of these operating systems.

# Logging on to a computer with a smart card

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logging on to a computer with a smart card**

To log on to a computer with a smart card, users do not need to type CTRL+ALT+DEL. They simply insert the smart card into the smart card reader, and the computer prompts them for their personal identification number (PIN) instead of their user name and password (and, if applicable, domain).

For smart card logon procedures, see Log on to a computer with a smart card. For a list of procedures to enable logging on with a smart card, see Checklist: Deploying smart cards for logging on to Windows.

# Using smart cards with system tools

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using smart cards with system tools**

In previous versions of Windows, smart cards were primarily used for user logon. In Windows XP and the Windows Server 2003 family, smart cards can be used with a number of system tools.

For making network connections, the user interface feature for mapping network drives can now use smart cards. The corresponding command-line tool **Net** also has the ability to use smart cards to provide credentials. For more information about **Net**, see Net use. For more information about mapping network drives, see To assign a drive letter to a network computer or folder.

In a secure environment, administrators will log on with normal user accounts for most of their regular work. When administrative functions need to be performed, a separate user account's credentials must be used. This is easily achieved with the **Runas** command. Smart cards can be used to provide the credentials to the **Runas** command, providing further enhanced levels of security. For more information about **Runas**, see Runas.

Domain administrators may also use smart cards to store their credentials. One operation that requires very secure credentials is installing Active Directory. This operation can accept credentials supplied from smart cards as well as the traditional user name and password. For more information, see Using the Active Directory Installation Wizard.

# Stored User Names and Passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Stored User Names and Passwords**
Stored User Names and Passwords is a feature of Microsoft® Windows® XP and the Windows Server 2003 family that stores user names and passwords for servers. This allows a user to connect to servers using user names and passwords that are different than those used to log on to the network. The user can store these for later reuse.

- Before using Stored User Names and Passwords, see Checklist: Using Stored User Names and Passwords safely.
- For tips about using Stored User Names and Passwords, see Stored User Name and Password Best practices.
- For help with specific tasks, see Stored User Name and Password How To....
- For general background information, see Stored User Name and Password Concepts.
- For problem-solving instructions, see Stored User Name and Password Troubleshooting.

# Checklist: Using Stored User Names and Passwords safely

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Using Stored User Names and Passwords safely**

| Step | Reference |
| --- | --- |
| Ensure strong passwords are used when creating accounts for remote resources | Strong passwords |
| Ensure strong passwords are used when creating local computer or domain accounts | Strong passwords |
| Secure your computer whenever not in use | Strong passwords |
| Use a different strong password for all resources | Strong passwords |

# Stored User Name and Password Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Protect your account**

- Storing user names and passwords as part of your user account information means that anyone who has access to your account can access that stored information. Users must protect their account from misuse. Locking or logging off of computers when they not attended, providing password protection to screen savers, and ensuring the use of strong passwords are elements that contribute to the protection of the account.

  For more information on locking a computer, see To lock a computer in a domain environment.

**Use strong passwords for all accounts**

- The risk of using weak passwords is not removed by Stored User Names and Passwords. To protect against this, use strong passwords to protect against an intruder guessing or stealing the password.

  For more information, see Strong passwords.

**Change passwords regularly**

- Although a strong password can help protect against intruders, it is possible to eventually guess or steal the password of a resource. For this reason, passwords should be changed periodically. This not only minimizes chances that an intruder can guess or steal a password through lengthy password-guessing processes, but also minimizes damages when a password is compromised without the user's knowledge.

  For more information, see Change an existing password.

**Use different passwords for individual accounts**

- Stored User Names and Passwords allows the user to supply a different user name and password to each computer that is used. This provides for additional security on a per-computer basis. Using different passwords for each computer helps ensure that one guessed or stolen password does not weaken security. If an intruder is able to determine one password that is stored by Stored User Names and Passwords and all other passwords are different, the intruder is limited to the damage they can do with that single password.

**Store user names and passwords only when appropriate**

- User name and passwords that are used to access extremely sensitive resources must be protected carefully. In these cases, store the user names and passwords only for the specific logon session by choosing the appropriate option in **Logon Information Properties**.

# Stored User Name and Password How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Store a new user name and password
- Store default Microsoft .NET Passport information
- View and modify stored user names and passwords
- Delete stored user names and passwords
- Change a domain password

# Store a new user name and password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To store a new user name and password**

1. Open Stored User Names and Passwords.
2. Click **Add**, and then type the information in the spaces that are provided.

## Notes

- You must be logged on as a computer administrator to complete this procedure.
- To open Stored User Names and Passwords, click **Start**, click **Control Panel**, and then double-click **Stored User Names and Passwords**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Store default Microsoft .NET Passport information

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To store default Microsoft .NET Passport information**

1. Open .NET Passport Wizard.
2. Provide the information requested by the .NET Passport Wizard.

## Notes

- You must be logged on as a computer administrator to complete this procedure.
- You may also encounter the .NET Passport Wizard when accessing Web sites that support Passport information.
- You can only store one .NET Passport user name and password per user at a time.
- Passports can only be created or associated with your user account through this wizard. You can only change the .NET Passport properties on the .NET Passport Web site.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Stored User Name and Password Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Stored User Names and Passwords:

- Stored User Names and Passwords overview
- Benefits of Stored User Names and Passwords
- How Stored User Names and Passwords works

# Stored User Names and Passwords overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Stored User Names and Passwords overview**

When you log on to a computer running an operating system in the Microsoft® Windows Server 2003 family, you can supply a user name and password. This becomes your default security context for connecting to other computers on networks and over the Internet. However, this user name and password may not provide access to all of your resources. Stored User Names and Passwords provides a way to store these as a part of your profile.

There may be cases where you want to use different names and passwords for connecting to different resources. Examples could include:

- You want to log on to your computer with a standard account, but connect to certain computers as an administrator for maintenance and troubleshooting reasons.
- You work at home and want to use your work user name and password to connect to work-related servers.
- Your account is in a domain and you need access to computers in an untrusted domain.
- You want to access Web sites with user names and passwords that are specific to each of those sites.

For example, administrators may log on to the network using their standard user name and password but need to connect to a remote server with administrative access to perform specific functions. In this case, the user must be able to supply a different user name and password for this connection. The user may also want to store this user name and password for reuse at a later date. This is the function of Stored User Names and Passwords.

A user may also need to connect to secure Web servers using a specific user name and password. Stored User Names and Passwords allows users to connect to different Web servers using supplied user names and passwords and store them for future reuse. The user names and passwords can be either specific to a unique Web server or they can be generic so that they will be supplied when the user attempts to log on to a secured Web server.

Stored User Names and Passwords also stores saved information as part of a user's profile. This means that these user names and passwords will travel with the user from computer to computer anywhere on the network.

# Benefits of Stored User Names and Passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Benefits of Stored User Names and Passwords**

The benefits of Stored User Names and Passwords include:

- The user has a single sign-on experience.
- The user does not need to log off and on to supply multiple user names and passwords for different computers.
- The user can store any number of user names and passwords to be reused later.
- The user can store user names and passwords in a user's profile to provide portability and privacy of the user names and passwords.
- The user can supply different strong passwords for a variety of resources and store them in a single and easy-to-use location.

# How Stored User Names and Passwords works

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How Stored User Names and Passwords works**

Stored User Names and Passwords obtains its information in two ways: explicit creation and learning from the user. When users enter a user name and password for a target computer or domain, that information is stored and used when the users attempt to log on to an appropriate computer. If no stored information is available and users supply a user name and password, they have the ability to save the information. If the user decides to save the information, Stored User Names and Passwords then receives and stores it.

When Windows XP or a member of the Windows Server 2003 family attempts to connect to a new computer on the network, it supplies the current user name and password to the computer. If this is not sufficient to provide access, Stored User Names and Passwords will attempt to supply the necessary user name and password. All stored user names and passwords will be examined, from most specific to least specific as appropriate to the resource, and the connection will be attempted with those user names and passwords in that order. Because user names and passwords are read and applied in order from most to least specific, no more than one user name and password can be stored for each individual target or domain.

Stored User Names and Passwords also allows the user to save the supplied user name and password for reuse. This information is stored in a secure part of the user's profile and cannot be accessed by other users. If the user is configured to use a single profile across the enterprise, the stored user names and passwords will be retained wherever the user logs on to the network.

# Stored User Name and Password Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- My computer connects to computers with the wrong access level or account.
- My computer cannot connect to resources that were previously available.
- My computer obtains incorrect access while using a shared user account.

**My computer connects to computers with the wrong access level or account.**
**Cause:** A user name and password was stored for this account that is providing more or less access to resources than expected.

**Solution:** Remove the stored user name and password by following the steps in Delete stored user names and passwords.

**My computer cannot connect to resources that were previously available.**
**Cause:** A user name and password was stored for this account that has expired or has changed its password without updating the stored information.

**Solution:** Correct the stored user name and password by following the steps in View and modify stored user names and passwords, then try to access the resource again.

**My computer obtains incorrect access while using a shared user account.**
**Cause:** A user name and password was stored for this shared user account that provides access to this resource.

**Solution:** Remove the stored user name and password by following the steps in Delete stored user names and passwords. To ensure this problem does not reoccur, disable Stored User Names and Passwords for this shared user account by using a Group Policy object. For more information on creating Group Policy objects, see Group Policy (pre-GPMC).

# Passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Passwords**

Passwords provide the first line of defense against unauthorized access to your domain and local computers.

- For tips about using passwords, see Password Best practices.
- For help with specific tasks, see Password How To....
- For general background information, see Password Concepts.
- For problem-solving instructions, see Password Troubleshooting.

# Password Best practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

**Create an extensive defense model.**

- Educate your users about how to best protect their accounts from unauthorized attacks. For more information, see Encourage your users to follow best practices for password protection.

- Use the system key utility (Syskey) on computers throughout your network. The system key utility uses strong encryption techniques to secure account password information that is stored in the Security Accounts Manager (SAM) database.

  For more information about the system key utility, see The system key utility. For information about how to create or update a system key, see Create or update a system key.

- Define password policy that ensures that every user is following the password guidelines that you decide are appropriate. For more information, see Define password policy so that all user accounts are protected with strong passwords.

- Consider whether implementing account lockout policy is appropriate for your organization. For information about the risks involved in applying account lockout policy, see Be cautious when defining account lockout policy.

**Encourage your users to follow best practices for password protection.**

- Always use strong passwords. For more information, see Strong passwords.

- If passwords must be written down on a piece of paper, store the paper in a secure place and destroy it when it is no longer needed.

- Never share passwords with anyone.

- Use different passwords for all user accounts.

- Change passwords immediately if they may have been compromised.

- Be careful about where passwords are saved on computers. Some dialog boxes, such as those for remote access and other telephone connections, present an option to save or remember a password. Selecting this option poses a potential security threat.

**Define password policy so that all user accounts are protected with strong passwords.**

- Define the **Enforce password history** policy setting so that several previous passwords are remembered. With this policy setting, users cannot use the same password when their password expires.

- Define the **Maximum password age** policy setting so that passwords expire as often as necessary for your environment, typically, every 30 to 90 days. With this policy setting, if an attacker cracks a password, the attacker only has access to the network until the password expires.

- Define the **Minimum password age** policy setting so that passwords cannot be changed until they are more than a certain number of days old. This policy setting works in combination with the **Enforce password history** policy setting. If a minimum password age is defined, users cannot repeatedly change their passwords to get around the **Enforce password history** policy setting and then use their original password. Users must wait the specified number of days to change their passwords.

- Define a **Minimum password length** policy setting so that passwords must consist of at least a specified number of characters. Long passwords--seven or more characters--are usually stronger than short ones. With this policy setting, users cannot use blank passwords, and they have to create passwords that are a certain number of characters long.

- Enable the **Password must meet complexity requirements** policy setting. This policy setting checks all new passwords to ensure that they meet basic strong password requirements. For a full list of these requirements, see Passwords must meet complexity requirements.

- For information about how to apply or modify these policy settings, see Apply or modify password policy. For information about each of these policy settings, see Password Policy.

**Be cautious when defining account lockout policy.**

- Account lockout policy should not be applied haphazardly. While you increase the probability of thwarting an unauthorized attack on your organization with account lockout policy, you can also unintentionally lock out authorized users, which can be quite costly for your organization.

- If you decide to apply account lockout policy, set the **Account lockout threshold** policy setting to a high enough number that authorized users are not locked out of their user accounts simply because they mistype a password.

- Authorized users can be locked out if they change their passwords on one computer, but not on another computer. The computer that is still using the old password will continuously attempt to authenticate the user with the wrong password, and it will eventually lock out the user account. This might be a costly consequence of defining account lockout policy, because the authorized users cannot access network resources until their accounts are restored. This issue does not exist for organizations that only use domain controllers that are running Windows Server 2003 family operating systems.

- For more information about account lockout policy, see Account lockout policy overview. For information about how to apply or modify account lockout policy, see Apply or modify account lockout policy.

# Password How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Change an existing password
- Reset a password
- Reset a local user account password with a password reset disk
- Create a password reset disk
- Apply or modify password policy
- Apply or modify account lockout policy
- Create or update a system key

# Change an existing password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change an existing password**

1. Press CTRL+ALT+DEL.
2. Click **Change Password**.
3. In **User name**, type the user name of the account that you want to change the password for.
4. In **Old Password**, type the existing password.
5. In **New Password** and in **Confirm New Password**, type the new password, and then click **OK**.

**Note**

- Performing this task does not require you to have administrative credentials. Therefore, as a security best practice, consider performing this task as a user without administrative credentials.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Reset a password

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset a password**

- For a local user account
- For a domain user account, and you are on a member server or a workstation that is joined to the domain
- For a domain user account, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

**For a local user account**

1. Open Computer Management (Local).
2. In the console tree, double-click **Local Users and Groups**.

   **Where?**

   - Computer Management (Local)/System Tools/Local Users and Groups

3. In the console tree, click **Users**.
4. In the details pane, right-click the user name, and then click **Set Password**.
5. Read the warning message, and then, if you want to continue, click **Proceed**.
6. In **New password** and in **Confirm password**, type a new password, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. Power Users can reset passwords of accounts they create. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**For a domain user account, and you are on a member server or a workstation that is joined to the domain**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Active Directory Users and Computers**, and then click **Add**.
4. Click **Close**, and then click **OK**.
5. In the console tree, click **Users**.

**Where?**

- Active Directory Users and Computers/*Domain name*/Users

6. In the details pane, right-click the user name, and then click **Reset Password**.

7. Type a new password in **New password** and in **Confirm password**, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

#### For a domain user account, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

1. Open Active Directory Users and Computers.

2. In the console tree, click **Users**.

   **Where?**

   - Active Directory Users and Computers/*Domain name*/Users

3. In the details pane, right-click the user name, and then click **Reset Password**.

4. Type a new password in **New password** and in **Confirm password**, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

### Caution

- After a user's password is reset, some types of information are no longer accessible, including the following:

  - E-mail that is encrypted with the user's public key

  - Internet passwords that are saved on the computer

  - Files that the user has encrypted

  To prevent data loss when you reset a local user account password, use a password reset disk to reset the password. For more information about password reset disks, see Related Topics.

- Because data can be lost when passwords are reset, use this procedure only if there is no other way to access the account.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a password reset disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a password reset disk**

1. Press CTRL+ALT+DEL, and then click **Change Password**.
2. In **User name**, type the user name of the account that you want to create a password reset disk for.
3. In **Log on to**, click your *LocalComputerName*.
4. Click **Backup**.
5. Follow the steps in the Forgotten Password Wizard until the procedure is complete. Store the password reset disk in a safe and secure place.

## Notes

- Password reset disks can only be used for local computer accounts, not for domain accounts. For information on how to reset passwords for domain accounts, see "Reset a password" in Related Topics.
- You cannot change your password and create a password reset disk at the same time. If you type a new password in **New Password** and in **Confirm New Password** before you click **Backup**, the new password information is not saved. When the wizard prompts you for your current user account password, you must type the old password. You can change your password after you create the password reset disk.
- You can change your password any time after you create a password reset disk. You do not have to create a new password reset disk if you change your password or if the password is reset manually.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Reset a password

# Reset a local user account password with a password reset disk

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reset a local user account password with a password reset disk**

1. Start your computer, or log off from it.
2. At the **Welcome to Windows** dialog box, press CTRL+ALT+DEL. In **User name**, type your user name, and then click **OK**. The **Logon Failed** dialog box appears.
3. Click **Reset**, and then insert your password reset disk into drive A.
4. Follow the instructions in the Password Reset Wizard to create a new password.
5. Log on to your computer with the new password, and then store your password reset disk in a safe place, in case you need it to reset your password in the future. It is not necessary to make a new password reset disk when you change your password.

## Notes

- Follow the steps in this procedure if you are logging on to a local or workgroup environment. For information about how to reset a forgotten password if you are in a domain environment, see "Reset a password" in Related Topics.
- A password reset disk must have been created for the local account for the **Logon Failed** dialog box to appear. If a password reset disk has not been created, the **Logon Message** dialog box appears, informing you that your logon information is incorrect. If a password reset disk has not been created, and the user account password has been forgotten, you must reset the password to access the user account. For more information about resetting passwords, see "Reset a password" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Apply or modify password policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify password policy**

- For a local computer
- For a domain, and you are on a member server or a workstation that is joined to the domain
- For a domain, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

**For a local computer**

1. Open Local Security Settings.
2. In the console tree, click **Password Policy**.

   **Where?**

   - Security Settings/Account Policies/Password Policy

3. In the details pane, right-click the policy setting that you want, and then click **Properties**.
4. Select the options that you want, and then click **OK**.

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For a domain, and you are on a member server or a workstation that is joined to the domain**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. In **Select Group Policy Object**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object (GPO) in the appropriate domain, site, or organizational unit--or create a new one, click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, click **Password Policy**.

**Where?**

- *Group Policy Object* [*computer name*] Policy/Computer Configuration/Windows Settings/Security Settings/Account Policies/Password Policy

8. In the details pane, right-click the policy setting that you want, and then click **Properties**.
9. If you are defining this policy setting for the first time, select the **Define this policy setting** check box.
10. Select the options that you want, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

#### For a domain, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

1. Open Active Directory Users and Computers.
2. In the console tree, right-click the domain or organizational unit that you want to set Group Policy for.
3. Click **Properties**, and then click the **Group Policy** tab.
4. Click an entry in **Group Policy Object Links** to select an existing Group Policy object (GPO), and then click **Edit**. You can also click **New** to create a new GPO, and then click **Edit**.
5. In the console tree, click **Password Policy**.

   **Where?**

   - *Group Policy Object* [*computer name*] Policy/Computer Configuration/Windows Settings/Security Settings/Account Policies/Password Policy

6. In the details pane, right-click the policy setting that you want, and then click **Properties**.
7. If you are defining this policy setting for the first time, select the **Define this policy setting** check box.
8. Select the options that you want, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

**Note**

- Password policy ensures that all users are creating passwords that adhere to the guidelines set by administrators. For more information about each of the password policy settings, see "Password policy" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Apply or modify account lockout policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify account lockout policy**

- For a local computer
- For a domain, and you are on a member server or a workstation that is joined to a domain
- For a domain, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

**For a local computer**

1. Open Local Security Settings.
2. In the console tree, click **Account Lockout Policy** (console tree location is: Security Settings/Account Policies/Account Lockout Policy).
3. In the details pane, right-click the policy setting that you want, and then click **Properties**.
4. Select the options that you want, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open Local Security Policy, click **Start**, point to **Settings**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Local Security Policy**.

**For a domain, and you are on a member server or a workstation that is joined to a domain**

1. Open Microsoft Management Console (MMC).
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. In **Select Group Policy Object**, click **Browse**.
5. In **Browse for a Group Policy Object**, select a Group Policy object in the appropriate domain, site, or organizational unit--or create a new one, click **OK**, and then click **Finish**.
6. Click **Close**, and then click **OK**.
7. In the console tree, click **Account Lockout Policy** (console tree location is: *Group Policy Object* [*computer name*] Policy/Computer Configuration/Windows Settings/Security Settings/Account Policies/Account Lockout Policy).
8. In the details pane, right-click the policy setting that you want, and then click **Properties**.
9. If you are defining this policy setting for the first time, select the **Define this policy setting** check box.

10. Select the options that you want, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.

#### For a domain, and you are on a domain controller or on a workstation that has the Windows Server 2003 Administration Tools Pack installed

1. Open Active Directory Users and Computers.

2. In the console tree, right-click the domain or organizational unit that you want to set Group Policy for.

3. Click **Properties**, and then click the **Group Policy** tab.

4. Click an entry in **Group Policy Object Links** to select an existing Group Policy object (GPO), and then click **Edit**. You can also click **New** to create a new GPO, and then click **Edit**.

5. In the console tree, click **Account Lockout Policy** (console tree location is: *Group Policy Object* [*computer name*] Policy/Computer Configuration/Windows Settings/Security Settings/Account Policies/Account Lockout Policy).

6. In the details pane, right-click the policy setting that you want, and then click **Properties**.

7. If you are defining this policy setting for the first time, select the **Define this policy setting** check box.

8. Select the options that you want, and then click **OK**.

### Notes

- To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.

- To open Active Directory Users and Computers, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Active Directory Users and Computers**.

### Caution

- When account lockout policy is enabled, there is a risk of locking out legitimate users. To avoid locking out legitimate users who have simply mistyped or misremembered their passwords, set the account lockout threshold to a high number.

  Also, if a password is changed on one computer, but the user is logged on to another computer with the old password, the computer with the old password continuously attempts to authenticate the user by using the old password, and it eventually locks out the user account. This issue does not exist for organizations that only use domain controllers that are running Windows Server 2003 family operating systems.

### Note

- For more information about each of the account lockout policy settings, see "Account Lockout Policy" in Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create or update a system key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create or update a system key**

1. Click **Start**, click **Run**, type **syskey**, and then click **OK**.
2. Click **Encryption Enabled**, and then click **Update**.
3. Click the option that you want, and then click **OK**.

   For information about each option, see "The system key utility" in Related Topics.

## Notes

- Different administrative credentials are required to perform this procedure, depending on your environment:
  - If you create or update a system key for your local computer: To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
  - If you create or update a system key for a domain controller: To perform this procedure, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory, or you must have been delegated the appropriate authority. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- If the disk that stores the system key is lost, or if the system key password is forgotten, you cannot start the computer without restoring the registry to the state it was in before the system key was used. For more information on restoring the registry, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

This section covers:

- Strong passwords
- Password reset disks
- Preventing data loss from password resets
- Account lockout policy overview
- The system key utility

# Strong passwords

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Strong passwords**

The role that passwords play in securing an organization's network is often underestimated and overlooked. Passwords provide the first line of defense against unauthorized access to your organization. The Microsoft® Windows Server 2003 family has a new feature that checks the complexity of the password for the Administrator account during setup of the operating system. If the password is blank or does not meet complexity requirements, the **Windows Setup** dialog box appears, warning you of the dangers of not using a strong password for the Administrator account. If you leave this password blank, you will not be able to access this account over the network.

Weak passwords provide attackers with easy access to your computers and network, while strong passwords are considerably harder to crack, even with the password-cracking software that is available today. Password-cracking tools continue to improve, and the computers that are used to crack passwords are more powerful than ever. Password-cracking software uses one of three approaches: intelligent guessing, dictionary attacks, and brute-force automated attacks that try every possible combination of characters. Given enough time, the automated method can crack any password. However, strong passwords are much harder to crack than weak passwords. A secure computer has strong passwords for all user accounts.

A weak password:

- Is no password at all.
- Contains your user name, real name, or company name.
- Contains a complete dictionary word. For example, *Password* is a weak password.

A strong password:

- Is at least seven characters long.
- Does not contain your user name, real name, or company name.
- Does not contain a complete dictionary word.
- Is significantly different from previous passwords. Passwords that increment (*Password1*, *Password2*, *Password3* ...) are not strong.
- Contains characters from each of the following four groups:

| Group | Examples |
|---|---|
| Uppercase letters | A, B, C ... |
| Lowercase letters | a, b, c ... |
| Numerals | 0, 1,2, 3, 4, 5, 6, 7, 8, 9 |
| Symbols found on the keyboard (all keyboard characters not defined as letters or numerals) | ` ~ ! @ # $ % ^ & * ( ) _ + - = { } \| \ : " ; ' < > ? , . / |

An example of a strong password is *J*p2leO4>F*.

A password can meet most of the criteria of a strong password but still be rather weak. For example, *Hello2U!* is a relatively weak password even though it meets most of the criteria for a strong password and also meets the complexity requirements of password policy. *H!elZl2o* is a strong password because the dictionary word is interspersed with symbols, numbers, and other letters. It is important to educate users about the benefits of using strong passwords and to teach them how to create passwords that are actually strong.

You can create passwords that contain characters from the extended ASCII character set. Using extended ASCII characters increases the number of characters that you can choose when you create a password. As a result, it might take more time for password-cracking software to crack passwords that contain these extended ASCII characters than it does to crack other passwords. Before using extended ASCII characters in your password, test them thoroughly to make sure that passwords containing extended ASCII characters are compatible with the applications that your organization uses. Be especially cautious about using extended ASCII characters in passwords if your organization uses several different operating systems.

You can find extended ASCII characters in Character Map. Some extended ASCII characters should not be used in passwords. Do not use a character if a keystroke is not defined for it in the lower-right corner of the **Character Map** dialog box. For more information about how to use Character Map, see Using Character Map.

Examples of passwords that contain characters from the extended ASCII character set are *kUµ!¶0o* and *Wf©$0k#»g¤5ªrd*.

You can implement a password policy setting that enforces password complexity requirements. For more information about this policy setting, see Passwords must meet complexity requirements. For information about how to apply a password policy, see Apply or modify password policy.

Windows passwords can be up to 127 characters long. However, if you are on a network that also has computers running Windows 95 or Windows 98, consider using passwords that are not longer than 14 characters. Windows 95 and Windows 98 support passwords of up to 14 characters. If your password is longer, you might not be able to log on to your network from those computers.

For more information about passwords, see Passwords.

# Password reset disks

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Password reset disks**

It is not unusual for users to forget their passwords to local user accounts from time to time, especially when they use strong passwords. Before the advent of password reset disks, the only way for administrators to restore a forgotten local user account password was to manually reset the user's password. In the process, the following information was lost:

- E-mail that was encrypted with the user's public key
- Internet passwords that were saved on the computer
- Files that the user had encrypted

Password reset disks offer another solution to the problem of a forgotten password for a local user account. If users create password reset disks for their local accounts before they forget their passwords, they can reset the passwords without losing valuable data that was lost previously with administrative password resets.

When you create a password reset disk, a public key and private key pair are created. The private key is stored on a disk: the password reset disk. The public key encrypts the local user account password. If users forget their passwords, they can insert the password reset disk, which contains the private key, and decrypt the current password. The Forgotten Password Wizard prompts the user for a new password, which is then encrypted with the public key. Data is not lost because, basically, the user is simply changing a password. It is essential that password reset disks be stored in secured locations. For more information on how to create a password reset disk, see Create a password reset disk.

For more information about encryption, see Encryption. For more information about passwords, see Passwords.

# Preventing data loss from password resets

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Preventing data loss from password resets**
To keep protected information secure, after a user's password is reset, some types of information are no longer accessible, including the following:

- E-mail that is encrypted with the user's public key
- Internet passwords that are saved on the computer
- Files that the user has encrypted

To avoid such data loss, do not reset a user's password. When a new local user account is created, have the user create a password reset disk. Then, if the user forgets the password, the password reset disk can be used to reset the password without data loss. If a user forgets the password to a domain user account, the password must be reset manually.

For more information about how to create a password reset disk, see Create a password reset disk.

# Account lockout policy overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Account lockout policy overview**

Account lockout policy disables a user account if an incorrect password is entered a specified number of times over a specified period. These policy settings help you to prevent attackers from guessing users' passwords, and they decrease the likelihood of successful attacks on your network. For more information about how to implement account lockout policy, see Apply or modify account lockout policy.

Before you enable account lockout policy, it is important to realize that there is a risk of unintentionally locking authorized users out of their accounts. Such a result can be quite costly for your organization, because locked-out users cannot access their user accounts until the account unlocks automatically after a specified amount of time or until you unlock the accounts for them.

Authorized users can lock themselves out of an account by mistyping their password or by remembering it incorrectly, or by changing their password on a computer while they are logged on to another computer. The computer with the incorrect password continuously tries to authenticate the user, and because the password it is using to authenticate is incorrect, the user account is eventually locked out. This issue does not exist for organizations that only use domain controllers that are running Windows Server 2003 family operating systems. To avoid locking out authorized users, set the account lockout threshold to a high number. Remember, however, that the scenario in which a computer continuously tries to authenticate a user with an incorrect password is very similar to the behavior that is employed by password-cracking software. Setting the account lockout threshold high enough that the authorized user will not be locked out in this situation may inadvertently allow unauthorized access to your network by hackers. For more information about the account lockout threshold, see Account lockout threshold.

For more information about passwords and their policies, see Passwords.

# The system key utility

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**The system key utility**

Password information for user accounts is stored in the Security Accounts Manager (SAM) database of the registry on workstations and member servers. On domain controllers, password information is stored in directory services. It is not unusual for password-cracking software to target the SAM database or directory services to access passwords for user accounts. The system key utility (Syskey) provides an extra line of defense against password-cracking software. It uses strong encryption techniques to secure account password information that is stored in the SAM database or in directory services. Cracking encrypted account passwords is more difficult and time consuming than cracking nonencrypted account passwords. For more information on encryption, see Encryption.

There are three system key options in the **Startup Key** dialog box that are designed to meet the needs of different environments, as described in the following table.

| System key option | Relative security level | Description |
|---|---|---|
| **System Generated Password, Store Startup Key Locally** | Secure | Uses a computer-generated random key as the system key and stores an encrypted version of the key on the local computer. This option provides strong encryption of password information in the registry, and it enables the user to restart the computer without the need for an administrator to enter a password or insert a disk. |
| Administrator generated password, **Password Startup** | More secure | Uses a computer-generated random key as the system key and stores an encrypted version of the key on the local computer. The key is also protected by an administrator-chosen password. Users are prompted for the system key password when the computer is in the initial startup sequence. The system key password is not stored anywhere on the computer. |
| **System Generated Password, Store Startup Key on Floppy Disk** | Most secure | Uses a computer-generated random key and stores the key on a floppy disk. The floppy disk that contains the system key is required for the system to start, and it must be inserted at a prompt during the startup sequence. The system key is not stored anywhere on the computer. |

For information on how to implement the system key utility on a computer, see Create or update a system key.

Use of the system key utility is optional. If the disk that contains the system key is lost, or if the password is forgotten, you cannot start the computer without restoring the registry to the state it was in before the system key was used. For information on restoring the registry, see Restore the registry.

# Password Troubleshooting

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Troubleshooting**
What problem are you having?

- I changed the password policy, but the changes have not taken effect.
- When I define a policy setting in account lockout policy, the Suggested Value Changes dialog box opens, suggesting that I change my other policy settings.
- I am trying to log on to Windows 95, Windows 98, or another product, and the password is not working.

**I changed the password policy, but the changes have not taken effect.**
**Cause:** Policy settings have not been updated.

**Solution:** Click **Start**, click **Run**, type **gpupdate**, and then click **OK**. This refreshes policy settings, and it updates the changes to password policy on the computer.

**See also:** Gpupdate

**When I define a policy setting in account lockout policy, the Suggested Value Changes dialog box opens, suggesting that I change my other policy settings.**
**Cause:** **Account lockout duration** must be greater than or equal to the time defined in **Reset account lockout counter after**. If you define the policy settings so that the **Reset account lockout counter after** time is greater than **Account lockout duration**, the **Suggested Value Changes** dialog box appears, reminding you to change the policy settings so that they adhere to the policy setting guidelines.

**Solution:** In the **Suggested Value Changes** dialog box, click **OK** to change the policy settings to the suggested values, or click **Cancel**, and then define the policy settings yourself.

**See also:** Account Lockout Policy; Apply or modify account lockout policy

**I am trying to log on to Windows 95, Windows 98, or another product, and the password is not working.**
**Cause:** The password is longer than 14 characters. Windows 95 or Windows 98 computers only recognize passwords that are 14 characters or less.

**Solution:** Log on to another computer and change the password so that it is 14 characters or less.

**See also:** Change an existing password; Strong passwords

**Cause:** The system that you are using does not support unusual characters, such as spaces or characters in the extended ASCII character set.

**Solution:** Log on to another computer and change the password so that it does not contain these special characters.

**See also:** Change an existing password; Strong passwords

# Access Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Access control**
In order to secure a computer and its resources, you must take into consideration what rights users will have. You can secure a computer or multiple computers by granting users or groups specific user rights. You can secure an object, such as a file or folder, through assigning permissions to allow users or groups to perform specific actions on that object.

- For tips about access control, see Access Control Best Practices.
- For help with specific tasks, see Access Control How To....
- For general background information, see Access Control Concepts.

# Access Control Best Practices

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices**

- Best practices for permissions and user rights
- Best practices for assigning permissions on Active Directory objects

# Best practices for permissions and user rights

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for permissions and user rights**

**Assign permissions to groups rather than to users**

- Because it is inefficient to maintain user accounts directly, assigning permissions on a user basis should be the exception.

**Deny permissions should be used for certain special cases**

- Use Deny permissions to exclude a subset of a group which has Allowed permissions.
- Use Deny to exclude one special permission when you have already granted full control to a user or group.

**Use security templates**

- Rather than set individual permissions, use security templates whenever possible. For information on security templates, see Security Templates.

**If possible, avoid changing the default permission entries on file system objects, particularly on system folders and root folders**

- Changing default permissions can cause unexpected access problems or reduce security.

**Never deny the Everyone group access to an object**

- If you deny everyone permission to an object, that includes administrators. A better solution would be to remove the Everyone group, as long as you give other users, groups, or computers permissions to that object.

**Assign permissions to an object as high on the tree as possible and then apply inheritance to propagate the security settings through the tree**

- You can quickly and effectively apply access control settings to all children or a subtree of a parent object. By doing this, you gain the greatest breadth of effect with the least effort. The permission settings you establish should be adequate for the majority of users, groups, and computers.

**Privileges can sometimes override permissions**

- Privileges and permissions may disagree, and you should know what happens if they do. For more information, see Privileges.

**For permissions on Active Directory objects, make sure you understand the best practices specific to Active Directory objects**

- Active Directory has its own set of best practices regarding permissions. For more information, see Best practices for assigning permissions on Active Directory objects

  For more information, see Assign user rights for your local computer and Set, view, change, or remove permissions on files and folders.

  **Notes**

  - Inherited Deny permissions do not prevent access to an object if the object has an explicit Allow permission entry.

- Explicit permissions take precedence over inherited permissions, even inherited Deny permissions.

# Best practices for assigning permissions on Active Directory objects

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Best practices for assigning permissions on Active Directory objects**
For information on security and access control in Active Directory, see Securing Active Directory and Access control in Active Directory.

**If possible, avoid changing the default permissions on Active Directory objects**

- Changing default permissions could cause unexpected access problems or reduce security.

**Avoid granting Full Control permissions over an object or organizational unit**

- Granting someone Full Control allows them to take ownership of an object and modify the permissions on it. If someone has Full Control on a container, then they can Take Ownership of, and have Full Control over, all objects in that container. As far as possible, instead of allowing Full Control, give only the permissions needed by the user.

**Minimize the number of access control entries that apply to child objects**

- When using the Apply Onto option to control inheritance, be aware that not only will the specified objects inherit that access control entry (ACE) but *all* child objects will also receive a copy of that ACE. If there are enough objects that will get copies of this ACE, then that increased amount of data can cause performance problems on your network.

**When possible, assign the same set of permissions to multiple objects**

- Access control lists (ACLs) in the Windows Server 2003 family feature single-instancing: If multiple objects have identical access control lists (ACLs), then Active Directory will only store one instance of the ACL. For more information on how inheritance works for Active Directory objects, see Changing inherited permissions.

**When possible, assign access rights on a broad level rather than assigning individual user rights**

- Minimizing the number of access control entries will improve performance.
- Allow "Read All Properties" or "Write All Properties" rather than individual properties.
- Allow Read or Write access to property sets rather than individual properties.

  A property set is a collection of attributes. For example, the Personal Information property set includes the attribute's address, personal title, and so on. By setting access on the property set, you have automatically set access on all the attributes contained in that property set.
- Allow "Create All Child Objects" or "Delete All Child Objects," rather than specifying individual child objects.
- Allow "All Extended Rights" rather than allowing the individual extended rights.
- Allow "All Validated Writes" rather than allowing the individual validated rights.

**Note**

- There are times when assigning individual permissions is appropriate. For example, if a Help Desk operator needs Write access to two properties of a User object, then it makes sense to use one access control entry (ACE) for each of them, rather than trying use only one ACE by granting write access to the entire user object.

**Whenever possible, assign permissions to groups rather than users**

- Use groups to delegate authority over the directory. If one set of users needs Read permissions, and another set of users needs Change permissions, then create one group for each set of users and assign the permission to the group. If multiple global groups need the same access, create a local group containing the global groups and assign permissions to the local group.

  For more information, see Active Directory object permissions.

  **Caution**

  - The operation of your domain may become impaired if the total size of all the Active Directory permissions approaches the disk storage or processing speed capacity of your domain controller. Minimize the number of individual permissions that are propagated to child objects.

## Notes

- Inherited Deny permissions do not prevent access to an object if the object has an explicit Allow permission entry.

- Explicit permissions take precedence over inherited permissions, even inherited Deny permissions.

# Access Control How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Set, View, Change, or Remove Permissions on an Object
- Secure a file or folder
- Apply or modify permission entries for objects using Group Policy
- Take ownership of a file or folder
- View effective permissions on files and folders

# Set, View, Change, or Remove Permissions on an Object

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set, view, change, or remove permissions on an object**

- Set, view, change, or remove permissions on files and folders
- Set, view, change, or remove special permissions
- Set permissions on a shared resource
- Assign permissions to a registry key
- Set or remove permissions for a printer
- Change the permissions a user or group has to a connection
- Authorize WMI users and set permissions

# Set, view, change, or remove permissions on files and folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set, view, change, or remove permissions on files and folders**

1. Open Windows Explorer.
2. Right-click the file or folder for which you want to set permissions, click **Properties**, and then click the **Security** tab.
3. Do one of the following:
   - To set permissions for a group or user that does not appear in the **Group or user names** box, click **Add**. Type the name of the group or user you want to set permissions for and then click **OK**.
   - To change or remove permissions from an existing group or user, click the name of the group or user.
4. Do one of the following:
   - To allow or deny a permission, in the **Permissions for *User or Group*** box, select the **Allow** or **Deny** check box.
   - To remove the group or user from the **Group or user names** box, click **Remove**.

**Notes**

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- In the Windows Server 2003 family, the Everyone group no longer includes Anonymous Logon.
- You can only set file and folder permissions on drives formatted to use NTFS.
- To change permissions, you must be the owner or have been granted permission to do so by the owner.
- Groups or users that are granted Full Control for a folder can delete files and subfolders within that folder, regardless of the permissions that protect the files and subfolders.
- If the check boxes under **Permissions for *User or Group*** are shaded or if the **Remove** button is unavailable, then the file or folder has inherited permissions from the parent folder. For more information on how inheritance affects files and folders, see Related Topics.
- When adding a new user or group, by default, this user or group will have **Read & Execute**, **List Folder Contents**, and **Read** permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set, view, change, or remove special permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set, view, change, or remove special permissions**

1. Right-click the object you want to set advanced or special permissions on, click **Properties**, and then click the **Security** tab.

2. Click **Advanced**, and then do one of the following:

| To | Do this |
|---|---|
| Set special permissions for an additional group or user | • Click **Add**.<br>• In **Enter than object name to select (examples)**, type the name of the user or group, and then click **OK**. |
| View or change special permissions for an existing group or user | Click the name of the group or user, and then click **Edit**. |
| Remove an existing group or user and its special permissions | Click the name of the group or user and then click **Remove**. If the **Remove** button is unavailable, clear the **Inherit from parent the permission entries that apply to child objects. Include these with entries explicitly defined here** check box, and then click **Remove**. |

3. In the **Permissions** box, select or clear the appropriate **Allow** or **Deny** check boxes.

4. In **Apply onto**, click the folders or subfolders you would like these permissions to be applied to.

5. To configure security so that the subfolders and files will not inherit these permissions, clear the **Apply these permissions to objects and/or containers within this container only** check box.

6. Click **OK**, and then, in **Advanced Security Settings for *ObjectName***, click **OK**.

**Caution**

- If you select the **Replace permission entries on all child objects with entries shown here that apply to child objects** check box, then all subfolders and files will have all of their permission entries reset to those inheritable from the parent object. Once you click **Apply** or **OK**, you cannot undo this operation by clearing the check box.

**Notes**

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.

- The Everyone group no longer includes the Anonymous Logon permission.

- If you select the **Inherit from parent the permission entries that apply to child objects. Include these with entries explicitly defined here** check box, then this file or folder will inherit permission entries from the parent object.

- You can only set permissions only on drives formatted to use NTFS.

- If the check boxes under **Permissions** are shaded, the permissions are inherited from the parent folder.

- To change permissions, you must be the owner or have been granted permission to do so by the owner.

- Groups or users that have been granted Full Control for a folder can delete files and subfolders within that folder, regardless of the permissions that protect the files and subfolders.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set permissions on a shared resource

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set permissions on a shared resource**

- Using Shared Folders
- Using Windows Explorer

**Using Shared Folders**

1. To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.
2. In the console tree, click **Shares**.

   **Where?**

   - Computer Management/System Tools/Shared Folders/Shares

3. In the details pane, right-click the shared resource that you want to set permissions for, and then click **Properties**.
4. On the **Share Permissions** tab, make any of the following changes, and then click **OK**:

   - To assign permissions to a user or group for a shared resource, click **Add**. In the **Select Users, Computers, or Groups** dialog box, look for or type the user or group name, and then click **OK**.
   - To revoke access to the shared resource, click **Remove**.
   - To set individual permissions for the user or group, in the **Permissions for***group or user* box, select the **Allow** or **Deny** check boxes.

**Note**

- To open Computer Management, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Computer Management**.

**Using Windows Explorer**

1. Open Windows Explorer.
2. Right-click the shared folder or drive that you want to set permissions for, and then click **Sharing and Security**.
3. On the **Sharing** tab, click **Permissions**, make any of the following changes, and then click **OK**:

   - To assign permissions to a user or group for a shared resource, click **Add**. In the **Select Users, Computers, or Groups** dialog box, look for or type the user or group name, and then click **OK**.
   - To revoke access to a shared resource, click **Remove**.
   - To set individual permissions for the user or group, in the **Permissions for** *group or user* box, select the **Allow** or **Deny** check boxes.

### Note

- To open a Control Panel item, click **Start**, click **Control Panel**, and then double-click the appropriate icon.

### Important

- Share permissions apply only to users who gain access to the resource over the network. They do not apply to users who log on locally, such as on a terminal server. In these cases, use access control on the NTFS file system to set permissions. For more information, see Related Topics.

### Notes

- You must be logged on as a member of the Administrators group, Server Operators group, or Power Users group to complete this procedure. If your computer is connected to a network, network policy settings might also prevent you from completing this procedure.

- You can use Shared Folders to manage shared resources on both local and remote computers. For information about how to connect to another computer, see Related Topics. With Windows Explorer and the command line, you can manage shared resources on your local computer only.

- When permissions have been assigned both to the shared resource and at the file system level, the more restrictive permission always applies.

- It is usually easier to assign permissions to groups and then add users to groups, rather than assigning identical permissions to individual users.

- If you change permissions on special shared resources, such as ADMIN$, the default settings may be restored when the Server service is stopped and restarted or when the computer is restarted. Note that this does not apply to user-created shared resources whose share name ends in $. For more information about special shared resources, see Related Topics.

- File sharing options may be limited if simple file sharing is enabled. For more information about simple file sharing, see article Q304040, "How to configure file sharing in Windows XP," in the Microsoft Knowledge Base.

#### Information about functional differences

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign permissions to a registry key

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign permissions to a registry key**

1. Open Registry Editor.
2. Click the key to which you want to assign permissions.
3. On the **Edit** menu, click **Permissions**.
4. Assign an access level to the selected key as follows:
   - To grant the user permission to read the key contents, but not save any changes made to the file, under Permissions for *name*, for **Read**, select the **Allow** check box.
   - To grant the user permission to open, edit, and take ownership of the selected key, under Permissions for *name*, for **Full Control**, select the **Allow** check box.
   - To grant the user special permission in the selected key, click **Advanced**.
5. If you are assigning permissions to a subkey and you want the inheritable permissions assigned to the parent key to apply to the subkey also, click **Advanced** and select the **Inherit from parents the permission entries that apply to child objects. Include these with entries explicitly defined here** check box.

### Caution

- Incorrectly editing the registry may severely damage your system. Before making changes to the registry, you should back up any valued data on your computer.

### Notes

- To open Registry Editor, click **Start**, click **Run**, type **regedit**, and then click **OK**.
- You must have appropriate permissions to make changes to a registry key. To maintain security when making changes to a registry key for which you need administrative credentials, log in as a member of the Users group and run Regedit as an administrator by right-clicking the **Regedit** icon, clicking **Run as**, and clicking an account in the local Administrators group. The **Regedit** icon does not appear by default from the **Start** menu. To access the icon, open the Windows or WINNT folder on your computer.
- If you own a registry key, you can specify the users and groups that can open that key. To determine who can open your registry keys, you need to assign permissions to them. You can add or remove users or groups from those authorized to access your registry keys at any time.
- The **Special Permissions** check boxes indicate whether custom permissions have been set for this key, but you cannot set special permissions by clicking these check boxes. Click **Advanced** to set special permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Set or remove permissions for a printer

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set or remove permissions for a printer**

1. Open Printers and Faxes.
2. Right-click the printer for which you want to set permissions, click **Properties**, and then click the **Security** tab.
3. Do one of the following:
   - To change or remove permissions from an existing user or group, click the name of the user or group.
   - To set up permissions for a new user or group, click **Add**. In **Select Users, Computers, or Groups**, type the name of the user or group you want to set permissions for, and then click **OK** to close the dialog box.
4. In **Permissions**, click **Allow** or **Deny** for each permission you want to allow or deny, if necessary. Or, to remove the user or group from the permissions list, click **Remove**.

## Notes

- To change device settings, you must have the Manage Printers permission. For information about printing security permissions, see Related Topics.
- To open Printers and Faxes, click **Start**, and then click **Printers and Faxes**.
- To view or change the underlying permissions that make up Print, Manage Printers, and Manage Documents, click the **Advanced** button.
- A printer must be shared in order for the permission settings to affect the users and groups listed.
- You can also view the permissions assigned to you by clicking the group you belong to on the **Security** tab. For information on finding out what group you belong to, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Change the permissions a user or group has to a connection

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To change the permissions a user or group has to a connection**

1. Open Terminal Services Configuration.
2. In the console tree, click **Connections**.
3. In the details pane, right-click the connection for which you want to change permissions, and then click **Properties**.
4. On the **Permissions** tab, click **Advanced** to open the **Advanced Security Settings** dialog box.
5. In **Permission Entries**, select the user or group for which you want to change permissions, and then click **Edit...** to open the **Permission Entry** dialog box.
6. In **Permissions**, select or clear, as appropriate, the **Allow** or **Deny** check boxes next to the permissions you want to set for the group.

## Notes

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure. For more information, see Default local groups, Default groups, and Using Run as.
- To open Terminal Services Configuration, click **Start**, click **Control Panel**, double-click **Administrative Tools**, and then double-click **Terminal Services Configuration**.
- You must use the Remote Desktop Users group to control remote access to Terminal Server and Remote Desktop for Administration.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Authorize WMI users and set permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To authorize WMI users and set permissions**

1. Open WMI Control.
2. In the console tree, right-click **WMI Control**, and then click **Properties**.
3. Click the **Security** tab.
4. Select the namespace for which you want to give a user or group access, and then click **Security**.
5. In the **Security** dialog box, click **Add**.
6. In the **Select Users, Computers, or Groups** dialog box, enter the name of the object (user or group) that you want to add. Click the **Check Names** button to verify your entry and then click **OK**. You might have to change the location or use the **Advanced** button to query for objects. See the dialog box help for more details.
7. In the **Security** dialog box, under **Permissions**, select the permissions to allow or deny the new user or group.

| Level | Description |
|---|---|
| Execute Methods | Allows methods exported from the WMI classes or instances to be run. |
| Full Write | Allows full read, write, and delete access to all WMI objects, classes, and instances. |
| Partial Write | Allows write access to static WMI objects. |
| Provider Write | Allows write access to objects that are provided by providers. |
| Enable Account | Allows read access to WMI objects. |
| Remote Enable | Allows remote access to the namespace. |
| Read Security | Allows read-only access to WMI security information. |
| Edit Security | Allows read and write access to WMI security information. |

**Notes**

- To perform this procedure, you must be a member of the Administrators group on the local computer, or you must have been delegated the appropriate authority. If the computer is joined to a domain, members of the Domain Admins group might be able to perform this procedure. As a security best practice, consider using Run as to perform this procedure.
- To open the WMI Control console, click **Start**, click **Run**, type **wmimgmt.msc**, and then click **OK**.
- You can set permissions on a remote computer or a local computer. To access a remote computer, right-click **WMI Control**, click **Connect to another computer**, click **Another computer**, and then type the name of the computer to which you want to connect. If you are using WMI Control from the Computer Management console, right-click the **Computer Management** node to connect to the other computer.
- On computers running Windows 95, Windows 98, or Windows ME, all users have full control locally. Security settings are only relevant for remote connection to a computer running Windows 95, Windows 98, or Windows ME.
- You can delete a user's or group's authorization to access WMI services by selecting that user or group and clicking

**Remove**.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Secure a file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To secure a file or folder**

1. Open Windows Explorer, and then locate the file or folder you want to secure.
2. Right-click the file or folder, click **Properties**, and then click the **Security** tab.
3. In **Group or user names**, click the group or user that you want to change permissions for.
4. For users and groups that do not need the permission, clear the appropriate **Allow** check box, particularly for **Full Control**.
5. For the users and groups that need to use the file or folder, select the appropriate **Allow** check box for the permissions that are needed.
6. Repeat steps 3-4, as needed.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- The process of securing a file, folder, or other computer resource is sometimes called *lockdown*.
- Files and folders usually are sufficiently locked down by default.
- Incorrect permissions can cause security vulnerabilities and access problems, so locking down should be done cautiously and only when security considerations require it.
- Share permissions, not just NTFS permissions, can prevent access to a file or folder. Share permissions are not included in effective permissions calculations.
- An administrator can take ownership of any file on the computer.
- In the Windows Server 2003 family, the Everyone group no longer includes the Anonymous Logon group.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Apply or modify permission entries for objects using Group Policy

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To apply or modify permission entries for objects using Group Policy**

1. Open Microsoft Management Console.
2. On the **File** menu, click **Add/Remove Snap-in**, and then click **Add**.
3. Click **Group Policy Object Editor**, and then click **Add**.
4. In the Group Policy Wizard, on the **Select Group Policy Object** page, click **Browse**.
5. In **Browse for a Group Policy object**, do one of the following:

   - To use an existing non-local Group Policy object (GPO), select a Group Policy object in the appropriate domain, site, or organizational unit, click **OK**, and then click **Finish**.
   - To create a new non-local Group Policy object, in the **Domain, OUs and linked Group Policy Objects** box, right-click in an empty area, click **New**, type the name of the new Group Policy object, click **OK**, and then click **Finish**.

   **Note**

   - If the **Browse for a Group Policy object** dialog box has only one tab, and it has the label **Computers**, then you only have access to local Group Policy objects and you cannot complete this procedure. This probably means the computer is not joined to an Active Directory domain.

6. Click **Close**, and then click **OK**.
7. Do one or more of the following:

| To modify permission entries on | Do this |
|---|---|
| System services | • In the console tree, click **System Services**.<br><br>**Where?**<br><br>  • Computer Configuration/Windows Settings/Security Settings/System Services<br><br>• In the details pane, right-click the service you want to change, click **Properties**, select the **Define this policy setting** check box, and then click **Edit Security**. |

| | |
|---|---|
| Registry keys | • In the console tree, right-click **Registry**.<br><br>**Where?**<br><br>  • Computer Configuration/Windows Settings/Security Settings/Registry<br><br>• Click **Add Key**, in **Select Registry Key**, click the key that you want to change, and then click **OK**. |
| Files or folders | • In the console tree, right-click **File System**.<br><br>**Where?**<br><br>  • Computer Configuration/Windows Settings/Security Settings/File System<br><br>• Click **Add File**, in **Add a file or folder**, click the file or folder that you want to change, and then click **OK**. |

8. Do one of the following:

   - To set permissions for a group or user that does not appear in the **Group or user names** box, click **Add**. Type the name of the group or user you want to set permissions for, and then click **OK**.
   - To change or remove permissions from an existing group or user, click the name of the group or user.

9. Do one of the following:

   - To allow a permission, in the **Permissions for *User or Group*** box, select the **Allow** check box.
   - To deny a permission, in the **Permissions for *User or Group*** box, select the **Deny** check box.
   - To remove the group or user from **Group or user names**, click **Remove**.

**Notes**

- You must be logged on as a computer administrator to complete this procedure.
- To open Microsoft Management Console, click **Start**, click **Run**, type **mmc**, and then click **OK**.
- The security settings are refreshed every 90 minutes on a workstation or server and every 5 minutes on a domain controller. The settings are also refreshed every 16 hours, whether or not there are any changes.
- To complete this procedure, the computer must be joined to an Active Directory domain, and you must have permission to edit the Group Policy object.
- These settings are refreshed on an ongoing basis, so configuring many access control lists through Group Policy may increase the load on the network.
- In the Windows Server 2003 family, the Everyone group no longer includes Anonymous Logon.
- You can set file and folder permissions only on drives that are formatted to use NTFS.

- To change permissions, you must be the owner or have been granted permission to do so by the owner.
- For more information about permissions on other objects, see Permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Take ownership of a file or folder

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To take ownership of a file or folder**

1. Open Windows Explorer, and then locate the file or folder you want to take ownership of.
2. Right-click the file or folder, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, and then click the **Owner** tab.
4. In the **Change owner to** box, do one of the following:
   - To change the owner to a user or group that is not listed, double-click **Other users and groups** and, in **Enter the object name to select (examples)**, type the name of the user or group, and then click **OK**.
   - To change the owner to a user or group that is listed, click the new owner.
5. (Optional) To change the owner of all subcontainers and objects within the tree, select the **Replace owner on subcontainers and objects** check box.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- You can transfer ownership in two ways:
  - The current owner can grant the **Take ownership** permission to others, allowing those users to take ownership at any time. A user granted the **Take ownership** permission can take ownership of the object or assign ownership to any group that the user is a member of.
  - A user who has the **Restore files and directories** privilege can double-click **Other users and groups** and choose any user or group to assign ownership to.
- An administrator can take ownership of any file on the computer.
- In the Windows Server 2003 family, the Everyone group no longer includes the Anonymous Logon group.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# View effective permissions on files and folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To view effective permissions on files and folders**

1. Open Windows Explorer, and then locate the file or folder for which you would like to view effective permissions.
2. Right-click the file or folder, click **Properties**, and then click the **Security** tab.
3. Click **Advanced**, click the **Effective Permissions** tab, and then click **Select**.
4. In **Enter the object name to select (examples)**, enter the name of a user or group and then click **OK**. The selected check boxes indicate the effective permissions of the user or group for that file or folder.

## Notes

- To open Windows Explorer, click **Start**, point to **All programs**, point to **Accessories**, and then click **Windows Explorer**.
- If the specified object grants access to the Everyone group, the Authenticated Users group or the Local Users group, then the effective rights will always include those permissions, except when the specified user or group is the Anonymous group. Windows XP and the Windows Server 2003 family no longer include the Anonymous users in the Everyone group.
- The **Effective Permissions** tab shows information that is calculated from the existing permissions entries. Therefore, the information displayed on that page is read-only and does not support changing a user's permissions by selecting or clearing permission check boxes.
- Permissions are set only on drives formatted to use NTFS.
- **Share permissions** are not part of the effective permissions calculation. Access to shares can be denied though share permissions even when access is allowed through NTFS permissions.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Access Control Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Access Control:

- Access control overview
- Understanding Access Control
- Using Access Control
- Access Control Resources

# Access control overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Access control overview**
Access control is the process of authorizing users, groups, and computers to access objects on the network. Key concepts that make up access control are permissions, user rights, and object auditing.

**Permissions**
Permissions define the type of access granted to a user or group for an object or object property. For example, the Finance group can be granted Read and Write permissions for a file named Payroll.dat.

Permissions are applied to any secured objects such as files, Active Directory® objects, or registry objects. Permissions can be granted to any user, group, or computer. It is a good practice to assign to groups.

You can assign permissions for objects to:

- Groups, users, and Security identifiers in the domain.
- Groups and users in that domain and any trusted domains.
- Local groups and users on the computer where the object resides.

The permissions attached to an object depend on the type of object. For example, the permissions that can be attached to a file are different from those that can be attached to a registry key. Some permissions, however, are common to most types of objects. These common permissions are:

- Read permissions
- Modify permissions
- Change owner
- Delete

When you set up permissions, you specify the level of access for groups and users. For example, you can let one user read the contents of a file, let another user make changes to the file, and prevent all other users from accessing the file. You can set similar permissions on printers so that certain users can configure the printer and other users can only print from it.

If you need to change the permissions on an individual object, you can simply start the appropriate tool and change the properties for that object. For example, to change the permissions on a file, you can run Windows Explorer, right-click the file name, and click **Properties**. On the **Security** tab, you can change permissions on the file. For more information, see Permissions.

**Ownership of objects**

An owner is assigned to an object when that object is created. By default, the owner is the creator of the object. No matter what permissions are set on an object, the owner of the object can always change the permissions on an object. For more information, see Ownership.

**Inheritance of permissions**

Inheritance allows administrators to easily assign and manage permissions. This feature automatically causes objects within a container to inherit all the inheritable permissions of that container. For example, the files within a folder, when created, inherit the permissions of the folder. Only permissions marked to be inherited will be inherited.

**User rights**
User rights grant specific privileges and logon rights to users and groups in your computing environment. For information on user rights, see the following: For more information, see User rights.

**Object auditing**

You can audit users' access to objects. You can then view these security-related events in the security log with the Event Viewer. For more information, see Auditing overview.

For more information about authorization and access control, see the Windows Server 2003 Technical Reference Web site. For information about authorization strategy, see "Designing a Resource Authorization Strategy" at the Microsoft Windows Server 2003 Deployment Kit Web site.

# Understanding Access Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Understanding access control**
This section covers:

- Permissions and security descriptors
- User rights
- Explicit vs. inherited permissions
- Ownership
- Effective Permissions tool
- How inheritance affects file and folder permissions
- Security identifiers

# Permissions and security descriptors

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Permissions and security descriptors**

Every container and object on the network has a set of access control information attached to it. Known as a security descriptor, this information controls the type of access allowed to users and groups. The security descriptor is automatically created along with the container or object that is created. A typical example of an object with a security descriptor is a file.

Permissions are defined within an object's security descriptor. Permissions are associated with, or assigned to, specific users and groups. For example, for the file Temp.dat, the Administrator group might be assigned read, write, and delete permissions, while the Operator group might be assigned Read and Write permissions only.

Each assignment of permissions to a user or group is known as a permission entry, which is a type of access control entry (ACE). The entire set of permission entries in a security descriptor is known as a permission set or access control list (ACL). Thus, for a file named Temp.dat, the permission set includes two permission entries, one for the Administrator group and one for the Operator group.

# User rights

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**User rights**

Administrators can assign specific rights to group accounts or to individual user accounts. These rights authorize users to perform specific actions, such as logging on to a system interactively or backing up files and directories. User rights are different from permissions because user rights apply to user accounts, and permissions are attached to objects. For information on permissions, see How inheritance affects file and folder permissions.

User rights define capabilities at the local level. Although user rights can apply to individual user accounts, user rights are best administered on a group account basis. This ensures that a user logging on as a member of a group automatically inherits the rights associated with that group. By assigning user rights to groups rather than individual users, you simplify the task of user account administration. When users in a group all require the same user rights, you can assign the set of user rights once to the group, rather than repeatedly assigning the same set of user rights to each individual user account.

User rights that are assigned to a group are applied to all members of the group while they remain members. If a user is a member of multiple groups, the user's rights are cumulative, which means that the user has more than one set of rights. The only time that rights assigned to one group might conflict with those assigned to another is in the case of certain logon rights. In general user rights assigned to one group do not conflict with the rights assigned to another group. To remove rights from a user, the administrator simply removes the user from the group. In this case, the user no longer has the rights assigned to that group.

There are two types of user rights: privileges, such as the right to back up files and directories, and logon rights, such as the right to log on to a system locally.

For more information, see Privileges, Logon rights and Security Configuration Manager tools.

# Explicit vs. inherited permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Explicit vs. inherited permissions**

There are two types of permissions: explicit permissions and inherited permissions.

- Explicit permissions are those that are set by default when the object is created, by user action.
- Inherited permissions are those that are propagated to an object from a parent object. Inherited permissions ease the task of managing permissions and ensure consistency of permissions among all objects within a given container.

By default, objects within a container inherit the permissions from that container when the objects are created. For example, when you create a folder called MyFolder, all subfolders and files created within MyFolder automatically inherit the permissions from that folder. Therefore, MyFolder has explicit permissions, while all subfolders and files within it have inherited permissions.

**Notes**

- Inherited Deny permissions do not prevent access to an object if the object has an explicit Allow permission entry.
- Explicit permissions take precedence over inherited permissions, even inherited Deny permissions.

For more information on inherited permissions, see How inheritance affects file and folder permissions.

# Ownership

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Ownership**
Every object has an owner, whether in an NTFS volume or Active Directory. The owner controls how permissions are set on the object and to whom permissions are granted.

**Important**

- An administrator who needs to repair or change permissions on a file must begin by taking ownership of the file.

By default, in the Windows Server 2003 family, the owner is the Administrators group. The owner can always change permissions on an object, even when denied all access to the object.

Ownership can be taken by:

- An administrator. By default, the Administrators group is given the **Take ownership of files or other objects** user right.
- Anyone or any group who has the **Take ownership** permission on the object in question.
- A user who has the **Restore files and directories** privilege.

Ownership can be transferred in the following ways:

- The current owner can grant the **Take ownership** permission to another user, allowing that user to take ownership at any time. The user must actually take ownership to complete the transfer.
- An administrator can take ownership.
- A user who has the **Restore files and directories** privilege can double-click **Other users and groups** and choose any user or group to assign ownership to.

For more information, see Take ownership of a file or folder and Restore files and directories.

# Effective Permissions tool

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Effective Permissions tool**

If you would like to find out what permissions a user or group has on an object, you can use the Effective Permissions tool. It calculates the permissions that are granted to the specified user or group. The calculation takes the permissions in effect from group membership into account, as well as any permissions inherited from the parent object. It looks up all domain and local groups in which the user or group is a member.

The Everyone group will always be included, as long as the selected user or group is not a member of the Anonymous Logon group. In the Windows Server 2003 family, the Everyone group no longer includes Anonymous Logon.

**Important**

- The Effective Permissions tool only produces an approximation of the permissions that a user has. The actual permissions the user has may be different, since permissions can be granted or denied based on how a user logs on. This logon-specific information cannot be determined by the Effective Permissions tool, since the user is not logged on; therefore, the effective permissions it displays reflect only those permissions specified by the user or group and not the permissions specified by the logon.

  For example, if a user is connected to this computer via a file share, then the logon for that user is marked as a *network logon*. Permissions can be granted or denied to the well-known security ID (SID) Network which the connected user receives, so a user has different permissions when logged on locally than when logged on over a network. For information about shared folders and share permissions, see Shared Folders and Share permissions.

  For information about granting access for effective permissions, see article Q331951 in the Microsoft Knowledge Base.

**Factors that are used to determine effective permissions**

- Global group membership
- Local group membership
- Local permissions
- Local privileges

**Factors that are not used to determine effective permissions**

The following well-known SIDs that are available in the Windows Server 2003 family are not used to determine effective permissions:

- Anonymous Logon
- Batch, Creator Group
- Dialup
- Enterprise Domain Controllers
- Interactive
- Network
- Proxy

- Restricted
- Remote
- Service
- System
- Terminal Server User
- Other Organization
- This Organization

Also, share permissions are not part of the effective permissions calculation. Access to shares can be denied through share permissions even when access is allowed through NTFS permissions.

**Factors that are not used for objects that are accessed remotely**

- Local group membership
- Local privileges
- Share permissions

**Retrieving effective permissions**
Accurate retrieval of the above information requires permission to read the membership information. If the specified user or group is a domain object, you must have permission to read the object's group information on the domain. Here are some relevant default domain permissions:

- Domain administrators have permission to read membership information on all objects.
- Local administrators on a workstation or stand-alone server cannot read membership information for a domain user.
- Authenticated domain users can only read membership information when the domain is in Pre-Windows 2000 compatibility mode.

For more information, see View effective permissions on files and folders and Security identifiers.

# How inheritance affects file and folder permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How inheritance affects file and folder permissions**

After you set permissions on a parent folder, new files and subfolders that are created in the folder inherit these permissions. If you do not want them to inherit permissions, select **This folder only** in **Apply onto** when you set up special permissions for the parent folder. In cases where you want to prevent only certain files or subfolders from inheriting permissions, right-click the file or subfolder, click **Properties**, click the **Security** tab, click **Advanced**, and then clear the **Inherit from parent the permission entries that apply to child objects. Include these with entries explicitly defined here.** check box.

If the check boxes appear shaded, the file or folder has inherited permissions from the parent folder. There are three ways to make changes to inherited permissions:

- Make the changes to the parent folder, and then the file or folder will inherit these permissions.
- Select the opposite permission (**Allow** or **Deny**) to override the inherited permission.
- Clear the **Inherit from parent the permission entries that apply to child objects. Include these with entries explicitly defined here.** check box. You can then make changes to the permissions or remove the user or group from the permissions list. However, the file or folder will no longer inherit permissions from the parent folder.

In most cases, **Deny** overrides **Allow** unless a folder is inheriting conflicting settings from different parents. In that case, the setting inherited from the parent closest to the object in the subtree will have precedence.

Only inheritable permissions are inherited by child objects. When setting permissions on the parent object, you can decide whether folders or subfolders can inherit them with **Apply onto**. For more information, see Selecting where to apply permissions.

You can find out what permissions a user or group has on an object with the Effective Permissions tool.

For more information, see Set, view, change, or remove permissions on files and folders.

# Security identifiers

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Security identifiers**

Security identifiers (SIDs) are numeric values that identify a user or group. For each access control entry (ACE), there exists a SID that identifies the user or group for whom access is allowed, denied, or audited.

**Well-known security identifiers (special identities)**

| Well-known SID | Description |
|---|---|
| Anonymous Logon (S-1-5-7) | A user who has connected to the computer without supplying a user name and password. |
| Authenticated Users (S-1-5-11) | Includes all users and computers whose identities have been authenticated. Authenticated Users does not include Guest even if the Guest account has a password. |
| Batch (S-1-5-3) | Includes all users who have logged on through a batch queue facility such as task scheduler jobs. |
| Creator Owner (S-1-3-0) | A placeholder in an inheritable access control entry (ACE). When the ACE is inherited, the system replaces this SID with the SID for the object's current owner. |
| Creator Group (S-1-3-1) | A placeholder in an inheritable ACE. When the ACE is inherited, the system replaces this SID with the SID for the primary group of the object's current owner. |
| Dialup (S-1-5-1) | Includes all users who are logged on to the system through a dial-up connection. |
| Everyone (S-1-1-0) | On computers running Windows Server 2003 operating systems, Everyone includes Authenticated Users and Guest. On computers running earlier versions of the operating system, Everyone includes Authenticated Users and Guest plus Anonymous Logon.<br><br>For more information, see Differences in default security settings. |
| Interactive (S-1-5-4) | Includes all users logging on locally or through a Remote Desktop connection. |
| Local System (S-1-5-18) | A service account that is used by the operating system. |
| Network (S-1-5-2) | Includes all users who are logged on through a network connection. Access tokens for interactive users do not contain the Network SID. |
| Self (or Principal Self) (S-1-5-10) | A placeholder in an ACE on a user, group, or computer object in Active Directory. When you grant permissions to Principal Self, you grant them to the security principal represented by the object. During an access check, the operating system replaces the SID for Principal Self with the SID for the security principal represented by the object. |
| Service (S-1-5-6) | A group that includes all security principals that have logged on as a service. Membership is controlled by the operating system. |
| Terminal Server Users (S-1-5-13) | Includes all users who have logged on to a Terminal Services server that is in Terminal Services version 4.0 application compatibility mode. |

| | |
|---|---|
| Other Organization (S-1-5-1000) | Causes a check to ensure that a user from another forest or domain is allowed to authenticate to a particular service. |
| This Organization (S-1-5-15) | Added by the authentication server to the authentication data of a user, provided the Other Organization SID is not already present. |

For more information on the Administrators (S-1-5-32-544), Power Users (S-1-5-32-547), Backup operators (S-1-5-32-551), and Users (S-1-5-32-545) groups, see Default security settings for groups.

For more information, see Well-Known Security Identifiers at the Microsoft Resource Kits Web site.

# Using Access Control

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using access control**
This section covers:

- Permissions
- Permissions for files and folders
- Active Directory object permissions
- Selecting where to apply permissions
- Changing inherited permissions
- Privileges
- Logon rights

# Permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Permissions**

Each type of object is controlled by an object manager. There is a different object manager for each type of object. The object types, their object managers, and the tools you use to manage these objects are as follows:

| Object Type | Permission Descriptions | Procedures |
|---|---|---|
| Files and folders | Permissions for files and folders | Set, view, change, or remove permissions on files and folders<br><br>or<br><br>Set, view, change, or remove special permissions |
| Shares | Share permissions | Set permissions on a shared resource |
| Registry keys | Maintain Registry Security | Add users or groups to the Permissions list |
| Services | Services permissions | Local computer security for file system, registry, system services |
| Printer | Assigning printer permissions | Set or remove permissions for a printer |
| Terminal Services Connections | Managing Permissions on Connectionsor Controlling connection access | Manage Connection Permissions |
| WMI object | Authorize WMI users and set permissions | Modify permissions or delete authorized users |
| Active Directory objects | Active Directory object permissions.<br><br>Best practices for assigning permissions on Active Directory objects. | |

# Permissions for files and folders

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Permissions for files and folders**

Folder permissions include **Full Control**, **Modify**, **Read & Execute**, **List Folder Contents**, **Read**, and **Write**. For information about these permissions, see File and folder permissions. Each of these permissions consists of a logical group of special permissions which are listed and defined below.

| Permission | Description |
|---|---|
| **Traverse Folder/Execute File** | **For folders**: Traverse Folder allows or denies moving through folders to reach other files or folders, even if the user has no permissions for the traversed folders. (Applies to folders only.) Traverse folder takes effect only when the group or user is not granted the **Bypass traverse checking** user right in the Group Policy snap-in. (By default, the Everyone group is given the **Bypass traverse checking** user right.)<br><br>**For files:** Execute File allows or denies running program files. (Applies to files only).<br><br>Setting the Traverse Folder permission on a folder does not automatically set the Execute File permission on all files within that folder. |
| **List Folder/Read Data** | List Folder allows or denies viewing file names and subfolder names within the folder. List Folder only affects the contents of that folder and does not affect whether the folder you are setting the permission on will be listed. (Applies to folders only.)<br><br>Read Data allows or denies viewing data in files. (Applies to files only.) |
| **Read Attributes** | Allows or denies viewing the attributes of a file or folder, such as read-only and hidden. Attributes are defined by NTFS. |
| **Read Extended Attributes** | Allows or denies viewing the extended attributes of a file or folder. Extended attributes are defined by programs and may vary by program. |
| **Create Files/Write Data** | Create Files allows or denies creating files within the folder. (Applies to folders only).<br><br>Write Data allows or denies making changes to the file and overwriting existing content. (Applies to files only.) |
| **Create Folders/Append Data** | Create Folders allows or denies creating folders within the folder. (Applies to folders only.)<br><br>Append Data allows or denies making changes to the end of the file but not changing, deleting, or overwriting existing data. (Applies to files only.) |
| **Write Attributes** | Allows or denies changing the attributes of a file or folder, such as read-only or hidden. Attributes are defined by NTFS.<br><br>The Write Attributes permission does not imply creating or deleting files or folders, it only includes the permission to make changes to the attributes of a file or folder. In order to allow (or deny) create or delete operations, see **Create Files/Write Data**, **Create Folders/Append Data**, **Delete Subfolders and Files**, and **Delete**. |
| **Write Extended Attributes** | Allows or denies changing the extended attributes of a file or folder. Extended attributes are defined by programs and may vary by program.<br><br>The Write Extended Attributes permission does not imply creating or deleting files or folders, it only includes the permission to make changes to the attributes of a file or folder. In order to allow (or deny) create or delete operations, see **Create Files/Write Data**, **Create Folders/Append Data**, **Delete Subfolders and Files**, and **Delete**. |

| | |
|---|---|
| **Delete Subfolders and Files** | Allows or denies deleting subfolders and files, even if the Delete permission has not been granted on the subfolder or file. (Applies to folders.) |
| **Delete** | Allows or denies deleting the file or folder. If you do not have Delete permission on a file or folder, you can still delete it if you have been granted Delete Subfolders and Files on the parent folder. |
| **Read Permissions** | Allows or denies reading permissions of the file or folder, such as Full Control, Read, and Write. |
| **Change Permissions** | Allows or denies changing permissions of the file or folder, such as Full Control, Read, and Write. |
| **Take Ownership** | Allows or denies taking ownership of the file or folder. The owner of a file or folder can always change permissions on it, regardless of any existing permissions that protect the file or folder. |
| **Synchronize** | Allows or denies different threads to wait on the handle for the file or folder and synchronize with another thread that may signal it. This permission applies only to multithreaded, multiprocess programs. |

For more information, see Set, view, change, or remove special permissions and Set, view, change, or remove permissions on files and folders.

**Note**

- You will not be able to access an encrypted file without the Encrypting File System (EFS) key, even if you have the necessary permissions. For information about EFS, see Encrypting File System.

# Permissions on a file server

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Permissions on a file server**

Access on a shared folder is determined through two sets of permission entries; the permissions set on the share (called *share permissions*) and the permissions set on the folder (called *NTFS file and folder permissions*). Share permissions are often used for managing computers with FAT32 file systems, or other computers that don't use the NTFS file system.

Share Permissions and NTFS Permissions are independent in the sense that neither changes the other. The final access permissions on a shared folder are determined by taking into consideration both the Share permission and the NTFS permission entries. The more restrictive permissions are then applied.

The following table suggests permissions that a security-conscious administrator could grant to the Users group for certain shared folder types. The recommended permissions have been tested, and work correctly; but there are alternative approaches. For example, some experienced administrators prefer always to set share permissions to Full Control for Everyone, and to rely entirely on NTFS permissions to restrict access.

| Folder type | Share permissions | NTFS permissions |
|---|---|---|
| **Public folder**. A folder that can be accessed by everyone. | Grant Change permission to the Users group. | Grant Modify permission to the Users group. |
| **Drop folder**. A folder where users can drop confidential reports or homework assignments that only the group manager or instructor can read. | Grant the Change permission to the Users group.<br><br>Grant the Full Control permission to the group manager. | Grant the Write permission for the users' group that is applied to **This Folder only**. (This is an option available on the **Advanced** page.) For more information, see Set, view, change, or remove special permissions.<br><br>If each user needs to have certain permissions to the files that he or she dropped, you can create a permission entry for the Creator Owner Security identifiers (SID) and apply it to **Subfolder and files only**. For example, you can grant the Read and Write permission to the Creator Owner SID on the drop folder and apply it to all subfolders and files. This grants the user who dropped or created the file (the Creator Owner) the ability to read and write to the file. The Creator Owner can then access the file through the **Run** command using *****ServerName******DropFolder******FileName*.<br><br>Grant the Full Control permission for the group manager. |
| **Application folder**. A folder containing applications that can be run over the network. | Grant Read permission for the Users group. | Grant Read, Read and Execute, and List Folder Content permissions to the Users group. |
| **Home folders**. Individual folders for each user. Only the user has access to the folder. | Grant the Full Control permission to each user on their respective folder. | Grant the Full Control permission to each user for their respective folder. |

**Notes**

- Granting a user Full Control NTFS permission on a folder enables that user to take ownership of the folder unless the user is restricted in some other way. Be cautious in granting Full Control.
- If you want to manage folder access by using NTFS permissions exclusively, set Share permissions to Full Control for

Everyone. This frees you from having to think about Share permissions, but NTFS permissions are more complex than Share permissions, so using NTFS permissions correctly requires deeper understanding on your part. For more information on NTFS permissions, search for the term "NTFS permissions" on TechNet on the Microsoft Web site.

- NTFS permissions affect access both locally and remotely. NTFS permissions apply regardless of protocol. Share permissions, by contrast, apply only to network shares. Share permissions do not restrict access to any local user, or to any terminal server user, of the computer on which you have set Share permissions. Thus, Share permissions do not provide privacy between users on a computer used by several users, nor on a terminal server accessed by several users.

- By default, Everyone does not include Anonymous, so permissions applied to Everyone do not affect Anonymous. This default behavior is new for the Windows Server 2003 family.

For more information, see Set, view, change, or remove permissions on files and folders and Share a folder or drive.

# Active Directory object permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Active Directory object permissions**

- Extended rights
- Validated writes
- Property sets

**Extended rights**

These permissions are for a special operation on an Active Directory object, where the operation is not necessarily related to read or write access to a particular attribute on that object.

| Extended right | Description |
|---|---|
| **Applies to Computers and Users** | |
| Receive As<br><br>**Applies to**: Computer and User | Exchange right: allows receiving mail as a given mailbox. |
| Send As<br><br>**Applies to**: User, computer, and inetOrgPerson | Exchange right: allows sending mail as the mailbox. |
| Send To<br><br>**Applies to**: Group | Exchange right: allows sending to a mailbox. |
| Change Password | Permits changing password on user account. You do need to know the original password to be able to make the change. |
| Reset Password<br><br>**Applies to**: User, computer, and inetOrgPerson | Permits resetting password on user account. With this permission, when you reset the password, you do not need to know the original password. |
| **Applies to Domain-DNS** | |
| Replicating Directory Changes<br><br>**Applies to**: Domain-DNS | Extended right needed to replicate changes from a given NC. |
| Add/Remove Replica In Domain<br><br>**Applies to**: Domain-DNS | Extended right needed to do a replica install. |

| | |
|---|---|
| Add GUID<br><br>**Applies to**: Domain-DNS | Extended right needed at the NC root to add an object with a specific GUID. |
| Change PDC<br><br>**Applies to**: Domain-DNS | Extended right needed to change the PDC. |
| Manage Replication Topology<br><br>**Applies to**: Domain-DNS | Extended right needed to update the replication topology for a given NC. |
| Replication Synchronization<br><br>**Applies to**: Domain-DNS, DMD, Configuration | Extended right needed to synchronize replication from a given computer. |
| Generate Resultant Set of Policy (Logging)<br><br>**Applies to**: Domain-DNS, Organizational-Unit | The user who has the rights on an organizational unit or domain will be able to generate logging mode Resultant Set of Policy (RSoP) data for the users/computers within the organizational unit. |
| Generate Resultant Set of Policy (Planning)<br><br>**Applies to**: Domain-DNS, Organizational-Unit | The user who has the rights on an organizational unit or domain will be able to generate planning mode RSoP data for the users or computers within the organizational unit. |
| **Applies to NTDS-DSA** | |
| Allocate Rids | Extended right needed to request RID pool. |
| Do Garbage Collection<br><br>**Applies to**: NTDS-DSA | Extended right to force the directory service to do garbage collection. Control right to force the directory service to do garbage collection. |
| Recalculate Hierarchy<br><br>**Applies to**: NTDS-DSA | Extended right to force the directory service to recalculate the hierarchy. |
| **Applies to a Group Policy container** | |
| Apply Group Policy | Extended right to determine if a Group Policy object applies or not. For a Group Policy object to apply to a user group or computer, the **Apply Group Policy** and **Read** permissions must be set. |
| **Applies to Site** | |
| Open Connector Queue | Allows opening connector queue. |

**Validated writes**

A validated write is different from a write permission which does not allow for any value checking. The value checking, or *validation*, ensures that the value conforms to required semantics, is within a legal range of values, or undergoes some other special checking that would not be performed for a simple low-level write to the property.

| **Validated write** | **Description** |
|---|---|

| | |
|---|---|
| Add/remove self as member<br><br>**Applies to**: Group | Validated write permission to enable one to add or remove one's own account from membership of a group. |
| Validated write to DNS host name<br><br>**Applies to**: Computer | Validated write permission to enable setting of a DNS host name attribute that is compliant with the computer name and domain name. |
| Validated write to service principal name **Applies to**: Computer | Validated write permission to enable setting of the SPN attribute which is compliant to the DNS host name of the computer. |

**Property sets**
A property set consists of a group of related properties (or attributes). Granting access rights to a property set rather than to individual properties greatly improves performance and simplifies security management.

**Domain Password**
Password and account lockout properties for the domain are stored in the Directory Service as attributes of the domain object. These properties can also be managed through the user interface using the **Domain Security Policy** Group Policy object, the values are then sychronized to the Directory Service. Password policies as well as all account policies are domainwide and applied to all members of the domain.

**Applies to:** Domain

- lockOutObservationWindow
- lockoutDuration
- lockoutThreshold
- maxPwdAge
- minPwdAge
- minPwdLength
- Pwd-Properties

**Other Domain Parameters (for use by the security account manager, also called SAM)**
Property set permitting control to a list of domain attributes.

**Applies to:** Domain

- domainReplica
- forceLogoff
- modifiedCount
- oEMInformation
- serverRole
- serverState
- uASCompat

**E-mail Information**
Property set that contains user attributes that describe user e-mail information.

**Applies to:** Group, User

**General Information**
Property set containing a set of user attributes that constitute general user information.

**Applies to:** User

- Display Name
- adminDescription
- codePage
- CountryCode
- ObjectSid
- primaryGroupID
- sAMAccountName
- sAMAccountType
- sDRightsEffective
- showInAdvancedViewOnly
- sIDHistory
- UID
- comment

**Membership**
Property set containing user attributes that describe group membership information.

**Applies to:** User

- memberOf
- member

**Personal Information**
Property set containing user attributes that describe personal user information.

**Applies to:** Computer, Contact, User

- streetAddress
- homePostalAddress
- assistant
- info
- country/region name
- facsimileTelephoneNumber (fax number)

- International-ISDN-Number
- Locality-Name

- Text-Country/Region
- Title
- userPrincipalName

**RAS Information**
System Internal: Do not use or modify this right.

**Applies to:** User

- msNPAllowDialin
- msNPCallingStationID
- msRADIUSCallbackNumber
- msRADIUSFramedIPAddress
- msRADIUSFramedRoute
- msRADIUSServiceType
- tokenGroups
- Token-Groups-Global-And-Universal

**User Account Restrictions**
Property set containing user attributes that describe account restrictions.

**Applies to:** Computer, User

- accountExpires
- pwdLastSet
- userAccountControl
- userParameters
- tokenGroupsNoGCAcceptable

**User Logon**
Property set containing user attributes that describe user logon information.

**Applies to:** User

- badPwdCount
- homeDirectory
- homeDrive
- lastLogoff
- Last-Logon
- lastLogonTimestamp
- logonCount
- logonHours
- logonWorkstation
- profilePath

**Web Information Contact**
Property set containing user attributes that describe user web related information.

**Applies to:** Web Information Contact, User

- WWWHomePage
- WWW-Page-Other url

# Selecting where to apply permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Selecting where to apply permissions**

When you set advanced permissions on files and folders, you can use **Permission Entry for *File or Folder Name*** to set which folders or subfolders will inherit permissions. In this dialog box, **Apply onto** lists the locations where you can apply permissions. How these permissions are applied depends on whether you select the **Apply these permissions to objects and/or containers within this container only** check box. By default, this check box is cleared.

**Important**

- For Active Directory objects, not only will the specified objects in the Apply onto field inherit the access control entries but ALL child objects will receive a copy of that ACE. The child objects not specified in the Apply onto field will not utilize the ACE whose copy they receive but if there are enough objects that will get copies of this ACE, then that increased amount of data can cause serious performance problems to your network. For more information, see Best practices for assigning permissions on Active Directory objects in Help.

For more information, see How inheritance affects file and folder permissions.

- When the Apply these permissions to objects and/or containers within this container only check box is cleared
- When the Apply these permissions to objects and/or containers within this container only check box is selected

**When the Apply these permissions to objects and/or containers within this container only check box is cleared**

| Apply onto | Applies permissions to current folder | Applies permissions to subfolders in current folder | Applies permissions to files in current folder | Applies permissions to all subsequent subfolders | Applies permissions to files in all subsequent subfolders |
|---|---|---|---|---|---|
| This folder only | x | | | | |
| The folder, subfolders and files | x | x | x | x | x |
| This folder and subfolders | x | x | | x | |
| This folder and files | x | | x | | x |
| Subfolders and files only | | x | x | x | x |
| Subfolders only | | x | | x | |
| Files only | | | x | | x |

**When the Apply these permissions to objects and/or containers within this container only check box is selected**

| Apply onto | Applies permissions to current folder | Applies permissions to subfolders in current folder | Applies permissions to files in current folder | Applies permissions to all subsequent subfolders | Applies permissions to files in all subsequent subfolders |
|---|---|---|---|---|---|

| | | | | | |
|---|---|---|---|---|---|
| This folder only | **x** | | | | |
| The folder, subfolders and files | **x** | **x** | **x** | | |
| This folder and subfolders | **x** | **x** | | | |
| This folder and files | **x** | | **x** | | |
| Subfolders and files only | | **x** | **x** | | |
| Subfolders only | | **x** | | | |
| Files only | | | **x** | | |

For more information, see Set, view, change, or remove special permissions.

# Changing inherited permissions

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Changing inherited permissions**

**Inheritance for all objects**
If the check boxes are shaded when you view the permissions of an object, the object has inherited permissions from the parent object. There are three ways to make changes to inherited permissions:

- Make the changes to the parent object, and then the child object will inherit these permissions.
- Select the opposite permission (Allow or Deny) to override the inherited permission.
- Clear the **Inherit from parent the permission entries that apply to child objects. Include these with entries explicitly defined here** check box. Then you can make changes to the permissions or remove users or groups from the **Permissions** list. However, the object will no longer inherit permissions from the parent object.

### Notes

- Inherited Deny permissions do not prevent access to an object if the object has an explicit Allow permission entry.
- Explicit permissions take precedence over inherited permissions, even inherited Deny permissions. For more information, see Explicit vs. inherited permissions.

On the **Advanced** page, in **Permission entries**, the **Apply To** column lists what folders or subfolders a permission is applied to. The **Inherited From** column lists where the permissions have been inherited from.

You can use the **Apply onto** field to select the folders or subfolders you would like permissions to be applied to. For more information, see Explicit vs. inherited permissions.

If the **Special Permissions** entry in **Permissions for *User or Group*** is shaded, it does not imply that this permission has been inherited. This means that a special permission has been selected. For more information, see Set, view, change, or remove special permissions and Selecting where to apply permissions.

**Inheritance for Active Directory objects**
For Active Directory objects, when using the **Apply Onto** option to control inheritance, be aware that not only will the objects specified in the **Apply onto** field inherit that access control entry (ACE) but *all* child objects will also receive a copy of that ACE. The child objects that are not specified in the **Apply onto** field will receive copies of the ACE but will not enforce it. If there are enough objects that will get copies of this ACE, then that increased amount of data can cause serious performance problems to your network.

If you assign permissions to a parent object and want child objects to inherit these permission entries, you can keep performance optimal by making sure all the child objects have identical access control lists (ACLs). In the Windows Server 2003 family single-instancing allows for the Active Directory to store only one copy of all identical ACLs. By creating ACLs that many objects can utilize, you can preserve the performance of your network.

# Privileges

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Privileges**

To ease the task of user account administration, you should assign privileges primarily to group accounts, rather than to individual user accounts. When you assign privileges to a group account, users are automatically assigned those privileges when they become a member of that group. This method of administering privileges is far easier than assigning individual privileges to each user account when the account is created.

The following table lists and describes the privileges that can be granted to a user.

| Privilege | Description |
|---|---|
| Act as part of the operating system | This user right allows a process to impersonate any user without authentication. The process can therefore gain access to the same local resources as that user.<br><br>Processes that require this privilege should use the *LocalSystem* account, which already includes this privilege, rather than using a separate user account with this privilege specially assigned. If your organization only uses servers that are members of the Windows Server 2003 family, you do not need to assign this privilege to your users. However, if your organization uses servers running Windows 2000 or Windows NT 4.0, you might need to assign this privilege to use applications that exchange passwords in plaintext.<br><br>**Default:** Local System. |
| Add workstations to a domain | This security setting determines which groups or users can add workstations to a domain.<br><br>This security setting is valid only on domain controllers. By default, any authenticated user has this right and can create up to 10 computer accounts in the domain.<br><br>Adding a computer account to the domain allows the computer to participate in Active Directory-based networking. For example, adding a workstation to a domain enables that workstation to recognize accounts and groups that exist in Active Directory.<br><br>**Default:** Authenticated Users on domain controllers. |
| Adjust memory quotas for a process | This privilege determines who can change the maximum memory that can be consumed by a process.<br><br>This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.<br><br>**Default:** Administrators. |
| Back up files and directories | This user right determines which users can bypass file and directory, registry, and other persistent object permissions for the purposes of backing up the system.<br><br>**Default:** Administrators and Backup Operators. |

| | |
|---|---|
| Bypass traverse checking | This user right determines which users can traverse directory trees even though the user may not have permissions on the traversed directory. This privilege does not allow the user to list the contents of a directory, only to traverse directories.<br><br>This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.<br><br>**Default:**<br><br>• On workstations and servers:<br>  • Administrators<br>  • Backup Operators<br>  • Power Users<br>  • Users<br>  • Everyone<br><br>• On domain controllers:<br>  • Administrators<br>  • Authenticated Users |
| Change the system time | This user right determines which users and groups can change the time and date on the internal clock of the computer. Users that are assigned this user right can affect the appearance of event logs. If the system time is changed, events that are logged will reflect this new time, not the actual time that the events occurred.<br><br>This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.<br><br>**Default:**<br><br>• On workstations and servers:<br>  • Administrators<br>  • Power Users<br><br>• On domain controllers:<br>  • Administrators<br>  • Server Operators |
| Create a pagefile | Allows the user to create and change the size of a pagefile. This is done by specifying a paging file size for a particular drive under **Performance Options** on the **Advanced** tab of **System properties**.<br><br>**Default setting**: Administrators |

| | |
|---|---|
| Create a token object | Allows a process to create a token which it can then use to get access to any local resources when the process uses NtCreateToken() or other token-creation APIs.<br><br>It is recommended that processes requiring this privilege use the LocalSystem account, which already includes this privilege, rather than using a separate user account with this privilege specially assigned<br><br>**Default setting**: No one |
| Create global objects | This security setting determines which accounts are allowed to create global objects in a terminal services session.<br><br>**Default:** Administrators and Local System. |
| Create permanent shared objects | Allows a process to create a directory object in the Windows Server 2003 family and Windows XP Professional object manager. This privilege is useful to kernel-mode components that extend the object namespace. Components that are running in kernel mode already have this privilege inherently; it is not necessary to assign them the privilege.<br><br>**Default setting**: No one |
| Debug programs | This user right determines which users can attach a debugger to any process or to the kernel. Developers who are debugging their own applications to not need to be assigned this user right. Developers who are debugging new system components will need this user right to be able to do so. This user right provides complete access to sensitive and critical operating system components.<br><br>**Default setting**:<br><br>● Administrators<br><br>● Local System |
| Enable computer and user accounts to be trusted for delegation | This security setting determines which users can set the **Trusted for Delegation** setting on a user or computer object.<br><br>The user or object that is granted this privilege must have write access to the account control flags on the user or computer object. A server process running on a computer (or under a user context) that is trusted for delegation can access resources on another computer using the delegated credentials of a client, as long as the account of the client does not have the **Account cannot be delegated** account control flag set.<br><br>This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.<br><br>**Default setting**: On domain controllers:<br><br>● Administrators |
| Force shutdown from a remote system | This security setting determines which users are allowed to shut down a computer from a remote location on the network. Misuse of this user right can result in a denial of service.<br><br>This user right is defined in the Default Domain Controller Group Policy object (GPO) and in the local security policy of workstations and servers.<br><br>**Default:**<br><br>● On workstations and servers: Administrators.<br><br>● On domain controllers: Administrators, Server Operators. |

| | |
|---|---|
| Generate security audits | This security setting determines which accounts can be used by a process to add entries to the security log. The security log is used to trace unauthorized system access. Misuse of this user right can result in the generation of many auditing events, potentially hiding evidence of an attack or causing a denial of service if the **Audit: Shut down system immediately if unable to log security audits** security policy setting is enabled. For more information, see Audit: Shut down system immediately if unable to log security audits.<br><br>**Default:** Local System. |
| Impersonate a client after authentication | This security setting determines which accounts are allowed to impersonate other accounts.<br><br>**Default:** Administrators and Service. |
| Increase scheduling priority | This security setting determines which accounts can use a process with Write property access to another process to increase the execution priority assigned to the other process. A user with this privilege can change the scheduling priority of a process through the Task Manager user interface.<br><br>**Default:** Administrators. |
| Load and unload device drivers | This user right determines which users can dynamically load and unload device drivers or other code in to kernel mode. This user right does not apply to Plug and Play device drivers. It is recommended that you do not assign this privilege to other users. Instead, use the `StartService()` API.<br><br>**Default setting**: Administrators. It is recommended that you not assign this privilege to any other user. Device drivers run as trusted (or highly privileged) programs. |
| Lock pages in memory | This security setting determines which accounts can use a process to keep data in physical memory, which prevents the system from paging the data to virtual memory on disk. Exercising this privilege could significantly affect system performance by decreasing the amount of available random access memory (RAM).<br><br>**Default:** None. Certain system processes have the privilege inherently. |
| Manage auditing and security log | This security setting determines which users can specify object access auditing options for individual resources, such as files, Active Directory objects, and registry keys.<br><br>This security setting does not allow a user to enable file and object access auditing in general. For such auditing to be enabled, the Audit object access setting in Computer Configuration\Windows Settings\Security Settings\Local Policies\Audit Policies must be configured.<br><br>You can view audited events in the security log of the Event Viewer. A user with this privilege can also view and clear the security log.<br><br>**Default:** Administrators. |
| Modify firmware environment values | This security setting determines who can modify firmware environment values. Firmware environment variables are settings stored in the nonvolatile RAM of non-x86-based computers. The effect of the setting depends on the processor.<br><br>• On x86-based computers, the only firmware environment value that can be modified by assigning this user right is the Last Known Good Configuration setting, which should only be modified by the system.<br><br>• On Itanium-based computers, boot information is stored in nonvolatile RAM. Users must be assigned this user right to run **bootcfg.exe** and to change the Default Operating System setting on **Startup and Recovery** in **System properties**.<br><br>• On all computers, this user right is required to install or upgrade Windows.<br><br>**Default setting**:<br><br>• Administrators<br><br>• Local System |

| | |
|---|---|
| profile a single process | This security setting determines which users can use performance monitoring tools to monitor the performance of nonsystem processes.<br><br>**Default:** Administrators, Power users, Local System. |
| profile system performance | This security setting determines which users can use performance monitoring tools to monitor the performance of system processes.<br><br>**Default:** Administrators, Local System. |
| Remove computer from docking station | This security setting determines whether a user can undock a portable computer from its docking station without logging on.<br><br>If this policy is enabled, the user must log on before removing the portable computer from its docking station. If this policy is disabled, the user may remove the portable computer from its docking station without logging on.<br><br>**Default:** Disabled. |
| Replace a process level token | Determines which user accounts can initiate a process to replace the default token associated with a started subprocess.<br><br>This user right is defined in the Default Domain Controller Group Policy object and in the local security policy of workstations and servers.<br><br>**Default setting**: Local Service and Network Service. |
| Restore files and directories | This security setting determines which users can bypass file, directory, registry, and other persistent objects permissions when restoring backed up files and directories and determines which users can set any valid security principal as the owner of an object.<br><br>Specifically, this user right is similar to granting the following permissions to the user or group in question on all files and folders on the system:<br><br>● Traverse Folder/Execute File<br><br>● Write<br><br>**Default:**<br><br>● Workstations and servers: Administrators, Backup Operators.<br><br>● Domain controllers: Administrators, Backup Operators, Server Operators. |
| Shut down the system | This security setting determines which users who are logged on locally to the computer can shut down the operating system using the **Shut Down** command. Misuse of this user right can result in a denial of service.<br><br>**Default:**<br><br>● Workstations: Administrators, Backup Operators, Power Users, Users.<br><br>● Servers: Administrators, Backup Operators, Power Users.<br><br>● Domain controllers: Account Operators, Administrators, Backup Operators, Server Operators, Print Operators. |
| Synchronize directory service data | This security setting determines which users and groups have the authority to synchronize all directory service data. This is also known as Active Directory synchronization.<br><br>**Defaults:** None. |

| | |
|---|---|
| Take ownership of files or other objects | This security setting determines which users can take ownership of any securable object in the system, including Active Directory objects, files and folders, printers, registry keys, processes, and threads.<br><br>**Default setting**: Administrators |

Some privileges can override permissions set on an object. For example, a user logged on to a domain account as a member of the Backup Operators group has the right to perform backup operations for all domain servers. However, this requires the ability to read all files on those servers, even files on which their owners have set permissions that explicitly deny access to all users, including members of the Backup Operators group. A user right--in this case, the right to perform a backup--takes precedence over all file and directory permissions.

For more information, see Logon rights, User rights and Security Configuration Manager tools.

**Note**

- At a command prompt, you can type **whoami /priv** to see your privileges. For more information about the **whoami** command, see Whoami.

# Logon rights

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Logon rights**

The following table lists and describes logon rights.

| Logon Right | Description |
|---|---|
| Access this computer from a network | This user right determines which users and groups are allowed to connect to the computer over the network. Terminal Services are not affected by this user right.<br>**Default:**<br>• On workstations and servers:<br>  • Administrators<br>  • Backup Operators<br>  • Power Users<br>  • Users<br>  • Everyone<br>• On domain controllers:<br>  • Administrators<br>  • Authenticated Users<br>  • Everyone |
| Allow log on locally | This logon right determines which users can interactively log on to this computer. Logons initiated by pressing CTRL+ALT+DEL on the attached keyboard requires the user to have this logon right. Additionally this logon right may be required by some service or administrative applications that can log on users. If you define this policy for a user or group, you must also give the **Administrators** group this right.<br>**Default:**<br>• On workstations and servers: Administrators, Backup Operators, Power Users, Users, and Guest.<br>• On domain controllers: Account Operators, Administrators, Backup Operators, Print Operators, and Server Operators. |
| Allow log on through Terminal Services | This security setting determines which users or groups have permission to log on as a Terminal Services client.<br>**Default:**<br>• On workstation and servers: Administrators, Remote Desktop Users.<br>• On domain controllers: Administrators. |

| | |
|---|---|
| Deny access to this computer from network | This security setting determines which users are prevented from accessing a computer over the network. This policy setting supersedes the Access this computer from the network policy setting if a user account is subject to both policies.<br><br>**Default:** No one. |
| Deny log on as a batch job | This security setting determines which accounts are prevented from being able to log on as a batch job. This policy setting supersedes the Log on as a batch job policy setting if a user account is subject to both policies.<br><br>**Default:** None. |
| Deny logon as a service | This security setting determines which service accounts are prevented from registering a process as a service. This policy setting supersedes the Log on as a service policy setting if an account is subject to both policies.<br><br>**Note**<br><br>• This security setting does not apply to the System, Local Service, or Network Service accounts.<br><br>**Default:** None. |
| Deny log on locally | This security setting determines which users are prevented from logging on at the computer. This policy setting supersedes the Allow log on locally policy setting if an account is subject to both policies.<br><br>**Important**<br><br>• If you apply this security policy to the Everyone group, no one will be able to log on locally.<br><br>**Default:** None. |
| Deny log on through Terminal Services | This security setting determines which users and groups are prohibited from logging on as a Terminal Services client.<br><br>**Default:** None. |
| Log on as a batch job | This security setting allows a user to be logged on by means of a batch-queue facility.<br><br>For example, when a user submits a job by means of the task scheduler, the task scheduler logs that user on as a batch user rather than as an interactive user.<br><br>**Note**<br><br>• In Windows 2000 Server, Windows 2000 Professional, Windows Server 2003 and Windows XP Professional, the Task Scheduler automatically grants this right as necessary.<br><br>**Default:** Local System. |
| Log on as a service | This security setting determines which service accounts can register a process as a service.<br><br>**Default:** None. |

For more information, see Privileges and Security Configuration Manager tools.

**Note**

- The default settings listed above are for Windows XP Professional and the Windows Server 2003 family.

# Access Control Resources

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Resources**

For more information about security, see the Microsoft Windows Resource Kits Web site.

For more information about authorization and access control, see the Microsoft Windows Resource Kits Web site.

For more information about authentication, see "Logon and Authentication" at the Microsoft Windows Resource Kits Web site.

For more information about security groups, see "Designing an Authorization Strategy" at the Microsoft Windows Resource Kits Web site.

For the latest recommendations on security, see the Microsoft Security page on the Microsoft Web site.

For information about the Microsoft Security Notification Service, see the Product Security Notification page on the Microsoft Web site.

# Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization Manager**
Authorization Manager provides a flexible framework for integrating role-based access control into applications. It enables administrators who use those applications to provide access through assigned user roles that relate to job functions. Authorization Manager applications store authorization policy in the form of authorization stores that are stored in Active Directory or XML files and apply authorization policy at runtime.

- Before using Authorization Manager, see Checklist: Before you start using Authorization Manager.
- For help with specific tasks, see Authorization Manager How To....
- For general background information, see Authorization Manager Concepts.

# Checklist: Before you start using Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Checklist: Before you start using Authorization Manager**

| Step | References |
|---|---|
| Review fundamental security concepts. | Security |
| Review related tools such as the Delegation of Control Wizard for comparison with Authorization Manager. | Delegating administration; Authorization Manager and role-based administration overview |
| Read background material about Authorization Manager. | Authorization Manager Concepts |
| Read about the difference between administrator mode and developer mode in Authorization Manager. | Authorization Manager and role-based administration overview; Set Authorization Manager options |
| Learn about authorization stores and applications, and about the difference between authorization stores that are stored as XML files and authorization stores that are stored in Active Directory. | Authorization stores and applications |
| (For developers) Review the latest information about Authorization Manager and authorization-related application programming interfaces (APIs) in the Platform SDK. | MSDN Library at the Microsoft Web site; TechNet at the Microsoft Web site; Platform SDK at the Microsoft Web site |
| Before you can use Authorization Manager for authorization stores that are stored in Active Directory, you must raise the Active Directory domain functional level to Windows Server 2003 .<br><br>**Caution**<br><br>• Raising the domain functional level is an irreversible step. | Domain and forest functionality; Raise the domain functional level; Raising domain and forest functional levels |
| Open Authorization Manager. | Start Authorization Manager |

# Authorization Manager How To...

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**How to...**

- Start Authorization Manager
- Set Authorization Manager options
- Assign an application group to a role
- Assign a Windows user or group to a role
- Add an authorization rule
- Refresh Authorization Manager
- Reload an authorization store
- Work with Authorization Stores
- Work with Applications
- Work with Role, Task, and Operation Definitions
- Work with Scopes

# Start Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To start Authorization Manager**

- Open Authorization Manager.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- To open Authorization Manager at a command prompt, type:

  **azman.msc**

  To open a command prompt, click **Start**, point to **All programs**, point to **Accessories**, and then click **Command prompt**.
- Authorization Manager opens without a default authorization store. To use Authorization Manager, you need to create or open an authorization store. For more information, see Related Topics.
- If you want to configure your own Microsoft Management Console (MMC) and include Authorization Manager as part of that console, see Related Topics. If you create and save your own MMC console, it opens to the configuration at the time you saved the file. It can open to an authorization store.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Author an MMC console file

# Set Authorization Manager options

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To set Authorization Manager options**

1. Open Authorization Manager.
2. In the console tree, right-click **Authorization Manager**, and then click **Options**.
3. In the **Options** dialog box, click either **Developer mode** or **Administrator mode**.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- In developer mode, you can create, deploy, and maintain applications. With developer mode, you have unrestricted access to all features.
- In administrator mode, you can deploy and maintain applications. With administrator mode, you have access most Authorization Manager features. In administrator mode, you cannot do the following:
    - Create new authorization stores
    - Create new applications
    - Define or modify operations
    - Change an application name
    - Change the version information for an application
- Administrator mode is the default. Before you can use administrator mode, you need to provide an application that supports roles, includes all of the necessary operation and task definitions, includes its own authorization store, and is ready for use in Authorization Manager. After you set up an application in developer mode, you do not have to use Authorization Manager in developer mode for that application. You can work in authorization mode instead.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign an application group to a role

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign an application group to a role**

1. Open Authorization Manager.

2. In the console tree, right-click the role to which you want to assign the application group, and then click **Assign Application Groups**. The role can be at the application or scope level.

   **Application level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/Role Assignments/*Role*

   **Scope level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/*Scope*/Roles Assignments/*Role*

3. In the **Add Groups** dialog box, select the check boxes next to the application groups that you want to add.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**

- This is one of the most common Authorization Manager procedures for administrators.

- To carry out this procedure, a role assignment needs to exist. For more information about creating a role assignment, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Assign a Windows user or group to a role

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To assign a Windows user or group to a role**

1. Open Authorization Manager.

2. In the console tree, right-click the role to which you want to assign a user or group, and then click **Assign Windows Users and Groups**. The role can be at the application or scope level.

   **Application level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/Role Assignments/*Role*

   **Scope level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/*Scope*/Roles Assignments/*Role*

3. In the **Select Users, Computers, or Groups** dialog box, type the name of the user or group that you want to assign to the role.

4. Click **Check Names**, and then click **OK**.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**

- This is one of the most common Authorization Manager procedures for administrators.

- To carry out this procedure, a role assignment needs to exist. For more information about creating a role assignment, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Add an authorization rule

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To add an authorization rule**

1. Open Authorization Manager.

2. In the console tree, right-click the role definition or task definition to which you want to add an authorization rule, and then click **Properties**. The role or task definition can be at the application or scope level.

   **Application level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/Definitions/Role Definitions (or Task Definitions)/*Role definition* (or *Task definition*)

   **Scope level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/*Scope*/Definitions/Role Definitions (or Task Definitions)/*Role definition* (or *Task definition*)

3. Click the **Definition** tab, and then click **Authorization Rule**.

4. In the **Authorization Rule** dialog box, in **Script path**, type the complete path to the authorization rule, including the file name extension.

5. Under **Script type**, do one of the following:

   - If your script has a .vbs file name extension, click **VBScript**.

   - If your script has a .js file name extension, click **JScript**.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**

- To perform this procedure, you need a role definition or a task definition. For more information about creating a role assignment, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Refresh Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To refresh Authorization Manager**

1. Open Authorization Manager.
2. In the console tree, right-click the item that you want to refresh, and then click **Refresh**.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- This procedure updates the user interface from the authorization store cache. If more than one process is modifying an authorization store and you refresh an item in Authorization Manager, the refreshed item might remain unsynchronized with the authorization store. To synchronize Authorization Manager with an actual authorization store, not just the cached copy, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

Reload an authorization store

# Reload an authorization store

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To reload an authorization store**

1. Open Authorization Manager.
2. In the console tree, right-click the authorization store that you want to reload, and then click **Reload**.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- This procedure updates Authorization Manager from the authorization store, not from the cache. If you want do a faster update that might be less thorough, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Authorization Stores

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with authorization stores**

- Create an authorization store
- Edit the properties of an authorization store
- Create a group within an authorization store
- Edit the properties of a group within an authorization store
- Delegate an authorization store
- Audit an authorization store

# Create an authorization store

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create an authorization store**

1. Open Authorization Manager.
2. In the console tree, right-click **Authorization Manager**, and then click **Options**.
3. In the **Options** dialog box, click **Developer mode**.
4. In Authorization Manager, right-click **Authorization Manager**, and then click **New Authorization Store**.
5. In the **New Authorization Store** dialog box, click either **Active Directory** or **XML file**.
6. In **Store name**, type the authorization store name or click **Locations** to find the authorization store.
7. (Optional) In **Description**, type a description for the new authorization store.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- To perform this procedure, you must be working in developer mode.
- If you are using an authorization store that is stored in Active Directory, use the LDAP name (for example, CN=myStore,CN=Program Data,DN=nwtraders,DN=com). If you are using an XML-based authorization store, use a path and file name that is valid at runtime (for example, C:\AuthStores\MyStore.xml).

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Create a role definition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a role definition**

1. Open Authorization Manager.
2. In the console tree, right-click **Role Definitions**, and then click **New Role Definition**. The Role Definitions folder can be at the application or scope level.

   **Application level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/Definitions/Role Definitions

   **Scope level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/*Scope*/Definitions/Role Definitions

3. In the **New Role** dialog box, in **Name**, type a name for the role.
4. In **Description**, type a description of the role.
5. (Optional) Specify any operations, tasks, roles, and authorization rules that you want to include.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- To perform this procedure, you need to use an authorization store that contains an application. The authorization store can also contain an application that contains a scope. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Edit a role definition

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To edit a role definition**

1. Open Authorization Manager.

2. In the console tree, double-click the role definition that you want to edit. The role definition can be at the application or scope level.

   **Application level**

   **Where?**

   - Authorization Manager/*Authorization Store*/*Application*/Definitions/Role Definitions/*Role definition*

   **Scope level**

   **Where?**

   - Authorization Manager/*Authorization store*/*Application*/*Scope*/Definitions/Role Definitions/*Role definition*

3. In the **Definition Properties** dialog box, modify the settings that you want to change.

4. Click the **Definition** tab, and then select any operations, tasks, roles, and authorization rules that you want to include.

**Notes**

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**

- To perform this procedure, you need to use an authorization store that contains an application, or both an application and a scope. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Work with Scopes

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Work with scopes**

- Create a scope
- Edit the properties of a scope
- Create a role assignment within a scope
- Edit the properties of a role assignment within a scope
- Delegate a scope
- Audit a scope

# Create a scope

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To create a scope**

1. Open Authorization Manager.
2. In the console tree, right-click the application within which you want to create the scope, and then click **New Scope**.

   **Where?**

   - Authorization Manager/*Authorization store/Application*

3. In the **New Scope** dialog box, in **Name**, type a name for the scope.
4. (Optional) In **Description**, type a description for the scope, and then click **OK**.

### Important

- The scope name must be recognized by the application, and the application must resolve the name at the time of the access check. Following are some examples of scope names: "*.txt", "C:\temp", and "Computers in Sales Department." The scope name must contain only printable characters. It must contain at most 65536 characters, and it must be unique (that is, it cannot match the name of another scope currently used by the application).

### Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- To perform this procedure, you need to use an authorization store that contains an application. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Delegate a scope

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To delegate a scope**

1. Open Authorization Manager.
2. In the console tree, right-click the authorization store that contains the parent application of the scope that you want to delegate, and then click **Properties**.
3. In the **Properties** dialog box, click the **Security** tab.
4. On the **Security** tab, under **Authorization Manager user role**, click **Delegated Users**.
5. Under **Users and groups that are assigned to this role**, click **Add** or **Remove** to add or remove users and groups.
6. In the console tree, right-click the application that contains the scope that you want to delegate, and then click **Properties**.

   **Where?**

   - Authorization Manager\Authorization store\Application

7. In the **Properties** dialog box, click the **Security** tab.
8. On the **Security** tab, under **Authorization Manager user role**, click **Delegated Users**.
9. Under **Users and groups that are assigned to this role**, click **Add** or **Remove** to add or remove users and groups.
10. In the console tree, right-click the scope that you want to delegate, and then click **Properties**.

    **Where?**

    - Authorization Manager\Authorization store\Application\Scope

11. In the **Properties** dialog box, click the **Security** tab.
12. On the **Security** tab, under **Authorization Manager user role**, click **Administrator**.
13. Under **Users and groups that are assigned to this role**, click **Add** or **Remove** to add or remove users and groups to which you want to assign the Administrator role.

**Notes**

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- To perform this procedure, you need to use an authorization store that contains an application, and the application must contain a scope. For more information, see Related Topics.
- XML-based authorization stores, applications, and scopes do not support delegation.

- If a scope within an authorization store that is stored in Active Directory contains task definitions that include authorization rules or role definitions that include authorization rules, you cannot delegate the scope.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Audit a scope

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**To audit a scope**

1. Open Authorization Manager.
2. In the console tree, right-click the scope that you want to audit, and then click **Properties**.

   **Where?**

   - Authorization Manager/*Authorization store/Application/Scope*

3. In the **Properties** dialog box, click the **Auditing** tab.
4. On the **Auditing** tab, select the **Authorization store change auditing** check box. This check box does not exit for XML-based authorization stores.

## Notes

- To open Authorization Manager, click **Start**, click **Run**, and then type: **azman.msc**
- XML-based authorization stores do not support auditing at the scope level.
- If you configure auditing at the application level or the authorization store level, this is indicated on the **Auditing** tab in the **Properties** dialog box for the scope.
- To audit your applications, you must have specific privileges and security settings. For more information, see Related Topics.
- To perform this procedure, you need to use an authorization store that contains an application, and the application must contain a scope. For more information, see Related Topics.

**Information about functional differences**

- Your server might function differently based on the version and edition of the operating system that is installed, your account permissions, and your menu settings. For more information, see Viewing Help on the Web.

# Authorization Manager Concepts

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Concepts**

This section provides general background information about Authorization Manager:

- Authorization Manager and role-based administration overview
- Using Authorization Manager

# Authorization Manager and role-based administration overview

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization Manager and role-based administration overview**

Network administrators, Information Technology specialists, and others responsible for computer-related infrastructure, are most effective when they help people do their jobs. The role-based management model enables you to assign users to roles. The settings that authorize users for specific roles are made automatically, by means of scripts. The scripts, called authorization rules, enable you to apply fine-grained control over the mapping between access control and the structure of your organization.

Role-based administration is often used to facilitate authorization and computer configuration. Authorization and computer configuration are two categories of roles that you can manage by using role-based administration.

- **Authorization roles** are based on a user's job function. You can use authorization roles to authorize access, to delegate administrative privileges, or to manage interaction with computer-based resources. For example, you might define a Treasurer role that includes the right to authorize expenditures and audit account transactions. Authorization Manager enables administrators to implement this type of role-based administration through applications. For more information about applications, see Authorization stores and applications.

- **Computer configuration roles** are based on a computer's function. You can use computer configuration roles to select features that you want to install, to enable services, and to select options. For example, server roles might be defined for Web servers, domain controllers, file servers, and custom server configurations that are appropriate to your organization.

**Using developer mode and administrator mode in Authorization Manager**

With Authorization Manager, you can use the following two modes:

- **Developer mode.** In developer mode, you can create, deploy, and maintain applications. You have unrestricted access to all of the Authorization Manager features.

- **Administrator mode.** This is the default mode. In administrator mode, you can deploy and maintain applications. You have access to all Authorization Manager features, but you cannot create new applications or define operations.

Applications that support roles usually create an authorization store, or use an existing authorization store, with pre-defined operations and tasks. In that case developer mode need not be used.

When you use developer mode, it is recommended that you run Authorization Manager in developer mode only until the authorization store, application, and other necessary objects are created and configured. After you initially set up Authorization Manager, run Authorization Manager in administrator mode. For more information about using developer or administrator mode, see Set Authorization Manager options.

**Comparing Authorization Manager to other management tools**

Authorization Manager is capable of implementing multiple configuration and permission changes at once. There are other management tools available with the Microsoft® Windows Server 2003 family of operating systems that are comparable to Authorization Manager.

- **ACL Editor.** The access control list (ACL) editor for access control on Active Directory directory service and Windows objects sets access control policy. Authorization Manager differs from the ACL editor by facilitating the use of role-based access control in applications that support roles. Sometimes you might not know precisely which permissions you need to set for authority to be delegated. Authorization Manager takes the guess work out of this process. For more information about access control, see Access Control.

- **Delegation of Control Wizard.** The Delegation of Control Wizard also sets multiple permissions automatically. Authorization Manager provides more scope and configuration options for role-supporting applications. For more information about delegation, see Delegating administration.

For more information about Authorization Manager, see Using Authorization Manager.

# Using Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Using Authorization Manager**

This section covers:

- Authorization rules
- Groups in Authorization Manager
- Authorization stores and applications
- Scopes in Authorization Manager
- Roles, tasks, and operations
- Authorization Manager auditing
- Authorization Manager delegation

# Authorization rules

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization rules**

Authorization rules are scripts, written in VBScript or JScript, that you can include in role definitions and task definitions. An authorization rule determines whether the role or task is allowed. For information about role definitions and task definitions, see Roles, tasks, and operations.

By using authorization rules, you can base authorization decisions on any conditions that a script can test. These include privileges and permissions, as well as time of day, billable expense limits, account balances, and other criteria.

With Authorization Manager, you can use authorization rules, but it is not designed for writing or debugging authorization rules. You can write your scripts in a text editor (for example, Notepad), in an integrated development environment like Visual Studio .NET, or in another application of your choice.

Authorization rules are usually written by developers. For more information about authorization-related application programming interfaces (APIs), see Authorization at the Microsoft Web site.

**VBScript example**

The following is a VBScript authorization rule that always grants permission:

```
AzBizRuleContext.BusinessRuleResult = True
```

For more information about VBScript, see VBScript at the Microsoft Web site.

**JScript example**

The following is a JScript authorization rule that always grants permission:

```
AzBizRuleContext.BusinessRuleResult = true;
```

For more information about JScript, see JScript at the Microsoft Web site.

# Groups in Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Groups in Authorization Manager**

In Authorization Manager, recipients of authorization policy are represented by the following different kinds of groups:

- **Windows Users and Groups**--These groups includes users, computers, and built-in groups for security principals. Windows users and groups are not used only in Authorization Manager. They are used throughout Windows.
- **LDAP query groups**--Membership in these groups is dynamically calculated as needed from LDAP queries. An LDAP query group is a type of application group.
- **Basic Application Groups**--These groups are defined in terms of LDAP query groups, Windows users and groups, and other basic application groups. A basic application group is a type of application group.
- **Application groups**--These groups include basic application groups and LDAP query groups as special cases. Application groups are specific to Authorization Manager role-based administration. An application group is a group of users, computers, or other security principals. An application group is not a group of applications.

**Windows Users and Groups**

For more information about groups in Active Directory, see Understanding Groups. For more information about security principals that are not stored in Active Directory, see Local Users and Groups.

**LDAP query groups**

In Authorization Manager, you can use LDAP queries to find objects in Active Directory and other LDAP compliant directories. For example, the following query finds everyone except Andy:

```
(&(objectCategory=person)(objectClass=user)(!cn=andy))
```

The following query finds all members of the DogLovers alias at northwindtraders.com:

```
(memberOf=CN=DogLovers,OU=Distribution Lists,DC=nwtraders,DC=com)
```

You can use an LDAP query to specify an LDAP query group by typing the desired LDAP query in the space provided on the **Query** tab of the **Properties** dialog box of the application group.

**Basic application groups**

Basic application groups are specific to role-based administration.

To define basic application group membership, you need to:

1. Define who is a member.
2. Define who is not a member.

Both of these steps are carried out in the same way: First, you specify zero or more Windows Users and Groups, previously defined basic application groups, or LDAP query groups.

Second, the membership of the basic application group is calculated by removing any nonmembers from the group. Authorization Manager does this automatically at runtime.

Nonmembership in a basic application group takes precedence over membership.

Circular membership definitions are not allowed, and result in the error message "Cannot add *GroupName*. The following problem occurred: A loop has been detected."

**Application groups**

When you create a new application group, you need to determine whether you want it to be an LDAP query group or a basic application group. For Authorization Manager role-based applications, any authorization you can do with Windows users and

groups can also be done with application groups. Application groups are more dynamic and flexible.

For more information about creating application groups, see Create a group within an authorization store and Create a group within an application.

For information about editing the properties of an application group, see Edit the properties of a group within an application and Edit the properties of a group within an authorization store.

# Authorization stores and applications

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization stores and applications**

With Authorization Manager, you can provide authorization services to administrators that you support by creating Authorization Manager applications that access authorization stores.

In Authorization Manager, there is no default authorization store and there is no default application. To create an authorization store, you must work in the Authorization Manager developer mode. For more information about working in developer mode, see Set Authorization Manager options.

You can store authorization stores in either XML files or Active Directory. The following table compares the two types.

| Authorization store type | Delegation support | Authorization store is specified by | Windows support |
|---|---|---|---|
| Active Directory | Supported at the authorization store, application, and scope levels | A URL, beginning with the protocol prefix MSLDAP:// or an LDAP distinguished name (for example, CN=myStore,CN=Program Data,DN=nwtraders,DN=com) | Windows Server 2003 domain functional level Active Directory domain only<br>**Important**<br>• In Windows 2000, Active Directory does not support authorization stores. |
| XML | Not supported<br>The XML file is secured as a whole by its NTFS file system access control entries (ACEs). | A URL beginning with the protocol prefix MSXML:// or a Path (for example, C:\Temp\MyStore.xml or \\ServerName\ShareName\MyStore.xml) | Any NTFS partition |

An application is specific to an authorization store, and it is always located directly under its parent authorization store in Authorization Manager. For more information about creating an application, see Create an application. Scopes, roles, tasks, and operations are always specific to an application. For more information, see Scopes in Authorization Manager and Roles, tasks, and operations.

**Using application groups**

An application group is a group of users of an Authorization Manager application. You can create application groups at any of the three levels in the Authorization Manager console. The following table lists the different Authorization Manager levels where you can create application groups.

| Level | Application group can be used in |
|---|---|
| Authorization store | The authorization store, and applications and scopes underneath it |
| Application | The application, and scopes underneath it |
| Scope | The scope |

For more information about application groups, see Groups in Authorization Manager.

**Delegating authorization stores and applications**

Authorization stores that are stored in Active Directory, and the applications that they contain, support delegation. For more information about performing delegation, see Delegate an authorization store and Delegate an application.

**Note**

- XML-based authorization stores, applications, and scopes do not support delegation.

# Scopes in Authorization Manager

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Scopes in Authorization Manager**

A scope is a subdivision within an application that separates resources from other resources that are used by that application. You do not have to use scopes. A scope can be a folder, an Active Directory container, a file-masked collection of files (for example, *.doc), a URL, or any item that can be accessed by the application and its underlying authorization store. You can use scopes to prevent unintended resource sharing and to support auditing and delegation.

If you have Authorization Manager groups, role assignments, role definitions, or task definitions that you do not want to apply to an entire application, you can create them at the scope level. The application that contains the scope must be able to recognize the scope name. For example, file-based applications might have scope names that include file names or paths. Web-based applications might have URL-based scope names. Registry applications might have scope names based on registry hives, and Active Directory scope names could specify organizational units. You cannot define operations at the scope level.

**Auditing scopes**

You cannot perform Authorization Manager runtime auditing on scopes. You can perform Authorization Manager authorization store change auditing on scopes contained in authorization stores that are stored in Active Directory. For more information about auditing, see Authorization Manager auditing.

**Delegating scopes**

Scopes within authorization stores that are stored in Active Directory support delegation. For more information about delegating a scope, see Delegate a scope.

XML-based authorization stores do not support delegated administration. If a scope within an authorization store that is stored in Active Directory contains task definitions that include authorization rules, or role definitions that include authorization rules, you cannot delegate the scope.

# Roles, tasks, and operations

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Roles, tasks, and operations**

A role is a set of permissions that a user must have to do a job. Well-designed roles should correspond to a job category or responsibility (for example, receptionist, hiring manager, or archivist) and be named accordingly. With Authorization Manager, you can adds users to a role to authorize them for the job.

A task is a collection of operations, and sometimes other tasks. Well-designed tasks are inclusive enough to represent work items that are recognizable (for example, "change password" or "submit expense").

An operation is a set of permissions that you associate with system-level or API-level security procedures like WriteAttributes or ReadAttributes. You use operations as building blocks for tasks.

You can define roles, tasks, and operations only in developer mode, not administrator mode. To set developer mode, see Set Authorization Manager options.

**Role definitions**

The role definitions that are appropriate depends on the structure and goals of your organization. Roles support inheritance from other roles. To define a role, you specify a non-arbitrary name, a friendly description, and some lower-level tasks, roles, and operations that are part of it. This provides a mechanism for role inheritance. For example, a Helpdesk role might include a Product Support role. You can specify an authorization rule, which may be either VBScript or JScript. For more information, see VBScript at the Microsoft Web site and JScript at the Microsoft Web site.

If there are several authorization rules associated with a role definition (for example, it has several subroles and tasks), the authorization rules run synchronously. In Authorization Manager, the order has no effect on authorization.

**Role assignments**

A role assignment is a virtual container for application groups whose members are authorized for the role. A role assignment is based on a single role definition, and a single role definition can be the basis of many role assignments.

The most common procedure that administrators carry out is the assignment of application groups, or Windows users and groups, to a role. For step-by-step instructions, see Assign an application group to a role or Assign a Windows user or group to a role.

**Task definitions**

A task definition is smaller than a role definition and can be used to define roles and other tasks.

With Authorization Manager, you associate tasks with roles in an intuitive way. For example, the Recruiter role might include the Interview task. Tasks, like roles, are defined in a way that is appropriate to the organization. To define a task, you specify a name, a friendly description, and some lower-level tasks and operations that are part of it. You can also specify a VBScript or JScript authorization rule.

For more information about creating or editing task definitions, see Create a task definition and Edit a task definition.

**Operation definitions**

Operations are small computer-level actions that are used to define tasks and usually are not relevant to an administrator. You define operations only in developer mode.

You can set operation definitions at the application level, but not at the authorization store level or the scope level. An operation definition includes a name, a description, and an operation number. The operation number X must be an integer from zero to 2147483647 (that is, 0 ≤ X ≤ 231 - 1). The operation number is used by the application to identify the operation, so entering a wrong operation number will cause a bug in the application. For more information about creating or editing operation definitions, see Create an operation definition or Edit an operation definition.

# Authorization Manager auditing

Updated: January 21, 2005

Applies To: Windows Server 2003, Windows Server 2003 R2, Windows Server 2003 with SP1, Windows Server 2003 with SP2

**Authorization Manager auditing**
You need the **Generate security audits**privilege and the **Manage auditing and security log** privilege to do auditing. For more information about these privileges, see Privileges.

With Authorization Manager, you can use two kinds of auditing: runtime auditing and authorization store change auditing.

**Runtime auditing**
